The prettiest spring-blooming shrub I have seen among new things is a Japanese Apricot, sent over in a lot of Japan Plums from Tokio some five years since, and fruiting only last year. The blossoms are very abundant, being fragrant, and massed as they are, and tinted slightly, but deeper in color than the common Apricot, they have attracted much attention. The fruit is small and bitter.

Berkeley, Cal.

Charles Howard Shinn.

The Liquidambar.

THE North American Liquidambar, or Sweet Gum, as it is more familiarly called, is the type of a small genus of three or perhaps four or five species of trees peculiar to eastern North America, Mexico and Central America in the New World, and to Asia Minor and eastern Asia in the Old World. The genus belongs with the Witch Hazels and is characterized by naked flowers, usually of only one sex, produced in nodding, racemed, globular heads or catkins—the male consisting of a cluster of numerous stamens with short filaments intermixed with minute scales, the females of many two-celled and two-beaked ovaries from the axils of the minute scales, all cohering together, hardening in fruit, and forming a spherical, woody head of pods which opens between the oval-shaped beaks. The styles are two, stigmatic on the inner surface; ovules numerous, seeds few, covered with a wing-angled seed-coat.

The North American Liquidambar (*L. styraciflua*) is one of the most beautiful and characteristic trees found in the forests of the eastern portion of the continent. It rises under exceptionally favorable conditions to a height of more than 150 feet, with a tall, perfectly straight trunk, four or sometimes five feet in diameter, destitute of branches for seventy or eighty feet, and covered with pale brown, slightly furrowed bark. The branches are small and short in proportion to the height of the tree, and the outline of the head, even upon young trees which have had abundant room for free development, is narrowly pyramidal. Broad, corkey wings grow on the young branches, and make this tree in winter a conspicuous and always striking object. The leaves are rounded, deeply five to seven-lobed, so that they appear almost star-shaped, three or four inches across; they are thin, and shining especially on the upper surface, perfectly smooth, and borne on slender petioles. They are pleasantly fragrant when bruised, and in autumn turn to the most brilliant scarlet. There are few trees of the American forest which surpass the Liquidambar in the splendor of the autumnal coloring of its foliage.

The wood of the North American Liquidambar is heavy, rather hard, tough, although not particularly strong, close grained, satiny and susceptible of a good polish. A cubic foot of the thoroughly seasoned wood weighs 36.82 pounds, or rather more than that of our common Wild Cherry and of the Black Walnut, but a good deal less than white oak. The color is bright brown faintly tinged with red, and of the sap-wood nearly white. It is difficult to season, showing a tendency to warp and shrink badly. Experience and the adoption of better methods are gradually overcoming this difficulty, however, and large quantities of this lumber are now manufactured into furniture or used in the interior finish of buildings for which, when once thoroughly seasoned, the hardness, solidity and pleasant coloring and texture adapt it. It has been used to a considerable extent in some parts of the West for the plates and even for the frames of buildings, and largely in some western cities for street pavement-blocks.

The Liquidambar first makes its appearance in Connecticut, near the shore of Long Island Sound, in the vicinity of New Haven. It is confined at first to the neighborhood of the coast, but soon extends further inland, and, with the exception of the Allegheny ridges, is found all over the United States from New Jersey and southern Indiana and Illinois to southern Florida and the valley of the Trinity River in Texas. The climate of western Texas is too dry for this tree; but it reappears on the mountains of central and southern Mexico, where it often forms an important part of the forest-growth, and extends to Guatemala and Central America, or is represented there by one or two closely related and little known species.* It is one of the most common trees of the Mississippi basin, where, on the deep, rich, and often submerged bottom-lands lining the streams, it forms, with the Cotton-gum (*Nyssa uniflora*) and the Cottonwood (*Populus monilifera*), a large proportion of the tree-growth. Here it attains its greatest size and best development, forming vast forests, of which an idea may be obtained from an illustration upon page 235, taken from a photograph, by Mr. Robert Ridgway, of the Smithsonian Institution, to whom this journal is indebted for the permission to reproduce it. It represents a forest scene near Mt. Carmel, in southern Illinois, and the tree with the tall, clear stem in the middle of the picture is a Liquidambar of not unusual size or height.

The American Liquidambar is destined to supply a large amount of useful timber long after more valuable trees like the Cherry, the Yellow Poplar and the Black Walnut are practically exterminated for commercial purposes. The fact that the real home of this tree in those parts of the country where it attains its greatest development is in deep swamps, always inundated every year during several weeks at a time, and incapable of being drained and therefore of being cultivated, will insure, with slight attention, its perpetuation, and will make the future supply of the wood of this tree reasonably certain.

The name Liquidambar, applied by Linnæus to this tree, has reference to the fragrant terebinthine juice which exudes from the stem. This exudation is sometimes collected by herbalists and used in the form of a syrup as a substitute for storax in the treatment of catarrhal troubles, or externally as an ointment. This resinous exudation increases in proportion to the warmth of the climate in which the tree is found. It is almost wanting in trees growing at the northern limit of the species, and is produced in much larger quantities from trees in Mexico and Central America than from those growing in any part of the United States.

The American Liquidambar is a tree of first-rate importance in ornamental planting. It is easily raised from seed; it can be transplanted without difficulty; it grows rapidly, and is not particular about soil. A single specimen upon a lawn is always a handsome object, and the narrow, pyramidal shape of the head adapts it for general street-planting. The leafless branches afford a curious and interesting sight, and the splendor of its autumnal foliage places it in the front rank of trees to plant for autumn effects. It is not, unfortunately, perfectly hardy in eastern New England, suffering here in severe winters.

Liquidambar Orientalis, Mill., furnishes the liquid storax of commerce. This tree forms forests of considerable extent in the south-western part of Asia Minor. It is described as a handsome tree thirty or forty feet high, resembling the Plane.† A detailed and very interesting account of the history, properties and uses of liquid storax and of the methods used by the wandering tribes of Turcomans for extracting it from the trees will be found in Flückinger and Hanbury's "Pharmacographia," p. 241. It is a remarkable fact (although not at all an isolated one, for there is still much to be learned of the plants from which eastern nations

* Henesley, *Bot. Am. Cent.*, i., 400.

† There is a good figure of this species in Hooker's *Icones*, t. 1019.

derive many of their most valuable products) that the real source of liquid storax, which is known to have been sent to India from the ports of the Red Sea as early as the first century of the Christian era, and was known in Greece during the sixth or seventh centuries, was not found out until a few years ago.

The origin of this drug long perplexed pharmacologists, and the first account of it was published in a Greek newspaper in 1841, and only definitely settled in 1851.† The chief market for this drug is still, as it always has been, India, and considerable quantities are consumed in China also.

New or Little Known Plants.

Cordia Greggii, var. *Palmeri*.*

THIS is another of the showy flowering shrubs discovered last year by Dr. Palmer in the mountains about Guaymas. In its general habit and more important characters it accords with the species to which it is referred as a variety, which is a native of the Sierra Madre region farther to the east, where it was first collected many years ago by Dr. Gregg. This variety differs mainly in its larger and

Fig. 106.—*Cordia Greggii*, var. *Palmeri*.

The Asiatic species of Liquidambar (*L. Formosana*, Hance) is found in southern and eastern China, in the Island of Formosa, and in Japan.‡ It is the Feng-tree of the Chinese, and it has quite recently been discovered that the wood of this tree is very generally used in making the cases in which Chinese tea is exported. Mr. Hemsley finds another Chinese species in Herb. Kew, of which little is yet known (*Journal Linnæan Society*, of London, xxiii, 297). Its wood is also used for tea-chests. C. S. S.

† See *Pharmaceutical Journal*, xvi, 41, 461. There is a figure of this species in Hooker's *Icones*, t. 1026.

‡ *Liquidambar Chinensis* (see Hooker's *Kew Journal of Botany*, iv, 164) is now referred to the genus *Altingia*, of which the type is *Altingia excelsa*, Noronha (*Liquidambar Altingia* of Blume), a widely-distributed tree from east Bengal to China and the Malayan Islands.

broader flowers, the other differences in foliage, etc., being less conspicuous.

It is a much-branched and rather compact shrub, growing to a height of five to eight feet, with numerous small pubescent and light green leaves, strongly veined and sharply toothed. It is a very free bloomer, bearing the flowers in clusters at the ends of the branches, broadly funnel-form, pure white and fragrant. The fruit is somewhat fleshy, enclosed within the dilated calyx-tube, and contains a very hard 1-4-seeded stone. In the size and beauty of its flowers this species equals the *Cordia Sebestena* and others of the same group.

Cultural Department.

Boronias.

THERE are about fifty species of *Boronia*, all of which are peculiar to Australia. Of this number nearly one-half have been cultivated at one time or another as green-house flowering-plants, but only a few of them are represented in gardens now. The introduction of *B. elatior*, *B. megastigma* and *B. heterophylla* within the last ten years or so has been the means of attracting attention to the older and almost forgotten species, which twenty years ago ranked among the choicest flowering-plants for the conservatory and for exhibition. The best of these are comprised in the list which follows. There can be no question as to the first-rate merits of *Boronias* as garden-plants, even in these days when there is so much to select from. They form shapely bushes under ordinary treatment, they bloom freely and last a long time, the flowers are pretty and generally very fragrant, and they have the additional attraction of distinctness. A specimen *Boronia* is unlike any other green-house flowering-plant. Its nearest relations, the *Croweas*, *Eriostemons* and *Correas*, are as different in appearance from *Boronia* as they are from each other. There is a good opportunity for any horticulturist on the lookout for an interesting and useful hobby in these neglected hard-wooded green-house plants from the Cape and from Australia. In the more southern states of America these plants would probably prove hardy and would thrive well. The *Boronias* are most abundant in West Australia from the Swan River southward. Here the hottest months are December, January and February, when the maximum temperature reaches 100° Fahr., the coldest months being July and August, when the thermometer falls to freezing-point. Undulating plains, covered with a profusion of vegetation, and a sandy soil, characterize this region. Springs abound, water being found at only a few feet from the surface, even in the hottest and driest weather, so that the plants are able to support long seasons of drought. These facts may be of some guidance to those readers who are situated in California and other southern states.

As green-house plants for temperatures approximating to those of England, *Boronias* should be treated as follows: Young plants may be obtained from imported seeds, from cuttings or by grafting. Some growers prefer grafted plants. Others, who are equally successful, prefer them on their own roots. If grafted the best stock is *B. pinnata*, which should be about two years old, with the base of the stem slightly woody. Splice-grafting is usually preferred. The cion should be about one and a half inches long, and firm enough to cut easily. The operation should be performed in February. Cuttings may be put in at the same time or in autumn. They should be obtained from the lowest and least sappy branches, planted in a very sandy peat-soil, covered with a bell-glass and placed in an intermediate temperature. When rooted and hardened off they may be transferred singly into thumb-pots and placed on a sunny shelf in a green-house. The soil should always be good peat, with a good proportion of coarse silver sand. Re-pot as often as necessary, bearing in mind that small shifts are best and that these plants do not require much root-room. The shoots must be stopped often, so as to get a good foundation for a well-furnished bush. *B. megastigma* requires constant attention in this respect, or it will run up into a thin, scraggy specimen. *B. elatior* and *B. heterophylla* may be cut back hard after they have flowered, and they will make all the better plants for it. A green-house where the temperature does not fall below 45° in winter, and where a constant supply of fresh air and light can be maintained is the most suitable place for *Boronias*. Re-pot large plants in March, and after they have been started in a close, sunny green-house let them have plenty of light and air, with a moist atmosphere in the evening and morning. In August all except *B. serrulata* may be placed out-of-doors to ripen their growth; this species, however, will not bear this exposure, but must be kept in the green-house always. It also likes a few degrees more warmth in winter. Under this treatment perfect specimens almost as high as a man have been grown in England.

The following species are the best of those known. They are all in cultivation in a few collections in England, whilst the most popular may be had of any nurseryman.

B. heterophylla, although the last to be introduced, is by far the handsomest of all known *Boronias*. As is now known to most of your readers, it was sent to Kew in 1881 by Miss North, the famous artist and traveler, and it has since been distributed by Messrs. Veitch, of Chelsea. It forms an elegant little shrub

with numerous branches clothed with dark-green, pinnate leaves, which vary in the number of pinnae, and are sometimes simple. The flowers are in axillary whorls, and are egg-shaped, drooping, half an inch long, the color being bright rosy-red, almost crimson. It differs from *B. elatior* in having larger leaves, fewer leaflets and brighter-colored, larger flowers. According to Baron von Mueller, who described it nearly thirty years ago, it is found "in West Australia, on the Kalgee River, in places sometimes inundated."

B. elatior was introduced by Messrs. Veitch in 1876. In habit it resembles *B. heterophylla*. The branches are hirsute, the leaves crowded, pinnate, two inches long, and the flowers on short axillary peduncles; they are nearly globose, open at the apex, nearly one-half inch long, very profuse on the branches, and dull rose-red. They are developed in spring and early summer. When well managed—and it is one of the easiest to cultivate—this species forms a bush four feet high, with hundreds of branches clothed with six inches of flowers. As a small pot-plant it is equally beautiful.

B. megastigma is not attractive in color, but what it lacks in that respect is more than atoned for by its powerful and delicious fragrance, as sweet as violets and even more penetrating. One small plant in flower is sufficient to scent the air of a large green-house. It is slender in habit, with thin branches, heath-like foliage and axillary flowers. These are formed of four spreading concave petals, which are purple-brown on the under side; yellow above. The stigma is four-lobed, large, truncate at the top, and purple; the stamens are in two series, one bearing large purple anthers, the other small yellow ones. This plant is scarcely ever out of flower. It is a native of King George's Sound, from whence it was introduced and flowered first in Kew.

B. pinnata is a free-growing, free-flowering, handsome shrub only surpassed in beauty by *B. heterophylla*. It has pinnate, smooth leaves, with from five to nine leaflets, and rather large axillary or sub-terminal corymbose flowers. The petals are one-half inch long, spreading and overlapping, fleshy, pale rosy-purple in color. They remain on the plant a long time: This species will continue in bloom from November till the following May. Twenty years ago it was one of the most popular of all flowering-plants for exhibiting. It has been in cultivation many years, and is a common plant in New South Wales and Victoria.

B. titrandra is very similar to *B. pinnata*, but differs in having smaller flowers. It blooms in April and May, and lasts about two months. The flowers are colored bright rosy-pink. Syn. *B. Drummondii* and *B. pulchella*.

B. Fraseri is a compact shrub three feet high, with green, pinnate, shining leaves and axillary corymbs of from four to six deep rose-red flowers on short peduncles. The corolla is one-third of an inch across and composed of four ovate spreading petals, which are downy on both sides. The stamens are fleshy and white. When well managed the whole of the upper six inches or so of the branches is heavily laden with flowers. They are developed in spring. Introduced from New South Wales about thirty years ago. Syn. *B. anemonifolia*.

B. crenulata is a distinct and pretty plant with fragrant flowers. The branches are slender, semi-erect and clothed with box-like leaves one-fourth inch long, obovate, overlapping each other and pointing upwards. The flowers are borne on axillary peduncles about the top of the branches, and are bright rosy-red. They measure one-half inch across.

B. serrulata is much like the last-named, but is a more robust grower; the flowers are larger, darker and more fragrant. It is a native of New South Wales, where it is known as "the native Rose," probably on account of its odor, which resembles attar of roses. The two species last mentioned are almost unknown in English collections now. They certainly are more difficult to manage than the other kinds described here, but under favorable conditions they form attractive, pretty specimens.

W. Watson.

Kew.

Lima Beans.

THE Lima Bean is one of those vegetables which I have found to do better by having a permanent location in the garden than in rotation with other crops. It requires a richer soil than the ordinary dwarf Bean, and will pay well for special attention. Most growers use poles for these Beans which are entirely too tall. The crop is harder to secure from the tall poles, and the extra height is an absolute disadvantage since it encourages the upward growth of the vine and retards its fruiting. If poles are used at all, a height of five feet is enough. Before setting the poles run furrows with a plow where the rows are to be. In these furrows place the manure

A Liquidambar in Southern Illinois—See page 232.

or commercial fertilizer, then with a crowbar set the poles firmly in the furrow four feet apart. Next throw a furrow to the row of poles from each side, leaving them standing in a ridge. Now, with a rake, dress this bed of earth into good shape, and around each pole plant four beans, eye downwards, and only just beneath the surface. The elevated ridge around the poles will heat up sooner than a flat surface, and the germination will be much more rapid. When the plants are fairly established pull up all but two to each pole, and give a little attention to starting the vines on the poles, as they frequently need to be tied at the beginning. But the best way is not to use poles at all. Set two or three stout posts in the line where the Beans are to grow, and then stretch galvanized wire-netting, four feet wide, from post to post, and plant the Beans along the ridge about six or eight inches apart. The wire will furnish points to cling to from the start, and the Bean plantation will look much better than with the poles.

Perhaps the Lima Bean will in time be able to support itself. The new Bush Lima furnishes a starting point for a dwarf variety to take the place of the old Lima. The Bush Lima, though a good thing, is, nevertheless, the smallest of all Limas, and cannot yet entirely supersede the old large Lima. But having secured the habit it will not be long before we have the big bean on the small bush. As grown here last summer the Bush Lima, or Bush Sieva, was fully two weeks or more earlier than the pole Sieva, and more than that in advance of the large Lima. It will thus be of great advantage

in localities too far north for the large Lima. But even if we succeed in putting the large bean on the small bush, it is hardly probable that we can put so many there nor keep up the succession as late as on the running vines. Therefore we had probably better not dispose of our poles or wire-netting. In fact, by the use of this netting it becomes easy to grow many desirable Beans which the pole nuisance has almost banished from our gardens.

Crozet, Va.

W. F. Massey.

Orchid Notes.

Dendrobium ochreatum (Cambridgeanum) is one of the showiest Orchids in bloom with us at present. Unfortunately it is not flowering freely, and is seldom seen in perfection. It is one of the few *Dendrobiums* that produce flowers on the young, immature bulbs—a great advantage, since the deep green leaves form a fine background to the rich golden flowers. These are produced in pairs from the sides of the bulbs, and are some two inches across, the roundish lip ornamented by a large crimson blotch. The bulbs are about a foot long, with the nodes somewhat thickened. This handsome plant was introduced in 1837 from the Khasya Hills, where it grows on trees and rocks. Under cultivation it thrives in small baskets of peat and moss suspended near the glass. During active growth it needs abundant heat and water, and after flowering should be placed in a cool, airy house thoroughly to mature the bulbs.

Dendrobium McCarthia is a large-flowered kind, very pretty and rare, found on forest trees in the southern part of the Island of Ceylon. It produces slender bulbs about two feet long, with swollen, dark-colored nodes. The flowers are borne in twos or threes on pendulous racemes from near the top of the stem. In form they are peculiarly flattened, with a sort of spur at the base, the color being white, streaked and suffused with rosy mauve. The lip has a large, rosy-purple blotch in the centre, and is edged with rose. This fine plant is usually difficult to keep in good condition, or even alive. With us it is doing fairly well in the warmest corner of the Phalaenopsis-house, growing in small, shallow pans, drenched with water during growth and kept a little dryer while flowering.

Dendrobium fimbriatum is an old and showy species that may now be seen in full beauty in a great many collections. It is a strong plant with stout bulbs four feet long, thickened in the middle and tapering to the top. The flowers are borne in loose racemes from near the top of the bulbs, which continue to bear them for many years. They are of a bright orange color, the large, roundish lip being beautifully fimbriated. This plant was introduced from the Himalayas in 1820, and grows freely in good open soil among a general collection of stove plants. A very pretty variety called *Oculatum* (*Pav-tonii*) differs from the type in having shorter and more slender bulbs, and the flowers are ornamented with a large maroon blotch on the lip.

Bletia Shepherdii is one of the best of this genus of terrestrial Orchids. It is a very robust grower with round, flattened bulbs, surmounted by lanceolate plaited leaves about two feet long. The scapes are branching, two to three feet long and bear an abundance of reddish-purple flowers prettily marked with creamy-white streaks on the lip. It comes from Jamaica, and is easily cultivated in pots of sandy peat with a little rich loam added. It should be treated as an ordinary stove plant, and needs a good rest after growth is finished.

Erises Fieldingii is a magnificent plant of bold habit growing nearly three feet high, the stem closely clasped with thick, dark-green leaves about one foot long. From the axils of these are borne drooping racemes, often branched and two to three feet long, thickly set with large white flowers, mottled

and suffused with a rich rose color that becomes much deeper on the lip. It is a native of Assam, and thrives in baskets or cylinders with Sphagnum moss in the warmest house, and should at no time be allowed to become dry. Of several varieties of this species the rarest is called *Williamsii*, a pure white form.

Cyrtopodium Andersonii is a noble plant, and one not often seen. It is only suitable for large houses, as it grows nearly five feet high. The bulbs are sheathed with the bases of the large lanceolate plaited leaves. The stout scapes which appear with the young growths are about five feet long, branching and bearing numerous rich golden flowers. It comes from the West Indies, and should be grown in very rich, loamy soil, kept open by nodules of charcoal. Steady heat, abundance of water and liberal applications of liquid manure will tend to make strong growths, and when these are mature the plant should be removed to a cool, airy house and kept dry until the flower-scapes appear. The bulbs should not be shrivelled.

Cattleya citrina is now in full flower, and the golden-yellow, tulip-like flowers hanging from among the glaucous foliage and whitish bulbs, with the peculiar drooping habit of the plant, combine to give it a striking appearance. This Orchid has been known a great many years, and is abundant in Mexico, where it grows on the under side of the branches of the trees. In cultivation it does not remain in good condition for many years, but newly imported plants grow very freely, and with us last longest in good condition if wired to bare blocks of wood and suspended near the glass in the Heath-house. They should be drenched with water during growth, and merely kept plump at other times. The flowers are deliciously fragrant, and will last fully a month in perfection.

Kenwood, N. Y.

F. Goldring.

Trilliums.—Wood-Lilies, or Wake Robins, as they are often called, are among the best of our native spring-flowering plants. Many of the species are valuable for pot culture, and when grown in this way may be easily brought into bloom several weeks before their usual flowering period. To grow Trilliums well a moist, shady place and rich vegetable mould are necessary, for when found growing wild they are usually in shady woods, where the decaying vegetable matter affords abundance of rich soil for them to luxuriate in year after year. *T. grandiflorum* is probably the best-known species, and deservedly so on account of its large flowers, snow-white when first expanded, and changing to rosy-pink with age. A quantity of this Trillium growing wild, and just in bloom, is a sight to see and remember. If visited a week or two later the appearance of the flowers is so completely changed that the place will hardly be recognized. *T. ovatum* is a Pacific Coast species and is as ornamental as *T. grandiflorum*, the flowers being pure white and fully as large. These two species are often confounded, but on examination are seen to be quite distinct in the shape of the petals and stigma. *T. erectum* is a species common in the Eastern States, having green leaves with dark purple flowers. A white variety is also quite common, with yellowish-white petals and purple ovary, a very distinct plant, known as *T. erectum album*. Another eastern species is *T. cernuum*, or Nodding Trillium. This also is white-flowered. *T. sessile* is a species with purple flowers and foliage prettily blotched with purple. The variety *T. sessile Californicum* is a plant larger in all its parts and with the coloring of leaves and flowers of a much brighter color. This is a very desirable plant, and worth cultivating for its foliage alone. *T. nivale* and *T. pusillum* are two dwarf species not exceeding six inches in height, both having white flowers. *T. petiolatum* is very distinct in its foliage, which differs from all others in being heart-shaped and borne on long petioles. All of these Trilliums are of easy cultivation when given the position named, and a little trouble taken to make the plants feel comfortable will be amply rewarded. The best time to plant Trilliums is as soon as possible after the foliage has died down in summer or early in the fall.

Dicentra eximia.—We received some two years ago a plant of the true *Dicentra eximia* from a correspondent in Tennessee, and after growing it for two seasons we find that it may be strongly recommended as a hardy border-plant. The flowers are borne in compound racemes on stems about a foot high, and are produced simultaneously with the beautiful, finely-cut foliage, which starts in April and continues until autumn frosts. As a border-plant *D. eximia* is as ornamental as the old *D. spectabilis* or Bleeding Heart, and is much to be preferred on account of its being persistent. *D. spectabilis* dies down during the hot summer months. We have found *D. eximia* to be easily propagated by division and also by seed,

which is ripened in fall. The plant is perfectly hardy near New York.

Passaic, N. J.

E. O. Orpet.

Summer Flowering Bulbs can be used with advantage to fill vacancies in the herbaceous borders and open spaces amongst dwarf shrubs, such as Glent Azaleas and Kalmias, when grown in beds or borders by themselves. The commoner varieties of *Gladiolus brenchleyensis* are often used for lines in formal borders, and planted so have a very telling effect. The rarer hybrids may be planted in dozens or half dozens, at intervals, in a border and are equally effective. Other bulbs which can be used in groups are *Crocsmia aurea*, orange; *Montbretia crocosmiflora*, orange-vermilion; *M. Pottsii*, red; *Galtonia candicans*, the large white summer Hyacinth, and scarlet and orange Tigridias. Dwarfier and rarer sorts for the rock-garden are *Milla biflora*, with pure white flowers; *Cooperia pedunculata* with fine white fragrant flowers; *Zephyranthes Atamasco*, *Z. candida* and *Z. rosea*.

Wellesley, Mass.

T. D. Hatfield.

Pontederia azurea.—A tropical aquatic has just flowered with me, and I think for the first time in the United States. It is distinct from and finer than the now popular *P. crassipes*, and will undoubtedly flourish in the open air in summer. After trial in this manner I will report further.

Bordentown, N. J.

E. D. Sturtevant.

Notes from a Spring-Garden.

Anemone Appenina is a delicate bulbous-rooted species of southern Europe, with doubly pinnate leaves, the leaflets thin and drooping and erect one-flowered scapes a few inches high. The flowers are pale china-blue an inch or an inch and a half across, delicate and rather fugacious. They appear in succession, however, and the plants, of which there is a broad and spreading clump in the shadiest part of the rock-garden, have been in flower for several days. This is a shade-loving plant, and flourishes best and lasts longest in flower when it is planted under trees.

In the depth and intensity of the blue color of its flowers no plant, perhaps, certainly no plant which can be cultivated in our gardens, surpasses or equals *Omphalodes verna*, a dwarf perennial a few inches high, of the Borage family, from southern Europe, common in English gardens, but not very often seen in those of this country, where it is rather difficult to establish and not long-lived, perhaps, because it is not very hardy here at the north. Once established, however, this charming plant spreads rapidly by rooting runners, and as it remains in bloom during several weeks, and as the color of the flowers is so wonderfully fine, it is worth a little extra trouble and patience to secure a good mass of it on one of the half-shaded slopes of the rock-garden or in some sheltered nook by a wood-walk under deciduous trees.

The yellow-flowered *Fritillaria imperialis* is at its best—a stately and splendid plant, and one which, in spite of its mephitic tendencies, causes as much admiration as any plant in the garden. It quite eclipses the old-fashioned, dull-colored Crown Imperial in habit, in brightness of foliage and in beauty of flowers. The Crown Imperial has held its own in gardens for centuries, and has seen the coming and the going of plants and of races of plants long since forgotten. It has survived many fashions, and, thanks to its tenacity of life and its real beauty, it seems destined to survive many others. This yellow-flowered variety should serve to extend its popularity and make it known among people who value plants largely because they are new or little known; not that the yellow-flowered Crown Imperial is a particularly new plant, or one that is difficult to procure, for it is sold by many of the bulb-growers of Holland, and the bulbs cost only a few cents apiece, but it is little known, and therefore rare in the gardens of this country. And this is true of another plant of this same genus—*Fritillaria pallidiflora*, a native of southern Siberia. This is a smaller plant, rarely attaining a height of ten inches, with very pale glaucous-blue leaves arranged along the stem, which bears at its summit three or four large, nodding, bell-shaped flowers, pale yellow in color, and striped and spotted on the inside with deep purple. It is hardy and long-lived, and for many years has flowered undisturbed in the same spot, which is one of the most exposed and driest in the whole rock-garden. It is truly a perennial source of pleasure.

And so is the Summer Snowflake (*Leucoium aestivum*), and I never look or think of it without wondering why it is that I never see it in other gardens, or why everyone who has a bit of ground and loves flowers does not plant a few bulbs of this plant. Its long, dark green, erect leaves, its

tall, bold scape and the cluster of white, bell-shaped, nodding flowers, which do not appear until the early-flowering bulbous plants have passed their blooming, all commend it to the lovers of hardy flowers, among which there is none, I think, which equals it in grace of carriage and in a certain charm of dignity, if such a word can be applied to a humble herb, which barely raises its head two feet above the ground, and whose annual appearance barely covers a quarter of the year.

Viola pubescens and *V. Canadensis* are both just now conspicuous objects in the rock-garden, as they have spread widely from self-sown seed, and the young plants are blooming freely. They are both native species, the former with yellow, the latter with larger white flowers, tinged with purple; and they are both easily cultivated, and improve both in size of plant and of flower under generous treatment. The Canadian Violet especially is an admirable garden plant, with its tall, leafy stems, which are sometimes two feet high, and its large and abundant flowers. It thrives, too, in the densest shade, a valuable quality in almost any plant; and it will flourish almost as well in an open situation in the full glare of the sun. There are several other of our wild flowers blooming here just now. Some of the showiest and some of the most graceful plants which are cultivated in gardens are found in the New England woods and fields, and there are no plants, when they are transferred to a New England garden, which give greater pleasure or cause greater admiration among persons who are not botanists and whose knowledge of flowers does not extend beyond the ordinary inhabitants of the conventional gardens of the present day.

The Wake Robbin (*Trillium grandiflorum*) is the showiest in flower of these plants now blooming here. It is an excellent garden plant, and if people who plant it are sometimes disappointed in the result at first, it is only because this *Trillium* requires three or four years in which to get fairly at home in its new quarters; but when it is once established it will produce larger flowers than it produces in the woods, and spread and multiply and flourish wonderfully.

Uvularia grandiflora is another inhabitant of northern woods; a graceful and attractive shade-loving plant, which is at its best just now. The common name of Bellwort is derived from the slender, bright yellow, Lily-like flowers, which nod two or three together from the summit of the slender, leafy stems. No plant is more easily cultivated, and once established it spreads rapidly, and will occupy all the space which can be afforded to it.

Boston, May 4th.

C.

Notes from the Arnold Arboretum.

THE season is one of promise. It is still early, and plants are flowering eight to ten days before they did last year. Few plants have suffered during the winter, and nearly all those which bloom upon the wood of the preceding season—that is, in early spring—are unusually full of flowers or of flower-buds.

The different species of *Prunus* are, of course, next to the Asiatic Magnolias, the most conspicuous of the small trees and shrubs which flower here in April. *Prunus Davidiana*, from northern China and Mongolia, was, as last year, the first to open its pale pink and rather small flowers, but it preceded by two or three days only the Sweet Almond (*Prunus Amygdalus* or the *Amygdalus communis dulcis* of many authors). The Sweet Almond is one of the familiar plants of European gardens and shrubberies, but for some reason or other is rarely seen in those of this country—at least in the Northern States. It is perfectly hardy, nevertheless, although, like most of the Almonds, Peaches and Apricots, often short-lived here, owing to the attacks of borers or of fungus. An Almond-tree in full flower is a beautiful object. The flowers are rather larger than those of the common Peach, or almost two inches across. The petals are pink, shaded towards the base to rose, while the calyx is purple. They appeared here on the 18th of April, and the trees are still covered with bloom, although many petals have, of course, fallen. These flowers have experienced during the past two weeks excessive summer heat, sharp frosts, violent thunder-showers and two prolonged north-easterly rain-storms. There are few flowers which can bear so much hard treatment and look fresh and bright at the end of three weeks.

The Almond is a native probably of Mesopotamia, Persia and the Trans-Caucasian countries, but it was early introduced into Europe by the Greeks, and has now become fairly naturalized in the countries of southern Europe and in Algeria. It is a tree twenty to thirty feet in height, with a spreading

head of rather sparse, upright branches, and it is only when the tree is in flower that it is an object of great beauty, as it is not remarkable in its foliage or in its habit or general appearance, which are not very unlike those of the common Peach-tree. The earliness and lasting qualities of the flowers, their large size, abundance and individual beauty are what make the Almond such a desirable tree for the garden. There are several varieties of the Almond in cultivation, but the variations are principally in the fruit. They are largely cultivated in southern Europe, especially in Portugal, and in the Orient, and recently somewhat in California, where the climate is well suited for this tree. The varieties with sweet and with bitter fruits were distinguished, according to A. De Candolle, by the Greeks and even by the Hebrews.

The plants found in nurseries are usually worked as tall standards upon Plum stocks, as the Almond is found to grow more vigorously and to last longer worked on the Plum than when it is grown on its own roots. The variety with sweet, hard-shelled fruit (*Douce à coque dure*) is much used in France as stock upon which to work the Peach, which is found, when treated in this way, more prolific in dry soils. According to Charles Downing ("The Fruits and Fruit-Trees of America") "the common Almond, the hard-shell Sweet Almond and the Bitter Almond are hardy in the latitude of New York, and will bear tolerable crops without care. The soft-shell Sweet Almond, or Ladies' Almond, will not thrive well in the open garden, as a standard, north of Philadelphia; but they succeed well trained to a wall or on espalier rails in a warm situation, the branches being slightly protected in winter."

It is well to record, perhaps, that the flower-buds of the Siberian Apricot (a wild form of *Prunus Armeniaca*, a common and widely-distributed tree through Siberia to northern China and Manchuria) were killed during the past year. It is a handsome, vigorous and perfectly hardy tree here, of rapid growth, but it has never flowered freely or set fruit, and this is the first time that the flower-buds have been killed.

The Japanese *Prunus pendula*, of which an illustration was published in the first volume of GARDEN AND FOREST, p. 196, flowered two weeks earlier than it did a year ago, but as usual the plants have been covered with flowers. It is certainly one of the most graceful of all small trees, and one of the freest and most constant bloomers. There is no tree of northern gardens with which it can be compared, and none when its pale pink, nodding flowers cover the long, drooping branches which possess its delicate refinement and peculiar charm. Fortunately it is hardy and a rapid grower, flowering early, and it is easy to multiply by grafting upon the common Cherry-tree, so that there is really no reason why this little tree should not be seen wherever gardens are cultivated or beautiful plants esteemed. And yet, strange to say, it is hardly known yet in European nurseries, while in this country, although a few plants have been cultivated for nearly twenty years, it is rarely seen outside perhaps a dozen gardens.

A variety of the cultivated Peach raised from seed sent to the Arboretum by Dr. Bretschneider from Peking, is now conspicuous with exceptionally large, abundant and deep-colored flowers. It has some value as an ornamental tree.

It is a curious fact, and one not very easily explained, that the Myrobalan Plum is so rarely seen in our gardens, although now that the purple-leaved Persian variety, the so-called *Prunus Pissardi*, has been so generally propagated, we are going to see more of it in one form at least. The green-leaved plant is far the handsomer of the two, however, when the trees are in bloom, and it is, moreover, one of the handsomest of the Plums at this season of the year, as the leaves, which are about half grown when the flowers are fully expanded, make a charming and effective setting for them, and afford what most "fruit-trees" lack in flower—a contrast of colors. The Myrobalan is a small tree of good habit. It is perfectly hardy, not particular about soil or exposure, and one of the freest bloomers of the genus. It is one of the plants which has most puzzled botanists, as although it has been in cultivation for centuries it is nowhere known in a wild state. It is probably a variety or form of the common Plum (*P. domestica*). The fruit is small, depressed-globular, scarlet or yellow, and of little value except for the handsome appearance which it presents as it hangs upon the branches. The Myrobalan is one of the best of the early-flowering trees to plant in a small garden or on a small lawn. Judged by the plants grown in the Arboretum, it is longer lived and less liable to be injured by borers than the purple-leaved *Prunus Pissardi*.

Prunus tomentosa is in full bloom, and as usual, an object of much beauty. It is a native of northern China, whence long ago it was carried to the gardens of Japan, where it is generally cultivated and highly esteemed. This little Cherry is a

spreading bush, growing three or four feet high by as much through. The stems are long and wand-like, and are now covered from end to end with pale pink flowers the size of those of a common Cherry-tree, which appear just as the young leaves, which are thickly clothed with tomentum (a peculiarity of this species), are unfolding. The flowers remain open during several days, and are succeeded by bright scarlet, almost transparent fruit, which is ripe here during the month of July. This is a very hardy shrub. It is easily raised from seed or from cuttings, and when it is better known its value will be appreciated, and it will be seen wherever shrubs are cultivated for ornament.

Amelanchier oligocarpa was first figured in GARDEN AND FOREST, i., p. 247. It has been in flower in the Arboretum for a week, and is the earliest of the genus, and a shrub of great beauty in cultivation. A native of cold, northern bogs only, it takes kindly to cultivation, which soon increases its stature and the size and abundance of the flowers, which are the size of a shilling, with broad, obovate, pure white petals. They are borne on long peduncles along the entire length of the stems, and are not fully open until the young leaves, which are bright bronze-green, are more than half grown. The pure white flowers in their setting of deep-colored leaves, the compact habit and general appearance of thrift and vigor which the plant displays in cultivation all commend it. It is one of the native shrubs unknown or entirely neglected by cultivators which the Arboretum is gradually calling attention to. The flowers of *Ribes saxatile*, the first of the genus to open, now cover the plants. They are yellow, produced in short, erect racemes, and make an agreeable appearance in contrast with the somewhat darker yellow of the foliage. This plant is a native of Siberia, long known to botanists and in gardens, in which it deserves a place, both for its pretty flowers and because of all the shrubs cultivated in the Arboretum it is the earliest to cover itself with leaves.

Of the shrubs, however, which flower here in New England during the last days of April, there are none which can be compared with the Forsythias for splendor of bloom, or with *Spiraea Thunbergii* for a profusion of pure white flowers. There are three Forsythias in cultivation—the old *F. viridissima*, a poor plant, comparatively, blooming fully a week later than the others, and with smaller and paler flowers, more erect branches, and less graceful habit. The others are *F. suspensa* and *F. Fortunei*, the latter a more upright growing variety of *F. suspensa*, with rather larger flowers, and by far the handsomest and most desirable of the three. It is hopeless to undertake a description of a large plant of this variety—ten or twelve feet high by as many through, with long, graceful, arching stems; a mass of brilliant yellow bells flashing in the sunlight, as I write—or to imagine how any other plant of its size can be more beautiful or give such an idea of marvelous profusion of flowers. There is some confusion in gardens in this country about the different species and varieties of Forsythias, and drawings have been prepared here to show the difference in the flowers and fruit, for publication in a later number of GARDEN AND FOREST.

Spiraea Thunbergii is handsome from the middle of April until the middle of November. It blooms profusely; the flowers, although individually small, cover the plant; the foliage is particularly graceful; the habit of the plant is good, and it is almost the very last in the autumn to change the coloring of its leaves, which, when most deciduous trees and shrubs are leafless, are brilliant with orange and scarlet tints.

Cercidiphyllum Japonicum is one of the introductions of the Arboretum which, although little is really known with regard to it yet, is a tree of so much promise that it may not be out of place to call attention to it. *Cercidiphyllum* is a Japanese genus of two species which is now considered to be more connected with the Magnolia family than with any other. *C. Japonicum* is a large timber tree in its native country, and, judging by the rapidity of its growth here, it promises to become a tree of considerable size in this country. The seed was first sent to the Arboretum in 1878 by Mr. W. S. Clark, at that time President of the Agricultural College at Sapporo, and the largest trees raised from that seed are about sixteen feet high. They are as fastigate in their manner of growth as a Lombardy Poplar or a fastigate Oak, and all attempts which have been made here to induce the young plants to assume a different habit by removing the lower branches have resulted in their death, caused, apparently, by the exposure of the stems to the sun. The young trees grow, perhaps, in dense shade naturally, so that when transplanted into the open, the lower branches are essential to protect the tender bark of the stems. This, as well as the slender branches are covered with thin, red-brown bark hardly to be

distinguished from that of the native Black Birch (*Betula lenta*), while those of the ultimate branchlets are dull red. The leaves appear here earlier than those of any other tree, with the exception of those of the Manchurian form of the Bird Cherry, figured upon page 295 of the first volume of GARDEN AND FOREST. They are opposite; round, or nearly so, deeply heart-shaped at the base, crenately-toothed, and, when they first appear, resemble, in color, the young leaves of the Purple Beech, with bright red stalks and conspicuous, narrow red stipules, half an inch long. They gradually lose their bronzed-red color, and later in the season are dark, rather dull, green, turning bright, clear yellow in the autumn. The flowers which have not yet been produced here are not conspicuous, and it is for its habit and its handsome foliage, so striking in the early spring, that the *Cercidiphyllum* will prove valuable if, upon longer trial, it is found really suited to this climate. The plants seem to flourish, and to grow most rapidly in peaty soil. The fact that it starts to grow so very early in the spring will prevent its being successfully grown in climates in which late spring frosts prevail. Here in New England, where such frosts are of rare occurrence, this tree is one which now seems to promise a good deal. It is worth, at any rate, a careful and extended trial.

Periodical Literature.

In *Harper's Magazine* for May, Dr. C. C. Abbott writes pleasantly and instructively of "A Meadow Mud-hole," telling how charming are the things which Nature often puts there, and how many more may easily be added by the hand of man. The greater part of his article is devoted to the Yellow Lotus (*Nelumbium luteum*) and its exotic cousin, the Rose or Sacred Lotus (*N. speciosum*). Of the former plant he tells the familiar tale—that it is native to the waters of the Western and Southern States and is occasionally found in the Middle States, but in the valley of the Delaware so rarely that it is believed to have been introduced there, probably by the Indians; but he then adds a fact less generally known. It seems that this Lotus has not succeeded with the modern cultivator, although he finds no difficulty with its foreign relative. The description given of a water-meadow in New Jersey where the Rose Lotus and many other exotic Lilies now grow in splendid masses, and the accompanying picture, indicate that he refers to Mr. Sturtevant's plantation, recently described at length in these columns. All this multitude of Lotuses, he says, have sprung from a single tuber, planted in 1881; and, he adds, a tuber set out a year ago in a "mud-hole" of his own already overshadows all the native plants in its vicinity. "For a time they are permitted to be co-occupants, but not for long. The lusty Lotus is even now reaching out to a wide stretch of marshy meadow; and there, too, I doubt not, it will flourish as at my neighbor's. It is a rightful ambition to be able to sit down beneath one's own Vine and Fig-tree. Let me add the Lotus, for it has come to stay." Selling cheaply in our city streets, too, "this famous flower of other lands must soon appear." Are not these words sufficient encouragement to the most humble of horticulturists to assist in the happy task of spreading this lovely plant? If a single tuber will so quickly develop a numerous progeny, and if a mere meadow mud-hole will serve as its home, should it not soon become as familiar an object as the white Water-lily, with which it contrasts so well? Like the Water-lily, too, it has the merit of being a persistent bloomer. "If not a joy forever, it is at least one of a protracted season. Buds or blossoms, they are alike beautiful. Among many that are pale yet distinctively tinted there often stands out one or more with the loosening petals tipped with deepest crimson. Far more are like gigantic Tea-rose buds that soon open like a Tulip, creamy-white and rosy at the tips. Often these glorious flowers measure ten inches across when fully open, and are supported by stems extending far beyond the tallest leaves. One such that I measured was more than eight feet high. When the flower is fully expanded, the huge seed-pod . . . is of the richest yellow, and surrounded by a delicate fringe of the same color. The seeds are seen imbedded in the flat, upper surface—gems in a golden setting so lavish that their own beauty is obscured."

In turning over the pages of this number of *Harper's* no flower-lover will fail to pause at those where old Andrew Marvell's beautiful "Thoughts in a Garden" are reprinted with delightful illustrations by Alfred Parsons, the well-known English landscape-painter. And to more practical minds Mr. James K. Reeve's "Agriculture as a Profession" will give food for serious thought.

Correspondence.

Opening Buds.

To the Editor of GARDEN AND FOREST :

Sir.—It is a very interesting thing to keep a record, year after year, of the dates of the appearance of flowers or leaves. When one has done so for thirty years he is able to refute some popular notions. One of these is, that the seasons are changing. If, however, we compare cycles of years, rather than contrast two contiguous seasons, we find a general level is maintained. A phenomenally early spring this year may be offset by a late one in 1890 or 1891. And, by the by, we have known earlier seasons than this, so far as the flowers are concerned. To be sure, the *Houstonia* opened on March 26th, but we find other things about on time. Thus: *Houstonia cærulea*, March 26th; *Potentilla Canadensis*, April 4th; *Acer dasycarpum*, March 23d; *Draba verna*, April 13th; *Hepatica triloba*, April 20th; *Nepeta Glechoma*, April 18th; Horse-chestnut, leaves appearing April 19th; *Anemone nemorosa*, April 19th; Magnolias, April 21st; *Viola sagittata*, April 23d; *Acer platanoides*, April 23d; *Caltha palustris*, April 24th; *Taraxacum Dens-leonis*, April 25th. The date for *Houstonia* here given is the earliest I have. Usually I have found it about the 9th to the 15th of April. The year 1865 presented some very early dates. That year I found *Anemone nemorosa* in full flower near Barrington, Rhode Island, April 15th. I especially recall the day from its sad historic interest.

I find our Horse-chestnut trees extremely variable. Why is it that a certain tree, like that in the yard of the Friends' meeting-house, leaves out a week before all others in town? I have observed the same thing with Lindens. Indeed, two standing side by side, manifest this difference. I greatly regret that in my twenty-six years of collecting, I did not keep a connected record of natural events. Such a diary is of immense use not only to one's self, but to science generally. Many, I imagine, are, under the inspiration of recent teachers, now so engaged.

Providence, R. I.

W. W. Bailey.

To the Editor of GARDEN AND FOREST :

Sir.—The laborer in a good cause is worthy of his hire in the shape of frank acknowledgement of his services. I am glad therefore to be able to tell you that I recently heard a gentleman say: "I am just building a new house, and although there is only an acre of ground around it, my conscience was absolutely bullied by GARDEN AND FOREST into employing a landscape-gardener to lay it out for me."

Providence, R. I.

H. G. B.

Maple Avenue Nurseries.

To the Editor of GARDEN AND FOREST :

Sir.—A ride through Chester County, Pennsylvania, is always a delightful experience, and especially so at this season, when the broad meadows which skirt its numerous streams, and the pastures on its hill-sides are mantled with the purest green, while the opening leaves of its frequent woodlands show a diversity and richness of color which even the foliage of autumn can hardly equal. Never were flowers upon early-blooming trees and shrubs more abundant. On all the wood-borders the Dog-woods are white as snow. The branches of the Judas-trees are quite hidden beneath the deep pink blossoms, and the Lilac bushes by every farm-house actually bend under the weight of their flowers. Just on the outskirts of the fine old town of West Chester are the nurseries of Hoopes Brother & Thomas, and in the border of specimen shrubs which extends for 300 yards beside a sheltering hedge every plant in bloom is apparently trying to produce more flowers than ever it did before.

A spacious and level lawn, in perfect condition, fronted by a long line of noble trees, makes an attractive entrance to these nursery-grounds. The land is not uniformly level, however, but is marked by the same diversity of surface which characterizes the county generally, and some of the elevations command prospects of great extent and remarkable beauty. The soil is fertile, easily tilled and well adapted to give a thrifty growth to young trees and shrubs, and, by a system of close evergreen hedges, they are well protected from the winds, so trying in winter to many plants which do not suffer from cold alone. It would be difficult to find anywhere in this country so great a length of such perfect hedge. The Hemlock hedge is much the most beautiful, and no conifer, when clipped to a line, can show so soft a surface. The Arbor Vitæ hedges, too, are admirable in their way—dense, uniform in color and texture, and showing no weak spot from end to end. But Mr. Josiah Hoopes considers the Norway Spruce the ideal hedge plant in this climate for practical purposes, and it is only excelled in beauty by the Hemlock. It is tenacious of life, endures the knife more patiently than any other conifer, and after

long cutting, becomes almost as solid as a wall of stone and quite impervious to any ordinary assault. Mr. Hoopes has not observed that the hedges have any injurious effect upon the plants near them by robbing them of food or moisture. The young stock certainly looks well now, and in one place a block of Japan Maples, which were fairly ablaze with brilliant color, looked brighter still for the dark-green background of the hedge behind them.

It is thirty-six years since Mr. Josiah Hoopes began business here in a small way, and now the firm of Hoopes Brother & Thomas has nearly 400 acres under cultivation. Their trade is nearly all wholesale, and their aim is to keep a full line of such stock as is in demand by other nurserymen and dealers. They can hardly be said to have any specialty, although the fact that last week they set out 115,000 hardy Roses indicates an extensive business in that direction. Fruit trees, of course, occupy the greater portion of their grounds, and for some years past the sales of Norway and Sugar Maples and European Sycamore have indicated a general activity in planting street trees. This year Mr. Hoopes tells me that there has been a marked increase in the inquiry for ornamental trees and shrubs, including the choicer conifers. Some fifteen years ago Mr. Hoopes planted a Pinetum which contained all the species and varieties of conifers then obtainable, which promised to be hardy in this climate, but a large proportion of them have failed, showing how unsatisfactory it is to plant trees of this family, except those which have proved themselves sturdy and useful for special purposes. Most of the foreign Pines have yielded to attacks of fungus; the Cypressess are practically all gone, and a large proportion of the Junipers and Yews. Among the noteworthy trees that remain I remarked a *Pinus cembra* var. *Helvetica*, *P. Manchurica* and *P. peuce*, all fine specimens. Among the Spruces, *Picea pungens* and *P. ajanensis* are making strong growth. A Spanish Fir (*Abies Pinsapo*), under the lee of a sheltering belt of trees, is in excellent condition. *A. concolor* is thrifty, and so are *A. brachyphylla*, *A. Cilicica* and *A. Nordmanniana*. Very interesting, too, is a particularly fastigate form of the common European Silver Fir, which is well furnished from the ground up.

The most interesting group of trees I saw, however, stood in the old nursery grounds, where most of them were planted by Mr. Hoopes in 1853. Here is an Oriental Spruce, some thirty feet high, and now fairly red with its abundant male flowers. A specimen of *Abies grandis* measures nearly two feet in diameter, and near it stand fine examples of *Picea Smithiana*, *Abies Cephalonica* and many more. Near the house a tall *Magnolia Fraseri* was just opening its great flowers, which are a delicate canary color on the outside, and I wondered why it is not more frequently planted. A collection of Beeches, including large trees of the cut-leaved and fern-leaved varieties, stands near, and among them is an immense Bird Cherry (*Prunus Padus*), with a trunk nearly two feet in diameter, and its branches meet the grass in a circle forty-five feet across. It was covered completely with fragrant flowers. Of the shrubs in flower some *Exochordas* were noticeable for their great size, while retaining the compact habit of smaller plants. A Japanese Judas-tree, near the house of Mr. Thomas, seemed about nine feet high, and was, of course, a mass of flowers. This plant had been used several years to supply cuttings for propagation, but as soon as it was left to itself it began to shoot upward and spread outward, and is still growing rapidly. It bids fair to become almost as large as our native *Cercis*. Some plants of *Rhododendron Vaseyi* were bearing abundantly their clear pink flowers. *R. Rhodora* was also showing its rosy flowers, and this was in a structure some 200 feet long, with top and sides lathed, for shade-loving plants like *Kalmias*, hardy Ferns and many herbaceous perennials.

In a long-established nursery like this, one can find scores of beautiful things to admire; but, after all, the general tidiness, good order and organized system with which the great volume of business moves smoothly forward is the fact which most impresses the visitor. The nursery will hold an honored place in the history of American horticulture, and the writings of Mr. Josiah Hoopes in various periodicals for several years past have exercised a wholesome influence in moulding taste and directing practice in horticultural matters.

Notes.

An unusual number of forest fires have been raging for a week past from the Shawangunk and Catskill Mountains of this state to the woods of northern Minnesota. The fires have been exceptionally destructive in Michigan.

In the plant collection of Monsieur Beaucarne, a Belgian amateur, which was sold a few weeks ago, one of the most remarkable things was a specimen of *Vanda Lowii* which measured five feet and five inches in height.

Mr. Goldring, one of our regular London correspondents, who has been in India during several months engaged in superintending the formation of some new gardens for the Gaikwar of Baroda, has now returned to England for the summer.

An English journal speaks of *Rhododendron fragrantissimum* as one of the most attractive flowers offered this year at Easter. "Plants in eight-inch pots have bushy, spreading heads, and the point of every shoot is terminated by a cluster of large, bell-shaped, bluish-white and sweetly-scented flowers."

"Chrysanthemum-Growing in America" (showing method of protecting the plants) is the title of a large illustration in a recent number of the *Garden* (London). The picture represents a corner of Mr. Gerard's garden at Elizabeth, New Jersey, although not the same one that was portrayed in these columns last autumn.

A plant of *Rhododendron Veitchianum* recently exhibited at Newcastle-on-Tyne is noted, by one of the English horticultural journals, as "one of the finest specimens of this *Rhododendron* ever seen. . . . It is a compact bush, is in excellent health, and furnished with upwards of 300 of its large, white flowers, which are crisped round the edges and quite five inches across."

Many of the political exiles who are wasting their lives in Siberia are men of cultivation and scientific knowledge, and one of the few industries or amusements with which they are permitted to console themselves is the formation of herbaria of local plants. In the May number of the *Century Magazine* Mr. Kennan speaks of having aided an exile whose term had expired to secure the money needed to take him back to his home by purchasing for a hundred rubles a collection which he had made.

The fourteenth annual meeting of the American Association of Nurserymen will be held in Chicago on June 5th and 6th. The programme, which we have received through the courtesy of the Secretary, Mr. Charles A. Green, shows that addresses on an unusually wide range of topics may be expected from speakers well qualified to give instruction. These meetings have proved of great value, both from an educational and from a business point of view, and the nurseryman who neglects to attend them fails to live up to his privileges.

A correspondent from Germantown writes that the woods about there, although much of their primitive character is lost, still produce many wild flowers. A collection of eighty-four kinds was gathered for the last meeting of the Germantown Horticultural Society in four hours. Of Violets alone nine species were shown. The collector of these flowers stated that the *Asplenium pinnatifidum* is quite abundant yet, in its locality along the Schuylkill, where Nuttall first found the Ferns on which he bestowed the name. It grows on rocks that are not easily reached, and hence will probably be safe from destruction for some time.

The great Tulip-bed in the centre of Union Square was not planted this year in as satisfactory a way as usual. Instead of the splendid effect of reds and yellows which has often met the eye, the dominant flower was a very dark, dull purple variety, which had neither purity nor brilliancy of tint to recommend it, and harmonized badly with the few more brightly-colored varieties that were associated with it. A Tulip-bed is nothing if not gorgeous, and it seems strange that, with so many effective sorts to choose from, this ugly one should have been so lightly favored. Doubtless, however, it was an experiment which will not be repeated.

Cercis Chinensis, often cultivated in this country as *C. Japonica* and introduced here from Japan several years ago through the Flushing Nurseries, is a plant of great beauty wherever it can be successfully grown. A very fine plant, no doubt one of the relicts of the Centennial, may be seen in the neighborhood of Horticultural Hall, in Fairmount Park, Philadelphia. It is there a broad bush four or five feet high, with many erect, rather spreading, stout branches, which, last

week, as the native species was just coming into bloom, were completely covered from the very base of the stems with flowers. These are considerably larger than those of the other species and of rather deeper color than the flowers of our common eastern Judas-tree. This plant is fairly hardy in the neighborhood of this city, but it only does really well in a rather milder climate. It may be seen in Washington in very great beauty. North of this city it is killed almost every winter. This *Cercis* is a native of northern and central China, and it is believed to have been introduced into Japan with many other Chinese plants. Seed gathered in the country of its most northern range may be expected to produce plants which will prove hardy in our northern states. The Chinese Judas-tree is said to be an important timber-tree in China, growing to a considerable height with a trunk several feet in diameter, so that it is possible that the shrub of our gardens is only a dwarf variety, produced or cherished by the Japanese, and that the typical tree is still to be introduced.

Mr. Douglas W. Freshfield recently read before the Royal Geographical Society in London an interesting paper on "The Peaks, Passes and Glaciers of the Caucasus." Few persons realize that the slopes of the central Caucasus are steeper than those of the central Alps, and that they are clothed by splendid draperies of ice and snow, amid which the freshness of the loftiest snowless slopes stands out with singular vividness. At a height of more than 13,000 feet Mr. Freshfield gathered flowers, while at 10,000 feet above the sea, near the great Mestia glacier, *Rhododendron Caucasicum* was growing in great clumps, and the grass was sprinkled with Poppies, Geraniums, Veronicas, Ranunculuses, Gentians, Forget-me-nots and Campanulas. "The steppe," says the abstract of the address printed in *The Garden*, "except in the river-beds, was treeless; but no sooner did the ground begin to rise than wild fruit-trees appeared, soon to be succeeded by dense groves. The glades were bright in summer with millions of wild Sunflowers. The flora of the basin was wonderful. A horse laden with baggage was entirely hidden by the growth of flowers; the head and shoulders of a mounted man only rose above them. Wild Sunflowers and a species like Canterbury Bells grew to a height of six feet and eight feet. There were no waterfalls, and neither lakes nor tarns. Of late years the glaciers had oscillated in a manner corresponding to the Alpine glaciers. They were all in retreat in 1868; about 1875 they began to turn, and last year were sensibly advancing. The humidity of the summer climate was at once a charm and a vexation. The atmospheric effects were beautiful and various; the sky of the northern steppe was luminous and soft; the light was the light of the east; the colors those of the Roman Campagna."

At this writing (May 7th) the great display of Tulips in the Public Garden in Boston is at its best, and surpasses that of any previous year in good taste, in the arrangement of the different varieties, in the beauty of the varieties themselves and in the individual excellency of the plants. Mr. Doogue has reason to be well satisfied. The display is specially marked by the absence of double and semi-double varieties, which are only sparingly used. They are always inferior in beauty to the single flowers. An exception may be made in favor of the semi-double Couronne d'Or, a variety with very large, bold flowers, orange streaked with red. Turban Violet, a double flower of a dirty purple, will not probably sufficiently commend itself to secure a place in the garden another season. This last is the only really bad flower in the collection. If we should venture a suggestion it would be that more of the bright scarlet and yellow-striped varieties be used in place of some of the self-colored flowers which predominate. The interest and value of the display is greatly increased by cards placed over each bed, on which the names of the varieties are handsomely printed. It is an open question whether the carpet of Pansies used to cover the ground in the Tulip beds adds to their effect or not. The Tulip is such a stately and gorgeous flower that it may lose something of its character if brought into too immediate contrast with any humbler herb. In the days when the Tulip played a greater part in the world than it does now they were planted always alone, and it would be well to contrast another year beds carpeted as they are this year with others in which the Tulip was allowed to grow alone. But nothing certainly could be more lovely in the way of a spring flower-bed than some circles thickly covered with Daisies, among which have been plunged pots of the Hoop-petticoat Narcissus, and which can be seen near the Charles Street entrance to the central walk. Large specimens of the double-flowered white and of the double-flowered scarlet Peach, completely covered with blossoms, are objects of surprising beauty.

The Attack on the Niagara Reservation.

LAST week we spoke of the constant watchfulness that must be exercised by the public-spirited portion of the community, if city parks are to be saved from invasion and spoliation. It should be added that the same unceasing vigilance is needed for the protection of other reservations which a wise policy has set apart for the general benefit and enjoyment of the people. The conveyance of the Yosemite Valley to the National Government, and subsequently to the State of California, was made to guarantee the protection of its wonderful scenery from defacement and vulgarization and to insure the preservation of its natural sublimity and beauty throughout all coming time. But experience has shown already that it is in constant peril from the attacks of private greed. There are complaints, which seem well-founded, of the slaughter of the game, the burning of the woods and the mutilation of the marvelous cones and basins of the geysers in the Yellowstone Park. In our own state all efforts to save the Adirondack forests from the destructive invasion of railroads have so far proved unavailing; and even the Niagara Reservation has within a few days narrowly escaped from an attack upon its integrity by a private corporation.

The organized effort to preserve the scenery of the Falls of Niagara, which resulted at last in the passage of an act to make certain lands about the Falls free forever not only to the people of New York but to all mankind, was one of the most remarkable movements of recent times. From the outset to the end, appeal was made directly to the most elevated sentiments and the most generous emotions of the people. They were invited to aid in the redemption of Niagara, not because it would enhance the value of their real estate, not even as a matter of local pride, but simply because the unparalleled sublimity and loveliness of this spot, with its power to kindle noble thought, was one of the priceless possessions of the race. Many men of this state and of all parts of the Union—men eminent in every walk of life—made bold to declare in a memorial to the Governor of New York and the Governor-General of Canada that "objects of great natural beauty and grandeur

are among the most valuable gifts which Providence has bestowed upon men. The contemplation of them elevates and informs the human understanding. They are instruments of education. They conduce to the order of society. They address sentiments which are universal. They draw together men of all races, and thus contribute to the peace of nations." Upon this high level the campaign was conducted throughout, and the victory was gained without a single appeal to sordid or selfish motives.

Notwithstanding the gratifying response of the people and of their representatives in Albany to the efforts of the public-spirited citizens who kept reiterating their appeal through the press and in public addresses and private correspondence until every intelligent reader of the state was informed of the exact condition of Niagara, of its danger, and of the reasonableness of the proposed legislation, it was always plain that an adequate appreciation of the value of the scenery of Niagara was not universal. There were good people who were willing to see the Reservation occupied by museums and monuments, and who would encourage the erection of buildings for educational ends, because they felt, in a vague way, that education was a good in itself, and who would not be made to understand that any unnecessary structures would help to mar the scenery, which was the essential thing to be saved. Every attempt at invasion of this sort has fortunately been repelled, and it was hardly to be expected that any private corporation would at this early day be bold enough to attempt the capture of the Falls in order to use them as a water-power for private advantage. It is a fact, however, that a bill with this intent has been introduced into both houses of the Legislature, and received a favorable committee report in both cases. The Niagara Hydraulic Electric Company was authorized, so far as the committees of both houses had the power, to build coffer-dams above the cataract, to erect machinery, and to bore a tunnel under the bank of the river. Of course it was claimed that all this would inflict no injury upon "the scenery," but it is plain to every one familiar with the way of similar corporations that this factory would have despoiled the spot of much of its natural charm, and would have been a wanton defacement and desecration which must have given pain to every beholder.

The moral of all this is, as has been well expressed by Mr. Harrison, the Secretary of the Niagara Association, that "great wisdom and decision will always be required adequately to protect the Niagara Reservation from the encroachments of greed and vulgarity. In the nature of things it can never be safe for the people of intelligence, good taste and public spirit of the State of New York or of the country at large to withdraw all oversight and interest from the management of the Reservation and the care of the scenery about the Falls." This bill was checked in the Senate, but other bills will be presented at every session of the Legislature, and the friends of Niagara and of American civilization must be in constant readiness to meet attack if they hope to save what has been gained.

There is rarely sufficient room near any tree for all the seeds which it produces to germinate or for the seedlings to develop into fully-grown individuals. Nature is lavish in sowing seeds that the succession of the plant may be insured. Most trees are gregarious, therefore, in extreme youth, from habit transmitted through many generations. They love company, and really thrive only when closely surrounded. Close planting is essential, therefore, to insure the best results. As the trees grow, the weaker are pushed aside and finally destroyed by the more vigorous, and the plantation is gradually thinned. This is the operation which is always going on in the forest when man does not intervene. It is a slow and expensive operation, however, and the result is attained by a vast expenditure of energy and of good material. The strongest trees come out victorious in the end, but they bear the scars of the contest through life. The long, bare trunk and the small and misshapen head—the only form of a mature tree found in the

virgin forest—tell of years or of centuries of struggle, in which hundreds of weaker individuals may have perished that one giant might survive. But man can intervene, and by judicious and systematic thinning help the strong to destroy the weak more quickly and with less expenditure of vital force. Thick planting is but following the rule of nature, and thinning is only helping nature do what she does herself too slowly, and therefore too expensively. This is why trees in a plantation intended for ornament, like those in a park or pleasure-ground, should be planted thickly at first, and why they should then be systematically thinned from time to time; and it is because this systematic thinning is altogether neglected, or put off until the trees are ruined for any purpose of ornament, that it is so rare to find a really fine tree in any public place or private grounds. Of the implements required to produce a fine tree the axe is certainly the first and most important.

The Art of Gardening—An Historical Sketch.—V. Judea and Phœnicia.

ON the whole we may conclude that while gardens were known and prized in Judea, they played no such conspicuous part in royal and priestly life as they did in most Oriental countries, while the private citizen—usually devoted to agriculture and devoid of wealth—rarely, if ever, created them on an extensive scale. Moreover, we can divine that the royal gardens themselves were primarily places for the propagation of fruit-trees and other useful plants. Even the poetical imagery of the Bible reveals this fact, speaking much more of fruits, sweet smelling herbs and serviceable trees than of plants prized for their beauty or for the luxury of the shade they gave. Flowers were not required in religious ceremonials, but incense was, and odoriferous herbs are constantly referred to in the Scriptures, sometimes as very precious things. A "balsam garden" at Jericho was important enough to be noticed by Strabo, but in reading authors of his time we must not forget the great influence which Greek and Roman conquest had then had upon the world. Of course, flowers cannot have been neglected in Judea—there is no civilized time or country when this has been the case. But their rôle was private, not public; and plants are only mentioned in connection with the temple in those simulated forms of Pomegranates, Palms and "flowers of Lilies," which entered into its carven decoration. So learned and enterprising a king as Solomon may well have filled his gardens with exotics obtained from his constant helpers, the traveling and trading Phœnicians, and the mention of planting "strange slips," in Isaiah xvii. 11, seems to indicate that they were especially valued. The Levitical law against the propagation of mixed species must, however, have stood in the way of such horticultural operations as have enriched the garden flora of modern peoples.

The Jews had a peculiarly keen sense for the beauty and grandeur of natural scenery and of wild-growing forms of vegetation. Why, then, were their gardens less numerous and important than those of other Oriental nations? Partly, as I have said, because of their relative poverty and simple ways of life, but partly because, while the Egyptians, for example, were artists by nature, the Hebrews were not. The same difference which shows in the history of gardening shows in that of other forms of art. Art of every kind was vitally essential to the religious ceremonials of Egypt, but it played a minor part in Judea, and in many of its developments was absolutely outlawed. It was proscribed as a spring of spiritual danger. But it would hardly have been proscribed for this or any other reason among a people endowed by nature with a strongly artistic temperament. The Jews were a highly imaginative race, but their imagination concerned itself most of all with moral and spiritual things, least of all with the things of art.

The Phœnicians were likewise a Semitic people, and therefore devoid of that instinct for the arts of design which covered Egypt, Assyria and Greece with splendid monuments. But, unlike the Jews, they were rich, luxurious, and given to sumptuous and sensual religious rites. A nation of traders and travelers by land and sea, wealth flowed freely into private hands and was as freely spent for private pleasure, while the native lack of artistic ideas was made good by perpetual borrowings. This we know from the works in the minor arts which have come down to us from the Phœnicians, and their technical experience is proved by the familiar fact that Solomon sent for Tyrian artificers to build his temple and his

palace. The highest merit of the Phœnicians in their own day must have seemed their manual skill; to-day it seems the part they played in carrying the works and the ideas of one country to another and thus developing the rudimentary gifts of their less advanced neighbors. They originated nothing, unless it be certain forms of decoration which, many ages later, bloomed into new and richer life under the hand of Byzantine artists. But they were the world's carriers—the transmitters and perpetuators of much that without their help would have perished where it was born.

Gardening was widely and successfully practiced in Phœnicia. The country was merely a narrow strip of land; but its soil was fertile, and the needs of a dense and wealthy population incited to careful culture. Ezekiel implies as much when he cries to the King of Tyre, "Thou hast been in Eden, the garden of God," and we know that hydraulic engineering, upon which agriculture and horticulture so largely depend in southern countries, was elaborated on an extensive scale in all parts of Phœnicia and its colonies.

The chief towns of the mother-country were isolated, rocky citadels, where the merchants plied their trade and gathered for defense in times of war. Here the poorer citizens lived in crowded, many-storied streets; but the rich had their homes in the suburbs, in countless villas surrounded by beautiful grounds. It is easy to imagine what these villa-gardens were. In this art, as in every other, the Phœnician must have borrowed from the Egyptian and Assyrian, and laid out his gardens in a formal way. So eminently practical a people were doubtless enterprising and successful horticulturists; and trading from far beyond the Pillars of Hercules to the shores of the Indian Ocean, and eagerly laying hands on everything new, beautiful or curious which came in their way, they must have filled their pleasure-gardens with a multitude of exotic plants.

Carthage, the greatest of Phœnician colonies, surpassed in wealth and splendor any city of the motherland; and we know that, like these, it was encircled by villas with gardens, which extensive works of irrigation kept fresh and green. The Roman conquerors were impressed with the beauty of these Carthaginian gardens, and it is said that some of them were so long preserved that they could be renewed and improved in very much later times by the new race of conquerors from Arabia. Of course the same taste that expressed itself in Carthage must have been displayed in all the colonies of Phœnicia, and we may picture the shores of the Mediterranean, even before the extension of the Roman power, dotted with garden-encircled villas, embowered in beautiful plants gathered from many foreign lands.

The sensual religion of Phœnicia—in which the gross worship of Astarte held a prominent place—demanded numerous temples; wherever there was a temple in the ancient world there was a "sacred grove," and we can hardly conceive such a grove without some characteristics, in arrangement and accessories, which would entitle it to rank among gardens. The Phœnician temple-garden, however, has perished from men's knowledge as entirely as the building which it enshrined.

All these gardens, at least in Phœnicia itself, must have been comparatively small. There was no room in such crowded suburbs for large demesnes, and palace-gardens cannot have been very conspicuous in a country which consisted of a number of almost independent towns, held loosely together by commercial interests, but ruled by no great potentate such as those who sat at Babylon, Nineveh and Susa. Nor in a community of busy traders, where even the king was a merchant like his subjects, can there have been a demand—even had there been a place—for those wide hunting-parks which the Persians so dearly loved. In Carthage the royal gardens may have been more extensive, but a people so inartistic as to have produced neither great architects, great sculptors nor great writers has naturally left few traces of itself on history's page. It is not because Carthage was conquered and ruined by the Romans that we know so little about her. Nineveh, too, was ruined, and Jerusalem. But the buried lithic records of the one and the magnificent literature of the other have preserved their memory green.

"All passes—Art alone
Enduring stays to us;
The bust outlasts the throne,
The coin, Tiberius."

Perhaps when the nations of to-day have perished, something besides their art will remain—the prosaic printing-press turns out its reports in quantities which Time itself may despair of destroying; but literally nothing remains of ancient nations except their art. No ancient land in which art—in

stone or in books—has not developed in some conspicuous, national, individual way, has left more than the memory of a name behind.

Foreign Correspondence.

London Letter.

The English Flower-Garden, by W. Robinson, London, was published in 1883, and now a second edition of the book is issued. In England we have no work which deals with the subject of the garden, and how to make it beautiful and interesting, so thoroughly as does this by Mr. Robinson. In the effort to reform the style of flower-garden which in England was prevalent ten years or so ago, no man worked with greater zeal and persistence than did Mr. Robinson. Indeed it might be said that he alone was the founder of the style of gardening known as the natural style, as it exists in so many English gardens to-day. With the aid of his various books and periodicals he has forced his views and opinions down the throats, as it were, of horticulturists, so that in place of the strong and bitter opposition which assailed Mr. Robinson and his followers ten years ago we have now general concurrence in all they taught; and English gardens have been greatly beautified in consequence. The herbaceous border, wild garden and natural arrangement in regard to almost all hardy plants are now features in all good English gardens. Following on a change in the style of gardening we have a great demand for hardy plants of all kinds, giving an impetus to the introduction and distribution of hosts of beautiful flowering-plants which a few years ago were practically unknown in horticulture. "Few know the many flowers fitted to adorn our open-air gardens. No stereotyped garden of half a dozen kinds of plants will satisfy any one who knows that hundreds of beautiful aspects of vegetation are possible in a garden in spring, summer and autumn. It is disheartening to see how little pleasure men get out of their gardens, and how near to a desert they make them in this country of verdure and fertility. Yet the smallest garden may be a picture and a pretty one. Not only may we easily have much more variety in any one garden, and that of the highest beauty, but if men would give up mere imitation we should be charmed with the contrasts between gardens. Even small gardens might refresh us with their brightness and their pleasant variety. In the larger gardens opportunities are great—and seldom used. They are stereotyped at the season when they ought to be full of delightful change." These are Mr. Robinson's words. His book is intended to show what a wealth of flowers and beautiful plants are available for out-door gardens. It is profusely illustrated, the descriptive and cultural information is all that one could wish for, and the suggestive observations on position, style and taste in arrangement which form the first part of the book, are sure to be of service to amateurs. Some of the most characteristic of English gardens are illustrated and described, as also are a few of what the author considers of the worst style. There is also a supplement by Mr. W. Goldring, in which the best of hardy trees and shrubs are described and directions given for their culture and management. Mr. Goldring is one of the very few English landscape-gardeners who combine a wide knowledge of plants of all kinds, with skill to use them to the best advantage in the construction of gardens. When this is the case it naturally follows that considerable variety in style and effect is easily obtained, whereas a landscape-gardener, with only a limited knowledge of plant-material, must necessarily make his gardens very much alike. "The English Flower-Garden" is too comprehensive a title for Mr. Robinson's book, as it does not embrace in-door gardening at all. There is as much pleasure in good in-door gardening as in that practiced in the open, whilst a great deal more care and skill are required in the management of in-door plants than is necessary for those which thrive out-of-doors.

Following on the heels of Primrose Day, we had last Tuesday a display of Auriculas, Polyanthus and other Primulas such as had scarcely if ever been seen in the south of England before. The Auricula Society flourishes almost if not quite as well in the neighborhood of London as in Manchester and other northern towns. Mr. Horner, the acknowledged king of the Auricula cult, read an interesting paper on the breeding of Auriculas, and recommended a more severe selection if better varieties were to be obtained. He despised Fancies and Alpines, notwithstanding the fact of so many preferring them to the show kinds. The history of the Auricula Society is most interesting. Its strongest supporters have been, and still are, men who live in towns, generally smoky towns. Mr. Horner told a story of a famous northern Auric-

ula grower who, when he saw the blackened grass, trees and shrubs which stand for St. Paul's Cathedral garden, right in the heart of London, declared that if he had that garden he would grow better Auriculas than had yet been dreamt of. Besides the Auriculas, however, there was a great display of Polyanthus of all shades; the common Primrose, too, was represented by many varieties, whilst of exotic kinds there were many very pretty and rare ones shown. *P. Sieboldii*, the Japanese variety of *P. cortusoides*, and one of the most ornamental of all Primulas, was exhibited in splendid form by Messrs. Ryder & Son, of Sale, near Manchester. There were all shades from white to purple, as well as variegated, each variety being represented by a large pan-full of plants six inches or so high, with perfect flowers and foliage. One of the easiest to manage, requiring the coolest and airiest position if grown in a frame or green-house, though it is perfectly hardy, this species should become as popular in the garden as any we have. The meeting was essentially a spring-flower day. Daffodils were shown in thousands, and never finer. *Lilium Thomsonianum*, with a spike two feet high, bearing fifteen elegant lavender-colored flowers, was amongst a group of hardy plants shown by Mr. Ware, as also was the double-flowered Lily-of-the-Valley, a curiosity only, and far less pretty than the single form, though apparently much larger in its proportions. A distinct and pretty Epiphyllum called Makoyanum was exhibited by Messrs. Veitch, and obtained a first-class certificate. It differs from all other known kinds in having flowers which in shape are like those of a Phyllocactus, *i. e.*, the petals all radiate from the centre instead of forming a kind of tube and irregular limb, as in *E. truncatum*. In the former the petals number about fifteen, and are narrow, acuminate, one and a half inches long, crimson outside, salmon-red inside. There is another, if not the same as this, known as *E. Gartneri*, and which was certificated at South Kensington in 1885. Rhododendron Her Majesty, from the same firm, also obtained a certificate. It is a beautiful flowered plant with small, oblong, leathery leaves and large-spreading, rather flattened flowers five inches across, the margins undulate and the petals of good substance. They were white, with a faint flush of rose. This plant is said to be a hybrid from *R. arboreum* and *R. Fosterianum*, but there were no traces of the former species in the plant shown by Messrs. Veitch.

In the collection of plants sent from Kew were flowering specimens of two very interesting root parasites, *viz.*, *Lathraea squamaria* and *L. clandestina*, the former a British plant, the latter a native of the European Continent. These remarkable plants are not easy to establish in gardens, but when once they take hold they increase rapidly and flower abundantly every year. *L. squamaria* grows only on the roots of the Elm, although it is supposed that *Rhododendron ponticum* is another host-plant for it. *L. clandestina* is on the roots of a Willow in wet ground near a lake. The flowers are clustered, tubular, one and a half inches long, and deep purple in color. *Heuchera sanguinea* is a delightful little plant for pot culture. In the Kew conservatory it has been a picture of elegance and color for a month or more. It is easy to manage if kept in a cold frame and placed in a slightly heated green-house in March. Nothing could be prettier than the flowers of this plant, and the color harmonizes with almost any flower. The prettiest arrangement at Kew is a mixture of the *Heuchera* with Lily-of-the-Valley.

The following rare and interesting as well as pretty-flowered green-house plants are now flowering at Kew:

Protea nana.—A dwarf species of a very ornamental genus of Cape shrubs, which fifty years ago were popular in English horticulture, though now hardly known. The plant under notice is a dwarf grower, being only fifteen inches high, well branched, the leaves linear, one inch long and pointed, the flower-heads terminal and drooping. Each head is cup-shaped, two and a half inches across, and is composed of numerous overlapping, petal-like bracts colored deep crimson. The flowers proper are arranged in a cluster, like the pappus in *Compositae*, in the middle of the cup. There are many species of *Proteas* in abundance at the Cape, and as they appear to be as easily managed under cultivation as Camellias, they are worth obtaining. Some of them bear very large flower-heads, colored brightly. They are also remarkable for the copious secretion of nectar in the cup-like flower-heads, some of the species secreting so much that the Boers collect it and make sugar from it.

Befaria glauca.—This is the Andean Rhododendron already mentioned in one of my letters. It is evidently a free-flowering plant when once it has got to the flowering age. The large, erect, crowded terminal racemes of rosy flowers on plants three feet high are distinct and ornamental.

Agapetes buxifolia.—A handsome, Ericaceous shrub with box-like leaves and numerous axillary tubular flowers, one inch long, and bright scarlet in color. For a cool greenhouse, such as suits Azaleas and Rhododendrons, this plant is perfectly adapted. It remains in bloom a long time—six weeks or more—flowers when quite small, and is easily cultivated, requiring a sandy peat-soil and plenty of water.

Goodia lotifolia is an elegant Cytisus-like shrub of bushy habit and very free flowering, every little branch developing a spike of yellow and brown flowers. These are very fragrant, and they remain on the plant a long time. Probably this plant, if taken in hand by florists, would prove quite as useful for spring flowering as the popular *Cytisus* (*Genista*) *racemosus*. The *Goodia* is a native of Australia, and has been in cultivation in England many years.

Bossiaea linophylla is one of the most graceful of all Australian leguminous plants. At Kew there is a huge bush of it eight feet high and this is a glorious picture now, every branch being a long, pendant string of bright yellow and purple-brown flowers, very small, but in great numbers and brilliant as jewels. Small plants of this species flower just as freely. There are many similar plants of Australian origin, but which are now scarcely known in gardens. The *Aotus*, *Dillwynia*, *Chorozema*, *Leptospermum* and several other genera are in flower in the Kew collections, but notwithstanding their beauty, they are not in favor with horticulturists generally.

The illustration of *Nelumbium speciosum* in New Jersey, published in GARDEN AND FOREST for April 10th, has created quite a sensation here. The magnificence of such a picture as is described by Mr. Sturtevant is enough to tempt horticulturists to America specially to see it. We have tried to cultivate this species and *N. luteum* out-of-doors in England, but without any success. Our summers are not, as a rule, warm enough to enable these plants to make the strong growth necessary to their withstanding the winter. Mr. Sturtevant ought now to obtain some of the extraordinary varieties of *N. speciosum* which are known to be in cultivation in Japan. I have tracings of many of these, some showing double flowers, others single, others with lacinated petals and so on, whilst in color they are said to be almost as variable as the garden Tulip. At Kew, in addition to the type, there are also living plants of the pure white and the deep rose-flowered varieties, as well as a few of the Japanese kinds, but these have not yet flowered.

Kew, April 26th, 1889.

W. Watson.

New or Little Known Plants.

Brodiaea Palmeri.*

THE latest addition to the characteristic Californian genus *Brodiaea*, which now numbers about twenty-five species, was found by Dr. Palmer in 1887 at the extreme southern limit of the range of the genus, near Los Angeles Bay, on the gulf side of the Peninsula of Lower California. It is a stout species, often two feet in height, with an unusual number of long, thin leaves, and is peculiar in developing a quantity of small bulblets at or below the surface of the ground. The flowers are numerous in the umbel, on slender pedicels about an inch long. As in many other species, they are bright purple in color, rather more than half an inch in length, funnel-form in shape from a narrow base, and are cleft nearly to the middle. The six filaments are distinctly roughened or papillose, and bear linear anthers, which are attached by the base and become closely coiled when old.

The dilated staminodia that are found in some species, and the wing-like appendages to the filaments in others, are here replaced by a row of short scale-like processes between the points of insertion of the filaments. While the form of the corolla is that of the group of species which constitute the section *Seubertia* or *Triteleia*, the basifixed anthers and the presence of these appendages are characters which belong rather to the true *Brodiaea* section, and weaken the distinction that has been made between these groups. The plant was found growing in abundance in low places on the sandy plains about Los Angeles Bay. It has not yet been tested in cultivation.

S. W.

* BRODIAEA PALMERI, Watson in *Proc. Amer. Acad.*, xxiv., 78.

Yucca angustifolia.

ILLUSTRATIONS of two large arborescent Yuccas which grow in the region adjacent to the boundary between the United States and Mexico have been published in earlier numbers of GARDEN AND FOREST. *Yucca angustifolia*, which appears in the illustration on page 247 of this issue, is the smallest of the Yuccas and the most northern of the genus in its geographical distribution. Linnæus knew the three species which occur in the southern and south-eastern states—*Y. filamentosa*, *Y. aloifolia* and *Y. gloriosa*—but no other Yucca was described until the publication in 1816 of the "Flora of North America," by Frederick Pursh, who then first made known the subject of our illustration from a specimen collected on the "banks of the Missouri River," and preserved in the herbarium of Thomas Nuttall, who doubtless discovered it in his first western journey.

Yucca angustifolia is a stemless, or very short-stemmed, species, with numerous linear, rigid, spiny-pointed leaves, scarcely contracted above the broad base, nearly flat on the upper surface, convex below, with slender marginate fibres. The flowers are an inch and a half to nearly two inches long, in simple spike-like racemes. The fruit is erect, capsular, six-valved, ovate-obtuse and sharply cuspidate. The large seeds are half an inch in diameter, with wide margins.

Yucca angustifolia occurs, often in great abundance, on dry prairies and plains from north-western Missouri and western Iowa to Dakota, Colorado and New Mexico. A Yucca peculiar to some parts of Arkansas, Louisiana and Texas, with wider, softer and less rigidly pointed leaves, and with a more paniculate inflorescence, was considered by Dr. Engelmann, whose knowledge of these plants was unrivaled, to be a form of this species (var. *mollis*).

Our illustration is made from a photograph taken in Colorado by Dr. R. H. Lamborn, to whom we are indebted for its use. It is a characteristic view of the arid western plains as they appear sometimes in early summer, enlivened by the beautiful flowers of this plant, the most conspicuous feature of their scanty vegetation.

Artificial Manures for Vegetables.

FEW of the amateur cultivators of suburban gardens realize the amount of fertilizing material used by the market-gardeners in their neighborhood, and they wonder frequently why their own little plots fail to produce as good an average as the large gardens. The amateur buys a load of manure and imagines he has enriched his garden, while the market-gardener would have spread five times as much on the same area. Another difficulty in the way of amateur gardeners is that few of them have gardens arranged for horse-culture. No spade work short of regular trenching can compare in thoroughness with the breaking down by a large plow and a pair of heavy horses, followed by a spring-toothed harrow and a home-made plank-drag. The difficulty of procuring manure is generally a formidable one to suburban cottagers, and at best it is disagreeable to handle and not nearly so convenient as the commercial manures which are now made in such a thorough manner by reliable firms. I grow many acres of vegetables every year, but experience has demonstrated that we can grow better crops, and cheaper, by using the concentrated fertilizers on the vegetables, and letting our accumulations of animal manures go upon our grass lands. But it should not be imagined that a thin sprinkling of commercial fertilizer will make a garden rich. I use from 600 to 1,000 pounds per acre of the best rawbone superphosphate, and for some crops mix in a portion of nitrate of soda and sulphate of potash. For Peas and Beans the superphosphate and a little potash is best; for Radishes and Lettuce superphosphate and nitrate of soda, which is also good for the Cabbage crop; but for these a top-dressing of nitrate of soda encourages a rapid growth and enables them to outgrow the worms. In using artificial manures in the garden I do not use them broadcast. All my vegetable crops are planted wide enough apart to allow of horse cultivation, land being the cheapest thing I have and human labor the dearest.

Fig. 107.—*Brodiaea Palmeri*.—See page 244.

When land is very valuable, and in small gardens, of course, vegetables must be planted closer and cultivated with hoes.

It is a good practice, on a large scale, to lay out the rows with a plow and sow the fertilizer thickly therein. A furrow is then thrown from each side, making a ridge immediately over the first furrow. This ridge is then chopped off flat with a hoe and the seed sown in a furrow marked thereon with a narrow hoe, or a seed-drill may be run through. After sowing the seed, cover and roll each row with a light hand-roller, so that the earth is well packed on the seed. The young plants

on the ridge are not so easily drowned out by rains, and can be worked earlier by horse-power. It is always easy to follow up one crop with a later one by splitting the rows and clearing up the remains of the first crop or burying it in the soil.

In buying fertilizers amateurs should always deal with the manufacturers, and never buy less than a 200-pound sack, even if the garden is very small. The manufacturer can supply a first-class superphosphate for \$30 to \$35 per ton, probably the latter price if bought by the single sack, but the little packages of fertilizers sold by seedsmen usually cost about four prices. In one of the recent bulletins of the Cornell University it was shown that an article sold by a leading seedsman under the name of "Economic Seed Manure" in fancy packages at the rate of \$2,000 per ton was really worth but little over \$30 per ton. It is best, therefore, to buy seed from a seedsman whom you are sure you can trust, but buy your fertilizers from a reliable manufacturer, and let some one else pay for the fancy packages. A superphosphate made from raw bones or bone-black is preferable to one made from South Carolina fossils. This last can be bought for \$15 to \$16 per ton; the raw bone phosphate at \$30 is more satisfactory for vegetables.

A rank odor in a fertilizer is often deceptive. It does not require a large percentage of ammonia to exhale a strong smell if it is in a volatile condition, and the fertilizer which has the most pungent ammoniacal smell is the one to avoid, because it is rapidly depreciating in value. But there are other and more worthless substances used in many fertilizers merely because they offend the nostrils, for manufacturers know that so many people judge this article by the smell, that they gratify this prejudice with old leather, fish scraps and the like. Shun "ammoniated" superphosphates; you can ammoniate it more cheaply and better yourself by adding nitrate of soda, and you can add the sulphate of potash for such crops as the Legumes and leave out the nitrogen. It is, therefore, desirable and cheaper to get these three materials separately.

Crozet, Va.

W. F. Massey.

Early Tomatoes.

IN the market-gardens of this latitude early Tomatoes are in the ground by the first of June, but in the family garden they can be often set out earlier with safety, as special protection can be given to a few plants when it cannot be used for a larger number. I remember an instance where Tomatoes had been set in the ground for a week when a frost threatened; the plants were nicely lifted on a wheel-barrow, rolled into the barn, and the next day set again in the ground and they went on growing, while others left out were killed. When set against a fence or building they are usually safe from frost. A temperature below 34° kills the leaves and the tender stems, but the plant will live and sprout again from the root if left, but will produce fruit late. The best plants are those grown four inches apart in flats. They are, in a measure, stunted, but not drawn up into spindling form, and if set in rich earth they will grow with great vigor. Tomatoes like warmth and moisture, and frequent waterings will keep them a growing.

As to varieties for the home-garden, I consider Dwarf Champion as good as any, as the bush is compact and the plant is easily staked. A barrel-hoop, raised a few inches above the ground by stakes nailed to it, will make a sufficient support for it. If the crimson color is an objection, the Volunteer or Perfection, indeed, any of Livingston's seedlings may be substituted for it. There is little to choose among varieties as far as earliness is concerned. All of the early kinds will ripen within a period of ten days. The commercial fertilizers seem well adapted to the Tomato, and a pint of any standard brand, well forked through the soil where the plant is to stand, is almost certain to bring large, smooth fruit.

Whether it pays to stake Tomatoes is a question. In the home-garden it is well to stop the growth of the vine by pinching, to encourage early fruit; but for late fruit I let them run at will. Thinning out the laterals to give free circulation of air is good practice, and helps to prevent rot, but the fruit often scalds if exposed to full sunshine. The best specimens of fruit will be found on the well-fed vines that have abundant room. Plants of Dwarf Champion can be set less than three feet apart, but the lustier growers would find themselves crowded at this distance.

West Springfield, Mass.

W. H. Bull.

Plants for Bedding.

IT is now time to think about the arrangement of beds and of the plants with which to fill them. As Coicous, Geraniums, Alternantheras, Echeverias and other plants found in the usual bedding lists are almost invaluable under proper conditions, but their exclusive use, especially when arranged in the form of national emblems, mottoes, medallions and other set patterns, cannot be considered elevating in their influence upon popular taste. A great variety of plants with ornamental foliage can be employed for bedding-out in our climate, and with fine effect, particularly when tastefully combined in sub-tropical beds.

Prominent among these are the finer varieties of *Canna Indica*, such, for instance, as *Imperator*, a grand variety where space is allowed for its full development, the strong shoots with their Musa-like foliage frequently attaining a height of seven to eight feet. And where a more dwarf variety is needed, *Adele Levallois* will be found most satisfactory, its bright green leaves rarely reaching a greater height than four feet. The free-flowering character of this variety is also a point in its favor.

Of bronze-leaved Cannas, *Adrien Robine* is one of the most beautiful, and makes an average growth of five to six feet in the season. *Canna metallica* is also good, and *C. Bihorelli*, though quite dwarf in habit, is very noticeable with its dark reddish-bronze foliage and bright crimson flowers. *C. Ehemanni*, now becoming well-known, should find a place in every garden, not only on account of its handsome growth, but also for its large and beautiful flowers.

Another excellent plant for our purpose, either in a mass by itself, or in combination with other tall-growing plants, is *Arundo donax* and its variegated form. These are free-growing and very graceful, and although hardy enough to stand the winter in favorable seasons, at least in the latitude of Philadelphia, yet they can be made to do better service by lifting them in the fall, and placing them in the green-house, where the variegated form, besides its pleasing effect, will prove useful for cutting.

Some of the strong-growing Aralias, for instance, the Rice Paper plant, *A. papyrifera*, and also *A. Sieboldii*, are very effective plants for summer bedding, their large, bold leaves making a pleasing contrast with the smaller foliaged plants. A few of the Dracenas may also be added to the list, notably *Dracena australis*, *D. indivisa* and *D. Draco*, all of which thrive admirably out-of-doors. The so-called New Zealand Flax, *Phormium tenax*, and its variegated form, and also *P. Colensoi variegata*, the latter having the leaves broadly margined with white, are all good plants for outside work, their strong, tough leaves being seldom injured by storms. *Grevillea robusta* is another good plant not so often seen as its merits deserve, being of easy growth, and presenting a most graceful appearance with its finely divided foliage. That charming Japanese grass, the striped *Eulalia*, must not be omitted, this being one of the most valuable additions to the list of hardy, ornamental grasses that has been made in recent years.

If favorably situated, some Codiaums or Crotons may be used to advantage, as may also *Aucuba Japonica*, the latter being capable of enduring much more hardship than the Crotons, and the female plants of the *Aucuba*, when nicely fruited, are very attractive as an edging for some of the beds. *Peristrophe angustifolia* is usually most successfully grown in a light soil, though this is not absolutely essential to its welfare.

Some varieties of Musa, especially *M. ensete* and *M. Cavendishii* do well in certain locations, but should be planted in somewhat sheltered positions, as otherwise their immense leaves will be damaged by the wind.

Many of the hardier Palms can be successfully used in outdoor arrangement, and the following species will be found among the most satisfactory for this purpose: *Chamærops humilis*, *Corypha australis*, *Latania Borbonica*, *Areca lutescens* and *Sabal Adansonii*.

Holmesburg, Pa.

W. H. Taplin.

Isopyrum biternatum.—This pretty native plant is well worthy of cultivation on account of its finely-cut foliage and pure white flowers, which are produced in early spring and have a charming effect when planted in the front row of the flower-border among other low-growing plants. This species is a native of the western States, and is perfectly hardy. Another interesting plant is *Synthyris reniformis*, which was flowering early in March, its blue flowers arresting attention by their intense color. Although this plant is found only on the Pacific Coast, it is quite hardy in the eastern States, and even when not in bloom is worth having for its large, shining, reniform

leaves. *Phlox bifida* has generally proved impatient of cultivation, and the more care bestowed upon it the more slender was the hope of success. Last spring we were induced to plant it in a gravelly soil, and, to our surprise, the plants are now in a vigorous condition and flowering freely. The petals are so deeply cleft as to remind one of the spokes of a wheel.

Gentiana acaulis.—What can equal in intensity the rich deep blue of the *Gentianella*? We have a number of strong plants covered with their lovely blue flowers. Many species of this genus are hard to cultivate, *G. verna* being one which we have tried and failed with miserably, and there are others of which the same might be said; but it is not so with *G. acaulis*, which is, perhaps, the finest species in cultivation. If planted in a rich, moist soil, where the roots may penetrate deeply and be in no danger of drouth, *G. acaulis* may be grown and flowered successfully year after year. Ours have received no protection from hot sun in summer and have passed through a winter which, on the whole, has not been a good one for alpine plants, which are usually at their best after a winter covering of snow, and yet the plants under note are now a sight to gladden the dullest eye. Those who wish to grow the *Gentianella* are advised to get strong plants to start with. Our experience with weak ones has taught us this lesson.

Polemoniums.—There appears to be some confusion about the species of this beautiful family of hardy perennials. In the Dictionary of Gardening *P. Richardsonii* is given as a synonym of *P. humile*. Now we have *P. humile* in bloom side by side with *P. Richardsonii*, and the two plants are quite distinct—*P. Richardsonii* has blue flowers nearly an inch in diameter and grows nearly two feet high. This we obtained from a reliable firm in England. *P. humile* is a much dwarfer plant, with a somewhat creeping habit, and the flowers correspondingly small. This we received direct from the Rocky Mountains. Also, the two (being synonyms) are given as flowering in July; here they are at their best in April. I should like to have the experience of other growers of these plants.

Passaic, N. J.

E. O. Orpet.

Notes from a Spring-Garden.

THE Poet's Narcissus (*N. poeticus*) is an old-fashioned flower, so very old-fashioned that it has been an inhabitant of gardens probably as long as gardens have existed. Everybody who has ever been in an old-fashioned garden knows it and loves it, and for many persons it is the most charming of all flowers; and it has other qualities besides beauty; for of all the different species and varieties of Narcissus it is here the hardiest, the least particular about the treatment it receives, and the most prolific in the production of new bulbs; so that once established in the garden, it soon spreads and multiplies rapidly, and from a single bulb planted in rich soil a hundred can be obtained at the end of a few years. The Poet's Narcissus, too, of all the bulbous plants which will grow in this climate, is the best to naturalize in the woods and even in hay-fields. It always looks perfectly in place in such positions, and a field of young grass with the flowers of Narcissus open among the leaves is one of the most delightful objects imaginable. The bulbs planted in this way last for years, and gradually spread, as the leaves have ripened and died down before it is time to mow. It is, moreover, an excellent border plant; it makes a graceful spring edging to the shrubbery, and, of course, is not out of place in the rock-garden. It is the latest of the family to bloom here, the flowers appearing immediately after those of *N. biflorus*, a character which adds to its value, as the flowers are open after the coming of pleasant weather, and contemporarily with those of many shrubs and herbaceous plants. No better piece of advice can be given to a beginner in gardening than to plant the Poet's Narcissus. Plant a few every year and so gradually extend the plantation. Wherever there is an unoccupied corner or a vacant place in the border, wherever the lawn-mower does not run, put in some of the bulbs. They cost a trifle; a hundred thousand can be bought for less than is often paid for a single small plant of some peculiar Orchid. There are several varieties of this plant in cultivation, but none of them are really better than the type, and are not worth cultivating except by persons particularly curious in such things.

Several species of Phlox are in flower. There is really none handsomer than the dwarf *P. subulata*, the Moss Pink, and it is none the less beautiful because it covers hundreds of acres of sandy and of rocky ground in New Jersey; and because the early settlers in this country saw and appreciated its beauty and took it into their gardens, where their descendants of the

old-fashioned sort still cherish it. The low mats of stems and gray-green minute foliage are now entirely hidden by the masses of rose-colored and in one variety of white flowers. Planted in pockets among the rocks it spreads and droops over them very charmingly, extending out over the walk, and so supplying that irregular natural edge of verdure so difficult to obtain and so essential in any attempt to bring a touch of natural arrangement into a rock-garden made with human hands. *Phlox reptans* is very fine, too, to-day. It is another dwarf species which is found on the moist slopes of the Allegheny Mountains. It has long, creeping pointed stems, from which flower-stems rise to a height of six or eight inches, bearing rather large reddish-purple flowers. Like the last it is an admirable plant for the rock-garden or to carpet the ground under shrubs, as it thrives equally well in broad sunlight or in partial shade. The rare and beautiful *Phlox Stellaria*, of which a figure was published in GARDEN AND FOREST, Vol. I., p. 257, is also in full bloom. It takes kindly to cultivation, although

it possesses real merit. It is now propagated and can be procured from the Dutch bulb-growers.

The pretty little *Tulipa Clusiana*, the Lady Tulip of gardens, is in bloom. It is one of the most delicate and delightful of the species of Tulips, with its slender white flowers, the three outer segments of the perianth brightly flushed with red. No collection of hardy flowers is too choice to contain it.

The English Globe-flower (*Trollius Europæus*) is a sturdy perennial, long a familiar object in gardens. It has palmately divided leaves, and large orange or paler yellow flowers of many-colored, concave sepals converging into a sort of globe, and concealing the smaller petals, and the stamens and carpels giving to it the appearance of a large semi-double Buttercup. It is a native of moist woods of north and central Europe, and is one of the easiest perennial plants to cultivate. Very hardy, too, and perfectly satisfactory here in New England, is another European plant referred to last year (p. 177), *Anemone ranunculoides*, which spread considerably last summer, and is

Yucca Angustifolia in Colorado.—See page 244.

liable to suffer during very severe winters, and should find a place in all collections of spring-flowering plants, for the charming pale-blue color of its deeply-notched corollas. There are few plants which give me greater pleasure, although it is not at all showy.

The Virginia Cowslip (*Mertensia Virginica*), which is not a Cowslip at all but one of the Borage family, is one of the desirable herbaceous plants which flower at this season. It is a smooth, pale plant, a foot high, with long-stalked obovate leaves, and large trumpet-shaped blue corollas, which, as they fade, turn to a delicate purple color. It thrives in deep, rich soil, and as it needs to be thoroughly established in order to bloom freely, it should not be disturbed or divided often. This plant is widely distributed through the Middle States, although nowhere very common, and was cultivated in England as early as 1799.

The double white *Anemone nemerosa* is finer than ever before this year. It lacks, of course, something of the charm of the wild plant, but the flowers are in themselves very beautiful, and they last long in perfection, and as a garden-plant

now handsomer than ever. It is a tuberous-rooted species, growing a few inches high only, with bright yellow flowers an inch or more across, and rather coarsely divided, dark green leaves.

Boston, May 8th.

C.

Notes from the Arnold Arboretum.

AMONG trees which bloom here during the last days of April and in early May, none compare in the magnificence and profusion of flowers with those species and varieties of *Magnolia* which produce them in advance of the appearance of the leaves. They are all natives of China and of Japan, and all belong to or are derived from three species. Most of these plants have been known in this country for many years, and their perfect hardiness and adaptability to the climate of eastern America have been abundantly demonstrated. They grow rapidly under proper conditions, and begin to produce their marvelous flowers when only a few feet high. They are not seen here, however, as often as might be expected, and, relatively, they are probably less frequently

planted than they were thirty or forty years ago. As no one ever sees a good plant of *Magnolia conspicua* in full bloom without being filled with admiration and with the desire to possess such a wonderful object, their comparative rarity in American gardens can only be explained by the facts that all these plants are rather difficult to transplant, unless it is done at the right time, and that they are fastidious about soil and require clean and constant cultivation until they are fully established. The secret of transplanting Magnolias successfully consists in doing it as the leaves are opening; that is in the case of these Asiatic species, just after the flowers have fallen. Magnolias have large, fleshy roots, which decay rapidly when they are cut or bruised, and do not, therefore, recover easily from transplanting unless the plants are moved at a time when they are in active growth, and so in a condition to make new root-growth rapidly. Magnolias moved early, while the roots are dormant, often suffer seriously or do not start to grow again, so that by many people they are considered difficult trees to transplant, while in reality they are not, if the peculiar character of their roots is considered, more difficult to manage than other trees. They all dread drought, and do best in peaty soil. Drainage does not appear essential, and fine plants are developed in positions where the ground is saturated with water during several months of the year, and where it is never completely dry during periods of protracted drought. Such constant moisture is not, however, necessary to them, and very fine specimens may be seen growing in good, ordinary garden-soil. They love the same treatment as the Rhododendrons—a soil of peat, leaf-mould, sand and turfy loam deep enough to prevent dryness at the roots, and an open situation in the full sun, that the flowering wood may be thoroughly ripened. The ground about them should be kept clean and well cultivated for a few years after planting, and abundant space be allowed for the free lateral development of the lower branches.

It is now known—thanks to the intelligence of an American horticulturist—that all of the Chinese Magnolias grow more rapidly and make larger and more shapely plants if they are grafted on some one of the strong-growing American species. *Magnolia acuminata* and *M. tripetala* are used for this purpose in American nurseries, and each is preferred by different cultivators. Only plants grafted upon one of these species should be bought or planted, as they are unquestionably better than any others.

These Magnolias are naturally shapely plants, and they suffer from crowding. Indeed, their proper use is as single specimen plants, isolated upon the lawn or rising from the midst of broad masses of Rhododendrons, whose dark-green foliage makes a proper setting for the blooming but leafless Magnolias. The foliage, when it does appear, is rather heavy; the outline of the plants is bushy and compact, and they do not compose well with other trees, if brought into immediate connection with them.

The earliest to flower is the little shrubby *Magnolia stellata* (the *M. Halleana* of some American gardens), the last introduced into our gardens, and still very rare here. It has been so often described in these columns that further mention of it is unnecessary beyond the bare facts that it is perfectly hardy, that it flowers here soon after the middle of April, and that it is one of the most beautiful and desirable shrubs of recent introduction.

Magnolia conspicua follows *M. stellata* in time of blooming, its flowers opening here in ordinary seasons about the first of May. This is the handsomest of the whole series in flower, and the most desirable, except that here in New England the flowering period is sometimes cut short by the north-east rain-storms, which often arrive simultaneously with the flowers; and that in climates where spring frosts prevail these early flowers are destroyed. *M. conspicua* is a shapely, round-headed tree, capable of reaching a height of fifty feet or more under favorable conditions. It is low-branched, the main branches dividing in many tortuous, branching divisions. The bark of the stem and of the main branches is smooth and ashy gray; that of the young branches is chestnut-brown. The flower-buds which are formed during the summer, are large, and protected during winter by thick, woolly, stipular sheaths. The flowers, with petaloid sepals, are pure creamy-white and pleasantly fragrant; they are cup-shaped, four or five inches deep, with obovate, mucronate sepals and petals, two inches broad, and red stamens. They are produced in the greatest profusion, and quite cover the trees as with a white sheet. They are quickly followed by the leaves, which are obovate, contracted into a short stout point, three or four inches long, downy when young on the lower surface, ultimately thick and deep dark green. The fruit is slender, often contorted, and two or three inches long. It is produced here abundantly.

Magnolia conspicua is a native of China, where it seems to be widely distributed from the neighborhood of Peking to Shanghai, and probably also of Japan, where it is very generally cultivated. It is the Yulan of the Chinese and of European gardens, and the *Magnolia Yulan* of Desfontaines and some other botanists. An interesting account of this tree may be found in the "Memoires concernant l'Histoire des Sciences des Chinois," written by the early French missionaries at Peking (iii., 441), from which it appears that the Yulan was cultivated under the dynasty of Tang in 627, and has since been always a favorite in the gardens of the Imperial palaces and of the temples, and that young plants are used for the decorations of the Imperial apartments in winter. It is the symbol of candor and of beauty; and a powder prepared from the green fruit is used to alleviate bronchial affections.

Magnolia conspicua was introduced into Europe as early as 1779, but it was much later before its beauty was appreciated and it became common in cultivation there. There seems to be no record of its earliest introduction into the gardens of the United States, and if there are any very large plants in the country they will be found, probably, near some of the large cities of the Middle or South Atlantic States. The best in the north are in the city of Newburg, where very fine symmetrical specimens may be seen, planted, no doubt, by Downing, or propagated in the nurseries which he early established there, and from which many good plants were sent into the gardens of this country.

Thunberg, who was in Japan from 1773-79, discovered there a small shrubby Magnolia, with slightly obovate or acuminate leaves, precocious, fragrant flowers, with very small yellow or yellow-green, narrowly acuminate sepals and large acuminate petals, deep purple on the exterior, and creamy-white on the interior face. This is the *M. obovata*, variously known also as *M. purpurea*, *M. discolor* and *M. denudata*. It was introduced into Europe a few years after its discovery. It is a hardy shrub, once a great favorite in gardens, although now much less commonly seen than formerly, having given way to that race of hybrids of which it is one of the parents.

The first of these hybrids dates from 1826. It sprang from a seed of a *Magnolia conspicua* in the garden of M. Soulangé-Bodin, of Fremont, in France, of which the flowers had been fertilized with the pollen of *M. obovata*. Whether this hybrid was the result of chance, or of intention, is doubtful. Loudon ("Arboretum," i., 278) speaks confidently of "accidental fecundation," but in the elaborate account of this hybrid, to which is joined the earliest figure, published in the *Annales de la Société d'Horticulture de Paris* (i., 90), it is expressly stated that M. Soulangé intentionally hybridized the flowers of *M. conspicua* with pollen of *M. obovata*. It is now known as *M. Soulangiana*, and is almost intermediate between the two parents, except in habit, which is arborescent, and not different from that of *M. conspicua*. The leaves are intermediate in size and narrowly obovate, with the point of those of *M. conspicua*. The flowers are also intermediate in size, with smaller sepals than occur on those of *M. conspicua*, although still petaloid, and the sepals and petals are streaked, especially towards the base, with purple. This plant, although far less beautiful in the color of its flowers than *M. conspicua*, has the advantage of blooming a week or ten days later, and therefore at a time when storms and frosts are less liable to injure the flowers. It is as hardy as either of its parents, and produces fertile seeds.

A number of other hybrids between these species appeared in Europe about the same time as *M. Soulangiana*, differing in the amount and in the shade of purple of the flowers, and especially in the size and shape of the sepals. *Magnolia Alexandrina* and *M. speciosa*, according to Karl Koch, originated in the garden of M. Cels, a famous French patron of botany and horticulture, and *M. Norbertiana*, another hybrid in that of Soulangé-Bodin. The plant which grows here under the last name is remarkable for its small greenish-white acute sepals, hardly larger than those of *M. obovata*. The flowers are only faintly marked with purple, are small, three to three and a half inches deep, and are the last to appear, being fully a week later than those of *M. Soulangiana*, and between two or three weeks later than those of *M. conspicua*. The trees are as free-growing as the others, and equally hardy. Whether this is the variety originally distributed as *M. Norbertiana* it is impossible to say, or to satisfactorily distinguish any of the various forms of these hybrids except the original *M. Soulangiana*. They vary little among themselves; descriptions, when they can be found, are not reliable, and there are no colored figures which can be depended on to refer to. Certain forms are known traditionally in certain nurseries or gardens under certain names, but such traditions are always misleading, and it seems hopeless, at least with the informa-

tion available in this country, to do otherwise than call all forms with purple and white flowers varieties of *M. Soulangeana*, and drop the other names.

A hybrid of more recent appearance and of doubtful origin is in some respects the most interesting of the whole series. This is the plant known in gardens as *Magnolia Lenné*. Van Houtte, who published a colored plate of the flowers twenty years ago, took it for granted that it was a hybrid between *M. conspicua* and *M. obovata*. He states, without further explanation, that it originated accidentally in Lombardy, where it was discovered by the nursery gardener, Turf of Erfurt, who introduced it into Germany, naming it in honor of Lenné, the Royal Garden Inspector at Berlin.* The origin of this plant is not as apparent as that of *M. Soulangeana*, however—that is, it is not as clearly intermediate in characters between its two supposed parents. It is shrubby rather than arborescent in habit, with wide-spreading stems branching from the ground. The branchlets are much smaller than those of the other *Magnolias* of this class; the leaves are larger than those of the other species, they are broadly ovate or sometimes slightly obovate and pointed at the summit, but quite destitute of the short contracted point found in those of *M. conspicua* and of *M. Soulangeana*. The flowers are the largest of the series, three and a half to four inches deep, with colored petaloid obovate sepals about one-half the size of the petals, which are broadly obovate, rounded at the extremities, fully four inches across, deep dark purple over the whole of the exterior surface, and pure snowy-white in the interior. The anthers are deep and the anthers paler purple. The flowers are deliciously fragrant, and the fruit and seeds, which are produced in profusion, are larger than those of either of the supposed parents. *Magnolia Lenné* might very well pass for a very robust, large-flowered variety of *M. obovata* were it not for the petaloid sepals and the broadly obovate petals, which point to the blood of *M. conspicua*, and a probable hybrid—a solution which, however, is not altogether satisfactory.

Magnolia gracilis of gardens I have never seen, but, judged by the figure in Hooker's "Paradisus Londinensis" (t. lxxvii.), it is nothing more than a slender form of *M. obovata*.

The handsomest of the *Magnolias* with precocious flowers, and the finest of the genus, with the exception, perhaps, of the evergreen, *M. grandiflora*, of our southern forests, is *M. Campbellii*, a large forest-tree, peculiar to the mountain valleys of Sikkim and Bhotan, at elevations of 8,000 to 10,000 feet. The flowers are white or rose-colored and eight or ten inches across. This species is apparently difficult to manage, although it has been cultivated for many years in different parts of Europe. It has flowered in a garden near Cork, in Ireland, where this tree is fairly hardy, but in northern Italy it has so far, I believe, failed to produce flowers, and I have not heard of it blooming elsewhere. It is hardly probable that it has been introduced into the United States, although, owing to the more humid summer climate, it might be expected to flourish in some parts of the Gulf States perhaps better than in southern Europe.

Principles of Physiological Botany, as Applied to Horticulture and Forestry.

XX.—INJURIES AND MALADIES.

(Conclusion of the Series.)

ONE of the severest accidents with which any of our young trees can meet is girdling or "ringing." The removal of a ring of bark from the stem does not at first appear to affect the vigor or freshness of the plant, because, at the outset, the upward supply of water is not cut off. During this period of apparent resistance to the injury an attempt is made by the tree to heal the wound by a growth of bark over it. If the ring is not too wide, it is possible to repair the injury by such a growth, but usually the younger, outside, wood of the stem is invaded by decay, the water-supply is more or less completely arrested, and then the tree yields. There are numerous instances of remarkable vitality in trees, by which they have been able to live, after a fashion, for many years, after they have been girdled. One of the most recent records of this kind attributes to a common Pine a lease of life for fifteen years after complete ringing. The account as given in the *Canadian Record of Science* for October, 1888, is very remarkable, and presents some features which cannot be readily understood. Examples of the survival of Orange and Olive trees, after serious injuries of this kind, are not rare.

* The best figure of *Magnolia Lenné* will be found in the *Revue Horticole*, 1866, t. 33.

Freezing, followed by rapid thawing, may be numbered among the most troublesome of the mechanical injuries to plants. It is well known that many species of plants in our climate are capable of being frozen and rapidly thawed many times in a single season without suffering any apparent injury, whereas there are tender species of exotics which are irreparably injured by being subjected to a temperature near, but not below, freezing. The difference between sudden and slow thawing of a frozen part can be seen by a simple experiment upon living plant-hairs placed for examination under a microscope. If the work is done with sufficient care, the protoplasm in the plant-cells can be completely frozen, and a separation of the watery parts of the living matter from its more solid constituents can be produced. This can be followed by a thawing so slow, and a repair so perfect, that the protoplasm will again assume its former character, and, when the proper temperature is reached, the motion which belongs to it normally is seen to begin again. Now, in certain instances, the freezing injures the cell-walls and the delicate protoplasmic lining, whereas in others the walls are not apparently harmed in any way. In the case of woody plants there is reason to believe that the water in some of the parts beneath is not frozen even when subjected to an extremely low temperature, but the subject has not yet been thoroughly examined under conditions of careful experiment. In such an unusual season as our present winter has been at the North, it is evident that harm results from the freezing which is sure to follow the partial starting of buds in mid-winter. Such injuries come under the general head of what is known as winter-killing, but there are others which are more obscure and are not easily explained in the same way. A few of them, for instance the killing of evergreens in some winters, and their complete immunity in others, can be understood upon the view that the process of evaporation of water from the leaves goes on even in cold days in winter, when from the cold ground little or no water can be supplied to the roots to take its place. But there are still some instances of the sort which cannot be yet understood.

The nature of the injury produced by lightning has been studied in the case of a few species of trees. Usually part of the stem is torn in such a way as to indicate that some of the water lodged in the woody tissues had been suddenly converted into steam, and by the expansion has shattered them. It does not appear that any tree is exempt from lightning.

MALADIES OF NUTRITION.—These belong rather to under-feeding than to over-feeding, although there are marked instances of the latter. Generally the lack of some mineral matter essential to a fertile soil is shown by a general dwarfing and unsatisfactory growth. The problem is not exceeded in complexity by any which falls under the observation of cultivators. Even the distance of a few rods on the banks of some rivers makes a difference in the bouquet of wine from grapes in adjacent vineyards. In some of these cases chemical analysis fails to detect differences in the character of the soil sufficient to account for these differences in the character of the grapes from precisely the same variety. Nor can it be a matter of exposure to the rays of the sun, nor any other one factor yet suggested. This is, however, an extreme case. In our own country there is known to be a difference in the character of the tobacco grown on a virgin soil and on an exhausted one which has been artificially restored to its former fertility. Larger and stronger plants can be raised on the fertilized soil, but the wished-for delicacy of leaf and flavor cannot, as a rule, be again obtained.

That the subject presents peculiar difficulties is illustrated by the disease known as peach-yellows. According to some assiduous investigators, this complex affection is due in part, at least, to an insufficiency of potash salts in the soil, which causes an undue accumulation of starch in certain parts and an irregular distribution in others. But there are other competent students of the subject who regard the malady as attributable to the agency of micro-organisms. From the principal facts bearing on this group of allied subjects, which is of paramount importance to every cultivator of plants, the reader is referred, with confidence, to works by Johnson* and by Storer,† in which the topic is treated with fullness and clearness.

It is to the experiment stations in this country and abroad that we must look for the solution of the many difficult and important questions of a similar nature remaining unsettled in the departments of Physiological Botany and Vegetable Pathology. Under the liberal governmental grants made for the purpose of supporting research in this field, stations have

* How Crops Grow, and How Crops Feed.

† Agriculture.

been established which are doing excellent work. In many states there are similar stations established and supported by state aid. It seems to be desirable to secure complete concert of action between these useful establishments. In this way alone the field of research may be in some satisfactory manner divided up, so that more strength can be given to investigations in regard to certain problems. Doubtless this co-operation will be in some way or in some measure secured as the work of the stations advances.

Further, it is evident that the public must not be impatient with investigations which seem, at the surface and at the outset, to be far from practical in their bearings. Many of the purely scientific questions which are waiting solution can be best attacked in the experiment stations where Horticulture and Forestry are made prominent features. The history of science has shown over and over again that the results of pure, scientific research are, sooner or later, likely to be turned to the highest practical account.

In the foregoing series of communications the writer has endeavored to point out the leading general principles which are believed to be established in regard to the life and work of plants. But even under the limitation of confining the treatment of the subject to those principles which have special bearings upon Horticulture and Forestry, he has been obliged to indicate at times the fact that certain portions of the subject have not as yet been sufficiently explored by investigators. In the examination of such subjects investigators can frequently be much aided by observations made by practical men. The establishment of a journal like GARDEN AND FOREST affords still another excellent opportunity for both these classes of observers to exchange views and thus advance general as well as special knowledge.

The series of papers now brought to a close has had for its aim the presentation of the more important principles which are now embodied in the leading text-books on the subject, bringing these matters, as far as possible, into language readily understood by the reader. It is to such authoritative works as the text-books referred to at the end of previous papers and of this, that the reader must turn for further study and for further guidance in the examination of the phenomena of plants.

Cambridge, Mass.

George Lincoln Goodale.

Periodical Literature.

The April number of the *Kew Bulletin of Miscellaneous Information* is devoted to a list of new garden-plants described and published during the year 1888 in various English and foreign periodicals, such as the *Botanical Magazine*, the *Gardeners' Chronicle*, GARDEN AND FOREST, *Revue Horticole*, *Reichenbachia*, several German publications and two or three nursery-garden catalogues.

It will be found an indispensable aid to all persons who wish to keep themselves informed of recent additions to garden plants, or whose business it is to deal in or to write of such plants. Hybrids of garden origin and garden varieties are necessarily omitted from this list, which they would swell to inordinate proportions. Of the 674 entries (including varieties) sixty are credited to this journal. This publication shows clearly the present tendency of horticultural fashions. Of the 674 entries 176 are of Orchids, with forty-five *Cypripediums*, while only twenty-eight trees, exclusive of Palms, are mentioned, nearly all unimportant garden varieties of common species. The number of *Bromeliaceæ* is large comparatively, while Ferns, a few years ago the most popular garden plants in England, hardly find a place. By far the largest part of the new shrubs figured are found in the columns of GARDEN AND FOREST.

When the first of this year's crop of Maple sugar reached the market, a correspondent of the *American Cultivator*, writing from Wilmington, Vermont, one of the great sugar-producing towns of that state, gave the following interesting information with regard to the improved methods of this industry:

"There has been as great improvement at the tree-tapping and catching the sap as in any department in the work. Sixty years ago my father used for tapping, a common three-quarter inch auger (not very common either at the present time, for it was made by a blacksmith of all work). This was bored into the tree about four inches, then a spout made of sumac, anywhere from eight to twenty inches long, so as to accommodate the trough, that might have to be placed at the latter distance from the tree on account of its spreading roots, or an immovable rock, was driven in, the basswood trough placed underneath was blocked up with stones, and the tree was tapped. The

distance between the spout and the trough was often of necessity so great that much sap was lost by the wind, but if leaves were a compensation, enough of these were found in the trough to give color to the sugar. At the close of the season the troughs were turned over at the root of the tree, where they remained till wanted the next spring. This size and depth of hole was a great improvement upon the practice of a previous generation. Then it was common to 'box' the tree—that is, to make a reservoir for the sap by chopping into the tree from which the sap was drawn into the trough. Trees could not stand such 'heroic treatment' many years.

"Our sugar makers now use a half-inch bit, or less, some preferring one three-eighths of an inch in diameter, and say the latter size will afford as much sap as a larger size. The flow of sap is not confined in upward parallel veins. It has a lateral flow as well when given the opportunity. This being the case, the larger bit will hardly draw more sap than the smaller, while it will do more injury to the tree. That the sap will flow laterally has been demonstrated by putting in a second spout, ninety degrees from the first, and even at this distance the flow from the first was perceptibly diminished. When another was put in on the opposite side from the last, the flow from the first was still further reduced."

Correspondence.

A Public Loss.

To the Editor of GARDEN AND FOREST:

Sir.—During the preparations for the recent centennial celebration in this city gratifying proofs were given of the fact that the people of New York feel it incumbent upon them to protect the trees and shrubs on public and private grounds from threatened injury. The trees which rose through the public stands were railed off so that their branches might not be broken, and where stands stood over shrubs, as around the Reservoir and on the south-west corner of Fifth Avenue at Washington Square, they, too, were carefully shielded; and now that the boarding is everywhere removed, singularly few signs of damage appear. A large tree was indeed pulled down in securing the triumphal arch at the lower end of Fifth Avenue; but it fell because, being rotted through, it could not stand a strain which was applied with no ill effects to its companions; if it was not already dead, it could not have long survived.

One exception to the general rule, however, was observed on Fifth Avenue, where within the owner's fence had stood, time out of mind, a large English Hawthorn-tree, perfectly healthy, luxuriantly developed, and if not symmetrical in form, owing to the close neighborhood of the house, only the more picturesque on that account, leaning out over the railing as though with an almost conscious impulse to get as far from the bricks and mortar as possible. Many citizens now in middle life recall this tree as one of the great joys of their childhood, and even in adult years have watched for the unfolding of its fragrant wealth of blossoms as for the first sure sign that summer had arrived. It was one of the finest Hawthorns in New York or in its vicinity, and certainly the prettiest object in the whole length of Fifth Avenue. Yet it was cut down in order, apparently, that the one window it obscured, in a house where both front and side windows commanded a view of the processions, might be freed from the screen of budding foliage. It is not too much to say that a wail of horror went up from the inhabitants of this quarter of the town when they missed the well-known Hawthorn. No one will question the legal right of property owners to cut trees on their own grounds, but certainly the owners of this particular tree did not realize the amount of pleasure it had given to hundreds of people, and was capable of giving to hundreds more, or they would not have destroyed it for what seems to have been an ephemeral purpose. Wealthy New Yorkers, escaping to the country early in spring, seldom realize, perhaps, what a treasure to the city-bound classes is every piece of natural beauty that New York possesses; and few examples of this kind remain anywhere in our streets which are as precious as was this slaughtered Hawthorn-tree.

Twelfth St., N. Y.

Waverly.

The Home of the Bean.

To the Editor of GARDEN AND FOREST:

Sir.—The valuable article in GARDEN AND FOREST of April 3d, as to the American origin of the Garden Bean has recalled some observations of Roger Williams bearing on this interesting question.

In his "Key into the Language of America," which Zachariah Allen, late President of the Rhode Island Historical Society,

had copied for the Society many years ago, from the original in the Bodleian Library, at Oxford, Mr. Williams discourses not only on the language of the Indians, but also on their birds and on the vegetable products of the soil, as well as on their religion and traditions.

In his introduction to the work, he says: "It is famous that the Sow-west (Sou-an-ia) is the great subject of their discourse. From thence their traditions. There they say (at the Southwest) is the Court of their Great God Kau-tan-tou-wit; at the Southwest are their Forefathers' souls; to the Southwest they go themselves when they dye; from the Southwest came their Corne and Beanes out of their Great God Kau-tan-tou-wit's field; and indeed the further Northward and Westward from us their Corne will not grow, but to the Southward better and better."*

Subsequently, when discoursing on the Birds or "Fowle," Mr. Williams comes to the "Crow, Crowes," he observes that "These birds, although they doe the Corne also some hurt, yet scarce will one native amongst a hundred kil them, because they have a tradition that the Crow brought them at first an Indian Graine of Corne in one eare, and an Indian or French Beane in another, from the Great God Kau-tan-tou-wit's field in the South west, from whence, they hold, came all their Corne and Beanes."†

The pre-historic traditions of the Narragansetts thus concur with, and, as far as they have authority, confirm, the conclusions of Professor Wittmach and others from the discovery of pre-historic Beans in pre-historic graves of Arizona and Peru.

William D. Ely.

Pearl River Nurseries.

To the Editor of GARDEN AND FOREST:

Sir.—Few people of the thousands who daily cross the Hackensack as it winds sluggishly through the salt marshes near its mouth have any idea of the beauty of the valleys down which this river and its affluents flow from the highlands in which they take their rise. A few miles north of the line which divides Rockland County, New York, from Bergen County, New Jersey, on a long ridge which separates the Valley of the Hackensack from the Valley of the Pascack, or rather of a rivulet which joins the Pascack a short distance below, are located the Pearl River Nurseries. From the crest of Pearl River Ridge the view across the broad valley to the east is bounded by the Palisades, while to the west stretches a prospect equally attractive across a country of glittering streams and fertile farms and frequent woodlands, with the distant Ramapo Mountains against the sky. It is a most attractive location, where Mr. John Thorpe established himself rather more than a year ago, but the nurseries belong rather to the future than the present. Just now the active work of the place is directed mainly to growing flowers for the market while the preparations are in progress for the production of plants which will in time be the principal business of the establishment.

No man in the trade is more widely known or more generally respected for his skill and for his unselfish devotion to the cause of horticulture than Mr. Thorpe. He was the founder of the Society of American Florists, its first president, and continues to hold a most influential position in its councils. He has been a most successful hybridizer, having originated many admirable Gladioli, some of the most popular Geraniums in cultivation and such standard Carnations as Black Knight, May Queen, Portia, Petunia, Rosalind, Charles Henderson and E. G. Hill. He was conspicuous among those who helped to bring the Chrysanthemum into the public favor it now enjoys in this country, and he originated such notable varieties as Jennie Y. Murkland, Wm. Elliott, Sam Henshaw, Mrs. J. H. Spaulding, Thorpe Jr., Mrs. Charles Pratt, Mrs. R. Brett and many more besides the famous Mrs. Carnegie. I found Mr. Thorpe making large preparations for the summer flower trade in New York. He says that, in spite of the great summer exodus to the country, there remains an immense flower-buying population in your city. These are not the wealthy society people, and they do not buy flowers because it is the fashion. They are men and women in comfortable circumstances who buy flowers because they love and enjoy them. They spend about the same amount of money for them in one season as in another, and in the summer they buy a great many more because flowers are cheaper. Formerly the great wholesale and commission flower-dealers closed their places in summer, but now the shops are kept open the year round. Mr. Thorpe added that summer buyers liked variety, and that he raised many kinds of flowers in abundance now which were scarcely known to the trade a few years ago.

*R. I. Hist. Coll., i., p. 27.

†R. I. Hist. Coll., i., pp. 85-6.

Among such flowers he named *Coreopsis lanceolata*, Gaillardias and the smaller Sunflowers like *Helianthus orgyalis* and *H. cucumerifolius*.

To meet this summer demand Mr. Thorpe has planted 2,500 running feet of Sweet Peas, 60,000 Asters, besides Mignonette, Dahlias, double and single, Corn-flower, Hydrangeas, Lilies, Calendulas, Stocks and many other kinds in similar abundance. He will have 20,000 Chrysanthemums for early winter, including 500 plants of Mrs. Carnegie. I was curious enough to inquire which varieties of Chrysanthemums he considered the best for cut flowers, and he replied that his list was comparatively brief. A Chrysanthemum to be profitable in this direction must, in the first place, be of a clear and desirable color, then it must be a good shipper—that is, it must be able to endure the rough handling of expressmen without becoming bruised and disheveled; and lastly, it must wear well—that is, hold its form and color well after it reaches the wearer. His list of the varieties, combining in the highest degree these good qualities, would be something like this: For yellow flowers—Golden Desgranges, first early; Gloriosum, early; President Hyde, medium, and Grandiflorum (a splendid shipper), late. For white flowers—Desgranges, Robert Bottomly, Blanche Neige and Puritan, named in order of earliness. Lilac or pink—La Triomphante, M. Boyer and Troubadour, and to these Mrs. Fottler would probably be added another year, since it is a most promising flower. Crimson—Thibaut and Keleleer and Cullingfordii. Bronze—Compte de Germiny, Val d'Andorre and G. F. Moseman.

Of the flowers now going to market I was especially struck with the Gladioli, which were really better than they can be grown in the open air. The varieties which Mr. Thorpe uses most freely for forcing are Shakespeare, Romulus, John Bull, Eugene Scribe and Brenchleyensis. The La France Roses were remarkably good, but what particularly struck me was a row of Niphotos Roses extending along the entire length of one side of a house some 125 feet long. These were grafted on seventeen strong plants of Marechal Neil four years ago, and they showed remarkable vigor. From these seventeen plants 16,000 Roses had been cut since October. They were bearing abundantly still, and Mr. Thorpe assures me that they are never without flowers. I noticed a distinct blush shading in the buds that is unusual in Niphotos, and thicker petals with a firmer texture than belongs naturally to these flowers, and readily agreed with the suggestion of Mr. Thorpe, that these variations can be attributed to the influence of the stock, which is much more vigorous than the Niphotos, which is naturally a weak grower.

A house full of Peach trees was an interesting sight, although from the Early Alexander trees—more than half the entire number—the fruit had already been gathered. The trees of Hale's Early still bore many Peaches. The ripe ones are sent to market every day, and have brought during the season from eight to twelve dollars a dozen. The trees are only two years old from the bud, and they are planted in boxes a foot wide, a foot deep and four feet and a half long. Four trees are in each box, and a man at each end can easily carry them out to a stone-boat, so that a horse can draw them to their out-door quarters. These boxes are now arranged across the middle space of the house, and are but little more than a foot apart, so that about 200 trees can stand in a house 100 feet long. When first brought in they might stand much closer, if necessary; but early in the winter the cool temperature of this house makes the space between the boxes available for growing Narcissus, and after the bulbs have flowered the space is again used to force Astilbe for Easter. During the summer the house will be used for growing Chrysanthemums. The Peach-trees show wonderful vigor, which Mr. Thorpe largely attributes to bone-dust and hard-wood ashes in the soil and waterings with liquid manure.

But amid all this diversity of occupation and the preparation for forcing vegetables as well as fruits and flowers, Mr. Thorpe has not neglected his experiments in cross-fertilization, and he now has some 800 seedling Chrysanthemums from special crosses—that is, from seed in which the parent plants have been selected for some special excellence. Ninety-nine out of every hundred will probably prove of no commercial value, but Mr. Thorpe's experience is that good varieties do not come by chance. His greatest successes have been those which came from a long and careful series of trials to ascertain the qualities likely to be transmitted by a given strain or a particular cross. Here is a field in which knowledge is gained only by years of patient application. The men who persevere in unrequited studies of this kind merit the gratitude of every one interested in horticultural progress.

Pearl River, N. Y.

S.

Notes.

Tea Roses of the best varieties, of fair quality and with the fashionable long stems, were selling in the streets of Boston last week, ten for twenty-five cents.

The trade journals note a marked decline in the demand for cut Tulips. For two or three seasons back Tulips of every kind had been extremely popular, especially for table decoration, but for some unexplained reason they have not been favorites this year.

A most instructive picture of the two large specimens of the California Fan Palms (*Washingtonia filifera*) at Los Angeles has recently been published in the *Scientific American*. These two trees, which stand near an ancient well, are believed to be the largest in existence and to have been planted by the founders of the early Spanish Missions in California, who may have brought them from the desert farther south, where this species is only known to grow naturally. The two trees which stand close together, one on each side of the well, mingling their leaves far above it, are about ninety-five feet high and their trunks are seven feet in diameter. They are believed to be a hundred years old.

The *Revue Horticole* recently noted the first success that has been achieved in the artificial crossing of two allied species of conifers. Monsieur Vilmorin, in the year 1867, fertilized a female flower of *Abies Pinsapo* with the pollen of *A. Cephalonica*, and procured one cone with a single fertile seed. This produced a plant which last year fruited for the first time. The hybrid tree, which is now twenty-one years old, is remarkable for its fine development, and in appearance stands midway between its parents, most closely resembling *A. Cephalonica*, however, both in length of its leaves and in their silvery color. In color and form the cones also are more like those of the male parent.

The illustrations of floral devices which were recently published in the *American Florist* and noticed in these columns, are commented upon in a late number of the *Gardeners' Chronicle* (London). "Some of the designs," it is written, "are exceedingly pretty and appropriate, but what shall we say of a table-cloth entirely covered with Pansy flowers of a huge bell similarly covered, or a floral butterfly? For the dead journalist a desk and inkstand, all made of flowers, are prepared as a funeral ornament. *Chacun à son gout*, but not too much of it." The French proverb is a wise one in the majority of cases, but to use it here is to use it unworthily. "To every one his own wish," would be a better phrase.

A pretty picture in a recent number of *The Garden* showed "A Growth of Hellebores in Winter" in one of those places where most people think "nothing will grow"—a shady garden corner beside a fence. "The soil is the poorest possible—a dry sand and under the shade of Fir-trees. A bank was thrown up to conceal a road, and the Hellebores, then young seedlings, . . . were planted in groups. On other parts of the same bank were varieties of minor Periwinkle, Solomon's Seal and common hardy Ferns, all doing well." *Iris fatida* was also used and Irish Ivy to cover the fence; and from the witness of the picture we can well believe that throughout the past winter this unpromising spot has been "the best clothed bit of the garden."

The hybrid Violets of the particular strain for which Mr. Robinson suggested in *The Garden* the name of Tufted Pansies, are among the most interesting flowers now in bloom. They are from the common Pansy crossed with an alpine Violet. They have a more tufted habit and grow rather more closely than the Pansy, endure the winter quite as well, flower very freely for a long time, and are delightfully fragrant. There are several named varieties, but in the garden of Mr. John N. Gerard, at Elizabeth, New Jersey, a bed of unselected seedlings now in bloom captivates every visitor. As Mr. Gerard says: "Some of the highly-bred Pansies have been improved a little too much; they once smiled, but now they grin," and these more modest hybrids, with their delicate self colors, make a pleasing change.

In the garden of Professor Charles N. Shepard, Charleston, South Carolina, is a Rose remarkable for its size and vigor. The original stock, a Banksian Rose, was planted more than fifty years ago, but—at heights varying from ten to fifteen feet—grafts of Maréchal Neil, Marie Van Houtte, Devoniansis, Cloth of Gold, Madame Eugénie Verdier and other choice varieties have been inserted, and these have made wonderful growth. The trunk at the base is nearly a foot and a half in

diameter and the branches cover two trellises, each some forty feet long and twelve feet wide, besides rioting over a piazza sixty-five feet long and forty-five feet high, while the topmost shoots are aspiring to cover the roof. From a photograph, kindly sent us by Professor Shepard, it can be seen that this great vine was thickly covered from bottom to top with finely-developed flowers.

Papyrus, universally used for writing upon in the ancient world, was manufactured out of the stalks of the plants of this name (*Cyperus*). The largest portion of the stalk was chosen and was split down one side; the soft centre was removed, and the sheath, about eight inches in breadth, was pressed, polished and rubbed with oil of Cedar to preserve it from decay. Two sheets were then gummed one upon the other in such a way that the fibres of one ran at right angles to those of the second, in order that sufficient consistency might be obtained; and then these doubled sheets were attached to one another to form rolls of any desired length. Papyrus was so generally used even in the later Roman period that Cassiodorus, says a recent writer in the *Revue Horticole*, wrote an epistle congratulating the whole human race upon the fact that the import duty laid upon it by Theodoric had been decreased. In the time of Xerxes an immense number of Papyrus cables were manufactured in Egypt for use in his fleets and in his bridge-building enterprises.

It is pleasant to know that the money bequeathed a few years ago by a gentleman of Chicago for the purpose of erecting a gateway to the yard of Harvard College, will procure a beautiful piece of work, which will greatly enhance the dignity of the group of buildings behind it, harmonizing with the solid simplicity of the older halls, yet ornate enough to be in keeping with so fine a modern example as Sever Hall. The design of the architects, Messrs. McKim, Mead and White, as published in the *American Architect and Building News*, shows a large wrought-iron gate, with simple uprights and a delicate traceried top, supported by two square, massive piers. These have sunk panels on their faces, enframed in simple borders, and bearing the arms of the college and appropriate inscriptions, and are crowned by a well-profiled cornice and a low coping finished with a ball. From these piers extends on either hand a stretch of wall lower than the gate, in which is a round-arched doorway, and, between this doorway and the gate, a fountain in one case, and in the other an oval-grated window for the use of the custodian when the yard is closed. These walls end in low piers, and the whole construction is recessed behind short, advancing arms of wall, finished with similar piers, from which, to right and left, extends a graceful wrought-iron railing. The design, if it is necessary to give it a name, may be called "Queen Anne," and is therefore in keeping with the oldest buildings in the yard, while handled with greater delicacy and refinement than one usually finds when the same name is suggested by a modern piece of work.

A correspondent of the *Gardeners' Chronicle* (London) speaks as follows of the botanical gardens at Maritzburg, Natal: "The Maritzburg Botanic Gardens were first enclosed and planted in 1874, and are 100 acres in extent, situate in the Zwartkop Valley, two miles from town. The site is very diversified, consisting of a gently sloping piece of ground in extent about thirty acres, which is watered by two perennial mountain streams, the remainder consisting of a steep hill-side rising to a height of some 300 feet above the rest of the garden, the sides of which are being planted with *Pinus insignis*, Acacias, etc. The local temperature is frequently over 80° in the shade during summer, and sinks to 3° and 4° of frost in the winter. . . . The lower part of the garden is about 2,300 feet above the sea, and is planted with a selection of trees and shrubs which, considering their age—none over seventeen years—it would be difficult to match elsewhere for vigor and size. Taking the girth of a few of the largest at five feet from the ground we find *Casuarina tenuissima* to be 5 feet 3 inches; *Acacia dealbata*, 7 feet; *A. melanoxylon*, 4 feet; *Cupressus macrocarpa*, 5 feet; *Pinus Canariensis*, 4 feet; *P. Pinaster*, 4 feet; *P. insignis*, 5 feet 6 inches; *Grevillea robusta*, 3 feet 9 inches; *Cupressus Lawsoniana*, 3 feet; *Eucalyptus globulus*, 5 feet 6 inches, all in fine health. There is a fair collection of flowering shrubs. . . . Of glass-houses there is scarcely a vestige. The garden of the capital of Natal contains but one iron conservatory, eighteen feet by nine feet, in a wretched state of repair, and not a glass frame of any kind! It may be added that the Government grant is only £350, and the public subscription list for last year only £28. Few plants are sold, but a considerable number of young trees are granted free to the railway and other Government institutions."

The Care of Young Trees.

PROFESSOR BEAL, in a letter printed on another page of this issue, suggests the reason why so few practical results and real benefits have followed the wholesale planting of trees which has been going on in this country, or in some parts of it, at least, during the last dozen years. The twelve trees planted only a year before with impressive ceremonies, which Professor Beal describes, are a fair sample of the newly-planted trees in this country. It is an easy thing to pull up a sapling tree and then thrust it back into the ground again with dry and mutilated roots, for this is what tree-planting means to a not inconsiderable part of the community who plant trees. This operation comes within the scope of the most limited intelligence, and it can be completed in five minutes. It is a much more difficult matter, and one that requires patience, the power of observation, and skill to select and plant a tree thoroughly well, and then to see that it is properly protected from all the enemies which beset plant-life and so has a fair chance to grow until it attains a size and strength sufficient to enable it to take care of itself.

We have already explained more than once how trees should be planted; and now that the planting season is over for this spring a few suggestions upon the care of newly-planted trees may not be out of place.

Newly-planted trees, except conifers, and unless they are very small, or planted very thickly together, need the support of stakes to prevent the swaying of their heads from loosening the roots before they have taken firm hold of the ground. It is best to fix the stake firmly in the ground before the tree is planted, but if that has not been done a stout stake should be driven down close to the stem. It should be as high as the tree, which should be attached to it with bast, or with strips of linen, or of thin canvas from a point two or three feet from the ground to the very top. Cord or wire or any tying material which is hard enough to cut or injure the bark should not be used in fastening the tree to the stake. The reason why a stake as tall as the tree is needed is, that when a short stake is used, the stem of the tree being immovable and the top

free to sway in the wind, the bark is bruised by rubbing against the top of the stake. Many young trees are injured in this way, and in some cases the stem is snapped off short in a gale just on a line with the top of the stake when the lower part of the tree only is held too rigidly.

Thorough cultivation is needed for newly-planted trees. It prevents them from becoming choked by weeds, and by checking evaporation increases the moisture available for their support. The surface of the ground, therefore, about newly-planted trees should be stirred once in every two or three weeks from the time they are planted until the middle of August or the first of September, when cultivation should cease, that a late growth may not be encouraged and that the wood may become thoroughly ripened before the advent of severe frosts. The weeds which start after the middle of August have only a brief life and cannot injure the tree. When a few trees only are planted, or when it is impracticable to stir the ground continually, the growth of weeds can be prevented and evaporation from the surface reduced by covering the ground with a mulch of strawy manure, meadow hay, spent tan-bark, or the clippings from the lawn. A thick mulch if it is left on the ground all winter harbors field mice, and there is no mulch really so effective as the scuffling hoe, regularly and thoroughly used. Young trees require constant watching if they are to grow into fine specimens. Borers must be looked for and removed, and all the harmful insects which prey upon trees destroyed. The judicious employment of the nails of the thumb and forefinger on a young growing shoot will save the use of the pruning knife and the saw in later years. A little summer pruning of this character during the second and even during the first year after planting is of immense value to trees. A tree may thus be induced to assume the proper shape without any loss of vital force, and without any outlay beyond that of a little intelligence. A branch growing in the wrong position, or with an excess of vigor, an incipient fork which later may destroy the beauty and even the life of the tree, a false leader or unimportant branch crossing and chafing against an important one, may be rubbed out when the tree is young with the movement of the hand without inflicting a serious wound upon the tree. This familiar example will serve to illustrate, perhaps, the value of a little judicious pruning. It is not uncommon where second-growth White Pine abounds to find tall trees with a trunk divided close to the ground into two stems of nearly equal size. Such trees have little ornamental or commercial value. They have grown with two trunks because when they were little seedlings the leader was broken off, or eaten off by some browsing animal, and was replaced by two leaders of equal vigor. Had some one interested in trees and familiar with their mode of growth passed by the injured seedling a year or two after the accident, and stopped the growth of one of the leaders by picking out the top, or by knocking it off with his cane, the tree would have grown up as straight and tall as if no accident had ever happened to it, and a good tree would stand in the place of a misshapen one.

If a young tree is expected to grow into a noble, symmetrical, long-lived specimen it should be examined two or three times a year, and such pruning performed as may appear necessary; and this must be done during several years, until it has assumed its permanent form and attained a size which renders further care beyond the removal of dead branches unnecessary.

Many noble trees have grown, of course, to very great age without care and without thought, but the proportion of really good trees to the whole number which spring up naturally or are planted in the world is very small, perhaps not one in a million, and if even a reasonable proportion of planted trees are to fulfil a fraction of the hopes which fill the hearts of those who plant them they must be nursed and watched and cared for intelligently. It would be interesting to know how many of the 600,000,000 trees (if that is the number), which western Arbor-day

orators boast of as planted in Nebraska during recent years, ever survived the first summer, or how many among them promise to become of any permanent value to the community; or to know what proportion of the people of the United States who plant trees do it intelligently, and so reap the benefits which should come from their expenditure of money and time and labor.

It has grown to be a custom in several parts of the country to reward children in the public schools for planting trees, the amount of the reward being in proportion to the number of trees planted. A much wiser plan would be to give the reward five years after the trees are planted to the child who had reared the best tree. Quality is better than quantity in tree-planting, and the experience which a child would gain in caring for a single tree intelligently during five years would be worth more to him individually in after years and to the country at large than the careless planting of a much larger number, which, like the twelve Michigan trees, were only planted to perish—a result which is not calculated to have a stimulating or useful influence upon a youthful mind.

Kew Gardens.

SO many of our readers visit London every summer that we are sure to do them a service by reproducing for their benefit the following extract from an article which recently appeared in the *Saturday Review*, upon the greatest botanical and horticultural establishment in the world, where lovers of plants have more to learn than in any other spot:

"From time to time one of those people who apparently enjoy creating a little sensation by airing their imperfect knowledge of facts uplifts his voice in the House of Commons as aggrieved at the great expense to which the nation is put in maintaining the Royal Botanical Gardens at Kew. He is possibly under the impression—as, indeed, are the majority of people—that Kew Gardens are mere highly ornamental open spaces, to which the public and the inhabitants of Kew, especially, are granted admission at all times. Under these circumstances the keeping up of so many costly conservatories is, in the opinion of those who are not aware of the truth, inexcusable; and, although they have a vague idea that the *Victoria Regia* costs a small income to enable it to bloom annually, to the delight of holiday-makers and of our cousins from across the Atlantic, they would willingly vote for such a decrease in the grant accorded by the nation to the Directors of these Gardens for their proper preservation that before many months the most beautiful of Water-lilies would have ceased to exist and the great Palm-house be a howling wilderness. There is, however, every just reason why, instead of being diminished, the grant to Kew should be augmented. Let any intelligent person take the trouble to go systematically around these Botanical Gardens, and he will be at once convinced of their great importance, not only to England, but to the colonies and the Indian Empire; for they are emphatically not mere pleasure-grounds, but have a distinctive function to perform in the commercial economy of the country, and are the headquarters of a vast organization, having ramifications in every part of the known globe—and, we might almost say, the unknown, for missionaries and travelers are constantly sending to Kew from newly-discovered lands specimens of the rarest of plants, many of which are absolutely unknown to botanists. The staff of learned men engaged here is not a large one, but its activity and intelligence cannot be over-estimated. Thanks to them, no less than three important publications are issued every month from Kew—the *Botanical Magazine*, edited by Sir Joseph Hooker; *Icones Plantarum*, which deals with the dried or colorless specimens of plants; and the *Bulletin of Miscellaneous Information*; and to these may be added a number of special pamphlets, issued from time to time, treating of fresh discoveries, which are sent out to the colonial Governors, directors of museums and botanical gardens, as well as to the leading scientific men of Europe.

"To the right of the grounds stands an ancient mansion of the Georgian epoch, which in by-gone times was inhabited by the King of Hanover. It is now the principal centre of the organization to which we have above alluded, and here is preserved unquestionably the largest collection of dried specimens of flowers and plants in existence. Hither come students of every nationality to gather information which cannot be ob-

tained elsewhere; and only the other day, when we were visiting the principal hall, a pile of pressed leaves and plants lay upon the table which had just arrived from a Jesuit missionary laboring in an unknown region of China. In the Gardens themselves are other special museums of great interest. The splendid Orangery has been converted into a museum for woods, tissues, roots, grains, seeds and models of edible fruits, many specimens of which figured in the great Exhibitions of 1851 and 1862, and in the Colonial and Indian Exhibition. And here we should not forget to mention the handsome gallery presented to the nation by Miss North, which contains the wonderful series of drawings of plants which she made during many years when on her extended travels through tropical regions. But, independently of the museums, the out-door gardens and the numerous conservatories are arranged on purely scientific principles, and, although they are very picturesque and beautiful, their utilitarian side is never for a moment lost to sight, so that the horticulturist can see for himself in the most practical manner how particular plants should be grown, as well as the results of their careful culture. None of the produce of the Gardens is sold, but the surplus of seeds and young plants is exchanged for other specimens from public institutions of a like character abroad. The great Palm-house is unquestionably one of the most beautiful and extensive in the world, and gives us as fair an idea of tropical beauty as it is possible to conceive without actually visiting a jungle; but close to it is a small conservatory of far greater value, in which plants of a useful kind are exhibited. Here, for instance, grows the Coca, whence the much-talked-of cocaine is derived. There are also several varieties of Teas, and a little plant, newly discovered—the *Gymnema sylvestre*, to which the attention of Kew was drawn by Sir Mount Stuart Grant Duff—from the leaves of which an alkaloid can be abstracted which deprives us of the taste of sweetness for at least forty-eight hours, without injurious effect; and hard by it is another newcomer, the Miraculous berry of the Gold Coast, the leaves of which, treated in the same manner, produce a totally different result, for they cloy the mouth with a saccharine sweetness so great that it matters not what we eat or drink afterwards it will always have, during the time the effect lasts, the flavor of honey. In short, Kew Gardens is a centre round which not only all the similar establishments in England but those of the whole Continent revolve; for it is acknowledged that it is the most complete of its kind in existence.

"The learned little world which does its work so regularly at Kew, in its various museums and offices, is of far greater importance to the world at large than is generally imagined. The chief secrets of botany are only now being disclosed; and, as within only a few years past such a wonderful anæsthetic as cocaine has been introduced, whereby certain operations can be performed with impunity, it would be hard to tell what fresh discoveries are in store for us, and it is only at such an institution as Kew that the scientist can diligently pursue researches which may eventually prove of inestimable benefit to mankind. Therefore, independently of their beauty as a pleasure resort, from a purely utilitarian point of view, Kew Gardens have claims upon the general public which it would be folly to ignore, and absolute wickedness to seek in any way to diminish. In connection with Kew it may be observed that, notwithstanding the enormous crowds which flock here on a fine Bank Holiday, scarcely a single instance of drunkenness or misbehavior has been registered; and it is pleasant to record that the tea-house and refreshment-kiosk, introduced after some demur, have proved very successful."

Boring Beetles in the Ash Finish of a Chapel.

A FEW years ago a self-constituted board of visitors invaded the chapel of the Theological Seminary at Andover, Massachusetts, and, like another board, not unknown to modern ecclesiastical history, proved the reverse of welcome to the faculty and trustees of that institution.

Under date of November 9, 1882, the treasurer of the seminary wrote us as follows: "You may have noticed in the public prints reference to a chapel in Andover, the finish of which is being eaten by worms. It is becoming a serious matter, for if it continues to spread, the finish of our new chapel will be ruined." A piece of the mop-board was sent us as a sample of the work, and a few days later Mr. Edward Taylor, the treasurer, wrote us that the evidence of the work of the borer had been found in various localities about the house, and that it was increasing, and he asked for information as to the best means of preventing further ravages from the worms, at the same time enclosing the following statements published by General Meigs, of Washington, and some suggestions which

are worthy of reproduction here. "The timber is suffering from a disease well known to the manufacturers of shovels and pickaxes, and called by them 'powder post.' A worm eats the ash handle, which show minute holes, and when jarred by striking a hard substance gives out a shower of fine powder, 'powder post.' It is so common that they do not attempt to keep long any stock of handled spades, shovels and picks; and I was advised by the late Mr. Oakes Ames, at the close of the war, to sell off at auction the large stock of such stores left in the army depots, as it would be impossible to keep the handles from destruction.

"Saturation with petroleum was tried, and I think gave protection and prevented the progress of the disease.

"Perhaps petroleum applied in abundance by a sponge or brush might arrest the destruction to the Andover church.

"Captain F. Petrie, Honorable Secretary of the Philosophic Society of Great Britain, has written me as follows: 'I believe it will be found an effectual cure if the wood-work, or even the parts affected, are painted with paraffine oil; I have not known it to fail. We are going to try it on places where we see them at work.'"

We suggested the application of a coat of oil to the "finish," as any oily substance if thoroughly applied would tend to soak into the wood, especially where mined by the borers, and kill them. It may be borne in mind that insects breathe by little openings in the sides of the body, and if a film of oil or any greasy substance spreads over the breathing pores or spiracles, the worms will speedily die by asphyxiation.

The oil was applied, with the results kindly communicated to us by Mr. Taylor, under date of March 28, 1888. "I have heard no complaint of these worms at work in our chapel for some time, in fact I think evidence of their work ceased to appear very soon after the application of the wash applied to the places where they gave signs of working. I think kerosene, or something of that kind, was applied, only in places where they threw out their champing, and this, I was told, was in what the carpenter called sap wood."

The piece of Ash sent us in 1882 was honey-combed by the mines or tunnels of what was probably the young of this beetle, and which were between one and two millimeters in diameter; in some places there were a dozen holes, or places of exit made by the beetle, to a square inch of the surface. Much of the wood had been affected by dry rot, the work, as we understand it, of a fungus. It is most probable that the lumber used was affected by the dry rot, and that the larvæ of the beetles began their work in situations thus affected.

We have observed somewhat similar beetles (probably *Sinoxylon*) boring in the wooden bottom of a trunk, which had also been affected by "dry rot."

Specimens of the depredator, found in August, 1883, and which proved to be rather a rare beetle, were sent to our leading coleopterist, Dr. G. H. Horn, for identification, who was kind enough to name it as *Teretrius Americanus*, Leconte.

It belongs to the family of mimic beetles, or *Histeridæ*, so named from their power of drawing up their limbs and feigning death. Now, this insect does not belong to a group of borers, for most of the species, as Westwood says, feed upon decaying vegetable and animal matter, or on dung, while others are much flattened, and thus are adapted for a life under the bark of trees. However, some forms appear to connect the family *Histeridæ* with that of the stag beetles (*Lucanidæ*), whose larvæ are wood borers, though attacking rotten wood.

In this connection I may quote from a letter of Dr. Horn, in which he says: "The idea that they do the boring is strenuously opposed by Mr. George Lewis, who says that they enter the holes made by the larvæ of *Lyctus* and *Sinoxylon* with murderous intent. I cannot see any reason why they should be wood borers. In fact, I cannot recall any coleopter that is an in-borer. I am, therefore, inclined to accept his idea that they enter the holes with predaceous intent."

While there are no facts to justify the inference that the beetles themselves gnawed into the wood, it is not improbable that their young or larvæ were the culprits. Yet, no larvæ were found in the piece of wood sent us, and only one or two of the beetles, and it is rather singular that more dead specimens did not remain in the wood. At present, then, we are inclined to believe that the *Teretrius* in the larvæ state made

the tunnels, though it is still not impossible that some species of *Sinoxylon*, a small beetle of the size and general appearance of the *Teretrius*, may have been the culprit. Moreover, we are inclined to believe that the ash wood used in making the finish was affected by dry rot, either before or very soon after it was put into the chapel.

Providence, R. I.

A. S. Packard.

The Lindens of Western Europe.

EUROPEAN Lindens were introduced early into the Eastern States, and, although now known to be not as well suited to the American climate as our native species, they are still favorites with many persons, and numbers of them are planted every year, especially in the neighborhood of the great nursery centres.

Planters of these Lindens in Europe, as well as in this country, rarely distinguish, however, between the three species of western Europe, which they generally regard as one and the same plant, usually called in nurseries *Tilia Europæa*; and the specific characters and the nomenclature of these trees are still, apparently, very imperfectly known, except by botanists familiar with the European flora.

Linnaeus, to be sure, in the "Species Plantarum," grouped the different European Lindens together under the general name of *Tilia Europæa*, distinguishing five varieties Scopoli, in the "Flora Carinolica" (1772), separated the Linnaean species into two—*Tilia platyphyllos* (the Var. ϵ . of Linnaeus) "*folia magna, subhirsuta*;" and *Tilia ulmifolia* (the Var. γ of Linnaeus) "*folia duriora, minora, nullibi villosa*." Hayne, in the "Abbildung der Deutschen Holzarten" (1815), further divided the Linnaean species by proposing a third—*Tilia vulgaris* (*T. intermedia*, DC. "Prodr.," 1., 513). Colored figures showing plainly the characters of the three forms were published by Hayne, with whose views as to the limitation of these species later botanists, from De Candolle to Nyman, have generally concurred.

I can find no distinguishing characters in the bark, in the habit of growth, or in the flowers, which in all three species are destitute of the petaloid scales that occur in those of our American species, or in the winter-buds of these trees as they are found growing here; but in the leaves and in the fruit they are clearly distinct, as will be seen from an examination of the figures upon pages 256 and 257, drawn by Mr. Faxon from specimens cultivated in the neighborhood of Boston, where, at least one species is common.

The following characters, therefore, may be found useful in enabling cultivators who cannot always readily refer to the old figures to distinguish the different species.

CONSPECTUS OF THE SPECIES

Leaves pubescent: fruit prominently four-ribbed at maturity 1. *T. platyphyllos*.

Leaves naked, except in the axils of the principal veins: fruit destitute of wings.

Leaves ample, the base more or less oblique, green on both surfaces: tufts of hairs pale: shell of the fruit thick and tough. 2. *T. vulgaris*.

Leaves small, sub-cordate or rounded at the base, pale on the lower surface: tufts of hair, rusty brown: shell of the fruit thin and brittle. 3. *T. ulmifolia*.

Tilia platyphyllos, Scop. Young shoots and petioles hairy-pubescent; leaves large, four and a half to five inches long by four inches broad, thick, distinctly yellow-green, cordate, or, sometimes, slightly oblique at the base, coarsely and sharply serrate, softly puberulent on the upper, densely pubescent on the lower surface; fruit top-shaped or oval, prominently four-ribbed at maturity, and coated with pale brown tomentum.

This tree may always be easily distinguished, even at a considerable distance, by the marked yellow tone of the green of its foliage. It is the first of the Lindens to bloom, the flowers appearing here sometimes as early as the middle of June; and the first to lose its leaves in the autumn. In dry seasons the leaves, even in Europe, begin to shrivel and turn brown in August, and sometimes fall in September—peculiarities which make this species the least desirable of the Lindens for ornamental planting.

Fig. 108.—*Teretrius Americanus*, Lec.

Fig] 109.—*Tilia platyphyllos*, Scop.

It is widely distributed through central and southern Europe, and is a southern rather than a northern tree, although, according to Dr. Bolle, who has favored me with some interesting notes upon European Lindens, it occurs sparingly in Denmark, western Sweden (where he has found it forming small groves on several islands in the neighborhood of Strömstad), in Poland, and eastward as far as the Ural Mountains. It is the "Grossblättrige Linde" of the Germans. This tree appears to have been a favorite with Le Notre, who planted it largely at Versailles, and it is the tree which forms the clipped alleys in the garden of the Tuileries in Paris. It is not very often seen in this country.

Tilia platyphyllos has produced more varieties than the other species, either from a greater tendency to sport, or because it has been cultivated longer and more generally. Ten or fifteen varieties, of no particular value, are met with in nurseries, the most distinct, perhaps, being *T. vitifolia*, *T. asplenifolia* and *T. corylifolia*.

2. *Tilia vulgaris*, Hayne. Young shoots and petioles glabrous; leaves ample, three and a half to four and a half inches long by three to four inches broad, thin, cordate or often oblique at the base, sharply serrate, green on both surfaces, and quite naked, with the exception of the tufts of pale hairs on the lower surface in the axils of the principal veins; fruit oval or sometimes nearly round, coated with dense, short tomentum, the shell thick and tough.

This is the "Zwischenlinde" of Karl Koch, and it is often called the Dutch Linden from the fact that it was early and largely propagated in Dutch nurseries. It appears to be the largest of the European Lindens, and the most generally cultivated, although the least frequently seen in a wild state. Nyman credits it to the countries of central and south-eastern Europe; but Dr. Bolle writes, "I can only remember to have seen this tree once myself growing

wild—a single specimen in the rocky chasm of the Virga Valley, near Botzen, in the Tyrol, where it seemed to be growing spontaneously. If its native locality is doubtful, however, it is certain that it has been cultivated as a park and avenue tree for nearly three centuries. The rows of trees which have been planted in our cities since the seventeenth century are comprised, almost without exception, of this species." It is the *Tilia vulgaris* which gives its name to the most famous street in Berlin, and which is so often seen in English parks and gardens; and it is the species—so far as I have been able to observe—which has been planted the most frequently in the United States. The old, and sometimes very large, Lindens which are still found in the suburbs of Boston and New York belong to this species, which is the one commonly planted on Boston Common. It flowers here during the last week of June, or nearly ten days later than *Tilia platyphyllos*.

3. *Tilia ulmifolia*, Scop. Young shoots and petioles glabrous; leaves small, two to two and a half inches long by nearly as much broad, thin sub-rotund or cordate at the base, sharply and minutely serrate, green on the upper, pale, or often nearly white, on the lower surface, which is conspicuously marked with large tufts of rusty brown hairs in the axils of the principal veins; fruit oval, obovate, or sometimes nearly round, the tomentum with more scattered and longer hairs than in that of the last species, the shell very thin, papery and brittle.

I retain for this species Scopoli's name of *T. ulmifolia* because it is the oldest (1772). The leaves, however, do not resemble those

Fig. 110.—*Tilia vulgaris*, Hayne.

of an Elm-tree in any particular; and the name is a much less appropriate one than *T. cordata*, Moench (1785), or *T. parvifolia*, Erhardt (1794), which is the best and the one now most frequently used by botanists, although De Candolle adopted for it Ventenat's name of *T. microphylla*, which was not published until 1803.

Fig. 111.—*Tilia ulmifolia*, Scop.

Tilia ulmifolia is the common Linden of northern Europe, although it is found, apparently, all over the Continent, especially at high elevations. In southern Italy, according to Bolle, it is more common than *T. platyphyllos*. "Both species," he says, "grow wild in the wooded regions of the Apennines, and both are very commonly cultivated in the Mediterranean countries. I must be pardoned for disagreeing with Karl Koch when he says 'this tree never grows so old or so large as *T. vulgaris* or *T. platyphyllos*,' now that I have seen the beautiful great Lindens at Paelitzaerder on the Paarstein Lake at Uckermark. There enormous trees, which all belong to *T. ulmifolia*, are scattered in isolated specimens over the whole island and shade the ruins of an ancient abbey built in the thirteenth century. The trunk of the largest of these old trees, which are still in an excellent state of preservation, girths nearly twenty-three feet; and there are many others scarcely inferior to it in size."

Tilia ulmifolia, although perhaps the most commonly and widely distributed of the European Lindens, has been, so far as my own observation goes, much less frequently planted in central Europe than either of the other species, and I do not remember having seen anywhere a very large or remarkable specimen. It is seen in this country more rarely even than *T. platyphyllos* and we have succeeded in finding only two or three small trees in the neighborhood of Boston. It does not flower until towards the middle of July or nearly a month later than *Tilia platyphyllos*. It would be interesting to know if there are anywhere in the United States large specimens of the small-leaved Linden.

Cultural Department.

Some Iron-clad Pears, Plums and Cherries.

ALTHOUGH the very large number of varieties of Apples, Pears, Plums and Cherries imported by Professor Budd and Mr. Charles Gibb from north-eastern Europe will require the experience of a great many years before we can determine their exact value and relative importance for all

sections of our cold North, one thing, at least, has already been settled in the last five years in regard to them. They are, in their earlier years, to a very marked degree more hardy against winter's cold than any we have before had in cultivation, except the few estrays which had already reached our shores from the same regions. It is only necessary to plant an Apple-tree like the Duchess of Oldenburgh, in a locality where the winter's temperature frequently touches the freezing-point of mercury, to become satisfied that here is a class of Apples entirely unlike those we possessed previously. The cheerful indifference with which such temperatures are endured by these trees is entirely unlike the woe-begone results seen upon many of the varieties which are classed among our hardy Apples.

This is the result, at least, of five years' experience with the Pears, Plums and Cherries brought to us by Messrs. Budd and Gibb from Baltic Germany, Poland and Russia. They are nearly all as indifferent to extremes of minus temperature as our native Plums and Cherries, while we find in them the ameliorations consequent upon centuries of cultivation and selection. Among upwards of 100 varieties of Apples, thirty-one of Cherries, seven of Plums and sixteen of Pears, selected from the most promising sorts for trial on my own grounds, it is yet premature to pass judgment upon any except as to the hardiness and vigor of growth exhibited by them for the four or five years that I have had them, which include two winters never exceeded, if ever equalled, for severity since thermometrical observations have been recorded in north-eastern Vermont and the Province of Quebec. A few of the Apples, Plums and Cherries have given me specimens sufficient to justify a strong belief that these fruits are likely to meet reasonable expectations as to their size, beauty and quality. The Plums are in color red, white and blue of varying sizes and seasons from early to late. The Cherries that have fruited belong to the Girotte or Morello class, variously crossed upon, and varied under culture, so that among them are several that approach closely to the Hearts and Bizarreaus in size and sweetness. Many are remarkable for the relative smallness of their pits, and the juice of some is deeply colored. Others, such as the heart-shaped Weichsel, show a cross between the sweet Mirello and the Dukes. This variety is used in east Europe as a lawn-tree on account of its symmetrical growth and its handsome striped leaves. The fruit is large, heart-shaped, purplish-black, and nearly sweet. Nearly all these Cherries are distinguished from our hardiest common sorts (Pie Cherry, etc.) in being hardy both in tree and in blossom-buds, so that they not only live and grow, but bear plentiful crops of fruit. There is a large family of these Cherries, classed together as Amarells, embracing a considerable variety, along with family likeness. The trees are rather small, and heavy bearers while quite young. The Astherm family is also an interesting one, numbers of which were brought into Iowa and Minnesota by German immigrants some twelve or fifteen years ago, and have proved reliable bearers in those states where all other sorts failed. The fruit of these varies, yet a family resemblance is seen in all of them. The Vladimir race, from the Russian province of Orel, is quite dwarf, with mild, sub-acid fruit, larger than Montmorency, and in some varieties nearly black, with a mild, sub-acid flavor.

Of the Pears I can only as yet report a most vigorous growth, so that some of my trees, five years planted (twelve to eighteen inches high at the start), are now fully nine feet high. They are evidently early bearers, as one showed a cluster of flowers last year, and two are this season crowded with fruit-buds. If the omnipresent small boy will allow them to mature I shall be glad to send specimens to GARDEN AND FOREST.

Newport, Vt.

T. H. Hoskins

Orchid Notes.

Epidendrum prismatocarpum.—Of the three hundred and more species which constitute the genus *Epidendrum*, by far the greatest number of them possess inconspicuous and dingy colored flowers, which render them only valuable to botanical collections. There are a few, however, whose flowers have sufficient beauty to make them favorites with cultivators, and among these must be classed the subject of the present note.

Although *E. prismatocarpum* is a very old inhabitant of our Orchid-houses, it is, nevertheless, by no means plentiful, which explains why it is heard of so seldom. As far back as 1852 it was described by Professor Reichenbach in the *Botanische Zeitung*, but it did not make its appearance in cultivation until about ten years afterwards, when it was sent to Europe from Veragua and Chiriqui, where it was first discovered by War-sewicz.

This species may be readily recognized even when not in

flower, by means of its long, deep-green, flask-shaped, pseudo-bulbs, from the apex of which are given off two shining, green, strap-shaped leaves, gracefully recurved, and an erect peduncle, bearing from fifteen to twenty large flowers, the sepals and petals of which are pale yellowish-green, covered with large blackish blotches, which give them a very bizarre appearance. A striking contrast is presented to the sepals and petals by the long, triangular lip, which is generally of a warm rose color. There is great variation among the flowers of this species, caused, no doubt, by different treatment and conditions. In some the blotches are pale and the flowers few and small, while in others the flowers are large and plentiful and richly colored. They are produced during April and May and will last for several weeks, so that the plant might be used with advantage as for exhibition purposes.

It should be potted firmly in peat and sphagnum moss, and as it grows during the winter months—a fact worthy of notice—water should be given freely according to circumstances, as well as frequent syringings, which keep pests away. The plants, although at rest during the latter part of the summer and autumn, must nevertheless receive enough water to keep the pseudo-bulbs and leaves in a plump condition. A temperature of about 60°-70° Fahr. suits it admirably.

Maxillaria Sanderiana.—The genus *Maxillaria*, although a tolerably extensive one—comprising upwards of 100 named species—cannot be said to be much of a favorite with Orchid growers. There are a few, however, which are always considered to be of sufficient value to find a place in every collection, and among these it is universally acknowledged that *M. Sanderiana* is the finest representative of the genus yet known. It was introduced to cultivation about four years ago by Messrs. Sander & Co., St. Albans, England, whose collector found it growing on the Cordilleras of Ecuador and Peru at an elevation of about 4,000 feet. Unfortunately, most of the plants sent home at that time had perished during the voyage, notwithstanding the care taken of them, consequently, there are as yet very few plants to be met with under culture.

A good specimen is now in flower here. It has ovoid, compressed pseudo-bulbs, and dark-green, elliptic-oblong leaves. The flowers, which are as large as those of any ordinary *Lycaste Skinneri*, are borne singly on the end of short scapes, which spring from the base of the previous year's pseudo-bulbs, and are covered with large, dull brown bracts. The upper half of the large sepals is pure white, the lower half being washed and blotched with very dark crimson. The petals are similarly marked, but are much smaller in size. The side lobes of the lip are erect, while the middle one is slightly recurved and crisped around the margin. The color is dull buff-yellow on the inner surface, with a brighter yellow callus on the disc, while the outer, or under, surface is blotched and stained with blackish-crimson. The flowers of this species present very little variation, although a faint, rosy tinge may sometimes be observed at the tips of the sepals and petals.

Taking into consideration the elevation at which this *Maxillaria* grows in its native country, it must not be regarded as a hot-house Orchid; and it will thrive in a house with a temperature ranging from 60°-65° F. When once established, this species may be as easily grown as some of its better known congeners. It is rather difficult, however, to get imported plants to begin to grow, and, in order to bring this about, the plants should be placed among broken crocks in a house with a warm and moist atmosphere until they begin to make new growths. They may then be put into baskets, in a compost of fibrous peat and sphagnum moss, and placed in such a position as to obtain an abundance of light and air during the summer months, which is the season when they make their chief growths, and during which period they may receive plenty of water. The plants require very little water in the winter, which is the resting period, and hardly any water at all is necessary during the flowering season, which is usually in April and May.

St. Albans, May, 1889.

John Weathers.

The Irises.—The new *Iris tenuis*, figured in an early issue of GARDEN AND FOREST, has proved hardy here during the past winter. The plants received last spring were planted under Pine-trees, the needles of which provided a good winter covering. Plants that were left out are coming up strong, and others lifted flowered nicely in pots. *I. tenuis*, as a decorative plant, has no greater value than many of the older sorts. *I. Douglasiana*, a pretty Californian species, is now in bloom, and is a very showy plant. We have had no experience as to the hardiness of this species, but it is well worthy of pot-room in winter. *Iris verna*, another native species, is now at its best, the perfume of its delicate blue flowers reminding one strongly of

Violets. This *Iris* does well in all kinds of soils and makes a good border-plant. *I. tenax* and *I. Missouriensis*, two species somewhat alike, are also in bloom, to be followed later by *I. oxypetala*, which is, perhaps, the best of all native *Iris*. *I. pumila* and its many varieties are, and have been, making a fine display. These were the first to bloom in the open ground, followed closely, however, by *I. arenaria*, a charming European species, with narrow grass-like foliage, almost hidden by the bright orange-yellow flowers, which are fragrant. This plant succeeds best in a sandy soil or when planted in the rock-garden. *I. Cengialti* is another comparatively new plant, and one which no lover of this beautiful family should be without. In general appearance it resembles *I. Germanica*, the flowers being fully as large, dark blue, with an orange blotch on each petal. The plant, however, is quite distinct, flowering two weeks earlier, and being dwarf, not exceeding one foot in height. *I. Sibirica hamatophylla* is now at its best. This plant has blood-red leaves, with blue flowers, and has the special value of producing a second crop of flowers later in the season.

Aquilegia Canadensis aurea.—We do not know if yellow forms of *Aquilegia Canadensis* are common, but we received, some three or four years ago, one plant which has proved to be sufficiently distinct and fixed to warrant the varietal name *aurea*. The flowers are pure yellow without a trace of red. We had thought it might probably be referred to one of the yellow species, but find that of the seedlings raised from isolated plants, about ten per cent. show a reversion to *A. Canadensis*. The plant under note does not exceed a foot in height, and is completely covered with its pretty flowers, resembling in color those of *A. chrysantha*.

Camassia Cusickii.—This species, figured in GARDEN AND FOREST, last year (i. 174, fig. 32), is again in flower, and gives promise of becoming a valuable addition to our hardy flower-garden. The whole plant is much stronger and larger than any other species with which we are acquainted. The flowers when first expanded are white, changing to pale blue after they have been open a few days. All the *Camassias* are perfectly hardy in the eastern States, but, like most bulbous plants, thrive best when planted in a porous soil. E. O. Orpet.

Passaic, N. J.

Setting Plants and Trees is not necessarily a laborious operation. I am surprised how little one need use a spade in the work. In fact I use the spade in garden work less and less each year. For setting all bush-fruits we plow a furrow with an ordinary winged potato-plow. Set the wings at their widest; they will then throw out a lot of loose earth which is easily used by the hands. Then return in the same furrow with the wings closed, plowing deep, so as to make mellow ground for the roots of plants. In nice garden soil, not too wet, we then discard tools and put in the plants with our hands. If the soil is too heavy or wet for this, one man uses a shovel while another places the plants. Yesterday we set a lot of Service Berries in a clay soil in this manner, one man shoveling in the furrow and another handling the plants, and did it so rapidly that I had difficulty in clipping the single shoot of the plants and dropping them as fast as they were wanted. The plow can be used to good advantage in setting orchards.

Digging big holes for trees should be unnecessary. Dr. Warder said that the hole for a tree should be as large as the orchard. This is the best of advice. It means that the ground should all be well prepared before a tree is put into it. Then one needs to dig only far enough to allow the roots to fall in easily. But the hole must be big enough for the roots. Do not twist or crowd them; and here is where the ordinary tree-planter will shirk. Before you know it he will stick in a tree with the ends of the roots all but peeping through the ground. "Don't be stingy with your holes," is advice which I have to give almost every day in planting-time. Get the fine earth firmly in and about the roots. This usually requires the work of the fingers, but it can be done without fussing.

Grafting.—All the kit of glue-pots and brushes and elaborate mastics are a nuisance in the top-grafting of an orchard. The only use I could ever find for hot wax was when grafting was so abundant that some of it had to be done in March and early April. Hard wax that will warm up in the hands and has grain enough to stretch is much superior to any other. Of course the hands must be greased, but the work is by no means disagreeable. The wax one buys of dealers is nearly worthless, so far as my experience has gone. It has not been worked by hand, "pulled," and has no fibre. It breaks.

Cornell University.

L. H. Bailey.

Chrysanthemums for the Border.—There are some varieties which are handsome as well as early, and they can be trusted to make a good display before frost. It must not be expected, however, that the individual flowers will be as large as those of later flowering kinds. It must be remembered, too, that, in order to have good Chrysanthemums anywhere or at any time, the plants must be well fed and they must not be crowded—two feet square is the least space in which they will thrive. Here are a dozen good, early varieties: The two forms of Madame Desgranges, yellow and white; Madame Domage, bluish; Chevalier Domage, yellow; Précocité Japonaise, red; Blanc Précoce, white; L'Ami Couderchet, lilac; Fiberta, yellow; Salter's Early, bluish; Roi des Précoces, red; Mandarin, pink; La Vierge, white.

Pearl River, N. Y.

Notes from a Northern Spring-Garden.

Corydalis nobilis is a handsome Siberian species, and a real acquisition to the list of hardy rock-garden plants. It grows some eight or nine inches high, with bi-pinnate, delicate leaves, with rather broad cuneate divisions and large, broad racemes of pale yellow flowers, tipped with green. It has been grown in gardens for more than a century, but is rarely met with in those of this country. It thrives in all soils and positions, and demands no special care or attention.

Clintonia borealis is at its best, and an attractive plant, with its yellow, nodding, Lily-like flowers, borne on slender scapes above the broad, strap-shaped leaves, which lie close to the ground; and still more attractive, perhaps, in August, when the flowers are succeeded by large, bright blue berries. It grows naturally under trees in rather dense shade, and in such positions, when it is transferred to the garden, it will be found to flourish, although we have not succeeded yet in inducing it to spread very far; and seedlings have not appeared yet. The Podophyllum or Mandrake (*Podophyllum peltatum*) is an easier plant to establish, and one of the most effective in foliage, with its broad, round, five to seven parted leaves, eight or ten inches across, raised a few inches above the ground on stout stems inserted in the centre. They look like miniature umbrellas, and quite hide the handsome, solitary, nodding, white flowers, which grow on separate bi-foliate stems, and the large fruit, which ripens in early summer—the May Apple, well-known to country boys. This plant is found in the low, rich woodlands of the middle and western States, where it is everywhere common. It spreads rapidly from underground creeping root-stalks, and will soon extend far beyond the place allotted to it in the garden.

Iris cristata, the crested Iris of the Allegheny Mountains, with its lovely pale blue, long-tubed flowers, is in full flower, and certainly one of the most beautiful of all the dwarf species. It spreads almost too rapidly, however, in the border or in the rock-garden, and it has now been transferred to a half-sunny slope on the edge of a wood, where it has already spread quite widely through a thick sod of Grasses and Sedges, which are unable to greatly retard its growth or to prevent it from flowering freely. It is one of the best plants which has been tried here for naturalizing in such situations, which can often be greatly improved by a cautious introduction of many plants chosen with reference to harmony with their immediate surroundings.

The rare and remarkable *Carex Fraseriana* is well established, and has been in bloom for several weeks in the dense shade of an over-spreading bush. It would hardly be taken for a *Carex*, with its broad leaves and globular heads of flowers, on slender scape-like culms. It is a plant not without beauty when in flower, but its interest is rather botanical than horticultural. It is one of the rarest of the genus in America, and is confined to the mountains of Virginia and Carolina.

There is a little prairie flower, very familiar to the inhabitants of the West, and a pleasant remembrance always to people who have traveled over the grass-covered plateaus beyond the Mississippi, known as the Shooting-star from the peculiar form of the flowers. It is the *Dodecatheon Meadia* of the botanists, a member of the Primrose family, and a beautiful plant in cultivation, with Cyclamen-like flowers, borne in ample umbels at the summit of a stout scape, about a foot high, springing from a cluster of oblong leaves. The corolla is rose-colored or sometimes white, with a very short tube, a thickened throat and a large, five-parted, reflexed limb, giving to the flower a fanciful resemblance to a comet or shooting-star. The *Dodecatheon* has been a popular plant in cultivation for many years, and many varieties have been raised by gardeners with enlarged flowers of different shades of color, but it is doubtful if any of them are superior in beauty to the wild form of the prairie. It flourishes in full sunlight, is easily

raised from seed, like most of the other plants of its alliance, is easily transplanted and fairly durable. Just now several masses are in full bloom, and are beautiful and attractive.

Aubretias are, so to speak, conventional rock-garden plants; that is, they are always included in lists of these plants, and if a beginner in this sort of gardening orders rock-garden plants from a dealer he is pretty sure to find some Aubretias in his order. They are natives of southern Europe, and several species and a number of varieties of the best known of these, *A. deltoidea*, are in cultivation. This is a charming plant, admirably suited for the margins of rocks, where it can spread and send its slender, trailing stems through the crevices, making a wide, moss-like mass of pale green, persistent foliage, which is now covered with a sheet of pale purple flowers, large in proportion to the height of the plant, being half an inch across. Not quite hardy here, it requires careful protection in the winter and an open, sunny position. The Aubretias may be readily increased by cuttings, or young plants can be raised from seed.

There are a number of dwarf shrubs now in flower well suited to embellish the rock-garden, where, owing to their dwarf size, they can be seen to better advantage than in the shrubbery, where, too, they are liable to be overcrowded and finally destroyed by more vigorous plants. The best known of these, thanks to Emerson's poem, is the Rhodora (*R. Canadensis* or *Rhododendron Rhodora*). It is a low, deciduous shrub, growing to a height of two or even three feet, with rosy-colored flowers, which appear before the leaves. It is easily cultivated, and can be readily transplanted from its native swamps into the garden, where it will grow and spread quite quickly if deep, peaty soil and an open position are provided for it. The flowers are very short-lived, and two or three days of hot sun quite finishes them. It is one of the plants which looks well only when seen in large masses, as it may be in some parts of northern New England, where sometimes covering acres of bog, its flowers look like a soft, rosy flush of light thrown over the ground. A far more beautiful plant in flower, and one of the most beautiful of all our native shrubs, is the little bog Kalmia (*K. glauca*), a delicate plant not more than a foot high, with wiry branches and straggling habit, narrow, revolute leaves, quite white on the lower surface, and few-flowered corymbs of very large, rosy-purple flowers, which make a great show just now. It is not a very easy plant to establish, and it is fastidious always and liable to die if exposed to too great summer heat, but the beauty of the flowers is so great that they are worth a real effort to obtain in good condition.

Daphne Genkwa is very fine this year, finer than I remember to have seen it, the mild winter having been, no doubt, favorable to the good development of the tubular, lilac-blue flowers, which in color have no counterpart among those of shrubs which are hardy in this climate. It is to be regretted that it is not more hardy here, for it is certainly one of the most attractive of the dwarf shrubs of Japan, where it is highly prized as a garden-plant and for its reputed medical properties.

The earliest of the Blueberries are in flower, and few shrubs are more beautiful than some of the dwarf species, like *Vaccinium Pennsylvanicum* and *V. Canadense*. They make a charming carpet under trees, where they are found growing naturally in half open situations. None of the *Vacciniums* are very easy plants to manage, but they can be grown by any one who will pay close attention to Mr. Dawson's directions for the management of these plants published upon page 183 of volume i. of this journal. They have many claims upon the lovers of beautiful plants—good habit and foliage, handsome flowers and fruit and brilliant autumn coloring.

Boston, May 11th.

C.

Notes from the Arnold Arboretum.

THE Peach is not in this latitude a very reliable flowering tree, the buds being often destroyed in winters of even ordinary severity. This year, however, Peaches are exceptionally fine, and trees of some of the double-flowered varieties have been objects of wonderful beauty. There are a number of these varieties in cultivation, and new ones appear from time to time; but the three best worth growing have been known for many years—they are the double pink, the color of the flowers being almost identical with that of the common Peach of gardens, the double white and the double scarlet, on which the flowers are blood-red. A fourth variety, in which the color of the flowers is intermediate almost between those of the pink and of the scarlet varieties, although showy and conspicuous, is perhaps a less desirable plant than either of the others. The double scarlet Peach, in

flower, is one of the most striking, almost startling, objects imaginable, while the double white, owing to the profusion of the flowers, when the buds are not destroyed by frost, is for a few days one of the loveliest of all spring-flowering trees. These double-flowering Peaches are in bloom generally a week or ten days later than the common Peach. Like them, they are subject to the attacks of fungus and of borers, and are short-lived, and must, therefore, be often renewed. Their beauty as ornamental trees is confined to the short flowering time, so that, in spite of the loveliness of the flowers, they should not be planted here as freely as some other showy-flowered trees, especially as the climate does not suit them particularly well. The variety with blood-red flowers may be seen in some of the public squares of Washington, where there are many fine specimens, in very great perfection, and it is doubtful if any one seeing this tree there in flower for the first time passed it by without an exclamation of admiration or without asking what it was.

A large number of the so-called "flowering" Apples are now at their best. They flower usually ten days later, but the unprecedented heat of the last few days has forced many plants into bloom long before their time. These small Apples, taken as a whole, surpass all other trees here in floral beauty at this particular period of the year, and there are no more satisfactory plants for the May decoration of the lawn or the shrubbery. They flower profusely, at least most of the varieties do, year after year; they are indifferent to cold, to heat or to drought, and they do not grow unmanageably large. They like rich soil, and well repay generous treatment.

It is hopeless, and certainly not necessary, in these notes, to try to unravel the intricacies of the synonymy of the Apples, or even to refer in every case the cultivated forms to recognized species. The species of Apples, their origin and distribution have puzzled the best-equipped botanists, and no two of them have ever held quite the same views with regard to these plants.

There is a very large number of these Apples in the Arboretum, gathered during many years from the best European collections and raised from seed obtained from all available sources. Speaking broadly, they may be referred to four types. There are, first, the varieties of the common Apple (*Pyrus Malus*) which are generally recognizable by the light gray bark, pale leaves, which are, with the petioles and shoots, woolly-pubescent on the lower surface while young, and by the minute, scale-like bract on the peduncle. There is a handsome variety with double flowers; others with pendulous branches or with dwarf habit, and one curious one with shrubby habit, narrow leaves, and small fruit less than an inch in diameter, and persistent upon the branches until after the flowering-time the following year.

Next should be mentioned the Chinese Apple (*Pyrus spectabilis*), a well marked species not difficult to distinguish, at least in the double or semi-double flowered form—the only one apparently now known in cultivation. The flowers were figured in this journal last year (i. 272, f. 214), and there are colored plates in the "Nouveau Duhamel" (vi. t. 42, f. 2) and in Watson's "Dendrologia Britannica" (i. t. 50). It is one of the handsomest of the whole race, and one of the most profuse and persistent bloomers. It is a shrub-like tree, reaching a height of twenty feet, characterized by the upright habit of growth of the branches, which give to fully grown specimens a sort of vase-like form, reddish-brown bark, oblong-ovate leaves, which, like the peduncles, are covered, while young, with fine, short tomentum, which disappears before the leaves reach maturity, when they are dark green, thick and leathery. The flowers are rose-colored or pink and white, and delightfully fragrant.

A large proportion of the Apples in the collection produce fruits, for which the lobes of the calyx fall off before it is ripe, and often before it is fully grown, and therefore are best referred to *Pyrus baccata*, in which this peculiarity is the most constant and most apparent character. These plants vary, except in the deciduous calyx, remarkably among themselves, and in looking at some of the extreme forms it is hard to realize that they may be referred to a single species. The habit, flower, foliage and fruit are all different, the last varying in size from a diameter of nearly three-fourths of an inch to one of less than one-eighth of an inch. But with all the forms before me it is impossible to find any real distinguishing characters in them, except the deciduous calyx. *Pyrus baccata* is itself a widely-distributed species in Siberia, through northern China to Japan and in the Himalayas. It has long been cultivated not only in Europe, but from time immemorial by the Chinese and Japanese, so that it is not surprising that innumerable forms have been developed, especially as all the *Pomaceæ* show a remarkable tendency to

seminal variation. The most beautiful of the various forms, referred here to *P. baccata*, are those of Japanese origin, known in gardens as *Pyrus Malus floribunda*, and its double-flowered variety (see this journal, i. 152, f. 30) introduced into this country by Dr. Hall, and variously known in American gardens as *P. Parkmanni* or *P. Halleana*. It seems identical with the plant grown in Europe as *P. spectabilis* Koido. These Japanese Crabs are low, bushy trees, with dark brown bark, branching from the ground, growing to a height, perhaps, of twenty feet, and spreading to a breadth of twenty or twenty-five feet. When they are in bloom they are wonderful objects, the branches being entirely covered with the flowers, which individually are not large and barely more than an inch across when fully expanded. The buds are crimson and very showy, so that the plants are perhaps more attractive just before the flowers open than at any other time. The flowers, when they expand, are pink, and then gradually fade to white before the petals fall; the effect of the white masses of flowers being often set off by a few unopened buds near the ends of the branches. Their fragrance is powerful and delicious, and may be perceived for a long distance when a large plant is in bloom. The fruit is minute, the size of a pea, dull-colored and devoid of beauty. In the semi-double form the petals are deep rose-colored, the calyx dark red, and the young leaves purple.

Among other forms of what are taken here to be varieties of *P. baccata* are several plants of very great ornamental value, with yellow-brown bark, symmetrical, arborescent habit, rather thin, glabrous acuminate leaves, and large, pure, snow-white, fragrant flowers, nearly two inches across when expanded, and small fruit. They have been raised principally from seed derived from the St. Petersburg Garden, and sent under several different names. There are in the herbarium wild specimens gathered in the northern island of Japan, which are identical with some of these forms.

Pyrus Toringo is a Japanese shrubby species which grows well here. The leaves are sharply and deeply incised, and often three-lobed; they are woolly-pubescent, as are the shoots when young; the flowers are smaller than those of the other Apples, and the fruit is minute, with deciduous calyx-lobes. *Pyrus Sieboldii* of gardens seems to be a form of this, still smaller in all its parts. Neither of these plants, except in this pubescence and in the shape of their leaves, are readily separated from *Pyrus baccata*.

Pyrus prunifolia, or a number of plants, which seem more readily referred to that species than to any of the others are the last of the series. *Pyrus prunifolia* is itself a doubtful plant, doubtfully known in a wild state, although generally credited to Siberia. According to Regel it is found in the Baikal, and to Karl Koch in north China, Tartary and southern Siberia. It has been cultivated for more than a century, and is the original of the garden Crabs; and if really a wild plant, it has been greatly changed by cultivation and by crossing with varieties of the common Apple. What are considered here forms of this plant are stout bushy trees branching from the ground and forming broad masses of foliage some twenty feet high by as much through. The bark is brown or gray-brown, considerably darker than that of the common Apple-tree. The leaves are broadly elliptical, sharply serrate, with long petioles, and, like the shoots, pubescent when young, especially on the lower surface. The flowers, with pubescent calyx-lobes and hairy styles connate to the middle, are larger than those of the other Apples, being fully two and a half inches across the expanded petals. They are pure white in some individuals, rose-colored fading to white in others, and very fragrant. The fruit has persistent calyx-lobes, is from half an inch to an inch in diameter, bright scarlet on some individuals, clear yellow on others. It retains its shape and color until winter, and remains upon the trees until the following spring. These trees flower much less freely than the varieties of *P. baccata*, and do not flower equally well every year, owing, perhaps, to the presence of some *Malus* blood, which it seems possible to trace also in the character of the pubescence and the coloring of the young leaves.

Considered from the point of view of ornament, the most valuable of all these Apples, as flowering trees, are the Japanese Crab (*Pyrus Malus floribunda*, of gardens) and its double-flowered variety (*P. Parkmanni* or *P. Halleana*, of gardens); next in value is the Chinese Crab (*Pyrus spectabilis*), then various large-flowered varieties of *Pyrus baccata*, the varieties of *Pyrus Malus*, *Pyrus prunifolia*, which is the only species with ornamental fruit, and the only one, therefore, valuable for autumn effects, and lastly *Pyrus Toringo*, which is rather curious than really beautiful. The North American Crab *Pyrus coronaria* does not flower until several weeks later, but

flowers here profusely. The flowers are individually very large, pale rose-colored, and more fragrant than those of the other species. The fruit which hangs from long, slender stems is ornamental, high colored, and very fragrant. *Pyrus coronaria* is a desirable plant for the garden, both for its flowers and its fruit.

The Forest.

A Word for the Jack Pine.

M. R. H. B. AYRES, of Minnesota, who is familiar with forest-conditions and the necessity of forest-preservation, sends us, at our request, the following note upon the proper use of the "Jack Pine" (*Pinus Banksiana*) lands so common in the north-central part of the state:

"In looking over the region the importance of keeping out fires is very evident. This sandy soil is not adapted to farming. People will be moving out of the country as soon as the timber is gone. It is therefore important to keep a growth of timber on that land which is not fertile enough to command sale to farmers.

"If fires can be kept from running over the land, timber will continue to grow, and will furnish repeated cuttings of log-timber, piles, ties, cordwood and material for wooden-ware, matches, paper, dyes, acids, tanning, etc. Even the very sandy lands that are cut clean and burned over, and are now worthless, will, if kept from fire, be seeded during the first year, and in a few years be covered with a dense growth of young Jack Pine, with many Norway and some White Pine scattered through them.

"I am aware that most Minnesotians would laugh at the idea of encouraging a growth of Jack Pine; but during a number of years I have given the subject careful attention, and am now convinced that this little, persistent, mean-looking and despised Jack Pine has duties as important and performs them as faithfully as the much sought White Pine. If there were no Jack Pine, I believe a large area in the state would be practically desert to-day, and in proportion as fires are permitted to destroy the young growth, the sandy and rocky land will become desert-like.

"When a tract of Norway Pine timber has been cut clean, and fire kept out, a dense growth of Jack Pine will spring up first; then young Norway Pine will be able to start in the shelter thus formed. As the Norway grows more rapidly, the Jack Pine is soon left as an undergrowth, which serves to prevent the growth of limbs on the trunks of the Norway. In about thirty years the Norway Pine will be large enough to do without the nursing of the Jack Pine, which may then be cut for cordwood, and the Norway, where too thick to leave for log timber, may be thinned for piles and ties, leaving the remainder a tract of clear timber to be coveted by every lumberman, and a good return for reasonable care to encourage tree-growth on land otherwise worthless and unsalable.

"I would earnestly recommend that the existing laws concerning forest fires be rigidly enforced, and such other measures taken as to keep the poor land in timber, thus holding what population there may be now, and even furnishing employment for a greater."

Felling Trees by Electricity.—Hitherto machines for felling trees have been driven by steam-power, but this is often inconvenient, especially in thick woods, because the heavy machinery, including a boiler, must be placed near the tree to be cut. These machines, therefore, can only be used on the borders of forests or in open spaces readily reached by good roads. The *London Times*, however, reports that electric power has been adopted in the Galician forests. Usually in such machines the trunk is sawn, but in this case it is drilled, with a series of holes close together. When the wood is of a soft nature the drill has a sweeping motion, and cuts into the trunk by means of cutting edges on its sides. The drill is actuated by an electric motor mounted on a carriage, which is comparatively light and which can be brought up close to the tree and fastened to it. The motor is capable of turning around its vertical axis, and the drill is geared to it in such a manner that it can turn through an arc of a circle and make a sweeping cut into the trunk. The first cut made, the drill is advanced a few inches and another section of the wood is removed in the same way, until the trunk is half severed. It is then clamped, to keep the cut from closing, and the operation continued until it would be unsafe to go on. The remainder is finished by a hand-saw or an axe. The current is conveyed to the motor by insulated wires brought through the

forest from a generator placed at some convenient site, which may be at a distance from the scene of operations. The generator may be driven by steam or water power and does not need to be transported from place to place.

Recent Publications.

The Book of Sun-Dials, compiled by the late Mrs. Alfred Gatty. New and enlarged edition, edited by H. K. F. Gatty and E. Lloyd. Messrs. Bell, London, 1889.

"Whoever loves a garden," it has well been said, "loves a sun-dial," and we need no further apology for introducing this book to our readers. The first edition was published in 1872, and has remained the standard authority on its subject. Now it is republished in a much enlarged shape, the number of dial-mottos quoted being increased from 377 to 728, and an appendix on the construction of dials being added.

The earliest form of sun-dial was an isolated column or obelisk, which served as the "gnomon," and threw its shadow upon the ground. Such an arrangement could not be scientifically accurate in its measurements, for, as the book before us explains, "the gnomon that indicates the time of day must slope to the horizontal plane at an angle equal to the latitude of the place, and must also lie due north and south." Despite the astronomical lore of the Chaldeans their dials were probably of the primitive columnar kind, as we know to have been the case with the one which Ahaz, king of Judea, set up in the eighth century B. C., probably having got the idea for it from Babylonia. Dials more nearly approaching to the modern kind were known in classic Greece and Rome; but it seems to have been a late day when their function was universally understood, for during the first Punic war a dial captured in Sicily was set up in the Roman forum, where, of course, it could not tell the hours with exactness. All through the middle ages the sun-dial was the usual, almost the only, instrument for marking the time, and it was not abandoned even when clocks and watches became cheap and common. Almost every old church once had its dial, and the clock which now appears on so many English churches usually shows the station formerly held by the gnomon and circle. A national English custom—shown in some of the great cathedrals as well as in very many parish churches—was to make the south door, not the one in the west front, the chief place of entrance; and over this door the dial was usually set upon the wall. In the early days of the Reformation, when so many mortuary crosses were injured or defaced as bearing superstitious emblems, it was common to turn them into sun-dials, cutting off the top to secure a level space where the gnomon and its brass plate might stand. The finest standing dials in Great Britain seem to date from the period when the classic style of gardening ruled—the seventeenth and the early eighteenth centuries. The most stately of all is perhaps the one which stands at Glamis Castle (famous through its connection with Macbeth), near Forfar in Scotland, which is an elaborate architectural construction bearing no less than eighty dial-faces. Pretty conceits are sometimes found in which the service of a true dial is simulated by growing plants. At Wentworth Castle, near Barnsley, for example, a tall Yew-tree serves as a gnomon, while an encircling plantation of Box is cut into the form of a dial-plate and its figures. In southern countries, where there is a more constant sun, dials are still more frequently found than in England, and every traveler will remember them as forming, very often, the quaintest and most suggestive feature in an ancient garden. Mrs. Gatty and her editors have covered a wide field in searching for the inscriptions which were almost invariably placed upon the sun-dial; and the large collection of mottoes given in the new edition now before us is both instructive and amusing. Of course brief familiar mottoes such as "Tempus Fugit," "Improve the Time," "Fugit Hora," "Docet Umbra," "Così la Vita," "Carpe Diem," *Brevis Hominum Vita*, "Via Vita," "Vigilate et Orate," *Vita Sic Transit* and "Work While it is Day," represent the most common class of inscriptions, but there are many in various languages which are much longer, and are either quotations from some poet or original exhortations to improve the passing hour and remember the coming of the night wherein no man can work. "You may waste but you cannot stop me" is one, and another is "Life is Short, Time is Swift, Much is to be done." From among the longer English verses we select a few, although choice is difficult where so many are interesting, and foreign languages are still richer in epigrammatic examples.

"Time's glass and scythe
Thy life and death declare;
Spend well thy hours and
For thy end prepare."

"Give God thy heart, thy hopes, thy gifts, thy gold;
The day wears on, the times are waxing old."

"Haste, traveler, the sun is sinking low;
He shall return again, but never thou."

"May the dread book at our last trial,
When open spread, be like this dial;
May Heaven forbear to mark therein
The hours made dark by years of sin;
Those only in that record write
Which virtue, like the sun, makes bright."

For Lady Abney at Newton, Dr. Watts wrote the following:

"So rolls the sun, so wears the day,
And measures out life's painful way
Through shifting scenes of shade and light,
To endless day or endless night."

But much prettier is the following, a modern imitation of the style of old mottoes, designed for a dial in a flower-garden, with which we must close our brief list:

"I stand amid the summere flowers,
To tell the passage of the houres;
When winter steals the flowers awaye,
I tell the passinge of their daye.
O man, whose flesh is but as grasse,
Like summere flowers thy life shall passe.
Whiles tyme is thine laye up in store
And thou shalt live for evermore."

Here and there in old American gardens sun-dials may still be seen, although it is doubtful whether any are erected at the present day or whether a skillful professor of "gnomonics"—the art of dial-setting—could be found in America. It would be interesting to know whether any inscriptions worth quotation exist on this side of the ocean.

Correspondence.

Arbor Day at Michigan Agricultural College.

To the Editor of GARDEN AND FOREST:

Sir.—I have been much interested from time to time in the sensible comments of GARDEN AND FOREST on the modes of observing Arbor Day. Where a programme is devised by persons who have little knowledge of botany, horticulture or forestry in its true and broad sense, there is great danger that the exercises may accomplish as much harm as good. We have had quite enough of mere unadulterated sentiment on this very important subject.

After such comments it may be venturesome to send a few notes on the observance of Arbor Day at this place. One hour was occupied by the writer and nearly sixty students who were introduced one after the other, each to present some selection from a reliable source, or to produce original notes:

(1) Reading the Arbor Day proclamation; (2) the origin of Arbor Day (in Nebraska); (3) verses from the Bible on trees, by the President of Y. M. C. A.; (4) quotations from Shakespeare; (5) uses of Arbor Days, GARDEN AND FOREST, p. 13, vol. ii.; (6) selection from Nebraska's Arbor Day book, B. E. Fernow; (7) "The Planting Season is at Hand," A. J. Downing; (8) "Cherish Trees," A. J. Downing; (9) "Plant Trees," A. J. Downing; (10) "What to Select," A. J. Downing; (11) "Plant Home-grounds," from Nebraska's Arbor Day book, Professor L. H. Bailey; (12) "Plant School-grounds next," L. H. Bailey; (13) "Plant the Roadsides," L. H. Bailey; (14) "What Shall We Plant?" L. H. Bailey; (15) "Plant Many Shrubs," L. H. Bailey; (16) verses; (17) "Plant a Tree," verses by Edith M. Thomas; (18) "Plant a Tree," Ex-Gov. Larrabee, of Iowa; (19) "Plant in Memory of Some Friend;" (20) "A Tree is a Valuable Possession," GARDEN AND FOREST, p. 37, vol. ii.; (21) "A Love for Trees," A. J. Downing; (22) "Tree-planting," Dr. O. W. Holmes; (23) "How to Take up a Tree;" (24) "How to Set a Tree;" (25) "Don't," a series of precautions; (26) "Value of Trees," Whittier; (27) "Beautiful Trees," A. J. Downing; (28) "The Beautiful in an Ornamental Tree," A. J. Downing; (29) "The Tree as Improved (?) by the Tree-pruner," A. J. Downing; (30) "Beauty of Autumnal Foliage," A. J. Downing; (31) "Proud Monarch of the Forest," verses; (32) "The White Oak," Dr. O. W. Holmes; (33) "Peculiarities of the American Elm;" (34) "Management of our Forests," GARDEN AND FOREST; (35) "Needs of American Forestry," GARDEN AND FOREST, p. 13,

vol. ii.; (36) "Needs of American Forestry," GARDEN AND FOREST; (37, 38 and 39), extracts from GARDEN AND FOREST, on "Providing for the Conservation of our Forests."

Two years ago a portion of the day was given up to comments by some of the professors in a lecture-room, where students and others had assembled. Each class and society, including the girls, planted a tree with some ceremony. The trees were publicly accepted by the president of the college, and good care guaranteed. At the last Arbor Day, reports were made stating the species of the tree, where it was located, how much the upper branches had grown last year, what care it had received and whether any insects had injured it. The statements brought out facts, showing that it is vastly easier to plant trees than to give them proper care afterwards. Not one of the entire number had made satisfactory growth, and only one had received any cultivation; none had been mulched, but they were left in the grass where, in several cases, the soil was too thin to guarantee thrift. Of the twelve trees one was dead, two others nearly so, one had been cut down and was sprouting up again, several others were having a severe struggle with grass and a thin soil and a lack of moisture. Several had been damaged by borers.

The last two classes planted trees this year and made reports.

The quotations above indicate that your journal is making some impression in at least one school of agriculture.

Agricultural College, Mich.

W. J. Beal.

The Newtown Pippin.

To the Editor of GARDEN AND FOREST:

Sir.—I was much interested in the letter of Mr. Robinson, the editor of *The Garden*. He had evidently been eating an Albemarle Pippin, a strain of the yellow Newtown Pippin, which the Americans, he quotes, probably never saw, for few of them stop on this side of the water. Doubtless the great majority of American Apple-growers have Apples better than the Newtown Pippin is with them, for there is no Apple grown which is so fastidious as to its location. Even here, where it reaches its highest perfection, it is utterly worthless a mile away from a mountain-side. And yet the lands, which of all others, produce this Newtown Pippin in the highest perfection, the mountain coves and slopes of the Blue Ridge in Albemarle, Nelson and Green Counties, of Virginia, can to-day be bought at very low figures. Here in Albemarle few growers of Mountain Pippins ever think of gathering and packing their own fruit. The agents of the English shippers come all through the hills, buy all the Apples at a set price, and at the proper time bring their barrels, gather and ship the fruit. Occasionally a large grower packs and ships his fruit direct to Liverpool, and makes largely by so doing. Last fall Apples of all kinds were very abundant and low in price, and yet the Liverpool shippers paid here for the fruit on the trees \$2.50 a barrel and furnished the barrels and packed them. The year before the price was \$4.50. It is well known that the Albemarle Pippin always leads in price Pippins grown elsewhere, and some are disposed to question its identity with the yellow Newtown Pippin. The great majority of us, however, are willing to admit their identity, but adhere to the name of Albemarle Pippin as expressive of the choicest Pippins sold.

Crozet, Va.

W. F. Massey.

To the Editor of GARDEN AND FOREST:

Sir.—I do not think the Newtown Pippin is unduly neglected. It is not a profitable market variety for the northern States, and is entirely eclipsed for profit by the Baldwin at the East and by the Ben Davis at the West, both of which are inferior in quality, especially the latter. Our people in this country well understand where to find the best returns, and with this view the Newtown Pippin has been generally discarded at the North as a market fruit. It is still cultivated both East and West as an amateur variety.

I have not had an opportunity of comparing the Albemarle with the Newtown Pippin, but have always taken it for granted from the examination of others who are competent pomologists, that they are identical.

In some localities further south the Newtown Pippin succeeds better than here. I have examined specimens from the neighborhood of Cincinnati which were larger and smoother than we have them. In some parts of Virginia (not on the lowlands) it has succeeded well and has been largely raised for market. In other places it has entirely failed. It was formerly more extensively raised in New York than at present, but its liability to become scabby was a severe drawback. R. L. Pell, who formerly had a large orchard of this Apple in Ulster

County, with all his care in cultivation, had to throw out many defective specimens in sorting for English markets. He informed me that in making an extra selection of the very finest he took at the rate of about one specimen in a half bushel, and these sold for about double the usual price—nevertheless, they did not pay cost. This was some forty years ago.

I never quite agreed with A. J. Downing that the Newtown Pippin stood at the head of all Apples, and was "unrivalled in all the qualities which constitute a high-flavored dessert fruit." Different individuals have varying preferences, and I have known a person who from early association preferred the coarse Pennock to all others. I would place such Apples as Northern Spy, Swaar, Red Canada and Jonathan, as quite equal in quality to the Newtown Pippin, while Esopus Spitzenburgh is hardly equalled in high flavor by any Apple. The Newtown Pippin loses less by shipment across the ocean than most others, which is doubtless one reason why it is so highly esteemed there.

I have no doubt that this fruit, as grown in favorable localities in Virginia, is better than in New York, judging from the fact that the Cincinnati specimens which I have received were larger and fairer than our spotted and defective ones here.

Union Springs, N. Y.

J. J. Thomas.

[The letter above was not written for publication, but every statement or suggestion made by Mr. Thomas in relation to our fruits is worth preserving.—Ed.]

The Germantown Nurseries.

To the Editor of GARDEN AND FOREST:

Sir.—These nurseries are situated within the limits of the city of Philadelphia, where land is worth four or five thousand dollars an acre, and when I asked Mr. Thomas Meehan, the senior member of the firm, if he was not cultivating rather expensive soil, he replied that he could not afford to conduct his business on cheap land. He went on to say that if his nurseries were moved back into the country the money saved by reduced interest on the price of land would be more than counter-balanced by the increased cost of labor and manure, of transportation, and, in short, of everything he had to buy for his business. As a matter of fact he sells hundreds of thousands of Osage Orange plants, raised on this city property, for hedges on western farm-lands. He added that in a remote location his business could not advertise itself as it now does so cheaply and to such advantage, and he considers this effective advertising an important factor in the success he has achieved. And really there are few places in the United States where a fine collection of ornamental trees and shrubs would attract so many interested and appreciative visitors. Germantown is as old as the big city, which absorbed it more than thirty years ago, and it has always been the home of wealth and refinement. Here lived noted botanical collectors early in the century, and rare and beautiful trees were planted on most of the old estates. Although these estates have been cut up, many of the venerable trees have been carefully preserved. A drive through the town will take one by a Pecan-tree, for example, a hundred feet high, which, by the way, bears fruit about every other year. Not many Pecan-trees were growing in the Middle States when the nut was planted, or the seedling set, which has developed into this superb specimen. Here, too, is a *Magnolia Fraseri* fifty feet high, which was certainly one of the first ever brought to the North, and a Yellow-wood, which Audubon probably brought here on horseback. Magnificent English Elms, and Yews unmatched in this country, not to speak of countless grand old native trees, testify that the people of Germantown in the first half of this century had learned to select good trees, and knew how to plant and how to care for them after they had been planted. Under the influence of such traditions and such living examples, the new-comers who have been drawn here to find a country life in the city are lovers of trees and shrubs, and Thomas Meehan & Son stand ready to satisfy their longings.

It was on the 22d of May when I reached Germantown, but the trees seemed already dressed in the full foliage of June. The Tulip-trees, which are very abundant here, were covered with flowers, and the White Fringe was blossoming on the lawns. On either side of the entrance to the Nurseries I found a Weeping Elm, and the pair bear witness to the genial conditions of soil and climate here, standing some forty-five feet high—a growth made in twenty years. These trees have a distinctively pendulous habit, and were among the earliest planted of the variety which has been sold as the Weeping, Red or Slippery Elm. The seed this year, however, makes it plain that this form is really a variety of the White or American Elm. Other trees besides the Elms grow here with notable

rapidity, and one of the most interesting studies is a long row of various kinds which were set out fifteen years ago when less than an inch in diameter. Of all these, a *Celtis* now takes the lead with a diameter of about ten inches, but many of the Oaks are following close after, among them a Red Oak, a Chestnut Oak, a Black Oak and a beautiful Swamp White Oak. These specimen Oaks reminded Mr. Meehan to say that he finds the Oaks, as a class, among the easiest to grow, and he has no difficulty in transplanting even large specimens. He added that if his business had developed in the direction of any specialty it was towards the sale of large trees. A man who moves into Germantown and builds a house insists on planting some trees about it that are big enough to drop a shadow on his lawn. He wants a tree which he can see now, and not a little seedling with only the hope of a tree in it. He asks for trees twenty-five feet high and he gets them. In Mr. Meehan's practice, that much-talked-of ball of earth about the roots is dispensed with, and yet large trees are rarely killed or severely checked by removal. His process is to spade out a circular ditch two feet deep, with a radius of six feet, say, from the centre of the tree—greater or less, according to size—and then to carefully throw back all earth from the roots within the circle with a fork. The saving of all the smaller roots he considers useless. No root carried away with the tree takes up any food or moisture. This work is done by the fine root-hairs that are thrown out after the tree is set. The best time to take up the tree is after the leaves have ripened in autumn, but before they have fallen; and this gives time to make working roots before frost, so that the tree can be supplied with moisture to protect it against excessive drying out in winter. Of course the earth should be packed tightly about the roots. Mr. Meehan's directions are to plant the tree as you would set a post—ram very firmly, and then a big tree will need no staking.

A walk through the sixty-five acres devoted to ornamental trees and shrubs showed that something like a thousand varieties are grown here, mainly for a retail trade. Among our western conifers I noticed thrifty specimens of Lawson's Cypress and *Thuja gigantea*, while *Pinus contorta*, which is often a disagreeable subject to handle, did not seem at all unhappy, a result which Mr. Meehan attributed to the fact that it was grafted on Scotch Pine stock. But space would fail if even the names were given of all the interesting conifers which are grouped here in the specimen grounds. One, however, must not be omitted—a *Thuja (Retinispora) squarrosa* which set out in life with the bluish-gray and closely-massed foliage of this variety. But after a year or so the tree saw fit to abandon this juvenile form, and it forthwith assumed another, throwing out the soft green, feathery spray of *T. plumosa*, and so it stands to-day, with the upper branches as distinct from those near the ground, as if one belonged to a graft and the other to the stock. Many other eccentricities were pointed out, as, for example, a seedling *Halesia*, which differs from the type in characters strong enough to place it in a distinct genus, while seedlings from it have reverted to the original form. I observed that our native shrubs were grown in great abundance, and Mr. Meehan said that for planting large places especially, there was a rapidly increasing demand for them, and, in fact, for native trees as well. Foreign shrubs, however, are not neglected, as a block of two or three acres of *Viburnum plicatum* testified. These plants were all white with snow-balls, and made a pretty sight; nor were they unprofitable, for every one had been spoken for by a city florist, and the money received for the crop would go far towards paying for the production of the plants. This was noticed as another advantage of tilling an urban farm.

Upon the lawn about Mr. Meehan's house are many trees of exceptional beauty and interest. The original Weeping Dogwood stands here, and no tree with pensile branches can be more graceful. Near it is a perfect specimen of the lovely Oriental Spruce, and not far away is a very large *Picea pungens* which has a softness of outline unusual in this somewhat rigid tree. The largest Golden *Retinispora* I have ever seen is here, and is, I believe, one of the first four which came to this country, having been presented to Mr. Meehan by Mr. Francis Parkman. A large specimen of the dark-leaved Japanese Maple was pointed out as an example of the vigor and health which characterize these trees when grown on their own roots, and nearly every other tree had some special interest from its history or from the lesson it taught. After the instructive walk through these grounds, a delightful hour was spent in the library, which contains a remarkable collection of works on horticulture and the sciences related to it. Many of the books are presentation copies from such authors as Darwin, Hooker, Gray and Engelmann. One little manu-

script volume contained a complete list, by Mr. Meehan, of all the evergreens growing in the plant-houses at Kew Gardens in 1845, and it is on record in Bromfield's "Flora Vetcensis," edited by Hooker & Salter, that at a period still earlier than this a new variety of *Veronica Chamedrys* had been detected in the Isle of Wight by Thomas Meehan, aged fifteen years. The eye of the botanist is still undimmed and his natural force is not abated, but these glimpses of his early life remind us how many years have been industriously given to his favorite pursuit. The city of Philadelphia now claims his services, and has for several successive terms, as Councilman. He has been active, among other things, in securing the purchase of Bartram's Garden and other land for small parks, and these will, no doubt, prove a source of health and refreshment to the thronging population of the great city of the future. Let us hope, however, that he will undertake no labors which will interrupt his studies or quite deprive the horticultural world of such instruction as he imparted for so many years in the columns of the *Gardeners' Monthly*.
Philadelphia.

S.

Notes.

An International Congress of Agriculture and Forestry will be held in Vienna during the summer of 1890.

The famous Botanical Gardens at Edinburgh are now for the first time opened to the public on Sundays.

Myosotis alpestris, Victoria, proves to be a perfect border-plant in this latitude, hardy without protection and easily multiplied by division or from seed.

The Cucumber Flea Beetle, which did so much damage to Potatoes in many places near this city last year, has again attacked the leaves of these plants, and the remedies so far tried have not been able to check its ravages.

Concerning *Magnolia Campbellii*, of which mention was made in this journal last week, Mr. S. B. Parsons writes that twenty years ago he imported a plant two and a half feet high, for which he paid five guineas. It grew well, but was not hardy in the open air.

Mr. Josiah Hoopes sends us some immense, snow-white clusters of the sterile flowers of *Viburnum macrocephalum*, with the note that it is one of the most conspicuous plants on his grounds, and the shrub is flowering better than ever before at the Arnold Arboretum. This *Viburnum*, which was mentioned in this journal last year (vol. i., p. 226), seems much more vigorous about Philadelphia than it is further north.

The crop of "May Haws," as the beautiful fruit of *Crataegus astivalis* is called, has been very abundant the past spring in western Louisiana. It ripens there in the latter part of April or early in May, and is gathered in great quantities and brought into the towns and sold for making jellies, jams and preserves, for which it is well suited. This is one of the most beautiful of all the Hawthorns, and would be a desirable ornamental tree in the South, although it is doubtful if it has ever been cultivated.

A report that will prove of special interest to residents of the territory drained by the Rio Grande has lately been made by Professor G. E. Curtis, of the United States Geological Survey. The report contains information as to the amount of snow which fell last winter along the tributaries of the Rio Grande, and this amount is used as a basis for estimating the probable amount of water which will be available for use by farmers and stock-raisers during the coming season. Questions as to the depth of snowfall were answered by 120 persons, and the general amount and distribution of the snow were clearly indicated. As a whole, the snowfall seems to have been above the average, although in one considerable region it was much less than usual. It will be interesting to observe how far the predictions as to the water-supply will be fulfilled.

During the week past the United States Nurseries, at Short Hills, New Jersey, have been thronged with visitors to see the remarkable display of rare Cypripediums now in bloom, as well as many other choice Orchids. The most wonderful specimen of all is a new *Cattleya*, belonging to the *Gigas* type. The stout pseudo-bulbs are between nine and ten inches long, and the leaves are very thick, one foot long by nearly five inches broad. The plant carries two spikes of flowers, one with six, the other with four flowers. The individual flowers are of enormous size, each of the petals being five and a half inches long by three broad, and the sepals are of the same length, the whole being a deep lake color. The lip is three and a half

inches broad, rich purple, with two yellow eyes. This is the first time the plant has flowered since its importation, and it is pronounced by enthusiastic Orchid-growers the grandest *Cattleya* they have ever seen.

The centre of bulb-culture in Holland, says *Gartenflora*, is still at Haarlem, as it has been during two centuries and a half. Hyacinths are especially in favor just now, and ground suitable for their cultivation has sold for as much as \$13,500 an acre, as against about \$1,000 given for land of other kinds. The expense of cultivation is placed at about \$300 an acre for Hyacinths and \$160 for Tulips; and it is noted that artificial manures are never used. Narcissus is also grown in vast quantities near Haarlem, chiefly for exportation to England. Formerly the export trade in cut flowers was enormous, one Haarlem firm having exported in a single season 10,000 cases; but an agreement was last year entered into by a majority of the Dutch florists to abandon the sale of cut flowers as competing with the interests of purchasers of bulbs. Attempts have been made to extract the perfume of Hyacinths, but only with moderate success, especially from the commercial point of view.

The *American Florist* recently published a picture of a very pretty basket of flowers in which Roses, Orchids and Carnations were disposed in a loose and graceful way, and so massed that both contrast and harmony were secured. Sensible words were spoken in the accompanying text where it was hoped that the sight of so charming an arrangement "will result in converting to more natural methods some of that altogether too numerous class who turn out those stiff, formal arrangements in which the grace and loveliness of each flower is annihilated by crowding together as compactly and evenly as the blades of grass in a smoothly-shaven lawn. In the 'elevation of our profession' the retail florist has a grand opportunity here to do his share. The better class of flower-buyers—people of wealth and taste who are large buyers—are quick to appreciate a really artistic arrangement and will pay well, not only for fine flowers, but for the taste and skill displayed in their arrangement."

A late number of the *Popular Science Monthly* contains a sensible letter on "Silk Culture in the United States" by Mrs. M. W. Brooks, of Salem, Massachusetts. This letter clearly shows, by quotations from various authorities, that the risks of this business are too great and the competition with Chinese labor too close for it to afford American women any fair chance of earning a livelihood. "The raising of silk-worms involves a minute and incessant labor such as Orientals appear to be alone thoroughly fitted for, and it is not at all adapted to the capacities of American women. . . . Silk culture is no experiment, even in this country; it simply does not pay a people who want to earn more than one cent per hour." An example is given of a case that has been quoted as "successful." In Johnson County, Missouri, two women and four children "tried the experiment for two years." The net profits at the end of the two years were \$57.90. It is no wonder that Mrs. Brooks thinks that the Department of Agriculture in Washington might do better work than that distribution of silk-worm eggs, in which it is still engaged.

On the 4th of May Professor Bickmore delivered at the Museum of Natural History, in this city, the last of the series of one hundred lectures to the teachers of New York City and State, which he has given under the direction of the State Department of Public Instruction. His subject was "The Forests of America," and, with the help of excellent stereopticon slides, he showed how the three main currents of wind which perpetually encircle the globe have governed the distribution of its forests. South of the Tropic of Capricorn, he explained, the wind blows continuously from the west, and is deprived of its load of moisture by striking the mountains near the western coast. Here, therefore, one finds a rich forest-region, while the dry pampas of Buenos Ayres stretch between the mountains and the Atlantic. In the equatorial regions, between the Tropics of Capricorn and Cancer, the wind blows steadily from the east; hence the enormous forests of Brazil and, across the Andes, the desert, because rainless, region of Peru. North of the Gulf of Mexico the current of wind is again from west to east, producing the heavy forests of the Pacific slope; and beyond the Rocky Mountains, which have condensed all moisture on their western sides, lies that vast interior region which, dry and unpromising as it seems, needs only water to make it blossom as the rose. The verdurous tree-clad condition of the eastern coast region is owing, of course, to the fact that local winds bring them moisture from the Atlantic Ocean.

Fairmount Park.

FAIRMOUNT PARK in Philadelphia illustrates two things: the importance of careful preliminary studies of the ground on the part of a landscape-gardener of experience and training before an urban park is located, and the necessity of devising some better method than now exists for the permanent management of parks in American cities.

Fairmount Park is one of the largest urban pleasure-grounds in the world. The site along the banks of the Schuylkill River is in itself beautiful; the surface is undulating and diversified, the soil is excellent, and there is no American park, with the exception, perhaps, of Druid Hill Park in Baltimore, which can show such noble trees—some natural, especially Tulip-trees and White Oaks, and some planted, for several fine old country places were embraced in the park. The drive along the Schuylkill in the East Park is certainly in itself, in spite of many disfigurements, one of the noblest pleasure drives in existence, while the narrow gorges of the Wissahickon supply much that is charmingly natural and delightful. But Fairmount Park, in spite of its great size and of all these natural advantages, cannot be considered successful, either from a practical or from an artistic point of view; and no trace of a master mind can be found in its location or in its treatment. Much of its value to the people of Philadelphia is lost, because of its remoteness and difficulty of access from the centre of population; and the inadequacy and inconvenience of all the park approaches are serious injuries to the appearance of the city and a real drawback to the proper enjoyment of the park. The great drive in the East Park is reached through a narrow and rather obscure street filled with the tracks of a surface road, the immediate entrance to the drive itself being through the narrow arches of a railroad bridge. Railroad lines skirt the park in all directions. One of the main drives from the West Park to the Schuylkill plunges down a steep hill to a railroad grade-crossing of the most dangerous character, while the entrance to the beautiful Wissahickon drive is under a railroad bridge. Rail-

road tracks separate the West Park from the banks of the river, which is crossed by a railroad bridge within the park limits.

Had the people of Philadelphia when the spirit first moved them to possess a park called upon some man of experience and ability to advise them about its location and to propose a scheme of approaches and a system under which extensions of the city should be built, it is safe to say that they would have had a much more convenient and satisfactory park than they have at present; and that the cost of the advice would have been saved many hundred times over. The greatest landscape-gardener might not have succeeded in overcoming all the railroad difficulties in the situation, but it is safe to say that a man of adequate experience in the treatment of such problems could have brought the park into closer and more satisfactory relations with the centre of population than now exist and thus increased its value and usefulness. The mistake of not taking proper advice in the location of the park lands was repeated when it came to construction; and much of the work done within the park is not of a character to develop all its great natural beauties.

But Fairmount Park as it is now located cannot be changed, and it is not probable that the general scheme long ago adopted for laying it out will ever be greatly modified. Of the past history of the park, except as a warning to other cities, it is therefore less important to speak than of its present and future condition. The most casual examination shows that Fairmount Park is in a miserable and alarming condition. The roads are neglected and often badly gullied; the grass is totally uncared for, uncut, filled with weeds, and often killed out over considerable areas. The young plantations are choked with weeds and apparently abandoned to their fate. Old trees are perishing through neglect. The pretentious gardens in the neighborhood of Horticultural Hall show what a few years of neglect can accomplish, and how much out of place such gardens are in public grounds. Horticultural Hall itself, which contains some of the largest tropical plants which can be seen in the United States, would delight the enterprising and curious entomologist more than it can the lover of plants.

The condition of Fairmount Park shows what effect unrestricted political influence must have upon an organization requiring such careful, intelligent and sustained management as a great city park of rural character. It is merely a question of time, unless the management of city parks can be divorced from politics, when all their rural character and real value will be destroyed. The politicians have their grasp already firmly fixed upon Prospect Park in Brooklyn, and it is hoping beyond hope to believe that it can be rescued from their clutches. The Central Park in this city has been saved because there happens to be two or three men able to realize what the park is, and what its value to the community consists in, who have sufficient public spirit and sufficient ability to enforce their views upon the public. But new dangers threaten Central Park from all sides, and nothing but extreme vigilance can ward off the attacks of selfish and unscrupulous men.

There is, however, a ray of light in the east, when Mayor Hart's gallant and successful fight to take the Boston Park Commission out of politics and to place it in the hands of experienced men of affairs, brings hope to all interested in the development of the new park system. But even in Boston this change for the better cannot be permanent under existing political methods, and there can be no improvement in the management of American urban parks until they are placed under the control of bodies of men who are not dependent upon political patronage or political influence for their appointments, and who will manage this trust in the interests of the public, and not for the advancement of one or of the other political party. Fairmount Park is a lamentable spectacle, but it may be made to point a moral, and to illustrate the dangers of political influence in the management of parks.

Heinrich Gustav Reichenbach, for twenty-six years Professor of Botany and Director of the Botanic Garden at Hamburg, and the most learned orchidographer, is dead in his sixty-seventh year. It was as a student of Orchids that Professor Reichenbach was best known to the present generation of botanists and horticulturists; his earliest labors, however, were devoted to general botany; and he did good service in assisting his father in the preparation of his now classical "Icones Floræ Germaniæ et Helvetiæ," drawing with his own hand no less than 1,500 of the plates, and editing the final volumes after the death of the elder Reichenbach. The first of these devoted to Orchids was published in 1851—the result of ten years study of the family—and was his first important work upon the subject. He contributed the Orchids to Walpers' "Annales;" and in the "Xenia Orchidacea," a work which has appeared irregularly in parts since 1851, nearly a thousand figures of Orchids from his pencil have been published.

On the death of Lindley, in 1865, Professor Reichenbach became the recognized authority on Orchids, and his time has ever since been occupied in determining and naming the immense numbers of new species which have poured in upon him from all sources, and from all parts of the world. He was overwhelmed with material which he was never able to reduce to systematic order and make really available. His knowledge of details was enormous, but his mind was hardly a logical one in the broadest sense, and lacked precision and the power of grasping clearly the material at his disposal. Knowing Orchids as no one has ever known them, he never produced the systematic synopsis even of the genera and species which the world expected from him. But if the crowning work was left unfinished by Reichenbach, his labors have made its accomplishment by his successors possible, if not easy.

He realized fully the value of the garden collections of Orchids in their influence upon his studies, and there has not been a prominent grower in Europe of these plants during the last forty years whom Professor Reichenbach has not aided with sound information and friendly counsel. His sympathies and interests were broad as the surface of the globe; and not long ago we received a number of letters from him deploring the excessive importation of our hardy Orchids and other delicate herbaceous plants into Europe, and urging us to cry a halt upon this wanton and unnecessary destruction, which he felt could only end in utterly eradicating some of the most charming plants of the American flora.

It is not evident upon whom the Orchid mantle transmitted by Lindley to Reichenbach will now descend, or who there is that can take up the tangled web which has fallen from the hands of our learned and kind old friend.

Recent Botanical Discoveries in China.—III.

Gymnocladus Chinensis.—Easily distinguished from the North American species by its smaller, oblong and more numerous leaflets and much thicker pod. It is the Soap-tree of China, the beans of which are used by the Chinese women to wash their hair. Described as a very handsome tree, growing in the provinces of Anwei, Chekiang, Kiangsi and Hupeh; figured in Hooker's *Icones Plantarum*, t. 1412. It is in cultivation, I believe, in England and France.

Viola.—Violets abound in China, though recent collections have no new, specially ornamental species. *V. Websteri* is a very distinct plant with long, unbranched stems, furnished in the lower part with membranous sheaths in the place of leaves, and those on the upper part of the stems are long and narrow. The flowers are small.

Impatiens.—Several new species of this genus have been discovered, and, as far as one can judge from dried specimens, some of them are very pretty, notably *I. tubulosa*, described in the "Index," i., p. 102. Since the description was drawn up much better specimens have been received from Dr. Henry.

Psilopogonum Sinense.—An interesting new genus of the *Rutaceæ* allied to *Bœninghausenia* and the American genus *Thamnosma*, figured in the "Index," i., t. 3, p. 103. It is a

dwarf, herbaceous plant, with numerous, slender stems springing from a common stock, trifoliate leaves, and small yellow flowers arranged singly nearly opposite the leaves; mentioned here on account of its botanical features, though horticulturists no longer concentrate all their care and thoughts on showy subjects.

Xanthoxylum.—About fifteen species of this genus are now known to inhabit China, and some of the northern ones are certainly worthy of the attention of persons desirous of cultivating variety in shrubs. There are four or five from the extreme north, and *X. dissitum* from the neighborhood of Ichang, is a handsome shrub, or small tree, with ample pinnate leaves.

Kœlreuteria bipinnata.—Described as a very ornamental tree, from the hills near Ning-Po. It is figured and described in the *Revue Horticole*, 1888, p. 393. In foliage it is more like *Ailantus* than that of the old *K. paniculata*, that is to say, in the shape and size of the separate leaflets. Judging from dried specimens, the flowers are very similar. This tree is in cultivation in Europe. In the Kew Herbarium are specimens from Kwangtung of what appears to be a third species of this genus, with foliage almost exactly like that of a *Gleditschia*.

Mucuna (? *Stizolobium*) *sempervirens*.—This is a new shrubby evergreen climber or trailer, producing branches of enormous length, like *Wistaria Sinensis*; but it is doubtful whether it would bear the same amount of cold. *Wistaria Sinensis* ranges from the mountains near Peking to Ning-Po, and Kinkiang and Ichang, if not even further south. Indeed there is a specimen in the Kew Herbarium from Hong Kong, collected by Wright, though without any indication of its origin, whether wild or cultivated. When this beautiful shrub was introduced into England, about the year 1816, it was nearly killed by being placed in a hot-house. At the same time *Rhynchospermum*, or *Trachelospermum jasminoides*, will flourish in a hot-house and flower abundantly, and almost equally as well out-of-doors in the south-west of England. Of this I have seen specimens from the hills near Shanghai, as well as from Formosa and Hong Kong and Ichang, and Maximowicz reports it from the north-west provinces of Shensi and Kansuh. Therefore, *Mucuna sempervirens* may prove hardy in the south and west of England and in similar climates. Respecting the climate of Ichang, Dr. Henry says that it is considerably milder than that of Shanghai, especially in the winter, and that very good Oranges are grown there. As there is not more than a degree of difference in the latitudes of the two places, one would have supposed the contrary to be the case, Shanghai being on the coast and Ichang between four or five hundred miles inland. Dr. Henry describes the flowers as very large, purplish and somewhat fleshy, but when I described the plant, we had only quite young flower-buds, though flowers from Ning-Po were suspected to belong to this species. This point has not yet been settled, and later consignments by Dr. Henry are not accessible at the present moment. On the other hand, M. Franchet, who is elaborating the magnificent collections made by the Abbé Delavay, sends to Kew, flowers from the much more elevated region of Yun-Nan, which he identifies with *Mucuna sempervirens*, after having seen authentic fruiting specimens. These flowers are not more than half the size of those alluded to above from Ning-Po, which are two and a half to three inches long, and certainly do not belong to the same species; yet, the Yun-Nan flowers may belong to *M. sempervirens*, and their relatively small size be due to a colder climate. It seems unlikely that Dr. Henry would have described the Yun-Nan flower as very large. Be that as it may, there is a living, flourishing plant at Kew, and we may not have long to wait for fresh flowers. Dr. Henry writes to the effect that the creeper from which specimens were taken occurs on the banks of the Yangtse, and is remarkable for its size and beauty. It extends along the face of the bank, and is supported by trees and rocks. The diameter of the main stem is sometimes as much as a foot. The flowers are succeeded by pods a foot long constricted between the seeds.

Gleditschia.—Further material is still required for the exact delineation of the Chinese species of this genus. One thing is clear, the Hong Kong species, formerly associated with *G. Chinensis*, is quite distinct, and has been described and figured under the name of *G. australis*. It is remarkably different in the pod, which is sessile, relatively short, more or less curved, very much compressed, except where distended by the seeds, thus having a bullate appearance. *G. Chinensis* and *G. macracantha* are apparently distinct species. The latter differs from the former, not only in its larger spines and larger leaflets, but also in having a very hairy ovary, and a long, straight, flat, nearly sessile pod, containing nearly quadrate, flat seeds, about a third of an inch long. Only cultivated specimens of *G.*

macracantha are known, and of these there are some in the Kew Herbarium from Calcutta, St. Helena and European gardens. What has been taken as true *G. Sinensis* has a much longer-stalked pod, and the ovary is glabrous. The leaf characters offered by herbarium specimens afford little aid in the elucidation of the species. *G. Japonica*, as represented in our herbarium, has oblong, scarcely at all oblique leaflets, and only very young pods, so that no correct idea of the species can be formed therefrom. Both *G. Chinensis* and *G. macracantha* were founded on garden specimens, hence the confusion and difficulties that have arisen. *G. heterophylla* is a very distinct, shrubby species, from north China, having small leaflets, and a very short, thick pod. I am not aware that this is in cultivation.

Æsculus.—Until quite recently it was supposed that *Æsculus Chinensis* was in cultivation. In 1887 a young tree bore fruit in the celebrated arboretum at Segrez, and on comparison with type specimens it proved to be the Japanese *Æ. turbinata*, which is easily distinguished from the Chinese species by the much larger, fewer flowers in the clusters, and the broader leaflets of a rusty brown beneath. *Æ. turbinata* forms a small round-headed tree, hardy in the north of France and south of England. In foliage it is not unlike the common Horse-chestnut, but the leaves are borne on longer petioles and are fawn-colored on the under surface. The flowers are somewhat smaller and similarly colored, pink and white, with brown anthers. A colored figure may be seen in the Japanese *Phonzo Zoufon*, part LXII, plate 17, and the fruit is figured and described in the *Revue Horticole*, 1888, p. 496.

Kew.

W. Botting Hemsley.

New or Little Known Plants.

The Carolina Hemlock.*

THE fact that a coniferous tree of respectable size and of considerable multiplication could escape notice for nearly a century in a region so carefully explored as the hilly portions of North and South Carolina is an example of the difficulty of learning thoroughly the trees of a country, and of the danger of being deceived about them—a danger which even the most careful and experienced observer of forests cannot always avoid. It was not suspected until 1850, when Professor L. R. Gibbes noticed the difference in the Carolina trees, that there were two very distinct species of Hemlock growing in eastern America. William Bartram, who, three-quarters of a century before, explored the very region where the second species abounds, the two Michaux, father and son, as sharp-eyed tree-lookers, or, to use the more picturesque expression of the West, “tree-sharps,” as our woods have ever seen, who crossed and recrossed the region a dozen times; and, much later, Dr. M. A. Curtis, whose knowledge of the southern mountain-flora has never been equaled—all failed to notice, or, if they noticed, to record the distinct, compact habit, the darker green foliage and the larger cones, with broader spreading scales, of the Carolina Hemlock.

The Carolina Hemlock is a small tree, rarely attaining a height of more than sixty feet. It prefers the rocky banks of streams, at elevations of from 2,500 or 3,000 feet, although it is sometimes found on rocky slopes fully 1,000 feet higher. It is never gregarious, however, and it is rare to find more than half a dozen trees growing together. The two Hemlocks may be seen sometimes growing side by side with their branches intermingled, when their distinctive characteristics are made very apparent. No intermediate or connecting form has yet been noticed. The territory through which this tree is distributed is not a large one, and consists of that portion of the Blue Ridge which lies in Transylvania, Jackson and Macon Counties, North Carolina, and in the adjacent parts of South Carolina, at least as

*“*Tsuga Caroliniana*, n. sp., a small tree of the southern Allegheny Mountains, with larger (six to eight lines long, three-quarters to one line wide), darker leaves than the common Hemlock Spruce, retuse or often notched at tip, without stomata above, beneath with two pale bands each with seven or eight series of stomata, strengthening cells under the epidermis or keel, mid-rib, and edges; cones twelve to fourteen lines long, scales oblong, much larger than wide, in 8-13 order, spreading at right angles at maturity, broad bracts, slightly and obtusely cuspidate; scales (two lines long) with numerous (fifteen to twenty) small oil vesicles on the under side, twice shorter than the wing.” Engelm. in *Botanical Gazette*, vi., 223. —Sargent, *Report, Tenth Census, U. S.*, vol. ix., 207; *Gardeners' Chronicle*, xxvi., 780, f. 153.

far as Cæsar's Head, an outlying spur in Greenville County, South Carolina. Our illustration upon page 269, from a photograph by Mr. E. E. Brown, of Asheville, North Carolina, gives an idea of one feature of the scenery of the Blue Ridge—the mountain torrents which pour down through deep-cut rock gorges, over rocky and precipitous beds. It represents the falls of Little River, in Transylvania County, North Carolina, and the coniferous trees seen on the banks are large and old specimens of the Carolina Hemlock. The stage road between Hendersonville, in North Carolina, and Cæsar's Head, passes by this spot, which is one of the most accessible stations of our tree. It is ten miles from “Buck Forest Hotel,” once a famous hunting resort for Carolina sportsmen in the days before railroads destroyed the remoteness and much of the charm of this region, which can still boast, however, some of the finest and most rugged scenery in all eastern America, and a flora unsurpassed on the Continent in beauty and variety.

C. S. S.

Syringa Amurensis.

A FLOWER-CLUSTER of *Syringa Amurensis*, taken from a plant growing in the Arnold Arboretum, appears in our illustration upon page 271. This is the best known and most commonly cultivated of the Lilacs with white flowers, in which the tube of the corolla is short, and which belong to the section *Ligustrina*, so called from the resemblance of the flowers to those of the *Ligustrum*, or Privet.

Syringa Amurensis is a spreading shrub of graceful habit, growing here to a height of six or eight feet. The leaves are ovate or oblong, obtuse, or often acuminate, as on the specimen selected for our illustration, and are contracted into a long, slender petiole. The panicle of flowers is sometimes erect, and sometimes pendulous by the curving of the slender branches. It is short and compact, or more often long, one-sided, and sparsely flowered. The small creamy-white flowers are destitute of agreeable odor; they appear here from the 15th to the 20th of June.

Syringa Amurensis is a native of Manchuria, where it was discovered in 1857 by the Russian botanist, Radde. A few years later it was introduced into cultivation through the agency of the St. Petersburg garden, to which Maack sent seeds from the valleys of the Amour and the Ussuri. *Syringa Amurensis*, as might have been expected, is perfectly hardy here. It is interesting botanically as the type of a very distinct and little known form of Lilac, while as an ornamental plant it possesses considerable value.

Summer Propagation of Shrubs.

MANY of our choice shrubs can be readily propagated during the summer from green-wood cuttings, at much less cost than at any other time of the year; the material is more plentiful and more easily procured, and no fire heat is required. A much longer season, too, is available, another important advantage where large quantities of plants are required. The green-house can then be used in winter for the plants of more difficult propagation. Either a green-house or frames, or both, are required, according to the number of plants to be propagated. A house forty feet long by eighteen feet wide, with two side benches three feet wide, and a centre bench six feet wide, will, under good management, be able to turn out, with the aid of frames in which to harden off the plants, many thousand of the easy rooting kinds, between June and October, after which it can be cleared out and made ready for winter work. Many kinds of material have been used by propagators to strike cuttings in, but I have found nothing better than clear, sharp sand, not too coarse, but free from clay and iron rust. Sand that has been exposed to sun and air for some time is best, but it can be used fresh from the pit, if carefully selected. The sand should be spread on the benches from two to three inches deep for any ordinary soft-wood cuttings, and at this time of the year it is not necessary to drain a bed of this slight depth, if it is carefully looked after.

The sand should be well watered and made as firm as possible with a mallet or brick. Where cuttings are put in firmly they do much the best. They should be selected from young shoots of half-grown wood, if possible, and of medium size, all over-grown suckers being avoided. Cuttings with two to three eyes, certainly not more than four, will be long enough in the case of most plants, although much larger cuttings can be used. Remove the lower leaves, and cut off smooth below an eye, being careful to have a well-sharpened knife. If the upper leaves of the cuttings are large, it is well to shorten them somewhat, to lessen the surface exposed to the air and to help prevent wilting. Soft-wood cuttings of trees or shrubs should on no account be allowed to wilt. Except in rainy weather, I invariably keep a can of water with me, and the cuttings as fast as they are collected are sprinkled and put into a close-covered box until I get to the potting-shed. When cuttings are collected at a distance, I dip each lot, as soon as cut, in water, and wrap them immediately in damp papers, keeping them away from the air as much as possible. On reaching home they are at once spread on the damp floor, sprinkled, cut in lengths and, as soon as possible, put in the bed, where they should barely touch each other, especially in summer, for when they are crowded they are more liable to attacks of fungus, the growth of which is very rapid, often going through large beds in a single night. All care should, therefore, be taken to diminish the danger from it.

As soon as the cuttings are put in they should be well watered, to settle the sand firmly around them. The roof of the house should be shaded with a slight coat of whitewash. For the first week or ten days extra shading should be given inside over the cuttings with strips of light cotton cloth or paper, hung like a curtain, so that it may be easily drawn or rolled up when not in use. The cuttings will usually need shading from nine in the morning until three o'clock in the afternoon, or even later, according to the weather and the construction of the house. If very hot weather prevails a light syringing should be given twice or three times a day, and the floors or paths of the green-house should be dampened morning, noon and night. The temperature of the house should be kept as even as possible by closing early or late, according to the weather. When cloudy all the shade should be removed, if possible, and the syringing discontinued unless the cuttings show signs of wilting, when they may have a slight sprinkling. After the first week or ten days the extra shading should be slowly dispensed with. Most of the cuttings will be well rooted at the end of a month, when they should be at once transferred to boxes or pots of light, rich, sandy earth, planted firmly, and for a few days should be shaded and syringed just as they were on the cutting bench. At the end of a week they will be somewhat established, when they may be treated as ordinary plants, in a green-house or frame, during the first season until the new growth is well ripened. The pots or boxes should be well protected from extreme weather, either in frames or deep pits; otherwise many of the plants will not endure the first winter. It is also well to remember that the soil in boxes or pots, stowed away for winter in pits, should never be sodden or wet. In the spring the plants should be shaken out of the pots or boxes and transplanted into well prepared nursery-beds, kept well cultivated, and at the end of season most of them will be fine, healthy plants. I prefer the boxes to pots, as the plants make better roots, are more easily handled, and pack away better in pit or frame. The boxes I use are made by cutting an ordinary soap box into four, using cheap half-inch spruce for the extra bottoms. The boxes usually last two seasons if housed as soon as they are out of use.

The species of plants that I have found readily propagated in this way are *Berberis Thunbergii*, *B. vulgaris* and its varieties, many of the Clematises, Deutzias, Akebias, Ampelopsis, Baccharis, Bignonias, Callicarpa, *Cornus sanguinea*, *C. stolonifera*, and other Cornels, Cottoneasters, *Eleagnus longipes*, Euonymus, Forsythias, Helianthemums, Itea, Kerrias, Ligustrums, Loniceras, Philadelphus, *Prunus Japonica* and some others, Rubus, Ginkgo, Sambucus, Symphoricarpos, Hydrangea, Syringa, Schizophragma, Decumaria, *Ribes Gordonii*, Styra, Diervillas, Rhodotypos, Vinca, Pterostyrax.

Some Viburnums like *V. cassinoides*, *V. Opulus*, *V. plicatum*, *V. dentatum* and *V. Sieboldii* root readily from soft-wood cuttings; others are best propagated by layering or grafting. Some species of Roses, such as *R. multiflora*, *R. repens* and *R. setigera*, root quite easily, while others, like *R. rubiginosa* and *R. rubrifolia*, refuse to root at all.

Exochordas, Clethras, Andromedas, Hollies, Osmanthus, Sturtias, and other slow-rooting plants do much better under a

bell-glass or double-light frame. Where only small quantities of plants are needed, five or six inch pots, well drained, all the other conditions being the same, can be used in a frame with an easterly exposure instead of the propagating bench. Whatever methods are used, the greatest watchfulness and care must be exercised at all times, or the result will be failure, however well the mechanical part of the work is done.

One of the easiest methods of increasing woody plants during the summer is by layering. This for places where large quantities of plants are not wanted, is the surest way, and requires the least care, after the operation is once completed; and many plants difficult to propagate by cutting are sure in time to root from layers. At one time, in fact, few nurseries of any size were without a place set apart as a stool-ground, so-called, and many nurseries at home, as well as abroad, use this method for increasing many plants to-day. In forming a stool-ground, select a good piece of good, light loam, well enriched with rotted manure. Trench it well and set out the plants from three to six feet apart, according to their habit of growth. This gives plenty of room to work all around the plants after they have been thoroughly established. After removing the soil to the depth of from four to six inches, gently draw down the branches to be layered, fixing them in place by hooked pegs, and, with a sharp knife, after removing the surplus leaves, cut half way through the stem, just below an eye, then drawing the knife towards you, cut the branch lengthwise from one to two inches, according to its size. Cutting the stem of the layer on the under side, as is the usual way, is often followed by the breaking of the layer, if it is at all brittle. This is prevented by making the cut on the upper side and moving the tongue slightly to one side. After being pegged down the layer should be covered with from four to six inches of loam. In many plants it is not necessary to tongue the layer, a slight twist being sufficient. With others it is only necessary to bury the stem, while others again root if the branch is only held in contact with the surface of moist earth. The only attention demanded by layers is plenty of water during the dry season and keeping the ground clean. A special ground set apart for this work is not necessary. Any plant can be layered if a trench is dug around it and filled with good loam, into which the tongued or twisted branch is held. While many layered plants will root in a few weeks, others will take a year, and some two and even three. Some will need to be recut or ringed to make them root. After layers are rooted they should be severed from the branch, pruned and transplanted to the nursery, in the same way as other plants. Almost every hard-wood plant known can be rooted from a layer if the proper time is allowed.

Arnold Arboretum.

Jackson Dawson.

The Bush Honeysuckles.

WE have many species and varieties of the Bush Honeysuckles on the college grounds, most of which have proved as hardy in wood and perfect in leaf as the best of our native trees and shrubs of the west during our recent trying years. As a full list of those now in flower would have but little general interest, I will only name three or four typical forms that will prove valuable over large areas of the country for lawn planting and for ornamental hedges and screens.

Lonicera Xylosteum.—Our form of this variable species we found at Proskau, in north Silesia, where it is used for ornamental hedges and as a bee-plant. Its fine foliage, profuse creamy-white flowers, handsome fruit and spreading pendant habit, also fit it for single planting upon the lawn. In every respect it is an improvement on our common Tartarian Honeysuckle. While our other varieties and species are rarely visited by the bees, *L. Xylosteum* is swarming with them while in flower.

Lonicera alpigena.—Our form of the alpine Honeysuckle is also from north Silesia. Its foliage is large and handsome, and its thick-branched, drooping habit fits it peculiarly for hedge-row or for single lawn specimens. Its flowers are white, followed by red berries as large as small cherries.

Lonicera splendens.—This is listed as a variety of *L. Tartarica*, but it belongs to a very distinct type from east Europe or central Asia. Some of the best named varieties we have, such as *Elegans*, *Gracilis*, *Rubra grandiflora*, *Speciosa* and *Virginialis grandiflora*, evidently belong to this soft-foliaged type with red or yellow berries. We have also been very successful in growing seedlings from this strain. Out of every one hundred seedlings, now eight years old, from seed sent us by Professor Sargent, not one can be found that is not superior in foliage, habit, flower and berries to the old Tartarian form, and some of them have larger flowers and the bushes assume

a handsomer form than any of the French varieties we have. This is specially true of some of the white-flowering seedlings with yellow berries.

In connection with the remark that *L. Xylosteum* is a good honey-producing plant, I will add that our fine hedge-row of the Amur Barberry and our plants of *Acer Ginnala* are also thronged at this time with honey-seekers, while the Spiræas, Siberian Almonds and most other shrubs in flower are neglected.

Ames, Ia.

J. L. Budd.

Notes on Wild Flowers.

ONE of the earliest and prettiest spring flowers is the purple Saxifrage, *Saxifraga oppositifolia*. Its little tufts or mats of dense foliage start into growth as soon as the snow is off in spring, and the solitary rose-purple flowers which im-

At all events the plants in groups thrive better than where each plant is set separately with more room. Of the Dog-tooth Violets (*Erythroniums*), *E. Americanum*, with its pretty yellow flowers, is not difficult to grow. It should be planted in autumn, six inches below the surface, and will flourish in sun or shade. *E. grandiflorum*, from California and Oregon, is easily grown in the same manner, but like all of these early-flowering plants, it does best when planted in autumn.

One of the prettiest early flowers, and not a difficult one to grow if placed in a cool and shaded location, is that charming little Orchid, *Calypto borealis*. It is seldom in flower before the middle of May in its natural home in the dense shade of Arbor Vitæ trees, but when set in the coolest nook of our gardens it is fully a week earlier.

Of the Spring Beauties, *Claytonia Caroliniana* is mostly out of flower, and the *C. Virginica* is just beginning to bloom.

The Home of the Carolina Hemlock.—See page 267.

mediately follow are often so dense as to almost hide the foliage and produce a solid mass of color. It should be set in the autumn, and prefers a moist, loamy soil. It is desirable for slopes of rock-work. Another early species, with white flowers, is the common *Saxifraga Virginensis*, but it is not to be compared in beauty to the former.

Our two *Dicentras* (*D. Cucularia* and *D. Canadensis*) are both early, and are now gone to seed. Their fine, delicate foliage is as beautiful as their flowers. They do best in a rich, well-drained soil, with plenty of leaf-mould about their roots.

The Bloodroot (*Sanguinaria Canadensis*) is a pretty plant, with its large, kidney-shaped leaves and its early, solitary, handsome white flower. It likes the shade and moist, well-drained soil, with plenty of peat or leaf-mould. It does best when planted in clumps of six or ten, so that they will form dense masses of foliage which seem to keep the roots cool.

Both are pretty, and should not be overlooked in making a collection of this class of plants. A rich, shaded and well-drained situation is what they like.

Two very desirable plants now in bloom with us, in the open sunlight with ordinary culture, are the *Mertensia Virginica* (Virginia Cowslip), with its large, hanging clusters of blue or purple flowers, and the *Dodecatheon Meadia* (Shooting-star), with its purplish-yellow flowers. The former is the first in flower, but there is usually little difference in their time of bloom. *Mitella diphylla* (Miter Wort) is in bloom, and its long racemes of small, white flowers are pretty, but we think it not so desirable a plant as the False Miterwort (*Tiarella cordifolia*), which flowers at the same time, producing more showy flowers and much handsomer foliage.

Two charming little plants are *Thalictrum anemonoides* and the Wind Flower (*Anemone nemorosa*). The former seems to

take more easily to cultivation, and is with us longer in bloom. Both have white flowers half an inch or more in diameter, and both like partly shaded situations.

All of the Trilliums are still in flower or are just past blooming. *T. grandiflorum*, the finest of them all, is in its prime. This plant is fast growing in favor in the United States. Large numbers were sent to Europe fifteen or more years ago, but it is comparatively a short time since it has been sold to any extent by dealers in this country. It is very hardy, and does well either in the sun or shade, if in moist, well-drained soil. Not much inferior to *T. grandiflorum* is the Californian variety of *T. sessile*. Its petals are nearly white, and being just above the large, deep-green leaves, they appear to great advantage. The bulb is very large, and often sends up several strong stems, each bearing a flower. *Trillium erythrocarpum* (the Painted Trillium) is handsome, but somewhat difficult to grow successfully. It needs a rich, loamy soil, and the bulbs should be planted deep. All the Trilliums, and there are several other species, like a rich, well-drained soil, and the finest flowers are generally found in the shade.

But the Trilliums are not so interesting as the Lady Slippers. Of these, *Cypripedium parviflorum*, the small yellow species is now in flower, and its purple sepals with the bright-yellow inflated lip make it conspicuous. It is one of the easiest Orchids to grow, and will thrive, either in the shade or sun, and in loamy soil if peat or leaf-mould is plentifully mixed with the earth about the roots. *C. arietinum* is also in flower. This plant needs shade and a moist but well-drained soil. It is not conspicuous, but when brought to its highest state of cultivation it is very handsome. The flowers are small, dainty and reddish-brown and white in color. *C. montanum*, of Oregon and California, a pretty species with white flowers, somewhat resembles *C. candidum*, but usually has more than one flower, while the flowers of *C. candidum* are single. It is not so easily grown as the Eastern species, and needs protection in winter. If strong plants are set in well-shaded and well-drained, loamy soil they will flower for two seasons.

Window Ferneries.

A TASTEFULLY-ARRANGED window-garden of Ferns, even if of small dimensions, adds greatly in the embellishment of a home, and is not necessarily a costly experiment to the amateur. Attention is necessary to insure its well-being, but if the plants are selected with a view to their fitness, much disappointment will be avoided.

These miniature gardens may now be had in a variety of shapes and forms, and it may be mentioned that those enclosed by glass usually give greater satisfaction, on account of the less rapid evaporation of moisture.

But whatever plan be adopted, the pan or other vessel in which the plants are placed, should be well provided with drainage, broken stone and charcoal being an excellent mixture for this purpose, which should be placed in a layer in the bottom of the pan, the latter being pierced with holes, so as to allow the easy escape of the surplus water. In the matter of soil it will be found that many of the most suitable Ferns for house use are not very fastidious, provided the soil be light, though a mixture of two parts peat to one of loam, with a fair quantity of rather coarse, sharp sand, will always prove satisfactory.

It is generally best to use those species and varieties that are content with a green-house temperature of 50° to 55°, as, for instance, several kinds of Pteris, such as *P. argyræa*, *P. Cretica magnifica*, *P. serrulata* and *P. serrulata cristata*, and during the summer months *P. scaberula* may also be used, the deciduous habit of the latter making it somewhat unsatisfactory in the winter and spring. *Adiantum cuneatum*, *A. pubescens* and *A. Capillus-Veneris* will prove worthy representatives of the Maiden-hair Ferns, and *Onychium Japonicum* and *Davallia tenuifolia stricta* are among the best in their respective genera for this purpose. A very pleasing effect is produced by the mixture of a few of the coarser-fronded sorts, such as *Lastrea Sieboldi*, *Doryopteris nobilis* and *D. palmata* and small plants of *Polypodium aureum*, with their peculiarly glaucous fronds, make a good contrast with the more delicate-looking species. Small plants of various Palms and other foliage-plants may be used to advantage for centre-pieces in these window-ferneries, *Cocos Weddelliana* being specially adapted to this use, as is also *Geonoma gracilis*, though the latter will not stand nearly as much rough usage as the Cocos. Small plants of *Pandanus Veitchii* and *P. utilis* are admirable, and will keep in condition for a long time, as will also *Aralia Veitchii*, the elegant foliage

of the latter being quite enduring, and making a charming combination with the Ferns.

Another useful little plant for this purpose in this connection, is the Japanese Sweet Flag, *Acorus Japonicus variegatus*, it being easy to grow and very pretty.

A more finished appearance is given to the fernery if the surface of the soil is covered with a carpeting composed of one of the low-growing Selaginellas, such as *S. Kraussiana*, *S. Kraussiana aurea*, *S. densa*, or even *S. apus*, the latter, though a native and perfectly hardy, is not by any means to be despised on that account, being of rapid growth and neat appearance. In the treatment of window-ferneries the often-repeated injunction, never to allow growing Ferns to become very dry, still holds good, and while giving thorough watering at the root, it will be found best to keep the moisture off the foliage, else the latter may soon become disfigured.

W. H. Taplin.

About Melons.—Years ago it was a common practice to plant Melons, literally, in "hills" raised above the surface of the ground, and some still think such a practice necessary. When the seed is sown early there may be some advantage in this, since the elevation will be warmer than the flat surface. But, as a rule, in soil best suited for Melons—a warm, sandy loam—a more thrifty growth and more prolonged health of the vine can be secured by making the hills really hollows. Nothing so promotes the growth of a Melon-vine as the drawing of fresh earth to the stem, and a vine planted a few inches lower than the general surface of the soil, by a gradual drawing-in of the soil by the time cultivation ceases can be on quite a ridge, and thus get the advantage of the hill with the further advantage of having its roots in moister and cooler soil than would have been possible if planted on a ridge. These remarks will apply equally well to Watermelons as to Muskmelons.

In growing Melons for home use quality is the first consideration. Of late years the effort among seedsmen has been to produce a Watermelon with a tough rind, adapted to the long shipment from the South. This has been obtained at the expense of quality. In our home-garden it is of no sort of advantage to raise a Watermelon which will support a weight of half a ton, as some are said to do. Neither do we care for its being "iron clad" or "copper fastened," unless the inside is well worthy of such protection. The newer sorts of Watermelons, while they have been improved for the purposes of the shipper, have not been of the average quality of some of the older sorts. We have found none superior for this region to the "Gypsy" and the "Mountain Sweet." The "Volga" is said to be small and of high quality, but we are growing it for the first time this year and cannot give an opinion upon it. In Muskmelons it is also a good rule to select varieties, not by size and looks, but by their quality for the table. In Muskmelons size is often attained at the expense of quality. Many contrivances have been proposed for protecting young Melon-seedlings from the attacks of the striped bugs, which devour them when in the seed-leaf, but most of them are very troublesome. For many years I have used a little raw bone-flour, dusted over the young plants as soon as they are fairly up. If beetles are there they leave at once, and the plants are benefited by the application.

Early fruitfulness is promoted by nipping off the tips of the vines when about three feet long.

W. F. Massey.

Garden field-labels are a source of great annoyance. But if labels are not necessary the greater part of the annoyance is at once dispelled. In other words, plant and record your plantings in such a way that you do not need to depend upon labels. But they are convenient, nevertheless. For trees the best labels are made of zinc, cut into strips about one inch by five. The name is written with a pencil, and the opposite end of the label is bent about a limb. For stake-labels I use the ordinary twelve-inch, thin, commercial stake, always primed. These are inexpensive and are exceedingly handy for temporary use. But if more permanent or conspicuous stakes are used, I have found the best to be those which we have recently had cut for us at a planing-mill. They are eighteen inches long, three inches wide and one and a half inches thick, made of clear white pine, and sharpened by a buzz-saw at the mill. Early in spring these are all primed with white lead. They take a soft, broad pencil readily. If they are needed twice during the season, a mark is drawn through the name, and the other side is used. In the winter-time a thin shaving is taken off the stake to remove the name, another priming is given, and the label is again new. In this way the label lasts many years for many things, and although it is somewhat expensive to begin with, it is really the cheapest and most serviceable label made. I like the lead pencil better than a brush

and paint. The lead usually endures longer, and it is easily applied at just the moment the label is wanted. A carpenter's pencil is best for this work.

L. H. Bailey.

Heuchera Sanguinea.—This plant, now in bloom, justifies all that has already been written and said in its favor. The flowers are borne on long, slender stems and are of a bright coral red. The foliage is handsome also, being mottled with brown. The plants from seed vary considerably in this re-

Papaver bracteatum roseum.—The gorgeous Oriental Poppy is a conspicuous plant just now in the flower-garden, and its merits as a showy border-perennial are pretty generally recognized. *Papaver bracteatum* is, strictly speaking, only a variety of *P. orientale*, differing principally in the leafy bracts attached to the flowers. We have in bloom at the present time a variety of *P. bracteatum*, the flowers of which are fully as large, but the color is a beautiful clear pink similar to that of a Mermet Rose. This plant is known as *P. bracteatum roseum*, and is of English origin. One peculiarity of this plant is that seed-

Fig. 112.—*Syringa Amurensis*.—See page 267.

spect. Our plants are twelve months old from seed, but we find that side shoots are freely produced, and these root readily and soon form nice plants. It would be interesting to know if any one has tested the plant as to its hardiness in the Eastern States, it being a native of Mexico. It will probably prove tender, but even if this is so the plant has the value of producing flowers in winter when potted and placed in a warm house where a temperature of about 50° can be maintained.

lings raised invariably revert to the typical form; this necessarily makes propagation rather slow, and may account for the fact that it has not become common yet, though known to gardens for a number of years. In other respects the plant is as hardy and floriferous as *P. Orientale*, and promises to be quite an acquisition to the list of perennial Poppies, which already contains one sterling variety of American origin—*P. Parkmannii*.

Passaic, N. J.

Orchid Notes.

Cypripedium bellatulum.—This handsome addition to the dwarf-growing section of Lady Slippers, represented by *C. Godefroyæ*, *C. concolor* and *C. niveum*, was introduced to cultivation early last year by Messrs. Low & Co., of Clapton, near London, but, for certain obvious reasons, they did not mention its native home, which, however, is guessed to be somewhere in further India. Botanically speaking, *C. bellatulum* may be regarded as a very superior form of *C. Godefroyæ*, which it most nearly resembles in shape and coloring. It has already become amenable to cultivation, and there is no doubt that it will soon find its way into every collection of Cypripediums.

In habit it is very dwarf and compact, with elliptic-oblong leaves of a deep green color above, mottled with a paler shade, while the under surface is thickly covered with dark purplish spots and blotches in close contact. The purplish, downy scapes are three or four inches in length, each bearing a single flower about three inches or more across. The upper sub-orbicular sepal, and the oval, depressed petals are usually pure white, thickly covered with large and small brownish-purple blotches and spots, which give them a most handsome and attractive appearance. These blotches show through on the back of the segments, which are often suffused with a purplish tinge. The long, narrow pouch is very small in comparison with the other parts of the flower; it is also white, and covered on the inner, as well as the outer, surface with smaller brownish-purple spots. The staminode, which is longer than that of any other variety of this section, is similarly colored.

The color of the flowers is somewhat changeable, varying from pale yellow to ivory white, while the blotches in some flowers are much larger and more dense than in others. Two varieties of this species already exist; the one called Roseum may be distinguished by the suffusion of rose which pervades the segments of the flower; the other, known as Egregium, is said to have the upper sepal slightly trilobed, and the purple blotches on the front face of the flower are so light in character that no trace of them is discernible on the back.

This species requires very little attention, provided that it is grown in a warm and moist atmosphere. Some plants in the nursery are grown in pots, and others are planted out, and all are doing equally well. The compost used is peat and loam, with a little sphagnum mixed. Some of the plants have been in flower now for three weeks, and are still in perfect condition; they require a rather shady position and not much water.

St. Albans, May, 1889.

John Weathers.

Cattleya Mendellii.—This grand Orchid will now be found in full beauty in most collections, and, with *C. Mossiæ*, will keep up a fine show of bloom for some weeks. Its native home is on the eastern slopes of the Cordilleras, in Columbia, where it may be found on trees and rocks often exposed to the strong rays of the sun, but where there is abundance of water to bathe the roots. The flower generally measures about seven inches across, with white or tinted sepals and petals of wavy outline. Its chief beauty, however, lies in the large, spreading lip, which is very much crisped, with a front lobe of crimson-purple. There are many beautiful varieties; a pure white one with a slight dash of yellow in the throat is called Alba. Bella and Morgania are pale-colored forms; Imperator is an immense flower with a magnificent lip, but the best I have yet seen is one called Superbissima, which was sold in London a few years since for one thousand dollars; the half of this plant is in the collection here. *C. Mendellii* grows very freely, needing plenty of drainage, little potting material, strong heat with plenty of water during active growth, and a long, cool rest, but it should not be kept too dry.

Erides crispum was introduced, nearly half a century since, from Bombay, and may be considered one of the very best of the genus. It is very robust in growth, attaining a height of four or five feet, and when the leaves are retained to the base it makes a very handsome plant. The leaves, which closely clasp the stem, are flat, broad, dark green and leathery, six to eight inches long. From the axils of these arise the erect racemes, which are often branched and bear numerous large handsome flowers about two inches across, white suffused with rose, with a beautiful large lip of rosy-purple, very crisp at the edges, and terminating in a horn-like spur. The variety Lindleyanum is more robust in growth, with larger and more distinct colored flowers. The variety Warneri differs a good deal from the type in habit, is much shorter, more slender, and with short and very narrow leaves, the dark mark at base of the leaves being very conspicuous. All of the varieties grow freely in baskets or pots of moss and peat. With plenty of heat it is hardly possible to give too much water in the

growing season, and weak applications of liquid manure are beneficial. Only large plants of this Orchid bloom freely. It may be that it needs more sunlight to thoroughly ripen the growths.

Kenwood, N. Y.

F. Goldring.

Notes from the Arnold Arboretum.

Berberis Sieboldi.—A Barberry, sent some years ago to the Arboretum from the Flushing Nurseries, under the name of *Berberis "Hakodate,"* no doubt so-called from the place where the plant was first obtained, proves to be the little-known *B. Sieboldi* of Miquel ("Prol. Fl. Jap." 1). It is one of the handsomest of all the Barberries, and a most desirable garden plant. It is a stout shrub of compact habit, growing here three or four feet high, with branches covered with gray bark; and with short, slender, three-branched, chestnut-colored spines, very short petioles, oblong-lanceolate, or obovate leaves, rounded at the apex, densely setulose-ciliate on the margins, smooth, rather coriaceous at maturity, very bright green and lustrous. The fragrant flowers which are borne in short, semi-erect, many-flowered racemes, an inch and a half long, are pale canary color, with obovate rounded sepals and petals, and about the size of those of *B. vulgaris*. The fruit is large (one-third of an inch long), oval, and bright scarlet. This plant, which has the general habit and somewhat the appearance of *B. vulgaris*, may always be distinguished from that species by the ciliate margins of the leaves, which are quite destitute of rigid teeth. The leaves are more lustrous, the racemes are erect, not pendulous, as is *B. vulgaris*; the flowers are lighter colored than in that species, and in the autumn the foliage assumes the most brilliant coloring, which makes this plant a conspicuous object among the other Barberries of the collection at that season of the year. *Berberis Sieboldi* is perfectly hardy and very free flowering; and it is certainly one of the most desirable shrubs brought from Japan to this country. Seed of this species, under its right name, was distributed last year from the Arboretum among European gardens, where it does not appear to have been cultivated. A figure of this species has been drawn for publication in GARDEN AND FOREST.

Berberis heteropoda, a Turkestan species, has been for several years an inhabitant of the Arboretum. It is not, however, perfectly hardy here, but this year, favored by the mild winter, it is flowering much more freely than usual. It is a very ornamental and distinct species, with angled stems covered with dark gray bark, slender, simple, or three-forked spines, and obovate entire, or sometimes sparingly and minutely toothed leaves, which are pale bluish-green, lighter colored on the lower surface, and borne on very long, slender petioles. The pale yellow flowers in short, few-(3-4) flowered racemes, which are shorter than the leaves, and destitute of fragrance. The peculiar pale coloring of the foliage makes this a desirable plant, which might well find a place in gardens wherever the climate is not too severe for its full development. It attains in its native country, according to Dr. Regel, a height of six to ten feet. This species is considered in the "Botany of British India," a variety of *B. vulgaris*, but for garden purposes it is certainly abundantly distinct from that very variable and widely-distributed plant.

Berberis buxifolia (the *B. dulcis* of gardens) is in flower. It is a pretty species, with small oval or oblong, nearly sessile, entire leaves, and large, solitary, orange flowers. It is a native of Patagonia, and not very hardy here, even when carefully covered during winter. This year it is flowering more freely than usual.

A curious and beautiful Barberry now in flower here is not referable to any described species, while some of its characters suggest a possible hybrid between *B. vulgaris* and *B. Thunbergii*. It has the bark upon the branches of *B. vulgaris*, the simple, slender spines of *B. Thunbergii*, the tufted, entire obovate leaves of this last species. They are considerably larger, however, paler green, more membranaceous, and borne on long, slender petioles. The flowers are produced in long-stalked (sometimes nearly an inch long), umbellate racemes, of eight or ten or sometimes only of three or four flowers. They are larger than those of *B. Thunbergii*, bright yellow (those of *B. Thunbergii* are much paler), with rounded sepals and petals, and the red-marked filaments of the Japanese plant. They open a week or ten days later than those of *B. Thunbergii*, and a few days earlier than those of *B. vulgaris*, and possess a trace merely of the delightful fragrance of those of this species. The fruit resembles very closely that of *B. Thunbergii*, and hangs, as is the case with that plant, bright and fresh upon the branches throughout the winter and early spring. Several years ago, Max Leichtlin sent to the Arboretum seeds of "two red-fruited" Barberries, without any indication of their origin.

A large proportion of the seedlings raised from this seed proved to be *B. Thunbergii*, but among them were several individuals of this peculiar plant, which suggests in its umbellate inflorescence some of the forms of the sub-evergreen *B. aristata* of the Himalayas. But whether, as I suspect, it is a hybrid, or some species unknown here, it is an exceedingly ornamental and valuable garden plant; one of the neatest of the whole genus in its habit of growth, perfectly hardy, and very beautiful when its graceful branches are covered with its nodding umbels of large, bright-colored flowers.

Japanese Maples are not, as a rule, very reliable in this climate, too often dying suddenly in summer without any apparent cause; but one of the Japanese *Negundos* (*N. cissifolium*) has so far been an exception to this rule, proving here to be a handsome, small, round-headed tree, with erect, stout branches, of excellent habit and pleasing coloring. The largest specimens, although only ten or twelve feet high by as much through the branches, have now flowered and fruited here for several years. It is a tree with smooth, gray bark, that of the young branches being pale red or brown and three-foliolate leaves, borne on long, slender, bright red, hairy petioles. The leaflets are acuminate, deeply incised towards the apex, short-stalked, hairy on the principal veins on the under surface, and on the margins, with a few short, scattered hairs on the upper surface. They are membranaceous and of a delicate pale yellow-green color, which very late in the autumn turns to bright yellow. The slender racemes of yellow flowers are erect, but become nodding as soon as the fruit begins to form; they are four or five inches long, the rachis, pedicels and wings of the young fruit red and covered with long, scattered hairs. *Negundo cissifolium* is, apparently, perfectly hardy; it grows rapidly, and has not been attacked yet by any insect or fungus. It is well suited for planting on the borders of a small lawn, or as a single specimen tree in the garden, for which purpose its small size and round, rather formal habit, admirably adapt it.

The Judas-tree or Red-bud of the Middle and Southern States (*Cercis Canadensis*) is in bloom. It is one of the most beautiful flowering trees of the North American forest; and there are few more beautiful objects than the great masses of this tree in some parts of the South or South-west, notably along the eastern borders of the Indian Territory and in eastern Texas, when they are covered with their purple flowers in very early spring. There the Red-bud becomes a tall tree, with a stout trunk; further north, although nearly always arborescent, it never attains the size developed in the more favorable climate and more generous soil of the South. It is remarkable that so fine a plant should be neglected by our horticulturists, who hunt the remotest corners of the earth for novelties with which to embellish their gardens, and pass native species which cannot be matched anywhere. *Cercis Canadensis* is rarely planted in gardens in these days, and yet a plant in flower standing out alone before a dark background of Hemlocks or of Pines, or when it can contrast its purple flowers with the white floral leaves (the two plants flower here together) of the Flowering Dogwood (*Cornus florida*) is an object which fully satisfies the imagination, and one which is not easily forgotten. The Red-bud, although not a native of eastern New England, is perfectly hardy here; it grows rapidly, and is an object of beauty from the time the abundant flowers cover the naked branches until the late autumn, when the red-brown pods are ripe.

Prunus emarginata has very unexpectedly proved perfectly hardy in the Arboretum, where it has been growing during a number of years. It is a native of western North America, from the valley of the lower Fraser River southward to middle California, and eastward to Idaho and northern Montana. It is a small tree reaching, in the neighborhood of the coast, a height of thirty or forty feet, and occupying, generally, the low banks of streams. In the Arboretum it is a stout bush, eight or ten feet high, branching from the ground. The umbellate flowers, which the plants have produced this year in great profusion, are small, scarcely more than a third of an inch across when expanded, appearing simultaneously with the unfolding of the leaves, which are dark blue-green in color, ovate, minutely glandular-toothed, pubescent on the lower surface, as are the short petioles and young shoots. The fruit, which ripens about midsummer, is black, oval and half an inch long. This is an interesting plant, owing to the region from which it comes—a region with a climate so totally unlike that of eastern America that few of its plants thrive on this side of the continent.

Rhododendron Vaseyi (see GARDEN AND FOREST, i. f.) has flowered this year better than ever before. It is a garden plant of great beauty and value certainly. It flowers earlier than any of its race, and the clear pink color of the corolla is

quite unlike that of any of the deciduous-leaved *Rhododendrons*. Its value for crossing with other species has not been shown yet, but it is probable that its blood, mingled with that of some species with deeper colored and larger flowers, will produce some remarkable results. A cross with the *Rhodora*, which is quite within the limits of possible hybridization, might be expected to produce a large-flowered plant of great beauty.

Caragana arborescens, the Siberian Pea-tree, is an old inhabitant of gardens, and a perfectly hardy small tree of good habit and an unfailing bloomer at this season of the year, when the erect branches are covered with its handsome, bright yellow, pea-shaped flowers borne in fascicled clusters from the axils of the compound leaves. These have spinescent stipules, and consist of four to six pairs of small, oblong-oval vilous leaflets. This tree, which will grow to a height of fifteen or twenty feet, is often found in nurseries grafted as a tall standard; but it makes a much more beautiful object when it is grown on its own roots and is allowed to send out its branches from near the ground.

The shrubby *Caragana frutescens* is a native of Siberia also, and a desirable plant. It has larger solitary flowers of paler yellow, and smooth leaves with broader leaflets. It flowers a few days earlier than *C. arborescens*, and is equally hardy. Both species are easily grown from seed.

Periodical Literature.

THE May *Bulletin of Miscellaneous Information* issued by the authorities of the Royal Gardens of Kew is devoted to an account of the Persian Zalil (*Delphinium Zalil*) noticed in this journal (i. p. 6., ii. p. 227); to the economic properties of a number of New Zealand timbers, the most interesting of which are Red Myrtle (*Fagus Cunninghamii*), Huon Pine (*Dacrydium Franklinii*) and Black wood (*Acacia melanoxylon*); and to an interesting account of Lily flowers and bulbs used as food. From this it appears that the trade of Lily flowers from Chinkiang was last year over seven and a half million pounds. These flowers are the dried blossoms of *Hemerocallis graminea* and of *Lilium bulbiferum*. They are used by the Chinese for flavoring soups, and are also eaten as a vegetable. They are also said to be efficacious in pulmonary diseases, and to have tonic properties. Hankan is the chief place of export in China, and great quantities are sent from Japan to the Flowery Kingdom. Lily bulbs are an important article of food in Japan.

There are articles on Pa-ért tea, an article of commerce in the province of Yun-nan, in south-west China, said to possess medicinal and invigorating properties, and to be used to aid digestion after heavy meals; on the short-podded yam-Bean (*Pachyrhizus angulatus*), widely cultivated in the tropics for the starch of its tuberous roots.

This part concludes with a list of the officers of the Royal Garden, and of the other British and Colonial botanical establishments. The *Bulletin* is well sustained in interest, and in its practical value to all persons who have to occupy themselves with economic plants and plant products.

Recent Publications.

A Handbook of Cryptogamic Botany, by Alfred W. Bennett and George Murray. With 378 illustrations. London and New York: Longmans, Green & Co.

This is an attractive looking volume of about 450 pages, with a large number of well-executed figures. Since the appearance of Berkeley's "Introduction to Cryptogamic Botany," in 1857, there have been several excellent English translations of German works in which the different divisions of Cryptogams have been treated either incidentally or specially, but the present Handbook is the first attempt by English writers to prepare a general treatise on the subject. So much has been written of late years on the development and classification of Cryptogams that it is almost a hopeless task to summarize all that has been written, and the authors are to be congratulated on their success in presenting so nearly complete a summary of what had appeared up to the date when their book went to press. After a brief introduction—too brief to be in all respects clear to the reader who is not more or less of an expert—the different subdivisions are discussed, beginning with Vascular Cryptogams. Whether one should begin with the higher groups and go downwards, or the reverse, seems to us to be of comparatively little moment. Each plan has its advantages, and the only real question is, having settled upon one method rather than the other, How has the general plan been carried out?

Naturally, the part of the Handbook most symmetrically treated—if one may use such an expression—is that relating to Vascular Cryptogams and Muscineae, for those groups have been so long and so well studied that it is possible to give in a condensed form an account which not only will be recognized as accurate by experts, but will also be intelligible to students. With regard to Thallophytes it is quite another matter. He must be certainly very sanguine or strongly prejudiced who believes that any really satisfactory classification of Thallophytes has as yet been discovered. About all that can be done is to relate the facts known with regard to their structure and development in as clear and simple an arrangement as possible, without much pretense at classification, as the word is understood when speaking of higher plants. The subdivisions adopted are Algæ, Fungi, Mycetozoa and Proto-phyta, and, admitting that these subdivisions are arbitrary and, in a sense, mechanical rather than strictly scientific, this arrangement has what appears to us the supreme merit, in a work of this kind, of being more easily followed than other classifications which have been proposed, and it also brings near together orders of plants which, whether rightly or wrongly, are always studied together. For a long time to come we shall have algologists and mycologists, but we are not likely to have conjugatists, oosporists and carposporists. What the student needs is to have pointed out distinctly the parallelism of the reproduction in certain Algæ and certain Fungi—which the present method sufficiently accomplishes—and there the matter had better rest until experts have settled more clearly the doubtful points in the relationships of Thallophytes.

If we look at the manner in which the authors have carried out their general plan, we are struck at once with the unusual and disproportionate amount of space devoted to Algæ; 120 pages to Algæ proper and forty-three to algoid protophytes, while only 101 pages are devoted to Fungi, including Mycetozoa, and Bacteria barely cover seven pages. In most text-books considerably more space is given to Fungi than to Algæ. We do not, in the least, object to the amount of space given to Algæ, but, on the contrary, regard this part of the work as the most valuable, as it goes beyond what is given in similar treatises, and contains a deal of information which could have been obtained only by an extended and careful reading. But the relatively small space given to Fungi has made it impossible to treat adequately a number of subjects on which the student and general reader ought to have clearly expressed and fully explained information, and we consider this part of the Handbook too condensed to be followed readily by those who are not already pretty well informed. The placing of *Diatomaceæ* among Protophyta rather than near *Desmidiaceæ* is scarcely to be commended, for, although we agree with Mr. Bennett in thinking it very doubtful whether the *Diatomaceæ* are zygosporic in the strict sense, we still believe that they can be described better in connection with *Desmidiaceæ* than when removed to the ill-assorted group of Protophyta, with which they have little in common except that their reproduction is not well known. Nor can we agree that the position of *Ulvaceæ* is uncertain, but think that they belong to *Confer-voideæ* and not to *Floridææ*, for their resemblance to the genera *Porphyra* and *Bangia* is merely superficial, and does not indicate a real affinity.

In short, the Hand-book is a valuable summary of the present state of our knowledge of a branch of botany which is becoming more and more popular, and the editorial work has been well done, so that the errors which are seen at first reading are few and unimportant. We would, however, suggest that the name *Mazæa*, on p. 440, should be changed to *Nostochopsis*. If there is any general criticism to be made it is that the work, as a whole, has perhaps a little too much the air of a catalogue of orders and sub-orders, and one would be glad to have the essential and general parts brought out somewhat more plainly by larger type or other printers' device, leaving specific details to smaller type. There is only one point on which we have any serious objection to offer, and that is the introduction of new terms to replace others already well fixed in English botanical literature. In the introduction the following statement is made: "Many of the terms which we employ throughout this volume, such as sporangium, archegone, antherid, cænobe, sclerote, epiderm, etc., will probably be accepted at once; and it seems strange that the awkward and uncouth foreign forms of these words should have held their ground so long." We venture to hope that they will not be accepted, and would suggest that the reason why the so-called "awkward and uncouth foreign forms" have held their ground so long is because they have proved by experience to answer their purpose perfectly well. So far as technical botanical

terms are concerned there is no intrinsic reason why they should be English in form. It is one of the many points of superiority of the English language that it can absorb and make a part of itself technical terms, whether classical compounds or derived from modern languages, and it is neither necessary nor in good taste to trim and prune words which have for years been accepted. Why, we would ask, is the commonly-accepted epidermis more uncouth than epiderm? or why is the French word sporangium any less foreign than sporangium, which has been adopted for years by good English writers? Why is the word mycelium, which has become so thoroughly a part of the language that it has almost ceased to be technical, to be abandoned for the decidedly un-English mycele? To quote a passage at random on p. 370: "The male cells are *pollinoids* formed in a flask-shaped antherid, somewhat resembling a perithece." The unprejudiced reader would hardly be struck by the peculiarly "English" look of the sentence, and the meaning would be quite as plain if, adhering to the common nomenclature, the sentence had run as follows: The male cells, called spermatia, are formed in a flask-shaped sack, the spermogonium, which somewhat resembles a perithecium. The substitution of the word "sperm" for "spore" in compounds, like "zygospore" and "oospore," only makes a bad matter worse. We can only regret that in a book, otherwise so good, the authors have allowed themselves to be carried away by what we must consider an unwise desire to substitute new terms for well-established terms which fulfil their purpose sufficiently well.

Correspondence.

To the Editor of GARDEN AND FOREST:

Sir.—Several years since, when the question of injury to conifers was being discussed in the *Gardeners' Monthly*, I had occasion to notice it somewhat in Cambridge and elsewhere. Red squirrels were abundant, and were seen to clip some of the twigs found on the ground, but the marks they left at the broken end or about the buds were wanting on many twigs, which nevertheless appeared as if broken across—never with the smooth surface, characteristic of self-pruned twigs of the Poplars, Elms, "brittle-branched" Willows, etc. In St. Louis, where red squirrels are unknown (at least to me), the ground is often covered by hundreds of freshly-fallen twigs under the Norway Spruce, etc., especially toward the end of winter. Careful and repeated observation for the last four years has convinced me that if fox or gray squirrels (which, however, I have never seen in the botanical garden), or birds of any kind are responsible for the injury, they work during the night, and leave no evidence of their work on the fallen twigs, which are quite like those seen in Cambridge. So far as our trees are concerned, I quite agree with Mr. Fernow that the twigs are simply shaken off. After a sleet-storm the number is sometimes very great.

St. Louis, May 5th.

Wm. Trelease.

To the EDITOR OF GARDEN AND FOREST:

Sir.—I have read your tombstone article with solemn interest. I am much amongst graves; and were it not for the broken lives and hearts I often see at the edge of newly-opened ones, cemeteries and their monuments would suggest nothing to me but the tragedy of human vanity. May your article help to bring such tasteless egotism into disrepute, and establish some congruity between the gravestone and the fact of death.

New York City.

Clergyman.

Vineland, New Jersey.

To the Editor of GARDEN AND FOREST:

Sir.—A land of Vines it is indeed, and the name which its venturesome founder bestowed upon this borough in the way of prophecy has been amply justified by the facts of subsequent history. And yet the belief that these sandy stretches in southern New Jersey were nearly worthless for any form of husbandry was almost universal twenty-five years ago, and the land had been called "The Barrens" time out of mind. The charcoal crop, however, was always a sure one, and there are men now living who have cut twice over some portions of the Vineland tract and carted the charcoal into Philadelphia, thirty-four miles away. This luxuriance of tree-growth ought to have suggested that the soil was not altogether destitute of plant-food. One Chestnut stump, at least, remains within the borough limits which is twenty-one feet in circumference, and its roots must have tapped big reservoirs of fertility somewhere. And yet no one had faith enough in the land to clear

and till it, and the farmer who declared that he would as soon think of raising a crop in a soil of pulverized glass as in the sands of "The Barrens" did not state the general belief with too great emphasis. Notwithstanding its proximity to Philadelphia, the tract of 34,000 acres was bought in 1860 for five dollars an acre, and to the daring purchaser the privilege was granted of paying only as fast as the land was re-sold to settlers. As the war closed greenbacks were floating freely, a good many people felt inclined to settle somewhere, a great volume of seductive advertising found its way into the press, and Vineland began to fill up rapidly with enthusiastic amateur farmers, who were convinced that five acres was more land than any man really needed to get rich upon. These hopeful people usually spent all their ready money in building a house, borrowed some more to set out a useless hedge and some trees and vines, and then began to rest, while their orchards and vineyards grew. A period of some depression naturally followed, but at last business has settled down upon a permanent basis, and the prosperity of the place seems established. Landis Avenue, the main street, is nine miles long, and many of the farms that front it contain only five or ten acres, and from these the owners are realizing a comfortable income.

But as Grape-vines and fruit trees took the place of scrub Oaks and Pines, the insects and fungi which prey upon them began to multiply, until the Downy Mildew and the Black Rot, not to speak of other rusts and blights, threatened to destroy the fruit industry. With some varieties of the Grape the rot made so clean a sweep of the crop that many vineyards were abandoned and rooted out. Colonel A. W. Pearson, one of the large growers, however, concluded that his vineyard was worth fighting for, and he began a series of experiments which attracted attention for their thoroughness, and finally he was selected by the Department of Agriculture as one of the agents to make trials of certain remedies which had been used with some promise in France. He feels confident that the two most destructive enemies of the vine can be held in check by preparations of copper sulphate. Last year, beside untreated vines on which ninety-five per cent. of the grapes were lost, vines sprayed with the Bordeaux mixture lost but two per cent. It was primarily to look at this experimental vineyard that I came to Vineland. It was too early, however, to see any effects of the diseases or their remedies, although an inspection of the methods of conducting the experiments was most interesting. It is not enough to discover some mixture that will kill the fungus. What is needed in practice is a certain remedy, which can be applied most cheaply and with least danger to the plant and to man. A great number of preparations are on trial, applied on belts running across the rows so as to take in every variety of vine, and with check lines of untreated vines between the belts sprayed with the different mixtures. A description of the remedies in detail would be tedious to your readers, and the reports at the close of the season will show which ones have proved of value.

The vines are set in rows nine feet apart, with a vine every six feet in the row. The stakes are short, and carry a single wire at a height of two feet and a half from the ground. The whole vineyard has been ploughed and cultivated till it is absolutely free from weeds, but as the fruit gains size tillage will be suspended, the weeds will be allowed to grow, and when ploughed under they will help to add a little humus to the light soil. On the 29th of May the fruit had already set on the Iron-clad variety, while the other kinds were not yet in blossom. This Iron-clad Grape, so-called because it has been proof against every attack of rot spores, is supposed by experts to be a natural hybrid between some form of *Vitis Labrusca* and *Vitis riparia*. The original vine, which is at least a hundred years old, still covers a great Oak on the banks of a little stream which empties into the Schuylkill a few miles from Philadelphia, and is good for something like a ton of Grapes every year. These vines show their remarkable vigor as compared with such varieties as Concord and Ives by the superior size of their stems, and the pressed juice of the Iron-clad Grape is so rich in color that three or four teaspoonfuls will give a fine claret color to a goblet of pure water. This color, as well as its freedom from rot, gives the Iron-clad exceptional value as a wine-grape, and its juice is in great demand where pure fruit syrups are used in soda fountains. And, by the way, Colonel Pearson finds that the manufacturer of unfermented wine, and of the syrups from strawberries, raspberries, blackberries, quinces, etc., are among the most profitable ways of utilizing fruits.

Colonel Pearson is using no bags, although he may cover some of his grapes for private use. A drive through Vineland, however, showed that in many vineyards this operation had already been performed, although the blossoms had not yet

appeared, and in many others, groups of women were fastening bags over every cluster of flower-buds, pinning the paper to the canes, and not to the stems of the clusters, which were still so tender that the wind would snap them off. These bags protect the grapes from the spores of the fungus which fill the air later in the season, and they were formerly applied when the grapes were about the size of peas. Last year, however, it was found that the infection entered the cluster sometimes before the flower-buds opened, and it was found, too, that many varieties were fertilized perfectly when the flowers were enclosed in paper so as to exclude foreign pollen. It is in view of this experience that the bags are being applied so early to thousands of vines. In Colonel Pearson's opinion, the practice does not pay for ordinary commercial vineyards, although it may pay when fruit of extra quality is desired.

As we drove by the freight-station the area was crowded with wagons bringing in strawberries. The crop is a week earlier than usual this year, and when at its height a dozen or more car-loads are shipped every day, while twenty car-loads of blackberries is an ordinary day's picking. The boast of the villagers that there is never any mud in Vineland is probably a patriotic exaggeration, but that water soon filters away from the surface was evident in the fields, where plows were moving a few hours after four inches of rain had fallen. The soil is by no means uniform, and there are mucky hollows, which look dark and full of humus, and there are places where the clay comes near enough to the surface to mix with the sand and make it consistent. But it is in soil of this character that the effects of dry weather are most apparent. Where the land is said to be "sand all the way down," and the porous sub-soil permits the water to filter quickly through it, the roots of crops seem to penetrate more deeply, and the Corn will be green and growing here when its leaves are curled and wilted elsewhere. Deep-rooting trees like the Chestnut might be expected to thrive even without such evidence as is given by the great stump alluded to in an early part of this letter. As a matter of fact, one of the most beautiful rows of trees I saw was of Chestnuts planted along one of the streets. Each lot-owner was obliged by the terms of his title to plant a double row of trees along his street-front and to seed with grass the strip between the wheelway and sidewalk. As a result the avenues, which are 100 feet wide, are already bordered with fine trees and a continuous stretch of good turf. The general effect would have been better if a single species had been used in each row, and it is unfortunate that so many Silver Maples have been used when better trees have proved themselves so well adapted to the conditions here. I have rarely seen more thrifty Chestnuts, or Oaks of various species, or Tulip-trees, or Lindens, or Honey Locusts than those which shade the walks of Vineland.

Vineland, N. J.

Exhibitions.

Rhododendrons in Boston.

The exhibition of the Massachusetts Horticultural Society, held in Boston last Saturday, was devoted principally to Rhododendrons, for which Mr. H. H. Hunnewell, whose knowledge of these plants is only equalled by his skill and enthusiasm in collecting them, offers every year a number of special prizes. Several large collections were shown; that of Mr. Hunnewell, which was not entered for competition, numbered several hundred heads of flowers, and included all the principal hardy and many half-hardy varieties. The flowers in all the collections were of good size and quality, for the mild weather and the abundant rains of the spring months have favored their development. Nothing very new or striking in hardy varieties appeared, however, while there were probably fewer flowers of half-hardy varieties shown than in previous years. Indeed, the collection of the half-hardy varieties of *Rhododendron Catawbiense* is looked upon with less favor in the neighborhood of Boston than was the case a few years ago. The truth is they are very unsatisfactory plants to manage. Many are shy bloomers under the most favorable conditions in England even; but when it is necessary to lift them in the autumn every year, and protect them in pits through winter, many of the varieties refuse to flower at all, or will only flower once in three or four years. The delicately-colored flowers of such varieties we only see to advantage under canvas, which is essential, too, to shield them from the hot sun and frequent rains of early June, so that if they are not wanted for a flower-show, such as Mr. Hunnewell has provided annually for his friends during the last twenty years, they are practically useless. And even where Rhododendrons are shown under canvas there are now so many high-colored hardy varieties that a

remarkable display can be made with them alone. Hardy varieties with flowers of the brightest scarlet are common now, as are those with white, pink, rose and all the self-colors. Only dark flowers, with light centres, and white or pale flowers, with dark blotches, are wanting among the hardy varieties. These, especially the last, are exceedingly beautiful and showy, but they are, unfortunately, very shy bloomers, and produce their flowers very sparingly even when they are not transplanted, as they must be in this climate every autumn. Mr. R. T. Jackson exhibited sixty-seven varieties of the German Iris, many of great beauty; and there were several unusually large and attractive collections of wild flowers staged. The exhibition, owing to the advanced state of vegetation in eastern Massachusetts, was held one week earlier than usual.

Notes.

Along one of the boundaries of the Germantown Nurseries is a fine hedge of "*Elaeagnus parvifolia*." This plant endures cutting well, and makes a close, solid growth. When the plants are in bloom the hedge is very fragrant, and the boys find its fruit palatable.

On the nursery-grounds of Messrs. Hoopes, Brother & Thomas, near West Chester, Pennsylvania, stands an *Acer pictum* (sometimes called *Acer latum* and *Acer Colchicum rubrum*), the trunk of which measures six feet three inches in circumference. The tree is about thirty-five feet high.

A charming combination of colors can be obtained by planting some of the varieties of the German Iris with pale blue flowers among plants of the Japanese *Azalea mollis*. They flower simultaneously, and a large bed arranged in this way, which recently came under our notice, was a refined and beautiful object.

Last week Mr. John MacElvery, of Flatbush, Long Island, sent to this city some fine spikes of the white variety of *Gladiolus Colevillei* which had bloomed in the open air after having received no special protection during the winter. The flower is delicate and graceful, and is largely grown in England by florists, who supply Covent Garden.

A correspondent, interested in Professor Goff's article on Muskmelons in a recent number, enquires how the vines can be saved from the attacks of the Squash-bug. To this Professor Goff replies: That if a tablespoonful of kerosene is stirred through two quarts of common land-plaster and the mixture is sprinkled on the vines, the effect will be good, although he cannot vouch for this as a sovereign remedy against this troublesome enemy.

The new Strawberry, known as the Pearl, is yielding a large crop of fruit, of very uniform size in some parts of southern New Jersey this year. The fruit is sharply conical and of excellent flavor. Colonel Pearson, of Vineland, and other large growers consider it most promising both for market and home use. Whether it will succeed on heavier soils remains to be seen. On the highly-manured lands of Bridgeton, a few miles away, it does not thrive as well.

Temple & Beard send us a specimen of a remarkable variegated-leaf form of the Sugar Maple which has been growing for several years in the yard of a house in New York, and which they have now transferred to the Shady Hill Nurseries. The whole blade of the leaf, with the exception of the principal veins and a few green blotches, is clear, bright yellow. If the yellow color is constant this will make an interesting addition to the list of abnormally colored trees—which many people consider beautiful.

In response to a request made in behalf of the West-End Improvement Association, the Torrey Botanical Club and the Park Commissioners of this city, Mr. Frederick Law Olmsted and Mr. J. B. Harrison, have prepared a paper upon the plantations of Central Park, with special reference to the alleged excessive thinning out of trees during the past winter. The report agrees with the views already expressed in this journal. Nothing was found to indicate that any of the cutting had been done without regard to the requirements of the Park design, but, on the contrary, evidences were apparent that a more liberal use of the axe is needed.

Mr. Carmen, of the *Rural New Yorker*, brought to his office, on Saturday, some flowers of a new Rose, which he obtained by crossing Harrison's Yellow upon *Rosa rugosa*. The flowers resemble those of General Jacqueminot closely in color, and they are very fragrant. The foliage is not quite as dark as that of *R. rugosa*, nor quite as leathery, but the leaflets are much larger. The plant seems to be as little liable to the attacks of insects and fungous diseases as its female parent.

Mr. Carman assures us that the plant bloomed constantly through the summer last year, and altogether it seems to possess a combination of sterling qualities.

A committee has been appointed to receive contributions for a monument to be erected in memory of the late William Court, who for so long a time represented in this country the house of James Veitch & Sons. Mr. Court was widely known and highly esteemed here, not only among dealers but among buyers of Orchids and other choice plants. The monument, as designed by a London architect, will cost about \$500, and all moneys above that amount will be disbursed for the benefit of Mr. Court's four orphan children. Contributions may be sent to Mr. Alfred Outram, of the firm of B. S. Williams & Co., London, or to any member of the American committee, which is constituted as follows: Robert Craig, Philadelphia, Chairman; A. D. Cowan, New York, Treasurer; Peter Henderson, New York; Wm. Elliott, New York; John Thorpe, Pearl River, New York; Wm. Gray, Albany, New York; John N. May, Summit, New Jersey; Robert Halliday, Baltimore; W. R. Smith, Washington; Wm. Robinson, North Easton, Massachusetts; David Allan, Mt. Auburn, Massachusetts.

A correspondent of *The Garden* (London) writes that he has preserved all the plant and flower catalogues which have been sent him during a period of forty years, and that they now supply much interesting information with regard to changes in taste and in commercial enterprise. Their lists, we are told, offer "hosts of beautiful and most interesting things never heard of now, and most likely very many lost to cultivation. One list offers: Acacia, 59 species; Berberis, 15; Canna, 57; Chorozema, 10; Genista, 14; stove and greenhouse Hibiscus, 9; . . . ornamental fruit-bearing Solanums, 23; . . . Kennedias, Hardenbergias and Zichyas, 25; ornamental Gourds and other cucurbitaceous plants, 117; and so on. Where are the seedsmen now that can offer us anything approaching this? . . . Why do not some of our great nurserymen, instead of ransacking the furthestmost corners of the earth for some new orchid, or seedsmen, instead of giving us the everlasting Cineraria, Calceolaria, Primula and such like, . . . re-introduce some of the multitude of beautiful and interesting plants cultivated in the last generation? They would be novelties to-day."

"A plan is on foot," says a correspondent of a New York daily paper, "to make an addition to Chicago's Lake Shore Drive, which, if carried out, will give this city one of the finest and most extensive systems of boulevards and drives in the world. The present idea is to extend the beautiful drive which runs along the lake, through the handsomest portion of the North Side and through Lincoln Park. This drive now stops at the north end of the park. The new plan, which is well under way, is to extend it as far north as Lake Bluff, twenty-five miles north of Chicago. This section of country is by far the prettiest in this neighborhood. The flat shores of Lake Michigan gradually slope upward until at Lake Bluff they assume the shape of almost perpendicular banks, rising to a height of 100 feet, and showing the waters of the lake far below. A heavy growth of timber stretches toward the west, while at other places it is broken by deep ravines that open up unexpected glimpses of the lake through the dark foliage. The new drive will run along as close to the lake as possible, and through the villages of Evanston, Highland Park, the new military post, Fort Sheridan, and Lake Forest.

Accounts of the opening of the Paris Exhibition prove that it will be of great interest to horticulturists and lovers of the art of gardening. The gardens of the Hôtel des Invalides contain the products of the French colonies and of the several Ministries. Along the Quai d'Orsay are the halls of agriculture and viticulture, the fisheries and the general food products, while the great Trocadero gardens are given up to fruits and flowers, grown under glass and in the open air. The whole of the Champs de Mars, formerly nothing but a dusty desert, is transformed into a charming park, with verdant lawns, shady paths, masses of shrubbery and multitudinous flower-beds. The plans were traced more than two years ago by Monsieur Alphand, Director of Public Works, and were mapped out on the site itself. Trees and shrubs were then set out and sods were laid, and the place now looks like a park of many years' standing. A good deal of injury was done by the crowds that attended the opening ceremonies, even the energetic *gendarmes* of Paris being unable to control so vast a multitude. Scores of blooming flower-beds were trampled into mire, and many shrubberies and lawns were seriously injured; but the damage was being repaired, and in a few weeks no trace of it will appear.

Specialized Gardening.

A READER of this paper asks us to describe a spring garden made a few years ago in the neighborhood of Boston, by a lady of taste, which has attained already to some local celebrity, and received last year a special prize from the Garden Committee of the Massachusetts Horticultural Society. It occupies the site of an old-fashioned formal garden, in a sort of amphitheatre, of a third of an acre, perhaps, in extent, formed by deciduous trees of fair size, in front of which were a few fine old shrubs, relicts of the past. The ground slopes gradually to the south and west, the centre of this slope being occupied by two noble Hemlocks, with wide branches sweeping on the turf. The problem to be solved was how to make this piece of ground most attractive during the months of May and June, the only part of the year when the place is occupied. The walks, of which there were a number, and all the flower-beds occupying the space surrounding the two Hemlocks, were first removed, and then a broad border was made continuously round the amphitheatre, except at three points, where entrances from the outside were left. This border was planted with shrubs, the general effect then being that of a small lawn of generally circular outline surrounding the two Hemlocks and in turn surrounded by a border of shrubbery backed with larger trees. No treatment could be more simple, and there is no description of garden which can be more easily made. The success of such a garden depends on proper natural surroundings, a fitting selection of plants for the borders, and the adoption of graceful and natural curves for the line dividing the turf from the plantations. The selection of plants, in themselves suited for such a garden and harmonious each with his neighbor, is a matter demanding taste and some technical knowledge; and the introduction of a single inharmonious element might easily destroy even an exceptionally good site like the one we have briefly described. The problem of selection has, however, in this particular case been greatly simplified by the fact that this garden was to be used during two months only; such plants as do not flower during these months could there-

fore be discarded. Generally speaking, tall shrubs, such as Lilacs, dwarf Apples, and various Plums occupy the back of the border; before these *Spiræas*, *Exochordas*, *Calycanthus*, *Forsythias*, Tartarean Honeysuckles, and others which may be expected under favorable conditions to attain a height of six or eight feet, are grouped as naturally as possible, while the margin of the bed, for a space of three or four feet wide, is occupied with isolated masses of *Daphnes*, *Andromedas*, small *Azaleas*, and other dwarf spring-flowering shrubs, the spaces between these masses being planted with such hardy bulbous and other perennial plants as bloom with them. This low growing margin is broken occasionally by a plant of *Spiræa Van Houttei* or of *S. Thunbergii* planted close to the turf, to send its branches out over the green, and so to remove all idea of stiffness or formality.

This garden is in itself a beautiful creation, and a good deal can be learned in it, of how to associate, and of how not to associate, plants when natural and pleasing effects are sought. It is surprising, for example, how entirely out of place a mass of high-colored garden Tulips or of double Hyacinths appear near the margin, and how admirably single Narcissi and Scillas look when used in a similar situation. All herbaceous plants, in fact, greatly altered by long cultivation, appear here inharmonious, while Violets, hardy Lady Slippers, Trilliums, Bloodroot and other inhabitants of the woods, produce the best possible effect. There is a danger always in such a garden of over-doing and of crowding in too many plants, either from the desire of possessing a great number of varieties or of producing immediate effects. Close-planting in the beginning is well enough, but unless some plants are removed as fast as they begin to encroach on their neighbors the whole feeling of the scheme will be destroyed, for certainly there is no more melancholy spectacle than a mass of shrubs so crowded together that they can grow only upwards, without lateral branches and without foliage and flowers, except at the very summit of the stems. A deciduous shrub is only really handsome when it has play for full and free development, and in the garden in question the neglect of timely thinning has already left its mark.

But it is time that we should leave this delightful spot, and turn to the general conclusion to which it naturally leads. It is that specialized gardening, that is, the concentration of effort in one direction must produce the most satisfactory results, and that it is, therefore, the wise and proper method to adopt. This is particularly true in America to-day. A large proportion of our best gardening is in connection with suburban homes; and every year the custom of leaving these homes about the 1st of July for a three months' vacation at the sea-shore or in the mountains, prevails more and more in this country. Anything like out-door winter-gardening in the Northern States is a delusion. The climate from December till April makes it impossible; so that when a man leaves his home early in July, and does not return to it until after frost has nipped vegetation, he can obtain the greatest amount of pleasure by growing only such plants as are at their greatest beauty between the 1st of April and the 1st of July. But specialism in gardening can, of course, be carried much further, and the further it is carried the greater may be the pleasure to be derived from it. Suppose, for example, that instead of a garden of mixed plants selected because they flower during May and June, a number of such gardens, each of which might have been much smaller, had been planted, one with Chinese Magnolias, another with dwarf Apples, another with Lilacs (and no one who does not know the varieties of these plants produced in recent years, can have any idea of the beauty of Lilacs), another with hardy Azaleas, another with Rhododendrons, and so on through a dozen other genera of plants, each of the series being arranged with perennial plants to flower simultaneously with its special tree or shrub. Each of these gardens would be perfect during a single week, perhaps, only, but it is easy to comprehend how the pleasure which could be ob-

tained from it would be great in proportion as it was concentrated. A man with abundant means and sufficient ground at his disposal might make a dozen such gardens without greater outlay than is required for the mixed planting now in vogue; or, in a village, a dozen men might join together and each one plant the surroundings of his villa or cottage with some plant or plants, for a particular effect, for one particular time, leaving to his associates to carry on the display from week to week. Such a scheme might be difficult to inaugurate, but if carried out to its possible limit it would develop a greater excellence in gardening, and produce more marvellous results than have yet been attained.

A lady who carries on a large farm and has for many years been a successful planter of trees, and a lover of them and of country life, sends us some male flowers which she has found growing on one of her young Pines, with the query, whether they are not some new form of disease which has appeared on her trees. We mention this fact, which does not astonish us as much, perhaps, as it should, as an illustration of how little even well educated and intelligent people know about the commonest trees which they see growing about them every day and as an argument in favor of giving children in the schools some elementary instruction about trees. The men or the women who can readily distinguish all the trees among which much of their lives are passed, and who have mastered some of the simple secrets of their life histories, have prepared for themselves an amount of pleasure which the person ignorant of such matters can hardly realize. This is a pleasure, too, of a sort which is as enduring as the trees themselves, and which, like them, bursts out each year into new and more vigorous growth.

A New England Village Street.

THE people of New England have reason to be thankful that their original forests produced many trees whose wood was of much greater value than that of the American Elm, for this, no doubt, is one reason why so many magnificent specimens of this tree have been left to shelter farm-houses and shade the highways of the Eastern States. It is plain, too, that its value as a street-tree was recognized there as soon as street-planting was begun, and many a New England town, like Old Hadley and West Springfield and Conway, has gained a name for beauty because the men who dwelt in it a hundred years ago appreciated the dignity and grace of the Elm, with its columnar trunk, buttressed at the base with sturdy roots, and its massive branches arching outwards to hold aloft its dome-like crown of foliage. The Sugar Maple is another of our noblest northern trees, although when young its outlines are rather too smooth and featureless. With advancing years, however, this Maple develops a certain individuality, with a more rugged contour and deeper shadows; and no one sees the avenue of Maples at Hyde Park on the Hudson, for instance, without a feeling of unqualified admiration.

Our illustration on page 283 shows a remarkable row of each of these trees. It is a view looking down the main street of Charlestown, New Hampshire, a town that was a frontier post in the old French war, and afterwards as a shire town, became the home of many people of more than ordinary public spirit and intelligence. In 1800, some of these residents planted a row of Elms on one side of the street and one of Sugar Maples on the other, and their successors continued the practice as the village grew, until the street is bordered with trees for about a mile. The two large Elms in the foreground on the right belong to a still earlier planting. They stand in front of the site of the old tavern which was kept by Colonel Abel Walker, and as the sign of the tavern, now in possession of the Massachusetts Historical Society, bears the date of 1785, they were probably planted as early, at least, as that year. Three other trees probably date from the same period, as they are larger than those known to have been planted in 1800, and

at five feet from the ground vary in circumference from twelve and a half to nearly fifteen feet, and appear to be nearly one hundred feet high. The avenue of Elms seen in the background is probably unsurpassed in New England, and later plantations on the side streets so hide the houses that the town looks like a continuous forest to one who looks down upon it from any of the neighboring hills.

The view is reproduced from a photograph taken by Mr. S. S. Webber, a grandson of one of the old residents who practiced medicine in the town for more than sixty years.

Horticulture in Ancient Egypt.

FROM an article on "Egyptian Horticulture," by Monsieur G. Delchevalerie, recently published in the *Revue Horticole*, we have gathered a few facts which may be of interest to our readers in connection with the chapter on Egyptian gardening-art that was printed in these pages not many weeks ago. On the tomb of Ti, in the vicinity of the great pyramid, which dates from about forty centuries before Christ, the harvest of the Lotus and the manufacture of wine are represented, together with irrigating machines and horticultural tools similar to those in local use to-day. The tree called "Heglig" (*Balanites Ægyptica*), was largely cultivated in the Thebaid, and was sacred to Isis because it would grow even in the desert sand, and also because its edible fruit was shaped like a heart and its leaf like a tongue. The Sycamore, as has been said, was one of the chief trees of Egypt and likewise the Doum Palm (*Hyphane Thebaica*) and, of course, the Date Palm. Lentils and Onions formed the main food of the people and Melons, Leeks, Radishes, Watermelons, Garlic and Chicory were everywhere cultivated, the last-named being indeed prescribed by a special law. Oil was obtained from the Castor-oil plant, Flax, Carthamus, Sesamum and Turnip. Olive-oil was obtained from Judea. Herodotus is careful to note that in his day the Olive was only grown in one or two districts and there not with great success. From two species of Lawsonia the ancient like the modern Egyptians obtained the henna with which to dye their finger-nails. In mummy cases many fruits have been found in a recognizable condition—Dates, Figs, Bananas, Lemons, Grapes, Doums, Pomegranates, Castor-oil beans, Sycamore Figs and Lotus beans, as well as bees-wax, gum-arabic and flowering shoots of Lawsonia. The Vine was grown for ornament over arbors and porches and was cultivated on trellises. An ancient legend explained that the first idea of pruning it came through observing a specimen which, after a goat had eaten off the tips of its shoots, bore with greater luxuriance than usual. Beer made from cereals was in common use among the lower classes, and as Hops did not grow in Egypt a bitter infusion of *Lupinus tenuis* was used instead. During the rule of the great conquering dynasties part of the tribute always exacted from subjected peoples was in the form of useful and ornamental trees and plants not indigenous in Egypt.

The cultivation of Sugar-cane was not introduced until the time of the Mohammedan caliphs, and then its chief use for a long period was to be eaten raw. At the present day the Egyptian laborer is never so happy as when squatting hour after hour on his heels beside the Nile chewing an immense stick of Sugar-cane. Nor did the ancient Egyptians cultivate the Bean which now plays so large a part in their domestic economy; it was considered by the priests an "unclean" plant. It is needless to repeat what has recently been said in these pages about the Sacred Lotus and the various Water-lilies which grew in Egypt. The Poppy was another favorite flower. The Papyrus does not now grow there spontaneously and it is a question whence the ancient inhabitants originally obtained it; probably from Upper Nubia and the Soudan countries where it grows in enormous thickets.

At a feast celebrated in Alexandria 284 years before Christ, during the reign of Ptolemy Philadelphus, a conspicuous feature in a splendid procession was a car, twenty cubits in length, which was drawn by three hundred men and surmounted by a wine-press full of grapes that were being pressed by sixty satyrs, singing vintage songs to the accompaniment of flutes. The wine ran out into the road and was served to the public by numerous children carrying vases of gold, silver and parti-colored enamel.

When Egypt fell under the dominion of Rome half a century before Christ, it became, as is well known, the granary of the imperial city, and furnished it with vast quantities of wine as well as cereals. This state of things lasted for three centuries and a half until about the year 330 A. D., when the

Greek Emperors at Constantinople obtained possession of the country. In 638 they were followed by the Arab invaders and the long line of Egyptian caliphs was established. Then, of course, the cultivation of the Vine was abandoned.

"California Lilacs."

ONE of the most prominent, as well as ornamental, shrubs of the Santa Cruz coast range of mountains is the *Ceanothus* in its various forms and species. As early as January some flowers begin to appear. But May is the month of its greatest glory. On the sea-side slope of these mountains there are five distinct species: (1) *Ceanothus cuneatus*, Nutt.; (2) *C. papillosus*, Torr. & Gray; (3) *C. incanus*, Torr. & Gray; (4) *C. thyrsiflorus*, Esch.; (5) *C. Andersoni*, Parry.

I mention them in the order of their blooming. The flowers are all of a pleasant fragrance, and when in bloom give a charm to these regions peculiarly attractive to the lover of nature.

Dr. C. C. Parry, the eminent botanist, who for forty years or more has made observations from time to time on the Pacific Coast, has published lately in the "Proceedings of the Davenport Academy of Sciences" a paper on the *Ceanothus*. To him I am indebted for much information in regard to these shrubs; and with him a few days ago I had the pleasure of a visit and trip of observation to the habitat of each of the above-named species.

The doctor having an eye for the beautiful as well as the new in botany, says: "If asked to designate a spot where they (the *Ceanothus*) occur in the greatest profusion and variety I should not hesitate to award the palm to the Santa Cruz range of mountains."

Ceanothus cuneatus has pale blue or whitish flowers in small, rounded clusters, small opposite leaves and branches, gray bark; a very pretty shrub, three to eight feet high.

C. papillosus has deep sky-blue flowers in small globose clusters. The dark green leaves, by which it is most readily distinguished, carry small pimples (papillæ) on the margin and upper surface. Whilst May is the month of its greatest bloom, flowers can be found at all seasons.

C. incanus is well-named, for the leaves and branches are hoary or white. The common name is White Thorn, so named because of its spinose branches. The leaves are broad, ovate and triple-veined. The flowers are whitish, in short racemes, and slightly fragrant. The bush is five to fifteen feet high, with a rounded shape, but with crooked and very angular branches.

C. thyrsiflorus is a graceful shrub, reaching in many cases thirty feet in height. It may be recognized at a long distance by its slender branches of pale green leaves and sky-blue sprays or plumes of flowers, looking like the smoke from a camp-fire. This species and No. 2 are not often found growing together. The traveler, however, will often pause to admire the flowering clusters of each as they stand against the mountain-side, giving an indescribable beauty to the landscape.

C. Andersoni is not very abundant, and only occupies the higher summits of these wooded mountains. With its sprays of pure white flowers, slender and somewhat drooping branches, small, modest, feather-veined leaves of a pale green, it readily attracts attention. When first seen by me in 1882 I secured a few specimens of the flowers, but thinking it possibly a hybrid, they remained unnamed in my herbarium until Dr. Parry saw them; and, after careful investigation, concluded that they belonged to an unnamed species, which he described in the paper I have mentioned.

The *Ceanothus* in these mountains are commonly called "Lilacs," or, as I have frequently heard, "Laylocks." They flourish most abundantly among the openings of Oaks, Redwoods, Pines and Firs, on the borders of basins and cañons. They are easily cultivated, and might be used to ornament grounds, or possibly for hedges. Nos. 1 and 3 might grow well in colder climates. I have found them at an altitude of 7,000 feet, where the winters are long and severe.

"Hybridity," says Dr. Parry, "which would seem to be largely favored by the profusion of showy and occasionally fragrant flowers, and which has been suffered to be largely instrumental in confusing species, is not a very troublesome feature in field observation where alone it can be properly studied."

And yet in our little walk among these plants we found some very curious combinations which could not be solved very easily in the field, much less in the herbarium. Some of these hybrids were very pretty, too. But the parents were found growing on either side, and the blending of characteristics were so apparent that a botanist would seldom be deceived.

Santa Cruz, Cal., May 15th, 1889.

C. L. Anderson.

New or Little Known Plants.

Rudbeckia laciniata.

THE most conspicuous feature in the herbaceous flora of North America is found, perhaps, in the great number of autumn-blooming plants of the natural order *Compositæ*. No foreigner visits any part of this continent during the months of September or October without being struck by the great masses of color produced by our Asters, Golden-rods, Sunflowers, and other plants of their order. There are among them many subjects which are admirably suited for cultivation in herbaceous borders, or for naturalization in less carefully kept parts of the garden; but although sometimes found in the best European gardens, they have never yet received in this country anything like the attention which they merit.

One of the best of these plants for the garden is *Rudbeckia laciniata*, a figure of which appears in our illustration upon page 281. It is an old inhabitant of gardens, having been cultivated by Tradescant, the gardener of Charles the First, as early as 1640, and is sometimes, although not very often now, found in collections of herbaceous plants here. A well-grown plant forms a stout mass of dark green and rather coarse foliage, sometimes four feet high, by nearly as much through, and covered during the month of September, year after year, without any care or attention, with long-stemmed, terminal heads of bright yellow flowers, which light up the herbaceous border or the margins of a wood-walk as few other plants are capable of doing.

Rudbeckia laciniata is a widely distributed plant, being found from Canada to Florida, and as far west as Montana and New Mexico.

The *Rudbeckias* are confined to North America; and twenty-one species have been distinguished. They all, with one exception, have bright yellow ray-flowers, and elongated dark brown or nearly black discs. They are all worth a place in the garden.

Cultural Department.

Bagging Grapes.

SINCE the enclosing of the clusters of grapes in paper bags to preserve them from the germs or spores of *Læstadiæ Bidwellii*, the seed, so to speak, of the Black Rot, was suggested, I have practiced it; in a small way at first to test its efficacy, and since I became satisfied on this point I have annually bagged all the best clusters of all the varieties subject to this malady, using from 12,000 to 15,000 bags for a small vineyard. But after all that has been written on the subject for the past few years, I frequently find people who have scarcely heard of the practice. These spores are invisible to the naked eye, but they float about in the air, and, lodging on the skin of the grape, are ready to germinate under favorable conditions of moisture and temperature. To prevent their coming in contact with the grapes the clusters are enclosed in paper bags, the mouth reaching over the cane, folded and secured with a pin. Some writers give instructions to gather the top of the bag around the stem of the cluster and pin it, but this is bad advice; first, because if it is done as early as is advisable to protect the fruit, the young clusters are too tender to withstand the strain of wind and water, and many of them break off before they acquire sufficient strength to resist the pressure; and, secondly, many, I may say most varieties of Grapes have such short stems that there is no room between the cluster and the cane to fasten the bag. The Brighton, Empire State, Noah and a few others are not subject to this difficulty, but for the first reason assigned the advice is dangerous.

A two-pound plain manilla paper bag of fair quality, such as grocers use, is the size generally recommended, but I use the one and a half pound size in preference. This bag measures six and three-eighths by nine and a half inches. The two-pound bag is of the same length, but a little wider, which is of no advantage, and costs more. An inch or two added to the length would be desirable for many varieties. The patent square-bottomed bag possesses no advantage over those of the old pattern, and in fact I should prefer the latter

at the same cost. The corners of the bags are cut off—at the bottom to let out any water that may enter, and the tops to facilitate its reaching around the cane. In fact, if the bags were open at the bottom they would probably be quite as efficient. The tighter and more perfect the roof or top of the bag to exclude the entrance of the fungus and water from above, the better. I sometimes use three-pound bags, enclosing two clusters in each, which answers very well where the clusters are close and compact, but with looser clusters they are apt to grow into each other.

Complaint is sometimes made that the bags are not a complete protection, as the grapes sometimes rot in the bags. This is true, but in such cases it is fair to presume they were infected before the bags were applied. It is a great mistake to defer bagging too late. The longer it is put off after the grapes are fairly set, the greater the risk of failure. I have demonstrated to my satisfaction that if the grapes are uncontaminated when the bags are applied, they will remain so till maturity if the bag remains perfect. Sometimes small hail-stones will perforate the bags, and the rot spores will thus gain an entrance; and sometimes a manufacturer will use paper of an inferior quality that will not resist the rain-drops, but generally, they will withstand the weather through the season. Some varieties of Grapes having strong, perfect flowers are self-fertilizing, and these can be bagged before they bloom, as they will fertilize perfectly in the bags. In fact, we have good reason to believe that many blossoms are fructified before they open. The Niagara, Cottage, Concord and Clinton are of this class. On the other hand, varieties with imperfect flowers seem to need the pollen of other varieties to enable them to set their fruit. To bag these before blooming would, of course, deprive them of this assistance. Bagging is not only a protection from rot, but from birds also. Bagged fruit is a little later in maturing, and in the case of white grapes a little greener in color, but the bloom and appearance is more perfect. I have not been able to perceive any tendency to tenderness of skin as claimed by some, in bagged specimens.

Does bagging pay is the question universally asked, and I can answer it in both the affirmative and negative. To the amateur who thoroughly appreciates fine, well-grown, perfect clusters that excite the admiration of all beholders, to the professional grower who competes for the prizes at exhibitions, or who aspires to fancy trade at fancy prices, I say yes. But to the one who cannot command five cents a pound or over for his fruit I say no, emphatically.

The experiments made during the past two years in this country with preparations of copper-sulphate for the prevention of the mildew of the Vine have seemed to indicate that these mixtures were also antidotes for Black Rot. If further experiments should fully establish this fact we can dispense with bags, save the labor, and grow grapes out-of-doors as in former years. I learn the rot has appeared already at Vineland, and this season will perhaps fully demonstrate the efficiency of this treatment. The preparation considered the best is what is known as the Bordeaux mixture, which is made as follows: Dissolve six pounds of sulphate of copper in hot water, and slake four pounds of fresh lime in sufficient water to make milk of lime; mix the two together, and add enough water to make twenty-two gallons. This mixture should be sprayed on the vines at intervals of ten days to two weeks during the summer. This can be done with any of the force-pumps with a nozzle that delivers the liquid in the form of mist. The Eureka Sprayer, a modification of the Vermorel machine sent over here from France, is recommended highly by those who have used it.

Montclair, N. J.

E. Williams.

Summer-Flowering Bulbs.

AN important point to remember in the culture of these bulbs is that their flowering season is the rainy season of their native countries. This is particularly true of the Tigridia and the Gladiolus, which bloom in cool, rainy or winter season, while their period of rest is in the excessive hot, dry weather peculiar to their home. The Calla, a native of the Nile, blooms when the roots are a foot under water in the spring, and rests at low water, when their roots are as dry as it is possible to be and live. The same is the case with many of the so-called Cape bulbs.

The Gladiolus will grow under any conditions, but it will not grow well. A cool, moist atmosphere is the one in which they delight. Climate alone is what makes them succeed so well in England. Last year we had rain in abundance, with low temperature, and never before have we had such perfection in Gladiolus flowers. We make a mistake in planting our bulbs

too early. They should be kept cool and dry, and in a dark room until the 1st of July, then they will come into bloom about the 1st of October, throwing up spikes that for number and size of flowers would hardly be recognized as the varieties that bloomed in midsummer. If planted early, so as to flower in July and August, they should be protected against the heat of the sun by a lattice or light canvas covering, and the bed should have a light mulching of newly-cut grass. This will keep the roots cool, and is not unsightly. The capabilities of the Gladiolus are only known to those who grow them in this manner. The soil makes but little difference with Gladioli. Any soil that will yield good crops of potatoes will be equally good for these plants. If it is heavy, plant shallow, say from one to two inches deep; if light, from four to six inches will be better. It is best to use ground made very rich for some other crop the previous year, as fresh manure does not suit them.

Lilies, quite as much as Gladiolus, need a good mulching to keep the roots cool and moist. A bed of Lilies that has been properly mulched a few years will yield enormously; more than thrice the number of flowers will be produced, and they will be much larger, with better defined colors and of greater substance. A Lily-bed should be made in a position where it can remain undisturbed for a number of years, and as long as the plants flower well. The Ascension Lily (*L. candidum*), the handsomest of all Lilies, should be planted in July or August, while the bulb is resting. They will live when planted at any time, but will flourish only when planted at the proper season.

Tigridias are Mexican bulbs, and do not endure our northern sun. Treat them as Lilies should be treated. In October the flowers remain open nearly the whole day, while in August they close before noon. Give them a moist, cool situation, and they will appreciate the treatment.

Dahlias are not properly bulbous plants, but they may properly be included in the same list. To be grown well they must have a cool and moist soil, which is usually a heavy one. If the garden does not afford such assist it by heavy mulching. If Dahlias are grown simply for distant effect give them plenty of room to branch out and plenty of plant-food, for they are great feeders. If individual blooms are desired, thin out the smaller branches and disbud. We prefer the former treatment, and want the plant to occupy all the space it requires, and to produce as many flowers as it likes.

Floral Park, N. Y.

C. L. Allen.

Notes on Wild Flowers.

Viola cuculata, now in flower, has the greatest number of forms of any of our northern Violets. Under cultivation the larger forms attain great size, and the profusion of large, deep green leaves make it a desirable plant. It likes a moist and rich clay loam, but will live in almost any soil. *V. pedata* (Bird's-Foot Violet) is a showy species, bearing numerous large blue flowers. A moist, loamy soil seems to suit it, yet it will grow in any ordinary soil. *Viola Canadensis* is the tallest species we have in New England, and it often reaches a height of two feet or more. The white flowers, veined with purple, are borne in great abundance. It is a more difficult plant to grow to perfection than the Violets before named, but if given a moist, rich soil in the shade it will become established.

Camassia Fraseri, now in flower, has a short, loose spike of blue flowers and grows about eight inches high. It seems to be hardy, having stood the past two winters here in the open ground without protection. *C. cusickii*, also in flower, is by far the largest *Camassia* we have seen. The bulbs are often twice the size of an ordinary hen's egg. The stems attain a height of over two feet, bearing long spikes, or racemes, of light blue flowers an inch in diameter, and there are frequently over forty of these to one spike. The plant is not difficult to cultivate, and, if planted deep, ought to be as hardy as most of the Lilies.

Aplectrum hyemale (Putty root) is not a showy Orchid. Its curious single leaf, which, like that of *Calypso* and of *Tipularia discolor*, comes up in autumn, remaining green through the winter until flowering time, then dying down to the bulb, is one of its chief attractions. It may be planted with success at any season, in moist, well-drained soil in the shade.

Arethusa bulbosa, now in flower, is one of the most charming little Orchids we have, although it is generally considered difficult to grow. It is a bog plant, and needs plenty of moisture. The finest plants we have seen were growing naturally in thick beds of Sphagnum moss. It sometimes attains a height of fourteen inches, but is oftener not more than six. We have planted it in autumn in a moist clay loam with good success. But the best place for it is in the Sphagnum beds of artificial bogs, where it would be sure to thrive.

Fig. 113.—*Rudbeckia laciniata*.—See page 279.

Our hardiest Lady Slipper is *Cypripedium pubescens*. We have transplanted it into all kinds of soil and at all seasons when the ground was not frozen, and it has always lived. It will grow in the sun, but prefers the shade. Its flowers are very like those of *C. parviflorum*, except that they are larger. Indeed, it is hard to distinguish between large specimens of *C. parviflorum* and small ones of *C. pubescens*. *C. acaule* is the most difficult to grow of our hardy *Cypripediums*. It likes a loamy, well-drained soil and needs shade. The flowers, always solitary, vary in color from a rose-purple to almost pure white, and in the highest colored forms are very showy.

Another pretty Orchid, now at its best, is *Orchis spectabilis*. Its flowers are pink-purple and white in color, borne on short stalks three to seven inches high. Its leaves are broad and lie close to the ground. It is an easy plant to cultivate if given just the right soil and situation, and will not thrive in any other. It needs plenty of fine, well-decayed leaf-mould or chip-dirt about its roots, plenty of moisture, yet perfect drainage and shade.

Fritillaria recurva, now almost out of flower, is a plant of the Lily family from California. It grows from six to twelve inches high, bearing several red flowers tinged with yellow, bell-shaped, three-quarters of an inch long by half an inch in diameter and resembling a Lily. It is one of the finest of this genus. The bulb is flat, an inch broad by one-fourth to half an inch thick. The plant needs well-drained soil and should be protected from frost in winter, or stored in dry sand in the cellar.

Phlox divaricata is a good plant for cultivation. The colors of its flowers are not so bright as those of some other Phloxes, but they are borne in great profusion and last a long time. It thrives in ordinary soil. *Silene Pennsylvanica* is now in bloom. The variety with pinkish flowers is a pretty plant, but the white variety is not so desirable. *S. Virginica* (Fire Pink), also in flower, is one of the finest species of this genus. Its flowers are large, not very numerous, but of a deep crimson color. It is easily grown from seed, or can be readily transplanted.

Charlotte, Vt., May 3d.

F. H. Horsford.

Orchid Notes.

A GREAT many *Cypripediums* are now in bloom at this place, the most distinct and conspicuous among them being the rare *C. Mastersianum*, a plant introduced from the East Indies, though the exact habitat is not at present known. The foliage of this plant resembles *C. ciliolare*; the sturdy, hirsute scapes bear a single flower which in general outline is like that of *C. Hookera* but is much larger; the sepals are green, the dorsal one having a deep border of yellowish-white; the petals and lip are reddish-brown the former prettily spotted with dark purple. The general characters of growth and flower suggests a natural hybrid between *C. hirsutissimum* and *C. Hookera*. Another fine plant is *C. macropterum*, a hybrid from *C. Lowii* and *C. superbiens*, which bears a resemblance to both parents, but has foliage more distinctly that of *C. superbiens*. This superb Orchid rivals the famed *C. Morgania* in the elegance of its flowers, and, like it, is of strong growth and bears three flowers on a scape. *C. orphanum* is rare and extremely attractive, being the very best of its section. It possesses the free-growing qualities and habit of *C. Druryi*, and flowers as freely as *C. barbatum*. *Cypripedium Lindleyanum*, though known for nearly half a century, has always been a very rare plant until quite recently. It is found growing in British Guiana in swamps and on rocks where there is considerable water. In cultivation it needs to be treated almost as an aquatic, with strong heat and a very light position. The scapes are about three feet long, bearing four to five yellowish-green flowers, closely veined and reticulated with reddish-brown. *C. leucorrhodum* is a hybrid of *C. Roezlii* and *C. Schlimii album*, and is the best of this class. The growth is very strong, and produces branching scapes with many pale-rose and white flowers, the lip being prettily speckled on the inside with green. *C. Sedeni candidulum* is very near this species in its flowers, but differs considerably in growth. Branching scapes of this very pretty kind now bear fifteen to twenty flowers each. Several plants of the grotesque flowered *C. caudatum* are in full bloom, also the hitherto very rare white variety, *C. Wallisii*, and the quaint, slipperless *C. Lindenii*. A plant of the gay little *C. barbatum Warneri* has twenty-seven flowers, while the bold, dark-flowered variety *C. giganteum* is represented by a plant with thirty-seven flowers. *C. selligerum majus* is an immense improvement on the type, and Veitch's *C. Harrisianum superbum* is the best of the many varieties of this old and well-known hybrid. A plant with us is showing ten scapes.

Erises crassifolium.—This species is again in flower with us. It is one of the handsomest of the genus. The habit is dwarf and thick-set, and, as the name indicates, the light-green leaves, sparsely dotted with purple, are very thick and fleshy. The racemes are long and drooping, bearing a number of large, handsome, purple-amethyst and white flowers. This plant, in cultivation, grows very slowly, and is seldom seen in bloom; but it will well repay any extra care it may require. We have plants doing fairly well in pots, also in shallow baskets with moss, but the best plant is in a cylinder. It requires the warmest treatment, with a very moist atmosphere and a minimum of potting material. It was introduced from Burmah about twelve years since.

Angræcum modestum (*Sanderianum*) is a charming, free-flowering and sweet-scented Orchid, introduced a few years since from Madagascar. The stem is somewhat short and slender, bearing broad, elliptic, bright green, leathery leaves. The pendulous racemes spring from the axils of these, which are a foot or more long, bearing about thirty pure white flowers, about one and a half inches across, the lip terminating in a spur some four inches long. The flowers last in perfection for three weeks. This Orchid should be found in the smallest collection. It will grow very freely in baskets or on blocks of wood, and should not have too much potting material. This may consist of moss alone or mixed with peat. The warmest house is best for it, with a plenteous supply of water at all seasons; the red spider attacks and disfigures the leaves at once if the atmosphere is too dry.

Cattleya iricolor is now blooming freely, and is remarkable for its distinct habit of growth, the color of its flowers and its rarity. The slender clavate bulbs are about four inches long and bear large strap-shaped leaves more than a foot long. The peduncles bear two to three flowers, four inches across, milk-white except the convolute lip, the base and side lobes of which are prettily marked with broken lines of purple and a transverse band of yellow. The native country of this species is unknown, and only one plant was ever imported. I am not sure whether there is any other part of this plant living or if the entire stock is here.

Kenwood, N. Y.

F. Goldring.

Astragalus hypoglottis.—This is a pretty little prostrate plant belonging to the Pea family, and is now in bloom with us, with its heads of blue and white flowers raised just above the foliage, and amongst a batch of seedlings are some pure white flowered forms, which are pleasing by contrast. This plant is a native of Great Britain, but has proved perfectly hardy here in the open ground, but it is hardly suitable for a mixed border where strong-growing plants are. In such a position it would speedily become smothered. Another plant which makes a suitable companion to the above is *Lotus corniculatus*, with its golden-yellow blossoms, which are also pea-shaped. When planted together these form an interesting group.

Ranunculus speciosus, with yellow flowers an inch across, and as double as it is possible for a flower to be, is just now at its best, and resembles a much-branched double Buttercup, except that the flowers are larger. This is one of the easiest plants to grow when planted in a wet or heavy soil. Under these conditions *R. speciosus* will increase rapidly and form nice strong clumps, with abundance of flowers every year.

Saxifraga granulata.—The Saxifrage family is a numerous one, embracing plants vastly different from each other in habit and general appearance from the pretty trailing *S. oppositifolia* of the Pyrenees, and others of a similar habit to the large, thick-leaved *S. crassifolia*, and *S. peltata* of the Pacific coast, probably the largest of the genus. The subject of this note is now in bloom, and its pretty, double, white flowers render it a desirable plant. The popular name, Fair Maids of France, is not in this case a misnomer. The rock-garden is the best place to grow *S. granulata*, but is not essential. We have grown it successfully for years in the open border, where it flowers every spring. After flowering, the plant dies down for the hot season, and care should be taken not to disturb the small bulbs which are about the size of peas. Growth will begin again in fall, and the leaves will remain green all winter; the flower stems are produced with the opening of the spring season.

Passaic, N. J.

E. O. Orpet.

Long, White, French Turnip.—This is the best of all Turnips for family use, and is known in Virginia as Sugar Turnip. The only trouble about it is that it needs earlier sowing than the flat, quick-growing sorts. At the north, June is none too early to put the seed in the ground. This is the hardiest of all Turnips I have ever grown. In this latitude it can be

left out just as Parsnips and Salsify are left, and it will be sound and sweet all winter. Another great advantage is that the tops in the spring make the best of greens—much better than Kale and almost equal to Spinach. With a good covering, in dry ground, this Turnip would probably winter over much further north. A good way to treat them is to sow the seed early in June in a bed, and transplant them later as vacant spots occur in the garden. Managed in this way the necessity for early sowing is not so inconvenient, and the Turnips are far superior to the flat sorts sown later. It belongs to the long Ruta Baga class.

A Hint About Pickles.—When working early sweet Corn for

the small plants now at much lower rates than at planting time in July and August, and much better plants can be had by setting them now in beds and caring for them until the time to transplant finally. A cold frame, which has been used for early plants, is a good place to put them. They should be dibbled two or three inches apart all over the bed, and then, instead of the glass sash, the frame should be covered with a screen made of laths nailed an inch apart. This will give a varying shade which will not draw the plants and will protect them from the scorching sun. With proper attention to watering, stout plants can be grown, which will come up with a good mass of roots and suffer little in moving.

Crozet, Va.

W. F. Massey.

Main Street, Charlestown, New Hampshire.—See page 278.

the last time plant a few Cucumber seeds between the hills of Corn, so as to have them about four feet apart each way. If a shovelful of manure is well chopped in before planting on each spot where a hill is to be, so much the better. Then as soon as the Corn is eaten, cut away the stalks and give the Cucumbers all the ground. Should the striped bug attack the young plants, as they seldom will at this season, dust bone-flour over them and they will leave at once. Brussels Sprouts can be set between Pea rows, and afterward allowed the whole ground.

Celery Plants.—Now that commercial growers produce Celery plants at such reasonable rates it hardly pays the private grower to take the trouble to raise them from seed. It is much better, however, to get these plants in advance of the time for setting in their final location. The growers will sell

The Climbing Hydrangea.—*Hydrangea radicans* bloomed abundantly this year, but the flowers, borne in large, flat corymbs, have little color and are not very interesting. The large, deep green leaves, however, appearing as early as they do, are very beautiful, and as the plant makes rapid growth whenever it has anything to cling to, it is a very valuable addition to our climbers.

Germantown, Pa.

Joseph Meehan.

Popular Gardening, in a recent issue, calls attention to the common and wasteful method of applying top-dressing to fruit and other trees, which consists of piling a heap of stable manure directly round the trunk. The roots of plants are capable of receiving nourishment through their young, growing tips only, so that unless the top-dressing is applied directly over the ends of the roots much of the value of the manure is wasted,

so far as immediate benefit to the tree is concerned. A picture of a tree with a horizontal section of ground showing the position and mode of growth of the roots clearly enforces the lesson, and indicates that the place to apply manure to a tree is a circle three or four feet wide drawn upon the ground just under the extremities of the lateral branches. A better way still is to cover the entire circle about the tree whose radius is equal to its height.

Notes from the Arnold Arboretum.

Pourthia arguta is flowering here freely for the first time. It is a graceful, hardy shrub, with slender, spreading branches, covered with smooth, pale gray bark, that of the branchlets thickly covered with warts, as are the peduncles and pedicels; lanceolate or elliptical, oblong, membranaceous, short-petioled, opposite leaves, pointed at both ends, finely and sharply serrate, and three inches long by one and a half inches wide. They are covered when young, as are the stout branches and inflorescence, with short, scattered white hairs, but become perfectly glabrous at maturity. The flowers are small, one-fourth of an inch across, pure white, and borne in flat, few-flowered, cyme-like, almost sessile corymbs, and are followed by small, red globose or ovoid, one to two-seeded pomes. The genus *Pourthia* was established by Decaisne ("Nouv. Arch. du Mus," x., 146) for a number of plants peculiar to the Himalayas, China, Corea and Japan, which, in herbaria, were long confounded with species of the allied genus, *Photinia*, which they resemble in general appearance. *Pourthia* can, however, be recognized by the minute serratures of the leaves, by the profusion of the warts which cover the young shoots, the petioles and peduncles, by the styles (two, or generally three), connate to the middle, and by the testa of the seeds, which contains ducts filled with resinous gum, a peculiarity which, as M. Decaisne pointed out, is not shared by the plants of other genera of *Pomaceæ*. The genus commemorates the labors of the French missionary, Pourthié, massacred in Corea in 1866.

Pourthia arguta is a native of the Himalayas from Sikkim to the Kashya Hills and to Burmah. It is apparently very variable, Sir Joseph Hooker describing no less than six varieties in the "Flora of British India" (ii., 382).

In cultivation here it is a remarkably neat and apparently a perfectly hardy plant, already nearly eight feet high, having inhabited the Arboretum for a number of years. The divergent habit of the branches and flower-bearing lateral branchlets give to this plant a peculiar and striking appearance quite unlike that of other plants in the collection. It flowers here about ten days earlier than its near ally, *Photinia villosa*, of which a figure was published in the first volume of GARDEN AND FOREST, p. 67.

The Dalmatian *Spiræa cana* is very fine here this year. It is one of the most variable of the *Spiræas* in habit, in the size and pubescence of the leaves and in the size of the inflorescence. Next to *S. trilobata* and its varieties, of which *S. Van Houttei* is by far the most beautiful, *S. cana* is the best of the late-blooming *Spiræas* which produce their flowers on the extremities of lateral, leafy branches. The most attractive of the numerous forms of this plant which are cultivated in the Arboretum is one with small, ovate, entire leaves (one-half to two-thirds of an inch long), covered with soft, silky-white tomentum, and with very abundant, although small, panicles of flowers. This is a perfectly hardy shrub of handsome, compact habit. It grows here to a height of two or two and a half feet.

There are many species and varieties of *Cotoneaster* in the collection. Among them are plants of considerable ornamental value, especially for the autumn decoration of gardens, as they nearly all produce showy fruit. Among the species now in flower the handsomest at this season of the year is the dwarf and here nearly prostrate *C. microphylla*. It is a low, intricately-branched shrub, with very stout, rigid, horizontal branches, ovate or obovate entire leaves, a third to half an inch long, the margins often somewhat recurved, very coriaceous, dark green and glossy on the upper surface, the lower covered with sparse hairs, which also occur upon the calyx and short peduncles. The flowers are rather large (half an inch across), solitary, greenish-white, with showy red stamens. The scarlet fruit is globose. *C. microphylla*, often confounded in gardens with *C. rotundifolia* and *C. buxifolia*, is a native of the Himalayas, from Kashmir to Bhotan, where it is found at elevations of from 4,000 to 10,000 feet above the sea level. *C. microphylla* is fairly hardy here, and is a useful plant for carpeting the ground under larger shrubs. Its neat habit, brilliant, although small, leaves, and handsome and abundant flowers and fruit make it a desirable subject for the rock-garden, or for the margins of small shrubberies.

Cotoneaster acuminata is also in flower. This is an erect shrub, with rather stout branches, with ovate, acuminate or acute leaves two inches long, pubescent or tomentose beneath (glabrous at maturity), as are the shoots of the year and the inflorescence. The flowers are dull pink, inconspicuous, in short, one to five-flowered cymes. They are followed, however, by handsome black fruit, which makes this plant a conspicuous object during the autumn months. It is a native of the Himalayas from Sumor to Sikkim, where it extends to an elevation of 13,000 feet. It attains sometimes a height of fourteen feet in its native country, where the wood is used for walking-sticks ("Fl. British India," ii., 385). *Cotoneaster acuminata* is perfectly hardy in the Arboretum, which it has inhabited for several years.

C. vulgaris is the most showy species of the genus in fruit in this collection. It is an erect shrub, with stout branches, broadly ovate, acute or obtuse leaves, one to two inches long, glabrous above, softly tomentose on the lower surface; small, inconspicuous, reddish flowers, in short, glabrescent, few-flowered cymes, and brilliant, bright red, drooping fruit, which remains upon the branches for a considerable time after the leaves have fallen; it is found from northern Europe, through Siberia and Persia to the Himalayas. There is a variety with black fruit which is not in this collection. *C. vulgaris* is a perfectly hardy plant, and although a very old inhabitant of gardens, it seems to be rarely cultivated in this country in spite of the fact that it is one of the most desirable of autumn fruit-bearing shrubs.

Rhamnus alpinus, now in flower, has the most ornamental foliage of the genus. The leaves are ample, four or five inches long, oval, lanceolate, crenately toothed, dark green and lustrous, and conspicuous for the exceedingly prominent primary veins. The flowers, like those of the other species, are inconspicuous, yellow-green, four parted, the females with four-lobed stigmas. The fruit is black. It is a dwarf shrub, attaining sometimes a height of three or four feet. Here it grows rather slowly, and its hardiness is not yet satisfactorily demonstrated. *Rhamnus alpinus* is a native of the mountain ranges of southern Europe from Spain to Turkey.

The Deerberry, or Squaw Huckleberry (*Vaccinium stamineum*) is a charming garden plant, and one which, when well established, grows freely in any good soil, requiring no special care or peculiar treatment. It is now covered with flowers, with open, bell-shaped corollas, and long, exserted stamens, hanging singly on graceful, slender pedicels from the axils of the small upper leaves or leaf-like bracts, and forming leafy racemes. *V. stamineum* is a widely-branching shrub, two or three feet high, with ovate or oval ample pale leaves, glaucous or white on the lower surface, and large, round or pear-shaped fruit, which is green or sometimes dull purple when fully ripe, and barely edible. The Squaw Huckleberry is found over a large part of the Northern States, and along the southern Alleghenies, growing always in gravelly soil, under the shade of deciduous trees, generally different species of Black Oaks. Brought into the garden, and treated generously, it will grow more freely than it does in its native home, and will delight and astonish those persons who are not familiar with the beauties of the American *Vaccinia*.

The English Bilberry, the pretty little *Vaccinium Myrtillus*, is in flower. This is a small, glabrous shrub, growing only eight or ten inches high, with angled green branches, ovate, thin leaves, globular, solitary, nodding, pale green flowers, tinged with red; and round, nearly black fruit, covered with a glaucous bloom. It is a native of northern and central Europe, extending to the great mountain ranges of southern Europe, often covering wide tracts of ground. It is hardy here, but a delicate plant, requiring special care and attention.

Exochorda grandiflora, a well-known garden shrub and a native of central China, has flowered this year in this neighborhood in the greatest profusion, and perhaps has never before been seen here in as great beauty. It is certainly one of the most beautiful of all spring-flowering shrubs. It is not, however, although known in European gardens for more than forty years, as common a plant as the great beauty and profusion of its flowers would lead one to expect. The truth is, it is a difficult plant to propagate; there is no stock upon which it will grow, and green wood cuttings root very slowly and with great difficulty. Seed, if it can be had, germinates freely, but young plants rarely produce seeds, which appear apparently only on old and long-established plants; and old plants are rarely seen. The *Exochorda*, from some reason or other, dies young, at least in this climate, and it is rare to see a bush more than six or eight feet high here. Generally before it reaches that size the branches begin to crack and to lose the bark. After this the plant gradually perishes, and generally disappears at the end of

two or three years more. Any seed which can be found should be carefully collected and sown, so that a succession of young plants can be kept up.

Lonicera parvifolia, a small, shrubby species from the alpine Himalaya is in flower. It is a neat shrub with minute leaves and small, greenish-white flowers with cylindrical, corolla-tubes a quarter to a third of an inch long—a pretty plant enough, but of no great beauty or horticultural interest.

Lonicera glauca (the *L. parviflora* of Gray's Manual) is a beautiful native Honeysuckle, which is now in flower. It has trailing or sometimes bushy stems, rarely more than four or five feet long, smooth leaves, green on the upper and very pale and glaucous on the lower surface, the upper pairs united and all closely sessile. The flowers are greenish-yellow, tinged with dark purple, and are produced in closely approximate whorls.

This is a northern plant, extending almost to the shores of Hudson's Bay, and not uncommon in northern New England and New York or on the high Carolina mountains—a good subject to naturalize on rocky banks or the borders of woods.

Lonicera Alberti (see GARDEN AND FOREST, i., 226) may be mentioned again, that the testimony of another year's trial may be recorded in its favor. It is certainly one of the best small shrubs of recent introduction. The habit is graceful and the coloring delightful. The flowers are abundant, fragrant and of good color; the fruit which was produced here last year very freely, is large (three-fourths of an inch in diameter), vinous-red and covered with a glaucous bloom. This is, so far as we know here, by far the most valuable of the ligneous plants introduced in late years from central Asia through the efforts of the Russian botanical explorers, the most active and successful of whom, Dr. Albert Regel, is very fittingly commemorated in this charming plant.

Lycium pallidum, figured last year in GARDEN AND FOREST (f. 54), is now loaded with its handsome, tubular flowers. The introduction of this species was certainly a very lucky hit. The fact that a plant of the dry south-west grows here so well and flowers so profusely is a remarkable and interesting fact.

May 25th.

The Forest.

Succession of Forest Growths.

THE following is from an address delivered by Mr. Robert Douglas before the Association of American Nurserymen at the meeting in Chicago last week:

It is the prevailing and almost universal belief that when native forests are destroyed they will be replaced by other kinds, for the simple reason that the soil has been impoverished of the constituents required for the growth of that particular tree or trees. This I believe to be one of the fallacies handed down from past ages, taken for granted, and never questioned. Nowhere does the English Oak grow better than where it grew when William the Conqueror found it at the time he invaded Britain. Where do you find White Pines growing better than in parts of New England, where this tree has grown from time immemorial? Where can you find young Redwoods growing more thriftily than among their giant ancestors, nearly or quite as old as the Christian era?

The question why the original growth is not reproduced can best be answered by some illustrations. When a Pine-forest is burned over both trees and seeds are destroyed, and as the burned trees cannot sprout from the stump like Oaks and many other trees, the land is left in a condition well suited for the germination of tree-seeds, but there are no seeds to germinate. It is an open field for pioneers to enter, and the seeds which arrive there first have the right of possession. The Aspen Poplar (*Populus tremuloides*) has the advantage over all other trees. It is a native of all our northern forests, from the Atlantic to the Pacific. Even fires cannot eradicate it, as it grows in moist as well as dry places, and sprouts from any part of the root. It is a short-lived tree, consequently it seeds when quite young and seeds abundantly; the seeds are light, almost infinitesimal, and are carried on wings of down. Its seeds ripen in spring, and are carried to great distances at the very time when the ground is in the best condition for them. Even on the dry mountain sides in Colorado, the snows are just melting and the ground is moist where they fall.

To grow this tree from seed would require the greatest skill of the nurseryman, but the burnt land is its paradise. Whenever you see it on high, dry land you may rest assured that a fire has been there. On land-slides you will not find its seeds germinating, although they have been deposited there as abundantly as on the burned land.

Next to the Aspen and Poplars comes the Canoe Birch, and further north the Yellow Birch, and such other trees as have provision for scattering their seeds. I have seen acorns and nuts germinating in clusters on burned lands in a few instances. They had evidently been buried there by animals and had escaped the fires. I have seen the Red Cherry (*Prunus Pennsylvanica*) coming up in great quantities where they might never have germinated had not the fires destroyed the debris which covered the seed too deeply.

A careful examination around the margin of a burned forest will show the trees of surrounding kinds working in again. Thus by the time the short-lived Aspens (and they are very short-lived on high land) have made a covering on the burned land, the surrounding kinds will be found re-established in the new forest, the seeds of the conifers, carried in by the winds, the berries by the birds, the nuts and acorns by the squirrels, the mixture varying more or less from the kinds which grew there before the fire.

It is wonderful how far the seeds of berries are carried by birds. The waxwings and cedar-birds carry seeds of our Tartarian Honeysuckles, Purple Barberries and many other kinds four miles distant, where we see them spring up on the lake shore, where these birds fly in flocks to feed on the Juniper berries. It seems to be the same everywhere. I found European Mountain Ash trees last summer in a forest in New Hampshire; the seed must have been carried over two miles as the crow flies.

While this alternation is going on in the east, and may have been going on for thousands of years, the Rocky Mountain district is not so fortunate. When a forest is burned down in that dry region, it is doubtful if coniferous trees will ever grow again, except in some localities specially favored. I have seen localities where short-lived trees were dying out and no others taking their places. Such spots will hereafter take their places above the timber-line, which seems to me to be a line governed by circumstances more than by altitude or quality of soil.

There are a few exceptions where Pines will succeed Pines in a burned-down forest. *Pinus Murrayana* grows up near the timber-line in the Rocky Mountains. This tree has persistent cones, which adhere to the trees for many years. I have counted the cones of sixteen years on one of these trees, and examined burned forests of this species, where many of the cones had apparently been bedded in the earth as the trees fell. The heat had opened the cones and the seedlings were growing up in myriads; but not a conifer of any other kind could be seen as far as the fire had reached.

In the Michigan Peninsula, northern Wisconsin and Minnesota, *P. Banksiana*, a comparatively worthless tree, is replacing the valuable Red Pine (*P. resinosa*), and in the Sierras *P. Murrayana* and *P. tuberculata* are replacing the more valuable species by the same process.

In this case, also, the worthless trees are the shortest-lived, so we see that Nature is doing all that she can to remedy the evil. Man only is reckless, and especially the American man. The Mexican will cut large limbs off his trees for fuel, but will spare the tree. Even the poor Indian, when at the starvation point, stripping the bark from the Yellow Pine (*P. ponderosa*), for the mucilaginous matter being formed into sap-wood, will never take a strip wider than one-third the circumference of the tree, so that its growth may not be injured.

We often read that Oaks are springing up in destroyed forests where Oaks had never grown before. The writers are no doubt sincere, but they are careless. The only Pine-forests where Oaks are not intermixed are either in land so sandy that Oaks cannot be made to grow on them at all, or so far north that they are beyond their northern limit. In the Green Mountains and in the New England forests, in the Pine-forests in Pennsylvania, in the Adirondacks, in Wisconsin and Michigan—except in sand—I have found Oaks mixed with the Pines and Spruces. In north-western Minnesota and in northern Dakota the Oaks are near their northern limit, but even there the Burr Oak drags on a bare existence among the Pines and Spruces. In the Black Hills, in Dakota, poor, forlorn, scrubby Burr Oaks are scattered through the hills among the Yellow Pines. In Colorado we find them as shrubs among the Pines and Douglas Spruces. In New Mexico we find them scattered among the Piñons. In Arizona they grow like Hazel-bushes among the Yellow Pines. On the Sierra Nevada the Oak region crosses the Pine region, and scattering Oaks reach far up into the mountains. Yet Oaks will not flourish between the one hundredth meridian and the eastern base of the Sierras, owing to the aridity of the climate. I recently found Oaks scattered among the Redwoods on both sides of the Coast Range Mountains.

Darwin has truly said "The Oaks are driving the Pines to

he sands." Wherever the Oak is established—and we have seen that it is already established wherever it can endure the soil and climate—there it will remain and keep on advancing. The Oak produces comparatively few seeds. Where it produces a hundred, the Ash and Maple will yield a thousand, the Elm ten thousand, and many other trees a hundred thousand. The acorn has no provision for protection and transportation like many tree-seeds. Many kinds are furnished with wings to float them on the water and carry them in the air. Nearly every tree-seed, except the acorn, has a case to protect it while growing, either opening and casting the seeds off to a distance when ripe or falling with them to protect them till they begin to germinate. Even the equally large seeds of other kinds are protected in some way. The Hickory-nut has a hard shell, which shell itself is protected by a strong covering until ripe. The Black Walnut has both a hard shell and a fleshy covering. The acorn is the only seed I can think of which is left by Nature to take care of itself. It matures without protection, falls heavily and helplessly to the ground, to be eaten and trodden on by animals, yet the few which escape and those which are trodden under are well able to compete in the race for life. While the Elm and Maple seeds are drying up on the surface, the Hickories and the Walnuts waiting to be cracked, the acorn is at work with its coat off. It drives its tap-root into the earth in spite of grass, and brush, and litter. No matter if it is shaded by forest-trees so that the sun cannot penetrate, it will manage to make a short stem and a few leaves the first season, enough to keep life in the root, which will drill in deeper and deeper. When age or accident removes the tree which has overshadowed it, then it will assert itself. Fires may run over the land, destroying almost everything else, the Oak will be killed to the ground, but it will throw up a new shoot the next spring, the root will keep enlarging, and when the opportunity arrives it will make a vigorous growth, in proportion to the strength of the root, and throw out strong side roots, and after that care no more for its tap-root, which has been its only support, than the frog cares for the tail of the tadpole, after it has got on its own legs.

There is no mystery about the succession of forest-growths, nothing in Nature is more plain and simple. We cannot but admire her wisdom, economy and justness, compensating in another direction for any disadvantage a species may have to labor under. Every kind of tree has an interesting history in itself. Seeds with a hard shell, or with a pulpy or resinous covering, which retards their germination, are often saved from becoming extinct by these means.

The Red Cedar (*Juniperus Virginiana*) reaches from Florida to and beyond Cape Cod; it is among the hills of Tennessee, through the Middle States and New England. It is scattered through the western states and territories, at long distances apart, creeping up the Platte River, in Nebraska. (I found only three in the Black Hills, in Dakota, in an extended search for the different trees which grow there. Found only one in a long ramble in the hills at Las Vegas, New Mexico.) Yet this tree has crept across the continent, and is found here and there in a north-westerly direction between the Platte and the Pacific Coast. It is owing to the resinous coating which protects its seeds that this tree is found to-day scattered over that immense region.

Correspondence.

Ulmus fulva pendula.

To the Editor of GARDEN AND FOREST:

Sir.—I appreciate the kindly notice your correspondent has given of me and my work. In regard to the "Weeping Slippery Elm," I am responsible for the name under which it has been distributed. It was regarded as a form of the Slippery Elm without the close examination that should have been made. Two of the trees originally grafted have now flowered with me. They prove to be not *Ulmus fulva*, but a form of the common White Elm (*U. Americana*). It is inconceivable that I should not have noticed this, as the Slippery Elm is readily distinguished by the rough bark on the younger twigs, very different from the smoother bark of the American or White Elm. As there are many weeping forms of the common American Elm, and it is necessary to re-name this, it will be better to drop the Latin designation for a mere variety like this. The grafts were sent to me by Mr. E. Beebe, then of Galena, Illinois, from a tree growing wild near there. An appropriate designation will be "Beebe's Weeping Elm."

Beebe's Weeping Elm is a very striking form. The branches curve over as they grow, much as the Weeping Willow does—the branches being thick and cord-like. I have seen some of

these curving branches that make an annual growth of twenty feet. They, however, get up to be trees of considerable size for all the curving tendency of the young growth. My trees are about thirty-five feet high, with trunks three and a half feet in circumference. The appearance at a little distance is precisely that of a Weeping Willow.

Germanstown, Pa.

Thomas Meehan.

To the Editor of GARDEN AND FOREST:

Sir.—A friend, whose son is a large grower of flowers in England, writes me expressing obligation to GARDEN AND FOREST for the note on the poisonous properties of *Primula obconica*. She says, in substance, "this has solved the mystery for us of the very troublesome inflammation of face and hands from which not only I but two of my daughters have been suffering this last year. It is undoubtedly *P. obconica* that has been the cause of it, for since we have avoided handling the plant the symptoms have gradually disappeared. I do not suppose any but those who grow the plant in large quantities need be afraid, and our men have divided and re-potted a great number without ill effects, so that it is only injurious to certain persons. It so happens that I have taken special trouble about our picking dead leaves, etc., little thinking that the evil was thus continually kept up. My eldest daughter, who has charge of boxes of cut flowers, has suffered greatly in her hands and arms, and, in some degree, in her face and eyes. Another daughter, who has used the flowers in wreath-making, of late showed similar symptoms, which puzzled our doctor extremely, though he said he was positive there was some local cause. It is such a charming plant that we are truly sorry, but I am afraid the fact remains." As *P. obconica* is now being so largely grown it seems well that this evidence confirmatory of your note should be given, as a warning to those who are susceptible to plant poisons.

Elizabeth, N. J.

Jno. N. Gerard.

Kissena Nurseries.

To the Editor of GARDEN AND FOREST:

Sir.—In the early part of this century the most attractive spot in the Middle States, for lovers of ornamental trees and other plants, was "The Linnæan Botanic Garden and Nursery," at Flushing, Long Island, of which Mr. William Prince was the proprietor. Mr. Prince was a man of excellent taste and a genuine enthusiast in horticulture. He gathered a notable collection of trees and shrubs, and in the now busy town, hard by the railroad station, there still stands to mark the site of the old nursery a noble Cedar of Lebanon, one of the best and oldest specimens of this tree in the United States. It was, perhaps, the success of this establishment, for so many years identified with the gardening art of the country, which led to the foundation, fifty years ago, of the Parsons' nurseries, which still remain, so that the town of Flushing has never lacked for choice material when any planting was to be done. This is made evident to the visitor not only by the unusual number of striking trees and shrubs on the private grounds of the town, but by the trees in its streets, which are exceptionally well planted. There are fine avenues of Elms here as elsewhere, but it is rare to find such long lines of Tulip-trees, or Lindens, or Beeches as are seen here. Mr. Samuel B. Parsons, the present head of the nurseries, who has done most of the planting, is particularly hopeful as to the future of the Beeches, and certainly a long, straight street with a row of well-grown English Beeches on either side would be worth a journey to see. This particular street, however, is comparatively new, and the trees have but just taken hold of the soil as if they were determined to grow. No better wish for them can be made than that they all may attain to as fair proportions as those of a tree of the same species standing near by on the private grounds of Mr. Parsons. In sweeping grace of outline, and in the lustrous beauty of its foliage, this particular tree is not equalled by any English Beech it has yet been my pleasure to see.

In their present estate, however, the Oaks are to me the most interesting street-trees in Flushing. That the conditions of the place are adapted to the best development of these trees might have been surmised from the size of the famous Fox Oaks, one of which was blown down in 1831, while the other survived until 1873, when it was destroyed by fire. A count of the annual rings then showed that the trees were 300 years old when George Fox preached under them in 1672. The giant White Oak on Parsons Avenue belongs, no doubt, to the same generation, and its knotted and furrowed trunk is twenty-three feet in girth. But the younger Oaks do not lack interest. Here they stand to prove that Oaks of many species grow rapidly,

and are in every way desirable for street-planting. A row of Pin Oaks, with perfectly straight trunks and shining strata of foliage, leaves nothing to be desired. And Willow Oaks, Chestnut Oaks, Over-cup Oaks are all equally good, each species having special merit of its own. In some places Mr. Parsons planted White Maples between the Oaks for immediate effect, with the intention of cutting them out as the trees began to crowd. But some of the later owners lacked the intelligence or nerve to remove the Maples, and now the beauty of both Oaks and Maples is lost beyond recall. In one instance I noted that an eccentric chopper had preferred the Maples, and had actually slaughtered the Oaks to save them.

In no commercial establishment in the country can a buyer find a more comprehensive list of trees and shrubs for ornamental planting than at the Kissena Nurseries. If the business has been directed towards any specialties, these have been Rhododendrons, in the first place, and after them in order, hardy Azaleas, Magnolias, Conifers and Japan Maples. Many of the hardy Rhododendrons sold here are Flushing seedlings, and the foreign varieties are propagated here—not imported—all being grafted on stock of *R. Ponticum*. Mr. J. R. Trumpy, the well-known propagator, who has spent a third of a century in this nursery, grafted last year 10,000 plants with his own hand. The Rhododendrons had largely passed their blooming season when I saw them, but there were still flowers enough to illuminate the broad acres where the larger plants stood. After all, the almost interminable stretches of younger plants closely set, of uniform size and perfect health, made quite as brave a show. Many of the Azaleas were yet bright with bloom, and these late-flowering sorts have a special value. One of the most brilliant of them, a plant which fairly flamed with orange and scarlet, is called Flushing Queen, and is a home-raised seedling. Many of these seedlings are among the best varieties, but the parentage of them all is unknown. It has not been the practice here to make special crosses, but to sow seed of the best, and then to select the best of the seedlings until plants worthy of a name are found. The Hardy Azaleas are grafted on stock of *R. nudiflorum* and *R. viscosum*. The deliciously fragrant *Magnolia Thompsoniana* was in flower, and so was the still more beautiful *M. parviflora*, and the large number of young Magnolias of various kinds showed the faith that an increase in the demand for these choice trees was imminent. Mr. Parsons notes that there is a more intelligent enquiry for trees of approved beauty, and the Magnolias are among those sought for. Space would fail me to enumerate all the select Conifers which are grown here in quantities. The season had come when the young growth was just covering the trees with the softest green, and I could hardly feel reconciled to the theory which rejects so generally this family of trees because many of them are short-lived. It is true, urges Mr. Parsons, that many of them are short-lived, but while they do live they have characters of beauty which no other tree can offer, and which no lover of Nature is willing to lose. If we can plant a bed of *Coleus* for its brightness during a single summer, why not plant conifers for their beauty in the heat of summer and the snows of winter—a beauty which we can command with no other material—during the vigorous life of the tree, whether that be ten or twenty or thirty or more years? Arguments like this are easily assented to at this season of the year in the Kissena Nurseries when surrounded by scores of specimens of as many species and varieties, every one of which is a perfect picture.

As we stood by long rows of variegated Japan Quince, with foliage as bright as that of the Japan Maples which have been sent out from here in such great numbers, I asked Mr. Parsons how many of these Japanese trees and shrubs had been introduced through these nurseries. To this he was unable to give a full answer without an examination of his books, but I hope to furnish you at some time with a complete list of these introductions, as the record would be worth preserving. The catalogue would include many of our best and best-known shrubs. From Dr. Hall, for example, came in 1862: The double form of *Deutzia crenata*, *Hydrangea paniculata grandiflora*, *Magnolia stellata* and *M. Kobus*, five varieties of *Wistaria*; *Acer polymorphum*, *Quercus Dentata*, *Thuyopsis dolabrata*, *Sciadopitys verticellata* and *Lilium auratum*, eight bulbs of which were afterwards sold to a European firm at eighty dollars, in currency, each. Besides these and others, these nurseries received the seeds of many conifers from Dr. Hall. Among them, of *Picea Ayanensis*, *P. polita*, *Retinispora obtusa* and *Pinus Koraensis*.

The consignments from Mr. Thomas Hogg were much more important, including such prizes as twenty-five species and varieties of Maples, the Japanese Chestnut, the *Cercidiphyllum*, two varieties of *Benthamia*, the *Stuartia*, whose

flowering in Europe last year created some sensation; *Daphne Genkwa*, *Deutzia scabra*, *Elæagnus longipes*, *Hydrangea paniculata*, *Styrax Japonica*, *Schizophragma hydrangeoides*, *Dimorphanthus Mandchuricus*; many fine conifers, including the Japanese Hemlock; nine varieties of *Retinispora*, *Pinus Thunbergii*, *P. densiflora* and *Taxus cuspidata*. This by no means completes the list of hardy plants for which the horticultural world has to thank Mr. Hogg, not to speak of many kinds adapted to green-house culture, which were also sent out through the agency of these nurseries. If we add to these importations such plants as the Weeping Hemlock, the Red-flowered Dogwood and many others, besides the seedlings raised here, we can begin to appreciate how large a place this firm will occupy in the history of American gardening.

Much of what was the original nursery-ground has been cut up into building-lots, but about the old place are still found a collection of noteworthy trees that cannot be matched elsewhere in this country. The great Weeping Beech has already been pictured and described in GARDEN AND FOREST—but near it stands a Purple Beech with a trunk ten feet in girth and branches spreading over a diameter of sixty feet. Near by is a Cephalonian Fir, which is at least forty years old, with perfect foliage and feathered to the very turf. The *Pseudolarix* here has a trunk four and a half feet in circumference. On the grounds of Mrs. Leavitt, a few rods distant, stands a characteristic specimen of the Oriental Spruce, with its deep shadows and rich green foliage. This tree is doubtless fifty years of age, but shows no deterioration. An immense *Magnolia Soulangiana* is not far distant, and is probably of the same age. It divides into four trunks close to the ground, which girth respectively four, four and a half, two and three-quarters and two and two-thirds feet. Its spread of branches altogether is forty feet. Words and numerals give faint ideas, however, of the charm which invests these trees and a score of others equally attractive on the home grounds of Mr. Parsons. The sum of the whole matter is that no one can say that he is familiar with the finest collections of trees which this country has to show until he has been at Flushing, where, for a hundred years at least, have been located some of the foremost establishments for propagating trees and shrubs for ornamental planting.

Flushing, L. I.

S.

Recent Plant Portraits.

PASSIFLORA EYNSFORD GEM, *Gardeners' Chronicle*, April 20th; a hybrid Passion-flower raised in England from *Constance Elliot*, a white form of *P. cerulea* crossed with *P. racemosa*. "The petals are a lovely shade of rosy-lilac, the threads of the corona being ivory-white, tipped with violet. It is exceptionally beautiful, even among a genus famed for good looks, and it has the advantage of being almost constantly in flower."

MUTISIA CLEMATIS, *Gardeners' Chronicle*, April 20th; a free-growing, climbing Composite from the high mountains of Bogota, with deep, orange-colored flowers, and a capital plant for the cool green-house.

SKIMMIA JAPONICA (seedling male form; *S. fragrans* of gardens), *Gardeners' Chronicle*, April 27th.

SKIMMIA JAPONICA (female; *S. oblata* of gardens), *Gardeners' Chronicle*, April 27th.

SKIMMIA FORTUNEI (*S. Japonica* of gardens), *Gardeners' Chronicle*, April 27th. Dr. Masters has been studying the various *Skimmias* grown in English gardens, with the result that he finds that much confusion has existed among botanists and cultivators about these plants, and that the plant universally known as *S. Japonica* is not that species at all, and that it is not even known to belong to Japan, but that the plant described as *S. oblata* is the true *S. Japonica* of Thunberg and of Siebold and Zuccarini, or rather the female of that species, in which male and female flowers are separated on different individuals. The *S. Japonica* of gardens, so considered by Lindley, with whom all this confusion originated, and afterward by Sir W. Hooker, when it was first introduced by Fortune from China, in 1849, Dr. Masters now first properly distinguishes under the new name of *S. Fortunei*. This is the common species in cultivation. Dr. Masters calls attention to the interesting facts that this plant is not represented by wild specimens in herbaria, and that its Chinese origin rests upon Fortune's own statements with regard to it, which he says have been generally overlooked, although published in the *Gardeners' Chronicle* for 1852, p. 739, from which it appears that Fortune found this plant in a nursery-garden at Shanghai, to which he was told it had been brought from a high mountain in the interior called "Nang Shang." It is certainly both interesting and curious that nothing more definite is known of

the origin of a plant which has become one of the most popular and universally used evergreen shrubs of English gardens; and these last results (of which more are promised) of Dr. Masters' studies of garden plants are a solid and valuable contribution to knowledge.

MACLEANIA PUNCTATA, *Gardeners' Chronicle*, April 27th; the berries of this vacciniaceous shrub—a native of the Andes of Ecuador—are now first made known from a specimen grown in the gardens of Chatsworth.

Notes.

It is expected that during the month of June three thousand varieties of Roses will bloom in the grounds of the International Exposition at Paris.

The larvæ of the Imported Elm-leaf beetle are already appearing, and the sooner the trees are sprayed the better. One pound of London Purple to one hundred gallons of water makes an efficacious mixture.

Those of our readers who intend passing the summer in England may be interested to know that important Rose-shows will be held as follows: July 2d, Boston, Sutton; July 10th and 11th, Brighton, Ealing; July 17th, Bedford; July 26th and 27th, Wilmslow.

Mr. Edward L. Greene will devote the next three months to exploring the forests of Colorado, Montana, Oregon, Washington and California, and his journey should throw much new light upon some of the perplexing questions relative to the trees of western America.

The summer meeting of the Wisconsin Horticultural Society will be held at Sparta, on June 19th and 20th. Prizes will be offered for the best essay on the native trees of Wisconsin and for the best plan for laying out a school-ground not exceeding an acre in area. Here is an example which some of the older states might follow with profit.

The Association of American Nurserymen, at their meeting in Chicago last week, elected the following officers for the year: President, Geo. A. Sweet, of Dansville, New York; Secretary, Charles A. Green, of Rochester, New York; Treasurer, A. R. Whitney, Franklin Grove, Illinois; Executive Committee, Leo Wetz, Wilmington, Ohio; S. D. Willard, Geneva, New York; S. M. Emery, Lake City, Minnesota.

M. Viullemin has recently discovered that the now widespread disease of the Lombardy Poplar is due to the attacks of a fungus (*Didymosphaeria populina*), against which a solution of sulphate of copper has been found effective. But as the lower branches of the trees are attacked first, it is suggested that their removal as soon as the presence of the fungus is detected will check the spread of the disease.

A plant of the new Strawberry originated by Mr. James Nimmon, of Dennison, Texas, and named Parker Earle, has been sent to this office from the experiment-grounds of the *Rural New Yorker*. The plant is remarkable for its strong foliage and for the abundance of fruit, held up from the ground by the stout peduncles. The berries are large, of excellent flavor, and their entire surface becomes white like wax before turning red.

A Brussels journal notes the fact that the Belgian Government has decided to grow plants for distribution in the schools in sufficient numbers to insure that each student shall have a specimen before him when he takes his botanical lesson. A subscription price of five francs yearly seems cheap enough, even if it stands only for an individual pupil; but in Berlin for a number of years plants have been cultivated for the same purpose and freely distributed by the government. When shall we be intelligent enough to follow German example in directions like this?

During the last session of Congress the sum of \$200,000 was appropriated for the establishment of a zoological garden in Washington. The necessary site for it has now been selected. It comprises about 150 acres, lies to the north-west of the city, about two miles from the White House, along the banks of Rock Creek, and is said to be admirably situated and in every way well adapted for its purpose. It is expected that before next winter the necessary arrangements will be so far advanced that the animals now inappropriately housed in the grounds of the Smithsonian Institution can be removed to their new quarters.

Patchouli, says a recent writer in the *Journal of the Agricultural and Horticultural Society of India*, is the product of *Oci-*

mum Basilicum, var. *pilosum*. The species is largely grown on the continent of Europe in pots for room decoration, under the familiar name of Sweet Basil. It is a small annual belonging to the *Labiata*, with little white flowers in simple racemes. The variety *Pilosum* seldom or ever flowers, the perfume being obtained from its aromatic leaves. Its cultivation is almost entirely confined to the Chinese of the Straits Settlements, who grow the plants from cuttings in raised beds.

A fine, colored plate of *Dictamnus fraxinella*, showing both the crimson and the white varieties, was recently published in the *Garden*. About a year ago one of our correspondents called attention to this plant, saying that it was once a great favorite, but now, despite its beauty and its peculiarly attractive fragrance, is seldom seen and almost forgotten. Nevertheless, it is a surprise to learn from the text which accompanies the picture in the *Garden* that no colored illustration of *Fraxinella* had ever before been published in England. The great peculiarity of the plant is the luminosity it develops on warm summer nights, owing to the aromatic juice which exudes from its pores, especially those of the pedicels of the flowers.

Professor Patrick, of the Iowa Agricultural College, undertook last winter to make a chemical study of apple twigs to ascertain whether he could detect differences of composition between the young growth of such varieties as are hardy, and those which are not hardy in that region. At the same time and for the same purpose a microscopic examination was made of apple twigs by Dr. Halsted. It would be a great advantage if hardy and tender varieties could be distinguished from each other by a chemical analysis or an examination of their cell-structure. Professor Budd, indeed, has expressed the opinion that there was an apparent difference in the structure and composition of the trees which proved hardy in Iowa and those which were tender. The results of Professor Patrick's analysis "lend, perhaps, some slight encouragement" to this idea. Professor Halsted found "no parallelism between microscopic structural differences and ability to withstand the influences of a trying climate."

The only plant of any size, probably, of the true *Abies amabilis* to be seen in the eastern States is growing in the nurseries of Mr. Josiah Hoopes, in West Chester, Pennsylvania. This, for many years and until 1880, when Engelmann and Sargent gathered a number of small seedlings in the mountains of the lower Fraser, and subsequently made arrangements for the collection of large quantities of seed, was the rarest of all the western American conifers in cultivation; the only large plants in Europe being those in the Botanic Garden at Edinburgh and in the Arboretum of Dropmore, derived from the scanty collections of David Douglas, who found this tree more than half a century ago on the Cascade Mountains, overlooking the great Falls of the Columbia. He discovered on the same day and in the same locality *Abies nobilis*. *Abies amabilis* was certainly well named, for it is by far the loveliest of the North American Firs. The West Chester plant is a graft from the Edinburgh tree; and although some fifteen years planted, it has been slow, like so many grafted conifers, in getting started to grow. It has at last, however, commenced to grow satisfactorily, and is now something like four and a half feet high with a diameter of branches of seven feet on the ground. It is healthy, and apparently quite hardy, giving promise of becoming a handsome tree.

A constant increase may be noted in the varieties of flowers sold by the street venders in this city. In a space of a block and a half there were counted, a short time ago, Roses of several kinds, among which La France, Bon Silene and General Jacqueminot were most conspicuous, Heliotrope, Pansies, Carnations of many colors, including large numbers of a fine scarlet kind with unusually long stems, Lilies-of-the-Valley, Peonies, white and red, Magnolias (the sweet-scented *M. glauca*), Corn-flowers, Syringa, Mountain Laurel, huge baskets full, and Daisies by the thousand, sometimes mingled with Red Clover blossoms. A few moments' observation showed that the preference of purchasers was distinctly for the wild flowers. Hot-house flowers are lovely in themselves, but they tell of nothing but themselves, while the wild flowers bring with them a picture of the spot where they grew, a vision of summer, a breath of country air, and eyes weary of brick and mortar are quick to appreciate the difference. Excellent taste is shown by many of the peddlers in making up their wares. The bunches of Daisies and Clover very often as fresh and natural as though a child had just picked them, and sometimes sprays of Beech leaves are prettily mingled with the Daisies.

The Danger from Mountain Reservoirs.

ON the very day when the city of Johnstown was annihilated and the prosperous Conemaugh Valley was transformed into a scene of desolation and death, which has never had a parallel in the history of the country, a dispatch was prepared in Washington for the Associated Press to the effect that Secretary Noble had approved of the plan for continuing the survey of the arid lands proposed by Major Powell, Director of the Geological Survey. This plan looks to the construction of a system of reservoirs in the mountain regions, where the waters are to be stored for use upon the dry plains below. The project contemplates operations of greater magnitude and importance than any which our hydraulic engineers have yet attempted, and many features of the proposed work demand more careful study than they seem to have received. The one point, however, which the Pennsylvania deluge forces upon our consideration is the threat of destruction which hangs over a valley when a vast amount of water is imprisoned above it. There are barriers which avail against the sweep of a tornado; no conflagration is so swift and fierce but that a hopeful fight can be organized to quell it; but there is absolutely no escape from a flood of water like that which raged through the Conemaugh Valley.

When we consider the thousands of square miles which it is proposed to irrigate, and estimate the vast amount of water that will be needed to give each acre as much as might fall elsewhere upon this space in a single summer shower, we can begin to understand what an enormous capacity these reservoirs must have to be of any practical benefit to agriculture. We are not prepared to deny that it is within the limit of engineering skill to construct dams that will not yield under the pressure of a given weight of water. But it is a fact that both in this country and in Europe the walls of reservoirs which have been pronounced safe by experts have opened to release torrents which have desolated a thousand homes. No one can tell what agencies of disintegration are at work in the foundations of such a structure. The engineer can measure the pressure of so many feet of water, and if he knows the

quality of every solid yard of material in his embankment he can estimate its power of resistance when his work is finished. But he never can be sure that some chemical agent is not corroding an obscure portion of his masonry, or that some insignificant animal is not undermining it. The work of government contractors has not always proved the staunchest, and when we consider the difficulty of making any adequate inspection of such enormous dams as those proposed for the mountain gorges of the West, we must believe that there is no security for the lives or property of the people who would venture to make their homes below them.

What we have said applies to the conditions of ordinary times and average seasons, but besides this there is the constant menace of some unusual danger. It is the opinion of Major Powell, we believe, that all the forests should be cut away from the mountains where the great western rivers take their rise, so that the water will not soak into the ground, but run away on the surface to be caught by his dams. Another benefit to be derived from making the mountains bare would be, according to this theory, that the snows would all blow into the cañons, where they would remain and find their way to his reservoirs later. It is conceivable, however, that a warm rain or a warm wind through those gorges might deliver the melted snow with great rapidity. The Ardèche is a small mountain stream in France, and yet the sudden melting of the snows in the deep valleys at its sources so swelled its current that it once delivered 1,305,000,000 cubic yards of water into the Rhone in three days. For this short period it flowed with a volume like the Nile, and what reservoir could be trusted to restrain an outpouring of this sort? An earthquake so moderate that it would do no other damage might easily make a fissure in the dam of some storage reservoir which would admit enough water to open a passage for the sea that was crowding behind it. In short, there is danger always from large bodies of water held in by artificial construction, and the Congress of the United States should exercise the utmost caution in appropriating money to build such reservoirs of death.

Of course it is easier to persuade Congress that great public works like these dams will be more efficacious to restrain the waters of the mountains and deliver them when they are needed than is Nature's way of clothing the upper slopes of the river basins with forests. Where millions of money are to be spent in any gigantic scheme there will be hundreds of eloquent advocates to urge its necessity. But perhaps the ruin in the Conemaugh Valley may be allowed to offer one plea for the lives which will be put in daily peril if the project is not arrested. This is but one of the arguments against this scheme, and we are glad to learn that Mr. Fernow, Chief of the Forestry Department, is preparing a report for the Senate Committee on Irrigation, which will discuss the matter from other points of view. It is high time that some organized effort was made to check a movement which has been gathering force from the plausible statement of half-truths, until the government seems committed to the construction of enormously expensive works, which all experience has shown to be inadequate for the purpose they are intended to accomplish, and fraught with serious danger to the lives and property of thousands.

M. Naudin has recently contributed to the *Revue des Sciences Naturelles Appliquées* an instructive paper upon the Australian Acacias, whose bark is valuable for tanning, and upon the advantages which may be expected from the general cultivation of these plants in Algeria. The three species which he considers the most valuable for Algeria are *Acacia pycnantha*, *A. decurrens* and *A. dealbata*.

The actual amount of tan-bark of good quality in California is not large. The Oak which supplies it (*Q. densiflora*) was never a very abundant tree, although widely and very generally scattered in some parts of the state, and the growth of the tanning industry on the Pacific Coast has

already made serious inroads upon the supply. The Hemlock is still fairly abundant in the immediate coast regions of Oregon and Washington; but the bark of the western Hemlock is inferior in quality of tannin to that furnished by the Tan-bark Oak of California or by these Australian Acacias. It is evident that sooner or later tan-bark will have to be produced in California from plantations specially made for the purpose. Australian trees are now known to flourish in the southern part of the State, where there are vast tracts of land suited to them; and these conclusions which M. Naudin reaches in the case of Algiers are equally applicable to southern California, where the climate resembles that of Australia as closely certainly as that of this last country resembles the Algerian climate.

"Algeria as a whole has the greatest climatic analogy with Australia—similar heat and similar droughts. Algeria, especially in the south, like Australia, possesses immense tracts of unoccupied land which can be made productive by the Acacia; and, like Australia, Algeria will be able through these trees to export tan-bark.

"The Acacias will produce, besides tan-bark, which is their principal product, valuable fuel, and possibly gums also as they do in Australia. Certain species, like *A. melanoxylon*, attain the size of forest-trees and produce timber. The wood of this interesting tree is exceedingly hard and richly-colored, and is much sought after by cabinet-makers. This species is already common in the parks and gardens of Provence, and springs up freely from self-sown seed in the garden of the Villa Thuret, as do many other Acacias; and I have not the least doubt that these trees can become naturalized on the other side of the Mediterranean more completely even than they can in southern France."

The Art of Gardening.—An Historical Sketch.

VI.—Persia.

IT is a familiar fact that the Persians, who succeeded the Assyrians and Babylonians in the dominion of eastern Asia, were the most luxurious and pleasure-loving of ancient peoples. When conquest had brought them enormous wealth and unlimited power, their effeminate, self-indulgent habits were the scorn of the hardier, simpler Greeks; and the school-boy of to-day is taught the enormous significance of the result of those wars which left the intellectual Greek instead of the sensuous Persian to be the guide and leader of the world's development. But even in those earlier times, when the Persian had not lapsed into sloth and dissipation, we can divine his pleasure-loving temperament; and it nowhere expressed itself more strongly than in the creation of gardens. In the annals of Persia we find the first distinct record of something more extensive and varied than the small formal enclosure around temple, palace or private dwelling—something which is rightly called a park and seems to have been conceived, in part, at least, in the spirit of what we now call landscape-gardening.

The Persian park, in its first estate, was doubtless a hunting-preserve. Nowhere do we read of such persistent and enthusiastic sportsmen as the Medes and Persians. Hunting on horseback was the chief royal pastime, and the chief means of training noble youths in vigor of body, quickness of mind and familiarity with the saddle. In the "Cyropedia" Xenophon tells us that when the grandfather of Cyrus the Great was persuading him to remain in Media he said: "All the animals which are now in the park, I give them to you; and I will collect others of all kinds which you shall hunt as soon as you have learned how to ride." When the lad had once tasted the excitement of the chase in the open he exclaimed, "Boys, what children we seemed when we hunted in the park! It seemed as though we hunted animals tied by the leg, for . . . they were within a narrow compass of ground." But narrow in such a connection does not mean narrow as one would use the word with regard to a formal walled garden; and there is abundant evidence to prove that very large parks, containing wide expanses of plain, lay near the royal residences and were formed by Persian princes in distant parts of the empire. For example, when Xenophon in the "Anabasis" speaks of Celænæ, "a populous, large and rich city of Phrygia," he says "here Cyrus had a palace and an extensive park full of wild beasts, which he was accustomed to hunt on horseback when-

ever he wished to give himself and his horses exercise. Through the middle of this park flows the river Mæander. Its springs issue from the palace itself, and it runs also through the city of Celænæ. Here Cyrus held a review of the Greeks in the park, and took their number, and they were in all 11,000 heavy armed troops, and about 2,000 peltasts." This, indeed, in extent at least, was a park more than worthy of the modern name, which could not have been entirely devoted to the preservation of wild roving beasts; and if the Cyrus of the "Anabasis"—Cyrus the Younger, a prince and satrap, but not the sovereign of Persia—had such a pleasure-ground, and another equally famous at Sardis, it is not surprising to find that his greater namesake, a century and a half before, and all the kings who followed on the throne, were no less well provided. Cyrus the Great, we are told, after he had conquered the Asiatic world, managed to enjoy "a perpetual spring with regard to heat and cold" by spending seven months of the year at Babylon, three at Susa, and the hottest two at Ecbatana, in the wind-swept mountains of Media. The love for out-door life and natural beauty implied in such a statement might alone suffice to paint the Persian character in this respect. Nor even after death was Cyrus deprived of the free and verdurous environment he loved. He died at Pasargadæ, "and here," says Strabo, "Alexander saw his tomb in a park concealed within a thick plantation of trees." It remains to-day in a naked plain, and is a tower with a stepped platform and a closed upper room in which the body lay; and the contrast is great indeed between such a monument, set in such surroundings as it once possessed, and the dark, sealed caverns, hid in enormous pyramids or excavated in barren hill-sides, where the kings of Egypt were laid to rest. When Darius transferred the capital of Persia proper from Pasargadæ to Persepolis he created gardens that long were famous, though the nature of the site proves that they cannot have been very large, and were probably terraced constructions.

Nor did great parks exist only in the vicinity of the chief royal towns. In his Life of Artaxerxes Mnemon, brother of Cyrus the Younger, Plutarch tells us that, returning from an expedition against the Cadusians, the king "arrived at one of his own mansions which had beautiful ornamented parks in the midst of a region naked and without trees;" and he emphasizes in the succeeding words the respect and affection in which the Persians held such spots: "The weather being very cold, Artaxerxes gave full commission to his soldiers to provide themselves with wood" by cutting down any of the trees, "without exception, even the Pine and the Cypress; and when they hesitated and were for sparing them, being large and goodly trees, he, taking up an axe himself, felled the greatest and most beautiful of them." Moreover, in the "Economist" Xenophon makes Socrates relate that the younger brother, not content with what he had done at Celænæ and Sardis, "wheresoever he travels takes care that there may be gardens, such as are called *Paradeisoi*, stocked with everything good and valuable that the soil will produce; and in these gardens he himself spends the greatest part of his time whenever the season of the year does not prevent him."

Princes and kings were rivalled in their gardening enterprises by their wealthy subjects. Xenophon cites the gardens of Belesis, governor of Syria; and the famous satrap, Tissaphernes, must have had several, for Plutarch says* that, despite his hatred of the Greeks in general, he cherished such love and admiration for one among them that "the most beautiful of his parks . . . received by his direction the name of Alcibiades, and was always so called and so spoken of." Could there, again, be more convincing proof of the exceptional affection that the Persians had for their pleasure-grounds?

The Persians' name for a garden was the word from which our "paradise"† has come; and it is but a just tribute to their national love for such places that it should have been adopted into every language, from Hebrew to English, and become the symbol of the highest delights which the body or the soul of man can enjoy. But the widespread effect of Persian taste upon matters of gardening art does not rest only upon the evidence of this universally borrowed word. Wherever their influence extended—and this means over the whole of western Asia and into Egypt and Ethiopia as well—they carried their love of gardens. The "Persian gallants" who destroyed the Babylonian monarchy, says Sir Thomas Browne in "The Gardens of Cyrus," maintained the "botanical bravery" of the hanging-gardens; and in later times a hunting-park lay near the palace which had been laid out, perhaps, by the great King. When Quintus Curtius, in his "Life of Alexander," tells of the

* "Life of Alcibiades."

† Literally, it means "enclosed."

king's expedition to Bazaria, a far-off district lying east of the Caspian Sea between Parthia and Bactriana, he says: "Of the barbaric splendor prevailing in these parts there are no stronger marks than the extensive forests in which are shut up untamed beasts of the grandest kinds. . . . In one park it was said the game had remained undisturbed through four generations." Our idea of the size of these parks is enhanced, furthermore, by the statement that Alexander entered one of them with his whole army when preparing for a lion-hunt. Pliny tells us that Cambyzes planted trees in Egypt. Syria was long a Persian stronghold, and so, too, the whole of Asia Minor, and in both regions many gardens are named which seem to bespeak the fact. A royal paradise, for instance, that had been established by the conquerors at Sidon, was destroyed in an insurrection under Artaxerxes Ochus in the fourth century B. C. Of course by the time of Strabo and Diodorus the Greeks and Romans had supplanted the Persians in eastern Asia. But, as we shall see, the Greeks and Romans themselves had learned the luxury of gardens from the Persians. The same influence doubtless penetrated with the armies of Alexander and his various successors into the Indian peninsula. In mediæval times we find the favored land of Persia, under the rule of a new race and faith, still the centre of sumptuous living and its handmaid, gardening art. And, in short, a study of the early history of the art of gardening leaves us convinced that the Persians were much more potent than any other people in its development and extension.

Recent Botanical Discoveries in China.—IV.

Æsculus Chinensis is a tree of altogether more slender proportions than *Æ. turbinata*; the relatively small flowers, the color of which I have not found described, are borne in long, narrow, dense panicles, and the small fruit is quite smooth. This species inhabits the mountains near Peking, and Maximowicz also reports it from the province of Shensi. This, doubtless, would be quite hardy in the southern and western parts, at least, of the British Islands, if not throughout, and in similar climates in the New World.

Aucuba.—Dr. Henry has sent specimens of a very singular variety of *A. Japonica*, very different from anything I have seen in cultivation. The peculiarity is in the shape of the leaves, which are from five to six inches long and exactly wedge-shaped, with a truncate, coarsely-toothed apex, the tooth formed by the excurvent midrib being two or three times as long as the others. The other teeth all result from excurvent veins, which are given at an angle of about 40°. In some of the specimens the apex is shallowly three-lobed, the central lobe, the smallest, being an acuminate prolongation of the midrib and a narrow portion of the blade, whilst the lateral lobes are rounded and four to six-toothed. Horticulturally this is more distinct than many of the species of botanists, though the difference is all in the shape of the leaves. A considerable series of specimens are all from the neighborhood of Ichang, where this shrub grows two to four feet high, according to notes accompanying the specimens. Among evergreens of known hardness this is one of the most desirable in our recent Chinese collections.

Buddleia.—An investigation of the Chinese species of this genus has led to the discovery that the plant cultivated in European gardens under the name *B. curviflora* is not the species described and so named by Hooker and Arnott. The latter is a native of the Loo Choo Islands, and probably less hardy than the one passing under the same name, which inhabits Japan, and is apparently restricted to that country. Moreover, it is the only one common in Japan, hence I have named it *B. Japonica*. There is a very good figure of it in the *Illustration Horticole* (xvii., 1870, pp. 133, f. 25), showing the prominently four-winged branches which, with other characters, distinguish it from *B. curviflora*, Hooker and Arnott.

One of the first fruits of Fortune's journey to China on behalf of the Horticultural Society of London was *Buddleia Lindleyana* (*Botanical Register*, 1846, t. 4), which he met with on landing at Chusan in November, 1843. He obtained seeds and posted them on the first opportunity, and in the following March there were young plants growing in the Society's garden. This was regarded as a striking illustration of the rapid communication then existing between England and the far East. I have seen this in a living state on very few occasions—that is to say, in flower—but it is a beautiful plant, much more so than one would imagine from the figure. Dr. Henry collected an elegant variety of this species in the neighborhood of Ichang with sinuately-lobed, long, taper-pointed leaves.

The new species of *Buddleia* offer nothing strikingly ornamental, though one I have named *B. albiflora* is well worth a trial, and if hardy, or rather where it is hardy, it would, doubtless, prove attractive. It is a tree from twenty to thirty feet high, with papery, lanceolate leaves, from six to nine inches long, and small white flowers in long, narrow, dense, terminal panicles. It is from the Patung district, which, as already pointed out, has a considerable elevation, and where there is a long stretch of what Dr. Henry regards virgin forest. *B. variabilis*, another new shrubby species, is remarkable for the great diversity exhibited by its foliage, both in size and in the indumentum, as well as in the shape. Taking the extreme forms, one would not suppose them to belong to the same species, and in aspect there is indeed less resemblance between them than there is between them and *B. albiflora*. Thus one variety from Ichang has narrow, oblong, entire leaves, from one and a half to two and a half inches long, with a short whitish tomentum beneath. The other extreme is from the mountains of Szechuen at an elevation of 6,000 feet. In this the largest leaves are nearly a foot long and broad in proportion, with a coarsely crenate margin, and the two at each node are connected by large ear-like expansions from one petiole to the other. Intermediate forms of every grade are contained in the rich collections of Dr. Henry and the Rev. E. Faber. The flowers are described as pink outside and orange inside; and as they are produced in large pendulous panicles they must have a very pretty effect.

Jasminum.—Among the old Chinese Jessamines none is a greater favorite in England than *J. nudiflorum* (*Botanical Register*, 1846, t. 48), another of Fortune's numerous introductions. Against a wall it flowers freely with us in midwinter, when there is almost nothing else, and the showy yellow blossoms are set off by the green branchlets in the absence of leaves at this season. I have seen only cultivated specimens of this species from China although M. Franchet (*Planta Davidiana*, i., p. 206) records it as common on both slopes of the Tsew-glin range of mountains in the northern province of Shensi.

There are several new species, the most interesting among them being *J. Sinense* and *J. serophyllum*. The former inhabits the provinces of Hupeh and Kwangtung, and would almost certainly require the protection of a green-house except in the very mildest parts of the United Kingdom. It has rather large, softly hairy, trifoliolate leaves and terminal clusters of long, narrow, white flowers; and, judging from dried specimens only, it must be a very ornamental plant. *J. serophyllum* is from Mount Omei, in the province of Szechuen, at an elevation of 5,000 feet. This likewise has trifoliolate leaves, and in aspect strongly resembles the Indian *J. caudatum* (*Botanical Register*, 1842, t. 26), but the somewhat smaller flowers are described as yellow. *J. pachyphyllum* is a new species from the island of Lantao, below Canton, and is allied to *J. paniculatum*, of which there is a very poor representation in the *Botanical Register* (ix., 1823, t. 690), but the new species has very thick, almost orbicular, leaflets.

Diospyros.—Dr. Henry sends numerous specimens of the important *D. Kaki* from the province of Hupeh, and as he does not state the contrary, I assume that they were taken from wild trees. He calls it the oil, or varnish Persimmon, and mentions that an oil is obtained from the fruit and is used for waterproofing the common Chinese umbrellas and hats. There are four or five new species, none probably of any really ornamental character, though it is difficult to judge of this from dried material. *D. Sinensis*, from Mount Omei, at 4,000 feet, is apparently a shrub, with small leaves and slender branchlets, and a small apheroidal fruit about three-quarters of an inch in diameter.

New or Little Known Plants.

Syringa Japonica.

THE late W. S. Clark, the first President of the Massachusetts Agricultural College, in the autumn of 1876 sent to the Arnold Arboretum from Japan, where he had gone to organize an agricultural college at Sapporo, in the northern island, a small collection of seeds. Among them were seeds of a plant belonging to the *Oleaceæ*, and described as a small tree. A number of specimens were raised; these flowered for the first time four years ago, and proved to be the *Syringa Japonica* of Maximowicz, which had not, I believe, been introduced previously into cultivation. Our illustration upon page 293 represents the largest specimen of this tree growing in the Arboretum, and now about eighteen feet in height. That upon page

295 shows, on a much reduced scale, a flowering branch. The photograph from which this last illustration was taken was made in the Arboretum three years ago, and was reproduced at the time in the *Gardeners' Chronicle*. A figure of this species, made from dried specimens, was published also in the *Nouvelles Archives du Muséum*, second series, ii., t. 2, in connection with Decaisne's monograph of the genus *Syringa*.

Syringa Japonica, as it appears in the Arboretum, is a tree of remarkably rapid and vigorous growth. The trunk is straight, and shows no tendency to divide near the ground; it is covered with brown-red, smooth bark, which separates occasionally into thin scales, and is conspicuously marked, as is that of the branches, with raised, white, oblong dots. It might be easily mistaken, except for these dots, for the bark of a young Cherry-tree. The branches are upright and rather slender; those of the year being round and covered with light-brown bark. The winter buds are very small, rarely more than an eighth of an inch long, the broadly ovate scales ciliate on the margins, tipped with a short, blunt point, and pale chestnut colored. The leaves are broadly ovate, contracted into a long, slender point, cuneate or sometimes rounded at the base. They are smooth on the upper and villous pubescent on the lower surface, dark green, thick and leathery, seven or eight inches long by three or three and a half inches wide, and borne on stout petioles an inch and a half or two inches long. The small white flowers, with short corolla-tubes, included in the calyx (like those of the other species belonging to the section *Ligustrina* of the genus), measure from a quarter to a third of an inch across. They are produced in immense compound panicles, eighteen to twenty-four inches long by sixteen or eighteen inches across, and appear here during the first week of July. The fruit is smooth, oblong and obtuse.

The hardness and vigorous growth, the excellent habit, ample, dark green foliage and splendid inflorescence, appearing at a season when few trees bloom, make *Syringa Japonica* one of the most desirable of the small trees recently introduced into gardens. The fact that it loses its leaves early in the autumn, and that they fall while still green, is the only drawback which has yet been noticed in it here as an ornamental plant. C. S. S.

Entomological.

The Imported Elm-leaf Beetle (*Galleruca xanthomelæna* Schr.).

EXPERIMENTS made during the season of 1888 at New Brunswick, New Jersey, by Rev. Geo. D. Hulst prove that this pest can be controlled by an expenditure of time and money, small in proportion to the result attained. The trees in Rutgers College Campus were effectually protected by spraying with a mixture of one pound of London Purple to one hundred gallons of water. In this proportion the larvæ are destroyed and the foliage is not injured. Some little difficulty is experienced in getting London Purple to adhere well to the leaves, and about three pounds of flour should be added to every fifty gallons of water, and thoroughly stirred. Better than this is the mixture of London Purple prepared by the Nixon Nozzle and Machine Company, of Dayton, Ohio, which I find by experiment adheres very firmly where brought into contact with the leaves. The underside of the leaves of the Elm, where the larva feeds, is covered with a rather dense velvety pubescence, which tends strongly to shed water, and consequently to prevent the proper distribution of the poison on the leaves. To remedy this about two quarts of kerosene emulsion should be added to it. This will give sufficient penetrating power to the mixture to spread it wherever it touches, and its effectiveness is thereby greatly increased. In my experience this spring I find quite a decided difference in the wetting power in favor of the mixture containing the kerosene. I should give the formula thus: Water, 100 gallons; London Purple, one pound; kerosene emulsion, one gallon. The kerosene emulsion may be made either with milk or soap, as is most convenient, in the proportion of two parts of kerosene to one of milk, or two parts of kerosene to one of soap-suds, made with half a pound of soap to the gallon of water.

The results of an application of this mixture are quickly noticeable. The young larvæ succumb almost immediately, and many of the eggs are destroyed where they are fairly hit by the mixture. Another point to be observed is the time of application. This should be just after the eggs are hatched and before the larvæ become half-grown. One application will then probably be sufficient, though the tree will be somewhat eaten by the imago. If the trees to be protected are small and few in number it will pay to spray twice—once when the beetles are beginning to oviposit, and again when the eggs are hatching. If sprayed too early a few beetles will be destroyed, which will be replaced by later arrivals, and little good is done. If sprayed too late the advanced larvæ will be ready for pupation, and will not be affected. Many a man has tried poisons to destroy insect pests, and declared them a failure; they were so not because of any fault of the poison, but simply because they were put on at the wrong time and in the wrong way. It is advisable to avoid wetting the trees more than necessary. The finer the spray, and consequent coating of poisonous moisture, the better the result.

The Elm-trees on Rutgers College Campus are probably as high as any trees that are ever sprayed, and to reach to the extreme tops of these I have the following apparatus: A Seneca Falls force-pump, mounted on a wheelbarrow-tank holding forty gallons, to which is attached a canvas-covered garden-hose fifty feet in length. The end of this hose is provided with a large-sized Nixon nozzle, and is lashed to a bamboo stick ten feet in length. With this I can reach twenty feet with the spray attachment from the ground; removing the spray attachment, I throw a small stream among the higher branches, which breaks into quite a fine spray at about twenty-five feet from the ground, and wets thoroughly a height of thirty feet. A light ladder about twenty feet long gives access to a position in the centre of the largest trees, whence the extreme tips may be reached. Few shade-trees are larger than the trees sprayed by me, and no more apparatus would ever be required. For the largest trees, over fifty feet in height, I use about twenty gallons of water, containing about one-fifth of a pound of London Purple, and a pint of kerosene emulsion, at a cost of seven cents, and the labor of applying the mixture. The result so far has been to destroy all the beetles and larvæ and most of the eggs, and has preserved fine-looking green trees, instead of skeletons with fragmentary patches of withered leaves.

Cultural Department.

The Late Garden.

ONE who has secured by careful planning and good management an early garden, can also have a late one, by persistent care in carrying forward the work; and a late garden brings, in many respects, as much pleasure and profit as an early one.

Corn, Beans, Cauliflower, Tomatoes, Lettuce, Endive, Cucumbers, Peas, Beets, Turnips, Radish, Celery, Spinach can yet be planted in vacant places. July 1st is not too late in the latitude of Boston to plant Cory or Crosby Corn; but it is too late for large varieties, like the Evergreen. It is now too late to plant the pole Lima Bean; but the early bush varieties will mature before frost if planted before July. Black Wax (yellow pod), Early China (green pod) and Bush Horticultural (shell) Beans will all attain edible size before frost. Cauliflower, Kohl-Rabi, Brussels Sprouts, Kale, Red Savoy and White Cabbage plants set now will have abundant time to perfect their growths before autumn. Tomato-plants set now will set fruit for ripening before frost, or, at least, fruit which will ripen on the vines after they are pulled up and put under cover. Lettuce-seed planted now, and again on the 15th of July, and thinned where it stands, will make heads to weigh a pound; in the summer months it will not make good heads if transplanted. Endive sown now, and for succession, up to July 20th, can be both thinned and transplanted and will furnish a very acceptable salad from October to December. Cucumbers for pickles, or for the table, can be planted the last week in June or the first in July. Peas will not produce a full crop sown at this time of the year, but are worth trying for. The Turnip-beets, sown up to the middle of July, will make sweeter and more tender roots for the table than those sown in May, as they will grow more quickly and not so large. Turnips of the English varieties, as well as the summer and winter Radishes, can be sown up to August. Celery, if the plants are large, can be set during July; and Spinach can be sown up to September in rich land, where it succeeds best. The Viroflay

(Henderson) is the best all-purpose Spinach I have tried.

As fast as the early Peas, Beans, Corn, Radishes, Beets, Lettuce, Onions and Potatoes mature fill the spaces with later crops; this keeps the weeds down, the garden full, and the table well supplied at a time when the average garden is empty or over-run with weeds.

W. Springfield, Mass.

W. H. Bull.

the growth of fine fruit. The nurserymen offer potted plants at such reasonable figures that it is a matter of small expense to renew a bed annually. The best plan is to have two beds continually; one planted in autumn and bearing its first small crop, and another with its best crop of the second year. The latter is to be plowed or spaded under as soon as the fruit is off, thus furnishing the best place for the crop of

Fig. 114.—*Syringa Japonica* in the Arnold Arboretum.—See page 291.

Strawberries.

AS soon as the fruit is gathered clean out the Strawberry beds and cultivate thoroughly. If plants are wanted, a portion of the bed should be specially reserved for this purpose, but the fruiting-bed should be kept scrupulously clear from runners. In small gardens it seldom pays to raise plants, since this interferes with the neatness of the beds and

winter Cabbages or Savoy. Then on some other vacant spot plant, about the first of September, another bed of Strawberries with strong, potted plants. In raising these potted plants I have abandoned the practice of layering the plants in pots buried along the rows. This is tedious and laborious, and interferes with weeding. Many of the pots, too, get buried and overlooked. My plan is to make the

soil perfectly clean and mellow between the rows where I want the plants. Runners are trained out and are induced to strike root as soon as possible. Then, as fast as they have made little roots half an inch to an inch long, they are lifted carefully and taken to the potting-shed at the greenhouse, where they can be potted in good soil and in a comfortable manner for the operator. I use three-inch pots, and as soon as potted the plants are set on a bed of coal-ashes in a frame, and shaded with screens made of laths nailed an inch apart, so as to give a varying shade and sunshine. Having them thus convenient for watering, they grow with great vigor, and soon make better plants than if the pots were left plunged in the garden to take the chances of rain or drought. Plants potted in this way in July, in a rich compost of rotted sods and manure, furnish the best material for setting a bed late in August or early in September, or in fact at any time when the ground is ready after the pots are filled with roots. By raising or buying a new set of potted plants in this way every year, one can always have, with good soil and culture, the finest fruit the variety selected is capable of yielding, and can avoid the nuisance of an old, worn-out, grassy Strawberry bed. These fall-planted Strawberries will give a moderate crop the following spring, and a full crop the second year, after which they should be destroyed. As to varieties, every one must experiment for himself, for no fruit varies so much with soil and local circumstances. But having a fruit that suits, it is folly to abandon it for some much-advertised novelty. Test promising novelties in a small way, but depend for fruit upon the sort that has done well in the past.

Crozet, Va.

W. F. Massey.

Lælia purpurata.

THIS magnificent Orchid has been known to cultivators more than forty years, and is certainly deserving of the title "King of the Orchids," which has been bestowed upon it, for it stands without a rival among its congeners on account of the size and beauty of its flowers. Unlike most other beautiful plants, *Lælia purpurata* is not rare, and poor, indeed, must be the collection which does not possess a specimen of it.

It has been stated in various works that this species was first discovered by M. Pays, of Bornhem, near Antwerp, hence the name of *Cattleya Brysiana*, under which it was formerly known in gardens and figured and described in books. Its real discovery, however, is attributed to François Devos, who found it growing in the province of Santa Catherina, in south Brazil, while traveling there in 1847. He sent plants to M. Verschaffelt, a nurseryman of Ghent, whence they were distributed over Europe. In England it flowered for the first time in the nurseries of Messrs. Backhouse, of York, who, at that time, were able to sell small plants of it for the sum of twenty-five guineas each. Now, however, it has become more plentiful, and good plants may be obtained at a very low figure.

The plants, which grow about two feet high, have spindle-shaped stems, which become furrowed when old, each bearing a single large, leathery, strap-shaped leaf, of a deep shining green, and an erect peduncle, bearing from three to seven large and beautiful flowers, each six or seven inches across. The oblong-lanceolate-acute sepals, and the ovate-oblong wavy petals, are of a delicate white color, while the lip, which forms the great attraction of the flower, is slightly trilobed; the two basal lobes are folded over the column, forming a tube (white outside and yellow on the inside), which is traversed by conspicuous radiating lines of a deep crimson-purple. The large anterior lobe, which is crisped and spreading, is also of a very deep velvety crimson-purple, which passes into rose at the apex, and is covered with deeper purple veins. The flowers will remain in good condition for three or four weeks if the plants are placed in a moderately cool and dry atmosphere.

There are many varieties of this species known, all distinguished more or less by the difference in color. Among the most distinct varieties are Schröderiana, with pure white sepals and petals, and a white border around the mauve-purple of the front lobe of the lip; Russelliana has the white sepals and petals tinged with rose, and a lilac-purple lip with deeper veins; while Williamsiana has the sepals and petals of a deeper rose color, and a very deep purple lip. Other varieties run so near to each other that it is impossible to distinguish them by sight only.

Lælia purpurata and its varieties thrive, when grown in a temperature of 60° to 65° Fahr., in a compost of good fibrous peat and sphagnum moss. The plants generally produce their flowers during May and June, and a short time after they are over the growing season begins. Any plants requiring it should then be re-potted, but they should be kept an inch or two higher than the rims of the pots, so that the roots may be able to creep over the surface of the soil. The plants should

be placed in such a position that they may obtain plenty of light, as this will induce them to develop and ripen good strong bulbs, without which it is impossible to expect a good crop of flowers when the proper season arrives. When growing, the plants may be freely watered, and a syringing in the latter part of each day is also beneficial. The plants should be slightly shaded when the sun is exceptionally hot, otherwise the leaves would become brown and shrivelled. During the winter months the plants should be considered at rest, and consequently require very little water, and when in flower, the less water given the better.

St. Albans, May 1st, 1889.

John Weathers.

Papaver Caucasicum.—This handsome perennial Poppy is flowering with us for the first time. It was received last year from southern Germany, and has proved to be quite hardy and worthy of cultivation. In general appearance the plant resembles a *Meconopsis*, the leaves being of a glaucous green and covered with hair-like prickles. The flower-stems are two to three feet high and branched from base to apex, each branch producing numerous flowers of a delicate salmon color, and measuring two inches across. *P. Caucasicum* is easily raised from seed, which is freely produced, and it usually flowers the second year from sowing.

Alstromerias.—These lovely Amaryllidaceous plants are too seldom met with in gardens, and the reason is not easily explained. There are at least two species that are perfectly hardy here in the Eastern States—namely, *A. Peruviana* and *A. aurantiaca*. These two we have grown for several years, and find them to do well and increase rapidly when planted in a warm, sheltered corner of the garden, near brick-work, or on a sloping bank, where there is no danger of moisture accumulating in winter. Alstromerias are gross feeders, and when planted need plenty of well-decayed manure worked in with the soil, the more so as their fasciculated masses of fleshy roots bear disturbance badly. Our plants have been in bloom several weeks, and will continue to produce their bright orange flowers on successional growths until frost stops them. Seeds are produced freely, and should be sown as soon as matured, otherwise they will remain dormant until the second year from sowing. As soon as the young plants are large enough to handle they should be potted, and in spring planted in their permanent beds. There are two other species said to be hardy, but these we have not tried.

Passaic, N. J.

O.

Sweet Peas.—The secret of having these beautiful flowers during the whole season does not lie in successive plantings. The earlier the seed is in the ground after it is in fair working order the better, and later plantings will never succeed as well as the first. To insure continuous bloom it is only necessary to cut the flowers as they are fully formed. The tendency of the plant is to produce seed, and if this is prevented by plucking the flowers others will be thrown out quickly to supply the loss. If the cutting is neglected a crop of pods will be produced at once, and the flowering will very shortly come to an end. By this constant cutting of the flowers I have kept Sweet Peas in bloom until October. The plants should not be hoed after they begin to form flower-buds, but after the last hoeing it is good practice to mulch the ground with some coarse litter. This will keep the roots moist in dry weather and hold the small weeds in subjugation. It may be worth mentioning that I have grown Sweet Peas for seven successive years on the same spot, and do not observe any deterioration in their quality. Every year I plant a few in some other part of the garden, and the difference between the two lots, if there is any, is in favor of those grown in the old Sweet Pea corner.

Boston, Mass.

M. B. Faxon.

Dwarf Pears.—It is commonly said that Dwarf Pears are so short-lived as to be unprofitable, but such is not of necessity the case. There are three requisites to longevity of Dwarf Pears and to success in their cultivation: (1) A perfect union with the Quince; (2) Systematic heading-in, in order that the top may not become too large and heavy for the root; (3) Good care always. Varieties which unite permanently with the Quince are comparatively few. Angoulême is undoubtedly the best, and Anjou is excellent. The best old Dwarf Pear orchard which I have ever seen is a ten-acre plot belonging to T. G. Yeomans and Sons, Walworth, Wayne County, New York. It was set in 1853, and notwithstanding its thirty-six years is still in prime of vigor. Two-thirds of the new wood is cut back every spring, and a fair-sized man can pick every pear on the trees without a ladder and without climbing into the trees. As I write the fruit has set profusely, and it has

already been thoroughly sprayed with London Purple. The orchard has always been a profitable one. The varieties are various, but the best are the Angoulèmes.

Cornell University.

L. H. Bailey.

Notes from the Arnold Arboretum.

THE Moonseed (*Menispermum Canadense*) is one of the most graceful of our native vines. The long, slender, twining stems and ample and abundant, delicately thin leaves, adapt this plant for covering small arbors and other structures or for clambering over trees and among shrubs. The flowers, which are white and borne in short axillary clusters, are not in themselves particularly conspicuous, and are quite hidden by the leaves, which conceal also the black grape-like fruit, which ripens in September. *Menispermum* is dioecious, so that plants of the two sexes must be planted if fruit is expected.

The cosmopolitan *Viburnum Opulus*, the so-called Cranberry-tree, with its showy, neutral ray-flowers, which are now expanded, is one of the most beautiful of hardy shrubs of large growth, although now less commonly planted than the variety in which all the flowers are neutral—the "Snowball," or than its Japanese relative, *Viburnum plicatum*. The wild form of *V. Opulus* is not only more graceful and far more attractive than any of the abnormal forms of *Viburnum*, but it seems to escape the visits of plant-lice, which so disfigure the leaves of the "Snowball," and sometimes almost exterminate it. There are growing in the Arboretum, side by side, *Viburnum Opulus*, from our northern woods, the European plant, and others raised from seed gathered by Dr. Bretschneider on the mountains near Pekin. The last is a distinct and very ornamental plant, with striking, narrowly acuminate leaves, sharply wedge-shaped at the base, and often almost destitute

Fig. 115.—*Syringa Japonica*.—See page 291.

M. Canadense is a common plant in the central portions of the country east of the Mississippi River, where it is found growing in deep rich soil along the banks of streams and in other moist situations. There is a second species in this collection, *M. Dauricum*, a native of Siberia, Manchuria and northern China, whence it has been introduced into the Arboretum by Dr. Bretschneider. It may be distinguished from the North American species by its rather larger leaves, which are here quite glabrous on the lower surface, and more broadly and conspicuously lobed; by the larger flowers, which expand here nearly a week earlier, and by its larger fruit. It is a perfectly hardy plant, and grows easily and rapidly, but from a garden point of view it does not seem in any way superior to our native species. The name, *Menispermum*, is composed of two Greek words, meaning moon and seed, having reference to the laterally flattened stone of the fruit, which assumes the form of a crescent from the ovary being incurved in its growth after the flower has fallen.

of the broad lateral lobes usually found on those of this species. The cymes of flowers are rather broader than those on the American plant. There is in the collection a curious dwarf variety of *V. Opulus*, which has never been known to flower before here. It forms a perfectly compact little round bush a foot and a half high and more than two feet and a half across. The leaves, inflorescence and flowers are all smaller than those of the ordinary plant, from which it does not otherwise differ. The variety is not without interest as a curiosity, and it might, perhaps, find its place in a collection of dwarf shrubs. Its compact habit and stiff and formal outline, however, do not make it a desirable object when planted on the margins of shrubberies composed of more graceful plants, while the rarity of its flowers detracts also from its value as a garden plant. It should not be forgotten in comparing the Cranberry-tree with the "Snowballs," that the former is one of the most ornamental of all shrubs in fruit, which hangs bright and scarlet on the naked branches almost until the return of spring, while the

"Snowballs," which produce neutral flowers only, are destitute of fruit.

The Scotch or Burnet Rose (*Rosa pimpinellifolia*, or as it is still more generally known, *R. spinosissima*) is a plant which was more frequently seen in gardens a quarter of a century ago than it is to-day, being, like so many of the beautiful wild single Roses, discarded in favor of the showier-flowered races which have come into fashion in late years. The Scotch Rose, nevertheless, is one of the most charming of hardy plants, with numerous varieties, differing in the color and size of the flowers. *Rosa pimpinellifolia* in its uncultivated state is a small, erect, much-branched shrub, rarely growing more than a foot high, thickly armed with straight, slender prickles, intermixed with glandular hairs. The leaves are composed of seven to nine glabrous-toothed, broad leaflets. The flowers are white or pink, one-half to one inch across, solitary on the ends of the short branches, with smooth, globular calyxes. The fruit is globular, or nearly so, black, or rarely red. This plant has been cultivated in gardens for centuries, and formerly, when Roses were less common than they are in these days, a good deal of attention was devoted no doubt to the selection and improvement of varieties. There are several of these varieties in this collection, some with pure white, others with pink, and one with semi-double flowers. The Scotch Rose is absolutely hardy, and grows and flowers year after year without other care and attention than the early dose of whale-oil soap, which is necessary in this climate to preserve the foliage of every Rose, always excepting that of the Japanese *R. rugosa*, which is unpalatable, apparently, to all insects. *Rosa pimpinellifolia* is widely spread over Europe and temperate Asia, occupying shrubby wastes, often close to the sea, or heathy hills.

As they are now in flower, a few words may be said about two of the twining-stemmed Honeysuckles of the eastern States. They are *Lonicera flava* and *L. Sullivanii*. The first is one of the rarest plants of the United States flora, being known to have grown wild only on the top of Paris Mountain, in Greenville, South Carolina. It was first made known by a notice published in 1802 in Dayton's "View of South Carolina." Later it was collected in the same locality by Fraser, who introduced it into English gardens, where it is still occasionally met with, it is said. It is very rarely seen in those of this country. It is a high-climbing, glabrous plant, with somewhat glaucous, thin leaves, which are broadly oval, the two or three upper pairs joined together into a disk. The flowers are borne in short, capitate, terminal clusters; they are slightly fragrant, bright yellow, later turning orange, with long, slender corolla-tubes, from half an inch to nearly an inch long, slightly hairy on the upper part of the interior surface. The plant, which has long been confounded with this beautiful species, and is now generally cultivated under the name of *L. flava*, is the much more common. *L. Sullivanii* (the *L. flava* of Gray's Manual), which was first distinguished in Ohio many years ago by Mr. W. S. Sullivan, and which is a widely-distributed plant from central Ohio to Winnipeg and to Tennessee. This plant may be distinguished from *L. flava* by its short, bushy stems, which barely climb or attain a greater height than six or eight feet; by the much thicker leaves, whitened with a glaucous bloom; by the inflorescence, which consists of several more or less approximate whorls of flowers, and by the flowers themselves, which have a short corolla-tube, less than half an inch long, conspicuously gibbous and very pale yellow. The leaves are two to four inches long, oval or obovate-oblong, those of the flowering-stems sessile, with the upper pair joined into an orbicular disk. The flowers of this species are not fragrant. This is the half-bushy Honeysuckle often seen in old gardens, with pale foliage, which becomes by midsummer quite mealy-white. It is a far less ornamental or desirable plant than the true *L. flava*, which some nurseryman would do well to take up and make common. Mr. Faxon, who has detected *L. Sullivanii* in the plant commonly cultivated, has made sketches of the two species, which will in time appear in the pages of GARDEN AND FOREST and illustrate the distinctive characters of the two plants, which are, moreover, clearly defined in Gray's "Synoptical Flora of North America."

The Scarlet Trumpet-Honeysuckle, a widely-distributed plant through the middle and southern States, and one of the most beautiful of the Honeysuckles in cultivation, is such a well-known plant that it need only be mentioned for the purpose of calling attention to a variety with clear yellow corollas, which is not as well known to cultivators, or as often seen in gardens as its great beauty entitles it to be.

Lonicera hirsuta is another of the climbing Honeysuckles of the eastern States, which is now in flower, and which well deserves a place in every collection of hardy shrubs. It is a

high-climbing, free-twining plant, with oval, prominently-veined, softly-pubescent, green leaves (destitute of the whitish bloom found upon those of *L. flava* and *L. Sullivanii*), the upper pairs connate. The corollas are orange-yellow fading to brown, viscid-pubescent on the outer surface, the tubes half an inch long. The throat and the base of the filaments are covered with hairs. This pretty plant is found growing upon rocky banks from northern New England and Canada to the Saskatchewan, and southward to Michigan and Pennsylvania.

It is surprising that the English Woodbine (*Lonicera Periclymenum*) is not more generally grown in the gardens of this country. It is one of the most beautiful of all the climbing Honeysuckles—a perfectly hardy plant, and the delicious fragrance of the flowers is unequalled. The flowers are pale red externally with yellow throats, and are produced from the ends of the branches in closely sessile heads which are stalked above the upper pair of leaves, which are closely sessile, although not united. This is a widely-distributed plant from Scandinavia to the shores of the Mediterranean. The "Dutch Monthly" Honeysuckle is a variety of this plant, so named, it is said, because it originated in one of the Dutch nurseries. The flowers are rather darker colored than those of the species. These Honeysuckles flower quite continuously through the summer months, and there are no more charming plants to train over the porch or veranda of a dwelling-house, that the fragrance of their flowers may be enjoyed constantly.

Lonicera orientalis is in flower. It is a low, shrubby species of western Asia, extending from Asia Minor to Kashmir and the temperate Himalaya, where it sometimes attains the size of a small tree. Here it is a slender shrub, with membranaceous, pale green, ovate, pointed smooth leaves, rather prominently veined; small, pink flowers and conspicuous black fruit. This plant, from an ornamental point of view, has little to recommend it as compared with some of the fine forms of the Tartarian Honeysuckle, or with some of the recently introduced Bush Honeysuckles from western Asia.

Another Himalayan species, *Lonicera quinquelocularis*, closely allied to *L. Xylosteum* of Europe and Siberia, is certainly better worth a place in the garden. It is a hardy shrub, growing to a height of from five to ten feet, with pubescent branchlets, ovate, or broadly lanceolate leaves, which are hairy on the lower surface; and clustered, sessile, axillary flowers, with short-tubed, hairy, yellow corollas. This plant is an old inhabitant of the Arboretum, where it is perfectly hardy, and decidedly ornamental. It is widely distributed in the Himalayas, where it is common between 4,000 and 12,000 feet elevation.

Elaeagnus Canadensis is still, in spite of some interesting introductions from western Asia, the most ornamental species of this genus, at least in foliage. It is a stoloniferous shrub, growing to a height of eight to ten feet, with unarmed branches, those of the year covered with ferruginous scales. The silvery-white, scurfy leaves are broadly or narrowly elliptical, one and a half to four inches long. The axillary tubular flowers are a third of an inch long, silvery on the outside and yellow within. They are deliciously fragrant, and are followed by abundant, globular, dry, mealy, edible fruit. It is a widely-distributed plant from northern Minnesota to the Saskatchewan and to Utah; it is abundant, and a characteristic feature of the vegetation of the upper Missouri valley, where it was discovered by Lewis & Clark during their transcontinental journey. *E. argentea* was introduced into English gardens as early as 1813, but is now not very often seen in cultivation. It is perfectly hardy, and the silvery whiteness of the foliage and the pleasant fragrance of the flowers make it an attractive garden-plant. *E. umbellata* is also in flower. It is a shrubby plant, three or four feet high, the gray branches covered with brown scurfy scales. The leaves are oblong lanceolate, silvery on the lower surface, bright green on the upper. The flowers are clustered, creamy-white, fragrant, and appear after the leaves are fully grown. Those on the Japanese plant turn brilliantly in the autumn. The fruit is succulent, ovoid or globose, one-third of an inch long. Another plant here (*E. parvifolia* of Wall. and of gardens) is evidently the Himalayan form of the species. This is a larger and stouter plant, growing into a broad bush ten or twelve feet high, with rather narrower pale green leaves, but not otherwise distinguished from the Japanese plant; it is less hardy, however, and suffers seriously sometimes during severe winters. *E. umbellata*, as now defined by botanists, is a widely-distributed plant from Japan (where it abounds in the northern islands, covering the sandy banks of streams, just as the American species does those in the northern

Rocky Mountains), through northern China to the Himalayas and Afghanistan.

The India form is an old inhabitant of gardens, and is not infrequently seen in those of the middle States.

The Forest.

Forest Interests in Pennsylvania.—I.

I HAVE been looking around in Pennsylvania for a few weeks examining the condition of the mountain woods, and calling on journalists and other leading citizens, with the object of stimulating interest in forestry subjects, and especially in the work of the State Forestry Association. As I was present at the inception of this organization, and encouraged its founders at that time by pointing out some of the difficulties they would encounter, I have always felt much interest in its work. It was established chiefly by the efforts of two or three earnest women, and its history illustrates very well the nature of some of the opportunities for service to the public welfare which have recently been opened to public-spirited women in our country.

During this visit to the principal towns of the state I had, as always, the cordial co-operation of journalists everywhere, and Governor Beaver gave me all possible assistance, as did also Mr. Edge, who is at the head of the State Department of Agriculture, the officers of the State College and Experiment Station and prominent men generally. The next annual meeting of the American Forestry Congress, of which Governor Beaver is President, is to be held in Philadelphia on the 16th, 17th and 18th days of October of this year, and the recent energetic action of the State Forestry Association will, doubtless, prepare the way for an interesting and useful session of the national body.

There is still a great deal of fine timber in some portions of the mountain forest-region of Pennsylvania. Most of the original growth was cut off many years ago; much of it for charcoal, and the various uses for wood connected with the manufacture of iron and the construction and operation of railroads, as well as for making lumber. The timber now standing is chiefly second growth. A great deal of it is very vigorous, growing rapidly and constantly increasing in value. I saw some wonderful groves of young White Pine. One in Centre County, to which I made an excursion with Professor Buckhout, of the State College, is one of the most beautiful and interesting tracts of young timber that I have ever seen. It is not extensive, but it is a piece of pure forest of White Pine, remarkably dense, and the trees are nearly uniform in size, except that some of the weaker ones are being dwarfed by overcrowding.

Professor Buckhout has begun some experiments in tree-planting, having set out about 3,500 small White Pines and Chestnuts, a few hundred of them on land belonging to the State College, near the Agricultural Experiment Station, but most of them on a small area from which the timber had been removed, up in the mountains, five or six miles from the college. His object is observation, experiment, comparison of results, as a means of increasing his own knowledge of tree-culture. There is, of course, no need of forest-planting in this part of the country, as the trees will come in themselves everywhere, if the ground is protected from fire and from pasturage. But there is need of tree-planting by farmers on small areas which are unsuited to other crops, and which are now mostly occupied by worthless trees, bushes or briars. Such nooks and corners are often nurseries and seeding-places for mischievous weeds, which stock the entire farm or neighborhood. They might as well be devoted to growing useful trees, and farmers need more knowledge than they now possess regarding the best kinds to plant. Professor Buckhout and some of the most intelligent farmers of Centre County believe that the Chestnut does not succeed on the limestone land of that region, though it grows well on the sandstone soil higher up in the mountains.

In nearly every part of the state there is much complaint of the failure and decay of small tracts of woodland. No matter how vigorous the trees may be in a large forest area, when farms are opened and much of the land is cleared, the trees in tracts which are left for timber soon begin to die at the top and to blow down. The most observant farmers believe that this results from the desiccating effect of the wind, which increases in force as more and more of the forest of the region is cut away. In many parts of the state it is noticeable that the remaining woodlands have very little underbrush. This indicates that when the larger trees mature and are removed the woods will come to an end. In many cases wood-

lands are destroyed by the encroachment of grass, which appropriates the nutriment in the soil which the trees require, so that they die of starvation. Of course, pasturing is always fatal to woodlands, though some farmers appear never to have observed this fact, or thought of the relation between cause and effect in their own experience in this matter.

Planting belts of White Pine or other suitable evergreen trees all around a tract of woodland might be some protection from the desiccating influence of the wind, but farmers say they do not know how the grass is to be kept out, especially after the process of thinning the woods is begun by the removal of some of the trees for use. If the farm woodlands continue to die out it may become more needful than it has been hitherto to consider the matter of planting trees. But it seems evident in such cases that the present generation of trees perishes by reason of the increasing dryness and impoverishment of the soil, and tree-planting would not remedy this unless we can find some kinds of trees which will live and thrive on dryer and poorer soil. Perhaps planting evergreens thickly among the trees might be useful in protecting the surface from desiccation and from light, and also by detaining the leaves for a mulch, which now mostly blow away from the woods which are nearly destitute of undergrowth. The best kinds of trees to plant are, in nearly all cases, those which are already growing well in similar soil and conditions in each region.

In the towns of the state and on the grounds about public buildings and private dwellings, as well as around old farm-houses, there are many thousands of trees which should at once be cut down, as they are mature, over-crowded, ugly, or for various reasons unsuited to the places they occupy. In most cases there are far too many of them, they having been planted much too thickly and never adequately thinned. This is true of the grounds around the Capitol at Harrisburg, and of those of the State College in Centre County. Many of the trees in the State-house grounds are misshapen, dwarfed and ugly, and are every year causing increased injury to better trees. At the State College nearly all the trees should be cut down. They are only valuable as an illustration of what ought not to be.

On one side of the principal walk leading up to the college from the main entrance to the grounds there is a close line of Norway Spruces, and on the other a row of White Maples. A more incongruous and unattractive arrangement I have scarcely ever seen. But nobody planned or intended it. It was not designed at all. As in so many similar cases, it simply happened so. There was a nursery there once, and some of the rows of young trees were removed, while others were, unfortunately, left to grow, and they have grown until now it is probable that nobody in the state would dare to cut them down. Yet they are intolerable as a feature of an important educational institution, established and conducted by the state, and which therefore represents the civilization of one of the most important and vital communities of our nation.

It would be an excellent thing to devote the next Arbor Day in this state to cutting down trees, and to begin the work on the grounds which belong to the state around the Capitol and the State College.

West American Oaks. Illustrations of West American Oaks from drawings by the late Albert Kellogg, M.D., with text by Edward L. Greene.

Dr. Kellogg devoted the last years of his life to the preparation of a series of botanical drawings of the Oaks, Pines and other trees of California and the adjacent regions, which he intended to publish with detailed descriptions. He did not live, however, to see this important work completed, and some of his old friends and associates have now secured the publication of his excellent figures of the Oaks, in handsome style, with full descriptive and critical notes from the pen of Mr. Edward L. Greene, the necessary funds being provided through the liberality of Mr. James M. McDonald.

The Oaks of California are perhaps the most difficult of all our trees to rightly understand and properly characterize. Some of the species are widely distributed over regions of varied climate, and show marked and striking varieties in different individuals; others of more restricted range vary greatly, some individuals growing as large trees, or as low and humble shrubs within an area, a few miles in extent. Leaves with entire and with sharply-toothed margins appear sometimes upon the same branch, and it is impossible without opportunity for wide and long study in the fields to reach anything

like an exact idea of their specific characters. Such opportunities Mr. Greene has enjoyed, to a fuller extent than any one who has studied these trees; and the results of his investigations cannot fail to be of the greatest value to dendrologists. Without undertaking, at this time, to criticise his conclusions, for which sufficient material does not exist in any of the eastern herbaria we will, in referring such of our readers as are interested in the trees of California to the work itself, simply note the following changes which Mr. Greene proposes.

Quercus Morehus, a species so named by Dr. Kellogg, but referred by Engelmann to *Q. Wislizeni*, Mr. Greene maintains as a species related to this last, but differing from it in habit and in the size and outlines of the leaves. It has been suggested that this may be a natural hybrid between *Q. Wislizeni* and *Q. Kelloggii* (a deciduous-leaved species) but Mr. Greene finds it abundant at Berkeley, many miles from any known station of *Q. Kelloggii*. *Quercus Breweri*, of Engelmann, as Mr. Watson has already pointed out (*Proc. Am. Acad.* xxii., 477) must give way to the older name of *Q. Erstediana*, of R. Brown Campst. *Quercus Gambellii*, of Nuttall, the south-eastern representative of our eastern White Oak, and considered by Engelmann as a variety of the Rocky Mountain *Q. undulata* is reinstated as a species, while *Q. grisea*, and *Q. oblongifolia* are considered, so far as concerns the New Mexican and Arizona plants, forms of *Q. undulata*; and a new species, *Q. Engelmanni* is proposed for the common evergreen White Oak, of southern California, heretofore considered identical with the New Mexican *Q. oblongifolia*. Another new species, *Quercus McDonaldi* is proposed for a small deciduous White Oak, found upon the Island of Santa Cruz with a var. *elegantula* from the borders of streams in the southern part of the state.

A new Scrub Oak, from the Peninsula of Lower California, discovered as late as last year, is described as *Q. turbinella*.

So little is known yet accurately about the trees of Western North America, their characters and life histories that we hail with delight all contributions toward a better knowledge of them. The most important of recent contributions of this nature, is certainly the work that is now before us.

Periodical Literature.

The chief value of an article called "The Migrations of Plants," published in the last number of the *Edinburgh Review* is that it directs attention to four books which have a wide fame with professed students in natural history. These are De Candolle's "Origin of Cultivated Plants" (1884), Mehn's "Wanderings of Plants and Animals from the First Home" (1885), Wallace's "Island Life" (1880), and Sir Joseph Hooker's "Address on Geographical Distribution," printed in the reports of the fifty-third meeting of the British Association for the Advancement of Science, held at York in 1881. Of course, however, since the article is based upon such works as these and intelligently summarizes many of their theories and reproduces some of the more curious facts they give, it has an intrinsic interest of its own and will be found pleasant and instructive reading by those who have not the time to study the authorities which it follows at first hand. Perhaps only one passage needs to be quoted with a word of warning. When the author says that "Darwin thought that the varying forms of florists' flowers and garden vegetables must convince us that selection is everything, and the choice of the particular species to be operated upon is by comparison nothing," he surely exaggerates a little; and when he adds, "you can convert such common subjects as Pelargoniums and Potatoes, Turnips, Radishes and Carnations to every size, shape and color by a few years' breeding and selection," he makes a palpable misstatement. If he can show the gardener how to take such flowers as Carnations, Pelargoniums, Tulips and Narcissi out of those ranges of color, which the careful cultivation of centuries has been unable to break through; if he can teach us how to grow blue Tulips, Carnations or Pelargoniums, for example, or scarlet Narcissi, or yellow *Phlox Drummondii*, he will earn the respect of the horticultural world and make a name for himself which it will be impossible for him to hide even under the discreet anonymity so carefully preserved for its writers by the *Edinburgh Review*.

Correspondence.

West American Oaks.

To the Editor of GARDEN AND FOREST:

Sir.—The publication of the late Dr. Albert Kellogg's drawings of Pacific Coast Oaks in quarto form, with text by that

most careful botanist, Edward L. Greene, of the State University, deserves, I think, some especial mention. The funds for the publication were furnished by Captain James M. McDonald a wealthy pioneer, one of the directors of the Overland Monthly Company, a director of the Art School and an ex-Supervisor of San Francisco. He is said to be furnishing funds for the publication of another monograph similar in character, to be devoted to the Californian Pines.

The monograph on the "West American Oaks" will attract the interest of all botanists, and I only wish to note here a few things about some of the men concerned in the work, chiefly about Dr. Kellogg. I first knew Dr. Albert Kellogg in 1878, when I became editor of the *Californian Horticulturist*. He was so child-like and so sincere a person that I came to have a great liking for him. In his own field he was a hard worker. He lived as one of the "Poor Scholars" of the Middle Ages, apart from the bread-and-butter struggle that went on about him. He gave up his profession many years before his death, and lived in poverty, devoting his entire time to botanical investigations. In 1853 he and six others founded the California Academy of Sciences, now so munificently endowed for original research by the gifts of Charles Crocker and James Lick. He left his drawings and papers on botany to his co-workers, Mr. W. G. W. Harford and Dr. W. P. Gibbons. I do not know how extensive his researches were, but I know something about his contributions to the early periodical literature of the Pacific Coast: All of the early publications, such as *Hutchings' Magazine*, the *Hesperian* and the *Pioneer* contained short but constant notes on our native plants, usually accompanied by drawings. The old *California Farmer*, the *California Culturist*, the early issues of the *Rural Press* and the special editions of other San Francisco weeklies contained many articles of value from Dr. Kellogg's pen. For years he was the only botanical writer on the Pacific Coast. He could have prepared and illustrated a better California botany for children than any we are now likely to have, so simple and fresh was his style. Day after day, month after month, year after year, he was at work in the old Church building, where the struggling Academy of Sciences had its home. Mr. Harford, Dr. Behr, Dr. Gibbons, Dr. Kellogg and a few others were always there, except when in the woods and mountains. It was a wonderful and loving little group of friends and workers in the midst of a great city, as yet too much devoted to material things. The daily newspapers hardly mention the lives of such men, but they shape the future, nevertheless. Men of broader scientific training came to work with them and carry on their plans to a higher fulfillment. Men of wealth put money in their hands to use in researches "for the good of humanity." To my mind the "West American Oaks" is a monument of a single-hearted, brave old botanical pioneer, and of the friendship of a group of men, rich and poor, who loved and honored him.

San Francisco.

Charles Howard Shinn.

Magnolias Near Baltimore.

To the Editor of GARDEN AND FOREST:

Sir.—Professor Sargent's paper on Chinese Magnolias reminds me that perhaps one of the oldest and finest specimens of *Magnolia Soulangeana* in America stands on the grounds of "Hampton," the seat of the Ridgely family, near Baltimore. This tree branches within two or three feet from the ground, and spreads over a large area. Five years ago the stem below the branches measured nearly eight feet in circumference. The tree was planted by the late Samuel Feast, since well known as a florist, nearly sixty years ago, when he was the head gardener at Hampton, and his brother, the late John Feast, was his foreman. Of the same importation the Feasts planted at Hampton a Purple Beech, a Cedar of Lebanon and other rare trees. The Beech is worth a long journey to see. It stands on a smooth lawn unencumbered by other trees, and its branches sweep the ground in a circle fully fifty feet in diameter, while its symmetrical head rises like a copper dome over fifty feet in the air. In the grounds of this old place, which has now been in the hands of professional gardeners for over a century, are many other magnificent specimen trees, particularly a row of native Cedars (*Juniperus Virginiana*) along the top of the old-fashioned terraced garden, of gigantic size, and covered with Ivy from bottom to top. Here is also, perhaps, the oldest green-house now standing in America. It is an orangery, built in the old style, with perpendicular glass on the south side and east end, and heavy stone walls on the other sides. The roof is shingled, and the ceiling overhead is lathed and plastered. This house was built about the same time as the old mansion (1784), and still shelters as fine a collection of the Citrus family as exists in this country,

with individual trees said to have been among its first inhabitants.

In the grounds at "Clifton Park," Baltimore, the property of Johns Hopkins University, are a number of large specimens of *Magnolia conspicua*, probably as large as any of this variety in the country. It is greatly to be feared that the fine trees in this park, of nearly four hundred acres, are doomed, as it is said that the financial needs of the university require that it be divided into city blocks and sold. The founder of the university intended this park for its site, but its managers have thought it better to buy and tear down brick blocks in the heart of the city on which to locate its buildings, and now will sell their useless but extremely valuable park, and sacrifice its wealth of trees.

Crozel, Va.

W. F. Massey.

To the Editor of GARDEN AND FOREST:

Sir.—Here is an old sun-dial motto which seems to me prettier than any of those you recently quoted, and which I do not find in Mrs. Gatty's book. I have, however, only the first edition:

"I am a Shade:
A Shadowe, too, art thou:
I marke the Time:
Saye, Gossip, dost thou so?"

New Haven, Conn.

F. L. M.

The United States Nurseries.

To the Editor of GARDEN AND FOREST:

Sir.—Some ten miles inland from Newark, New Jersey, where the Watchung Mountain range falls away sufficiently to allow a railroad to pass over it to the west, lies the town of Short Hills. It is a high and breezy situation, and the town is practically a spacious park, with villas scattered among the trees. Here for some years has been the home of Mr. James R. Pitcher, and his place has become famous for its interesting collection of plants, and particularly of Orchids. Not long since Mr. Pitcher determined to make his private collection the nucleus of a commercial nursery, and in this business venture he associated with him ten months ago Mr. W. A. Manda, who was at that time head gardener of the Botanic Garden in Cambridge. Unlike the other establishments which I have recently visited, the United States Nurseries have no history. They did not grow up from small beginnings, but started fully equipped for operations on a grand scale. Here are twenty-one green-houses, constructed in the most substantial manner, and stocked with Orchids, Palms, Ferns, Dracænas, Amaryllises and other ornamental plants, while seven acres of ground are entirely occupied with the best of hardy herbaceous plants. The first catalogue of the firm was devoted exclusively to Cyripediums, and it not only attracted attention for the beauty of its mechanical execution, but for the remarkable richness of the collection it offered. The catalogues of special classes of plants which have followed have been equally sumptuous, and the variety and completeness of the lists offered prove that the entire field, which the house proposes to occupy, has been carefully studied and provided for.

In a letter like this only general impressions can be given, for a detailed description of the noteworthy plants in any one of the houses would more than consume the space allotted to me. But a house full of Anthuriums makes a dazzling display, even when no close inspection is made of the nice shades of distinction among the twenty-five varieties that are in flower. In the Cool-Orchid house, too, where 3,000 Masdevallias are showing every tint of color, from vermilion to crimson and purple, the eye finds delight in the combined effect of the mass, even before time is taken to study the particular charms of individuals which represent seventy-five species and varieties. On the opposite stage of the same house are 6,000 plants of *Odontoglossum Alexandrae*, not all in bloom, but many of them white with flowers, and every one thrifty and promising. It would be difficult to find elsewhere as many Cyripediums in one collection. The list includes something like 400 species and varieties, while the number of individual plants approaches 20,000. Among them are many forms of the stately *C. Lawrenceanum*; a plant of *C. superbiens*, carrying eleven flowers, and admirable specimens of *C. Schraderea*, *C. grande* and *C. bellatulum*. Among other Orchids of conspicuous excellence in bloom I noted a variety of *Lælia purpurata*, with petals and sepals of deep rose, while the lip shows the intense purple of the species, and near it was a striking variety of *Oncidium crispum*, with flowers of an indescribable copper color.

Immense cases of imported Orchids are constantly arriving, but Mr. Manda is ambitious to originate some Cyripediums of his own, and the process of raising hybrid seedlings is interesting to amateurs. After the pollen has been transferred from the anther of one flower to the stigmatic surface of another flower of a different species, from six to twelve months elapse before the seed is ripe. The seed is fine as dust, and Mr. Manda sows it on the pots and among the moss where his plants are growing, so that it has the same temperature and moisture which the plants enjoy. The seeds do not begin to germinate until from four to six months after they are sown, and then the grower must wait patiently from four to twelve years for his plant to bloom. The species with thick leaves, as a rule, are longer coming into flower than others. Faith and hope are plainly virtues essential in one who would raise seedling Orchids.

Passing through a large Palm-house, where the most interesting specimen to me was a great *Encephalartos (Zamia) pungens*, we came at last to a house set full of Chrysanthemums, and chiefly of the famous Mrs. Hardy. Messrs. Pitcher & Manda paid a larger sum for this plant than was ever given before in this country for a similar plant of this class. But no other plant of the year has attracted so much attention or has been talked about so much since its figure appeared in the first number of GARDEN AND FOREST. Without doubt the enterprising purchasers have received already much more money than they paid for the plant, and even if they had not done so the Mrs. Hardy would have proved exactly the kind of advertisement which the new firm needed. The plants here look strong and vigorous, and seem to indicate that strength of constitution which was always claimed for this variety. Chrysanthemums, by the way, are one of the specialties of these nurseries, and all the more promising new kinds, including select importations from Japan, are here on trial.

Among the hardy herbaceous perennials I observed a large block of Pæonias. Mr. Manda finds that there is a growing demand for these plants, and he is gathering as rich a collection as possible. Tree-Pæonies, too, receive much attention, as do the Poppies, Phloxes, Primulas, Single Dahlias and Alpine plants. Hardy Orchids form another feature of special interest, and one must go far to find a better collection of native species. These native Orchids and other American plants, and with them certain Mexican and Japanese plants are now sent to Europe from these nurseries in very considerable quantities.

As was said at the beginning of this letter, these nurseries have their history yet to make; there are few places in the country, however, which can show collections of plants better worth visiting, and the very fact that such an establishment has been created within a few months is a striking illustration of the faith of forward-looking men that the gardens of the country will absorb an almost unlimited supply of the best material. Ten years ago an enterprise of this magnitude would have been looked upon as a venture of the wildest character.

S.

Short Hills, N. J., June 15th.

Recent Plant Portraits.

Botanical Magazine, May.

LICUALA VEITCHII, t. 7053; a handsome dwarf Palm (the *Pritchardia grandis* of Veitch's Catalogue), a native of Sarawak, in Borneo.

SMILAX OFFICINALIS, t. 7054; the plant which supplies the true Sarsaparilla of the British Pharmacopæia.

PENTSTEMON ROTUNDIFOLIUS, t. 7055; a shrubby Mexican species discovered by Mr. Pringle and figured in GARDEN AND FOREST, i., f. 73.

SAXIFRAGA LATEPETIOLATA, t. 7056; a rare biennial species, being known to grow only on a single Spanish mountain, the Sierra Sta. Maria, one of the Cerro de Chiva, in Valentia; and remarkable owing to the great breadth of the petioles.

LAPORTEA MOROIDES, t. 7057; one of the "virulently stinging Nettles that infest the humid forests of eastern tropical and sub-tropical Australia"—a shrub or small tree clothed with very fine virulently stinging hairs.

PHILLYREA VILMORINIANA, *Revue Horticole*, May 1st; a fruiting branch of this well-known broad-leaved evergreen shrub of the Orient.

AMPELOVITIS DAVIDII, *Revue Horticole*, May 1st; this, the *Vitis Romaneti* of some authors, is an interesting hardy plant from the north of China, of very considerable ornamental value.

HIPPEASTRUM RETICULATUM, *Gartenflora*, May 1st.

Notes.

The Legislature of California, at its last session, amended the state revenue laws so as to exempt fruit-trees and Grape-vines from taxation.

Syringa Pekinensis, Rupr., is in flower this year in the Arnold Arboretum. This is probably the first time that this plant has flowered in cultivation. A photograph of a panicle of flowers has been made, and will be reproduced in the pages of this journal.

On Friday last 2,200 plants of *Cycas revoluta* were sold at auction by Messrs. Young & Elliott, of this city. This was the largest importation of these plants ever disposed of here at a single sale. They varied from six to eighteen inches high and from twelve to sixteen inches in circumference, and were in excellent condition.

The collection of Orchids belonging to Mr. J. Wallace, of Paterson, New Jersey, was sold on Tuesday last at the auction-rooms of Messrs. Young & Elliott. The lot consisted of 1,700 established plants, and the prices realized were good. A strong plant of the beautiful hybrid *Cattleya Exoniensis* brought the highest price, which was seventy dollars.

The plant most commonly used in Japan for the making of lawns is said by a German horticultural paper to be the Shiba Grass (*Arundinella anomala*). It is an evergreen which grows to but four or five inches in height and requires to be cut only twice in the year. It must be propagated by division, as it rarely bears good seed, and plants grown from the seed do not, it is said, have the soft gray-green color which is so highly prized by the Japanese.

The retail florists of Brooklyn have been lately offering for sale fine plants of Pomponé Dahlias, about eighteen inches high and full of flowers. They are in four-inch pots, and sell for twenty-five cents each. Dahlias of such size are unusual in this market in early June, and a little investigation brings out the fact that most, if not all, of the plants come from the establishment of Kritchsmar Brothers, Flatbush, Long Island. This firm raised some 10,000 plants, 1,000 of which were sold to the Brooklyn Jockey Club for decorating their grounds. A large proportion of the Dahlias are of the old white variety, known as *Camelliaeflora*, but there are also colored Pomponé varieties which seem equally well-grown. The same growers every year plant a house full of the white Dahlia, mentioned above, for winter flowers.

It is proposed, in connection with the International Exposition of Geographical, Commercial and Industrial Botany, which will be held in Antwerp next year, to celebrate the third centennial of the invention of the microscope. An historical exhibit will be arranged, and another of the different forms of the microscope, as at present perfected; and these exhibits will be illustrated by a series of descriptive lectures, which can hardly fail to be interesting and instructive. The compound microscope was invented by two brothers, Hans and Zacharia Janssen, of Middelburg, in 1590. It was little employed, however, until the end of the first quarter of the present century, when the great improvements invented by Charles Chevallier led to its general use by men of science and made possible the discoveries to which the human race owes so much.

The play-ground in Franklin Park, Boston, a broad and beautiful meadow, one of the purest and simplest of Mr. Olmsted's creations, was formally dedicated to the public use on Wednesday of last week, in the presence of the Governor of the Commonwealth, the Mayor of Boston, 8,000 pupils of the public schools, and a vast concourse of spectators, before whom the School Regiment, made up of battalions from the High Schools of the city, paraded. The school children joined in singing "The Star Spangled Banner" when the flag was displayed from the tall staff in the middle of the meadow, and the people of Boston realized for the first time what it is to have a park. A few passing clouds and some drops of rain served to temper the heat of the day, and neither interfered with the success nor detracted from the beauty of one of the most picturesque and important events in the recent history of the New England metropolis.

Everyone knows that the stork is almost superstitiously beloved by the peasants of northern Germany and the Low Countries, and that iron supports upon which he may build his nest are set on cottage-gables in the belief that where a stork has his brood fire will never come. Nevertheless, travelers are often surprised when they see how tame the great birds become, following the agriculturalist through field and furrow, and often sleeping on one tall red leg close to where

he is at work and within sound of the rumble of the passing railroad train. So fond is the Dutchman of having storks about him, indeed, that he makes provision for its nests even in the centre of his bulb-fields. Here one may often see slender poles some twenty or thirty feet in height, supported by braces and bearing at the top a small round platform similarly strengthened. On these the storks build their nests, and here they perch, like sentinels protecting the beautiful crops.

The Woman's Division of the German Academic Association recently decided to promote the education of women in the art of gardening, "partly in order to enable the future housewife to care for her own garden, but chiefly to open new sources of income to the unmarried." A committee of the Association for the Promotion of Horticulture at once concerned itself with the matter, and announced that it would be considered at a general meeting on May 23d. Meanwhile, however, the subject was broached at an open horticultural conference in Berlin on the 8th of May, where 600 gardeners were present. An hour and a half was spent in discussing the advisability of educating women as gardeners, thirty speakers making themselves heard for or against the idea. A vote was then taken, and the following resolution submitted to the ladies' committee of the Academic Association: "The conference feels itself compelled to oppose the projects of the Academic Association in the interest of German gardening, as well as in those of womankind itself, because gardening demands much greater physical powers than usually are found in women, and because the industry is already at this moment suffering from overcrowding."

A writer in the *Garden* speaking of the American White Pine by the name most commonly employed in England, says: "When we consider how valuable a timber-producing tree the Weymouth Pine is, how rapid of growth, how easy of culture, and, withal, how distinct and beautiful, the wonder is that it is not more extensively cultivated on this side of the Atlantic. It is becoming a rare tree in its native wilds, the demand for its beautifully-grained and easily-worked wood being far in excess of the supply." It is true that our supply of White Pine for commercial purposes has been greatly reduced, partly by legitimate use, but still more largely by wasteful methods of cutting and destructive forest fires. But it is a great exaggeration to say that *Pinus Strobus* is becoming a "rare tree" in this country. Fine specimens of noble height, such as were easy to obtain a generation ago, are indeed rare to-day; but any one who has seen the way in which young White Pines spring up on deserted pastures and fields in New England can hardly fear that it is in danger of perishing from the land. It still gives a distinctive character to many broad districts of New England, but, all the same, the counsels which the English writer offers his countrymen with regard to the advisability of cultivating this tree, are even more insistently needed in this country. White Pines will grow whether we plant them or not; but it would be greatly to our advantage did we plant them more generally and systematically in regions where they once flourished in such stately forests.

More than one correspondent of a certain English horticultural journal has spoken with approval of the idea of growing Roses and Asparagus together, as conducing to a fine display of the beauty of the Roses, while not incompatible with good economical results as regards the Asparagus. "The two plants match," says one, "on the principle of strong contrast," and he exclaims with rapture over the effect when one comes upon "a glorious Rose-bed in the flower-garden overflowing with beauty and verdure, each drooping Rose resting its beautiful cheek on the soft, feathery fronds of bending Asparagus foliage." To many readers this will seem a singular perversion of taste. Not the principle of strong contrast, but the principle of harmony, is that which guides the man of true taste in arranging his growing plants or his cut flowers; and when a plant has such beautiful foliage as a Rose-tree, it seems perversity indeed to seek to enhance its effect by an intermixture of green of a totally different character. The massive loveliness of a double Rose is surely seen to better advantage resting its cheek on its own leaves or drooping in isolated perfection than swathed in the fluff of Asparagus shoots. In ancient times Plutarch wrote that there was no better way to show off the beauty of Roses than to plant them among Cabages. But such a mixture of alien forms is generally condemned to-day, while we have so long been accustomed to separating useful from ornamental plants in our gardens, that the mere fact of a utilitarian crop being grown in a Rose-bed would give a slight shock to the feelings, even though the effect might be better to the eye than the one which these English horticulturists admire.

Thinning Plantations.

IN "Observations on the Treatment of Public Plantations; More Especially Relating to the Use of the Axe," by F. L. Olmsted and J. B. Harrison, we have a more direct and explicit discussion of the evil of overcrowding trees in parks and public grounds, and of the necessity of proper thinning than has before been presented in this country in popular form. The Report is addressed to Mr. Killian Van Rensselaer, as it was prepared at his suggestion, in behalf of the West End Improvement Association, the Torrey Botanical Club, the Park Commissioners of New York and others interested. It had its origin in the popular outcry which arose in this city last winter in protest against thinning the trees in Central Park. Mr. Olmsted was one of the designers of the park, and he has had as much both of culture and experience in landscape-art as any member of his profession, and his judgment in all that pertains to the use of trees and their relations to each other, in parks and public grounds, is probably not surpassed by that of any living artist. The Report sets forth precisely what any man, possessing the technical knowledge, which is the only possible basis for an intelligent judgment of the matter, would be compelled to say under the circumstances.

One of the most serious hindrances to progress and success in the management of public parks in this country has, for many years, been the fact that a public sentiment has been cultivated, the effect of which, in numerous instances, has been to keep trees standing that should have been cut out, and, in a general way, as this Report observes, "to prevent the free exercise of any specially competent judgment upon the question of thinning public plantations." The popular feeling on the subject is natural and, at present, inevitable. It is only a special form or development of the general conviction that in this country men are competent to decide almost any question without special training or preparation. There has been, hitherto, little respect in America for technical knowledge, except in connection with the industrial and money-making

arts, and the popular mind is still inclined to reject the idea of its necessity. But the changes in the conditions of life here during the last twenty-five years have rendered it far more necessary than it was before. The need of special training in the management of public parks increases steadily, just as the requirement for technical knowledge in the other pursuits of civilized life is made more imperative by the increasing variety, complexity and costliness of modern ways of living.

The people of an entire community, or its principal citizens, may be possessed of a high degree of general intelligence, and may have much special culture of various kinds, without the special equipment or training which would enable them to determine whether the trees in a park have been properly thinned and developed or not. Their judgment regarding the question of cutting out particular trees is probably not more apt to be right than their judgment of the special medical treatment required in a case of pneumonia or yellow fever. But it will be a long time before this truth will be generally recognized and understood, and the work of the few men who have any special knowledge of matters pertaining to park management will often be thwarted by vexatious interference, or defeated altogether by attacks inspired by untrained and erroneous opinion. The development of a higher degree of special knowledge in the public mind is necessarily a slow work, as is also such an advance in civilization and general attainment as will enable our people to recognize the necessity for special training wherever it is required, and will also incline them to leave to men who possess adequate training and equipment the decision of whatever belongs to their special art or department of knowledge.

If this Report could be carefully considered by the most intelligent men and women of our principal cities it would help to prepare the way for an advance in the methods of park management in the matter with which it deals, but the entire discussion will have to be repeated again and again, with varying special illustrations as new cases of difficulty and error arise from time to time. Most communities are impatient for immediate effect in tree-planting, and trees are put in at first which every competent landscape-artist knows should be removed in a few years. But when the time for their removal has come, no one is likely to recognize its necessity unless he is qualified to judge of the matter by the special training and technical knowledge of a competent landscape-artist.

The Report is enriched by a great number of quotations from the leading writers of this country and Europe, bearing directly and most pertinently upon the question discussed. The authors conclude, after a very thorough examination of the park, that the tree-cutting, of which complaint was made, was not excessive, but that additional removals should be made, especially of trees which were not originally intended to remain permanently, and this conclusion is undoubtedly correct.

The manufacture of Red Cedar pencil-wood has for years been almost exclusively confined to Florida, where this tree grows to a large size and in great perfection. The business has been in the hands of a large foreign house, which supplies a good part of the world with lead pencils, and has been profitable. Large Cedar timber, straight grained, and of a suitable quality for pencil-stuff has become scarce in Florida along the streams on the west coast, where the best was found; and factories are springing up in different parts of the south, especially in Alabama, where, at Gurley, sawing pencil-stuff is already a considerable industry. The best Red Cedar, however, now left will be found near the Red River, in Texas, and in the Indian Territory, where this tree attains a greater size than it reaches in Florida, while the quality of the lumber is not, probably, in any way inferior.

The world has become so accustomed to using pencils made of red cedar that it will not readily adapt itself to any others. The supply of this lumber of suitable quality,

however, is not large in proportion to the demand, and cannot hold out many years longer.

The Red Cedar is the most widely distributed of North American conifers, and in some parts of the country it is one of the most common trees; but it is in a few favored localities only that it grows in a way to produce the straight-grained material essential for pencil-making.

The distillation of oil of Cedar, for which there is now a large commercial demand, from the sawdust and other refuse, has been profitable in the pencil-mills at Cedar Keys in Florida, and might be carried on to advantage in other parts of the country. It can be made, of course, from wood of the poorest quality.

Topiary Gardening in Japan.

WE have published, in recent issues of this journal (vol. ii., pp. 103, 211), good examples of topiary gardening as practiced in New England and in Old England, while the illustration upon page 307 of the present issue represents a garden in Tokio, in which the chief features are clipped Pines. They are specimens of *Pinus densiflora*, the species most often used by the Japanese for this purpose. An examination of these three pictures will show that the Japanese are not behind the Americans or the English in mechanical skill in reducing their trees to formal shapes, or in artistic skill in grouping them, so as to bring out the beauties of purely formal gardening.

We are indebted to Mr. James M. Codman for the photograph from which our illustration has been made.

Notes on the Production of Maple Sugar.

ONE of the most important and interesting of the early writings on the Sugar Maple is "An Account of the Sugar Maple-tree of the United States," by Dr. Benjamin Rush. It was written in the form of a letter to Thomas Jefferson, was read before the American Philosophical Society and published in the "Transactions" of the Society in 1792. Some of the statements hold good at this time, but others sound oddly when compared with modern knowledge and practice. Dr. Rush had a very high opinion of the merits and value of the Sugar Maple. He says: "Its small branches are so much impregnated with sugar as to afford support to the cattle, horses and sheep of the first settlers during the winter, before they are able to cultivate forage for that purpose. . . . The tree is supposed to arrive at its full growth in the woods in twenty years. . . . It is in consequence of the sap of these trees being equally diffused through every part of them, that they live three years after they are *girdled*—that is, after a circular incision is made through the bark into the substance of the tree for the purpose of destroying it." We are told that there are three methods of reducing the sap to sugar: "By freezing it," "by spontaneous evaporation" and "by boiling." After giving some figures to show that more sugar might be made from the Maple in the country than would be necessary for home consumption, Dr. Rush, in speaking of the benefits he expects from its general use, says: "They will, I hope, extend themselves to the interests of humanity in the West Indies. With this view of the subject of this letter, I cannot help contemplating a Sugar Maple-tree with a species of affection and even veneration, for I have persuaded myself to behold in it the happy means of rendering the commerce and slavery of our African brethren in the sugar islands as unnecessary, as it has always been inhuman and unjust." In a foot-note we are told that "Mr. Jefferson uses no other sugar in his family than that which is obtained from the Sugar Maple-tree. He has lately planted an orchard of Maple-trees on his farm in Virginia."

Since Dr. Rush wrote his paper much progress has been made in the production and manufacture of syrup and sugar from the Maple, although it has not received so much attention as has fruit-growing and some other kindred industries. It is a most important source of income on many of our northern farms, and the sugar-orchard, or "sugar-bush," as it is often called, is in many districts coming to be as well looked after and cared for as a vineyard or fruit-orchard. The annual profit is probably larger than the average of farm crops occupying the same acreage of ground, and the work is done before the ordinary farm labors have begun. In many well-managed sugar-orchards the dead and diseased branches are

carefully pruned off, and the wounds covered by some protecting substance to prevent injuries by insects or fungus diseases.

Some of the more thrifty proprietors, at the end of the sap-harvest, have the holes which were bored in the trees carefully plugged with neat stoppers of dry, sound wood, cut so as not to project beyond the surface of the last ring of wood formed. At the close of the growing season the new layer of wood and bark will have completely covered the wound. This is a great improvement on the barbarous method of making a great gash in the side of the tree with an axe and using a chip for a spout. The amount of abuse which a large tree will bear when standing in the forest is surprising. In some districts there are many large old trees to be found having the trunks for five or six feet from the ground, very rough and uneven, and often a foot greater in diameter than the trunk immediately above, caused by the earlier crude way of obtaining the sap. These trees may have been subjected to such rude treatment almost every year for half a century or more, and now, tapped in the more approved way, they continue to produce abundantly without showing other signs of injury or decay than such as are found in trees under natural conditions as they attain old age.

In regard to the manner of tapping the trees writers still seem to differ in their accounts as to the depths bored. Dr. Rush, in the essay already quoted, says: "The perforation is made with an axe or an auger. The latter is preferred from experience of its advantages. The auger is introduced about three-quarters of an inch, and in an ascending direction, and is afterwards deepened gradually to the extent of two inches."

In Emerson's "Trees and Shrubs of Massachusetts" (p. 564) it is stated that the holes are bored "to the depth of from two to six inches, according to the size of the tree, and M. Ed. André, in an article in the *Revue Horticole* for 1886, p. 284, says that the holes are often bored even to the heart of the tree. There are probably very few experienced men, owning sugar-orchards now, who have the holes bored more than a couple of inches in depth, and one inch is deemed quite sufficient by many. There is little to be gained, and a much greater possibility of injury to the tree by boring deeply into its trunk. Probably nearly all of the sugar-bearing sap comes from the outer layer of wood extending less than an inch deep. Many writers have stated that the south side of the tree gave the best flow of sap, but experienced men advise tapping the side bearing the most branches.

As yet most of the sugar-orchards are made up of trees of natural growth, and comparatively few plantations have been set out for sugar-making purposes. The twenty-five years required by the trees to grow before being regularly tapped seems a long period to many, but if properly planted with other trees among them the Maple-orchard could be made self-supporting, by annual thinning of wood, after the first few years. Trees on rocky hill-sides yield more profitable sap than those on low ground, so that some of the best locations would be on New England hill-sides that are now bare and unprofitable. The French Canadians in some portions of Canada are said to be planting large quantities of the Ash-leaved Maple (*Negundo aceroides*), with the idea of producing syrup and sugar from it, and because it is a fast-growing tree.

The time may not be far distant when nurserymen will give particular attention to the propagation of the best sugar-producing strains of Maples and other native trees. Careful comparative studies of the amount of sap obtained from different species of trees, and of the same species under different conditions, and of the percentages of sugar contained in the sap are much needed. Numerous analyses have been made of saps by different investigators, but the published results are very contradictory and unsatisfactory. While, no doubt, much depends upon the surroundings, vigor and other conditions attending the trees, it seems as if some general rules might be determined upon which would be approximately reliable. Dr. G. L. Goodale gives the average amount of sugar in the sap of *Acer saccharinum* as about eight per cent. (Physiological Botany, p. 360), which seems very high when compared with the results of other experiments. In the report of the Massachusetts Board of Agriculture, 1874-75 (p. 290) the analysis by Charles Wellington gave a result of 2.777 per cent.

In recording some interesting experiments made in Indiana (Proceedings A. A. A. S., 1879, vol. xxvii., p. 234) Dr. H. W. Wiley gives the highest percentage as 4.30, from a tree noted for the sweetness of its sap. In a series of experiments conducted at Lunenburg, Vermont, under the direction of Dr. Wiley, and published in Bulletin No. 5 (1885) of the Chemical Division of the Department of Agriculture, the highest percentage recorded was 10.20 in a small flow of sap from a speci-

men of Sugar Maple during one of the last days of the flow, the average being 5.01 per cent., and 9.88 per cent. was obtained from a similar flow of sap from an isolated White Maple (*Acer dasycarpum*), which averaged 4.36 per cent. of sugar during the season. The average of all the analyses from all the trees experimented upon is considerably less than 4 per cent. of sugar.

In making some experiments on the sap of the Ash-leaved Maple (*Negundo aceroides*), Dr. B. J. Harrington, of McGill College, Montreal, found in a series of careful experiments that the average amount of sugar in the sap of these trees was very nearly 2.50 per cent. In a slight test of the sap from a tree of *Acer saccharinum* on the college grounds he found a little over 5 per cent. of sugar. The detailed account of the experiments with the Negundo sap is published in the "Transactions of the Royal Society of Canada," vol. v., sect. iii., 1887.

Adulterations and imitations of both sugar and syrup are very common. An extract obtained from the bark of Hickory (*Carya*) is said to resemble the Maple flavor very closely when mixed with cane syrups. Such imitations may tend to lower the price of the pure product a little, but there will always be a demand for the true article. It is not likely that Maple will take the place of cane-sugar, as Dr. Rush hoped, but the consumption and perfection of production will continue to advance.

Arnold Arboretum.

J. G. Jack.

Foreign Correspondence.

London Letter.

NEVER were the florists of London so busy as they now are, at the very height of the season. Every day they must provide sumptuous and extravagant feasts of flowers at the houses of the great, where flowers seem to be more highly appreciated than ever. Those who are not behind the scenes wonder where the material comes from to supply the London fashionable world, and to many such an opportunity was afforded the other night to see for themselves the inner life of our great flower-market at Covent Garden. The market-growers and florists have interested themselves in a most commendable way on behalf of a charity established last year as the Gardeners' Orphan Fund, and in order to augment the funds they organized a public fête or show of their own productions, such as they send every day throughout the year to our central flower-emporium. The flower feast, for such it was, was greatly appreciated by thousands who never before saw a wholesale flower-market, and not a few seemed astonished at the gorgeous sight. The perfection to which popular plants are grown for sale astonished even professional gardeners, who have to grow miscellaneous collections of plants, whereas most of the great market-growers devote their sole attention to a few classes of plants, the result being that they bring the plants to absolute perfection.

The great flower-market at Covent Garden is truly a gorgeous sight, though there is necessarily a good deal of sameness among the plants exhibited. The flowers of the season were, of course, in strongest force, for the show was just on the eve of "bedding out" week, when millions of plants come through the market to be dispersed throughout the suburbs. Among the most prominent kinds of plants were Pelargoniums of all kinds, but especially the old Scarlet Vesuvius. It is surprising to see how comparatively few sorts are grown for the market, and it is equally remarkable how very few among the infinite variety of Pelargonium are able to conform to the market-growers idea of a standard sort. Forced Roses were plentiful, especially the delicate Tea-scented sorts, which seem to take with the public more than the high colored kinds, and this is, I fancy, on account of their perfume. Niphetos is the leading sort with all the growers. Stand after stand was filled with nothing but double Poet's Narcissus, which, for the time, quite usurps the proud position the Gardenia holds for the adornment of the coat. The florists have a clever way of making this Narcissus look so like a Gardenia that it puzzles one to detect the fraud. They "dress" the petals—that is, they extract the small ones, flatten the big ones and surround the bloom with a few leaves of the green Japanese Euonymus, whose shining foliage passes well for that of Gardenia.

Iris of all varieties of the Japonica group are coming into public favor more and more, especially now that a famous grower at Twickenham has turned his attention to them and has planted the best sorts by the acre. But the Iris is not everybody's flower, and only those who have the gift of artistically arranging flowers can make the Iris look as it should in a vase. The sorts most in demand are the dark purples and

clear yellows and whites. Marguerites are as popular as ever, and their culture is so remunerative that some of the smaller growers produce very little beside them. They were here to be seen of all sizes in pots, from plants a yard through to the tiny bits in thumb-pots for bedding out. The yellow sorts, such as *Compte de Chambord* and *Etoile d'or*, seem to be more difficult to grow than the white, as they were not nearly so fine. Among other popular flowers were Fuchsias, Violets and Pansies, Stocks, Petunias, Lilies of the Valley, Tulips, Scillas, Heaths, Spiræas and Miss Joliffe Carnations, which sort is undoubtedly the best for the market. The pyramidal Saxifrage (*S. Cotyledon*, var. *pyramidalis*) is now largely grown, and a group of a hundred plants, all with tall clusters of small white flowers, was one of the prettiest things I saw.

Orchids, singularly enough, were not plentiful, though there was evidence that these fashionable but expensive flowers are becoming more in demand as market flowers. The chief lots of cut blooms were of the Alexandrian Odontoglossum, which for wreaths, sprays and the like, are matchless. Cattleyas, Lælias, and other showy common kinds, were represented by a few flowers, but it is apparent that this Orchid does not find favor with the great growers yet. There was nothing very remarkable among the foliage plants, which, though not so plentiful as the flowers, were to be seen by the thousand. The plants with highly-colored leaves, such as Coleus, Caladiums, Dracænas, Crotons and the like, seem to be regaining their former popularity, and I am told by the great London nurserymen that fine foliage plants are likely to be as much in demand as they were a dozen years ago, when bright-leaved plants were as popular, almost, as Orchids are now.

W. Goldring.

New or Little Known Plants.

A Hybrid Catalpa.

THE name *Catalpa* × *J. C. Teas*,* is suggested for a plant whose hybrid origin is probable. The history of the plant is, briefly, this: J. C. Teas of Carthage, Missouri, while living in Indiana, in 1864, purchased a seedling *Catalpa* from Mahlon Moon of Morrisville, Pennsylvania, who had raised it from seed procured from Japan by Hovey & Co., the Boston seedsmen. According to the statement of Mr. Teas, to whom I am indebted for the facts in the case, this tree, which proved to be *C. Kämpferi*, was planted in his nursery among or near plants of *C. bignonioides* and *C. speciosa*, the two North American species; and it produced in due time one pod of seeds which were quite unlike those of any *Catalpa* with which Mr. Teas was acquainted. The seeds were planted and gave rise to a tree almost intermediate in character between *C. Kämpferi* and one of the American species. The appearance of this seedling tree and its progeny suggests that the pollen from a flower of one of the American *Catalpas* had fertilized a flower of the Japanese tree. The American parent was probably *C. bignonioides*, although Mr. Teas is inclined to believe that it was *C. speciosa*. The latter flowers two or three weeks earlier than the Japanese species, whereas the former flowers contemporaneously with that species during the first week of July.

Whatever may have been its origin, the hybrid of which a figure appears upon page 305 is an erect, vigorous, and rapid-growing tree, with the thin, scaly bark of the American species. The leaves are sharply three-lobed, or rarely entire, and more or less cordate at the base; they are slightly pubescent on the lower surface, and the mid-rib and primary veins are covered with scattered hairs; they are twelve to fifteen inches long and ten to twelve inches broad. The inflorescence, which is eighteen to twenty inches long by ten inches wide, is composed of two or three hundred fragrant flowers about an inch long, the corolla slightly tinged with yellow in the throat, and handsomely marked with broad purple stripes. The fruit is from twelve

* *Catalpa*, J. C. Teas; nov. hybr. Arbor excelsa, ramis horizontalibus; foliis amplis, longe petiolatis, ovatis acuminatis, basi rotundatis vel cordatis, integris vel sæpissime 2-3 lobis, lobo medio attenuato-acuminato, lateralibus brevibus divergentibus, subtus villosis-hirsutis; paniculis terminalibus amplis, floribus gracile pedicellatis, calycis labiis rotundatis mucronatisque, corollæ tubo campanulato, limbi 2-labiati, lobis 5, rotundatis, flavis vel albidis laniato-punctatis; capsula cylindracea seminibus alatis mollior villosis utrinque in caudas capillares-fissas productis.

to fifteen inches in length and not more than a quarter of an inch thick in the middle. The wings of the seed are half an inch in length and one-eighth of an inch in width, and like the others of the genus are tufted with long white hairs.

The leaves of this tree are much larger than those of either of its parents, having when they first appear the velvety character and the purple color peculiar to those of the Japanese plant, and the reddish spot at the insertion of the petiole with the leaf-blade which characterizes that species. They more generally resemble those of the Japanese species in shape, color and texture, while the pubescence which covers the lower surface is almost intermediate in character between those of the American and of the Japanese species. The inflorescence is much larger than that of the American or of the Japanese plants, being fully twice as large as that of *C. bignonioides*, and more than three times the size of *C. Kämpferi*. The flowers are intermediate in size; in color and in markings they most resemble those of the American species, although a tinge of yellow in the throat of the corolla points to their Japanese descent. The fruit of the hybrid is almost intermediate in size between those of the two parents, as are the seeds, which are perfectly fertile and often reproduce the original form in every particular. When, however, seedlings show a tendency to vary from the original form the variation is generally in the direction of the Japanese rather than of the American parent.

The hybrid is a more vigorous tree than either of the American or the Japanese species, and it grows rather more rapidly. It is too soon to speak of its value as a timber-tree, as the largest specimens in the western states, where this tree has been much more generally planted than at the east, are, according to Mr. Teas, only forty to fifty feet high, with trunks which do not exceed yet a diameter of eighteen inches. Of its value as an ornamental tree there can be no doubt. Its larger size and more rapid growth, its better habit and more showy inflorescence make it a far more valuable ornamental tree than the Japanese species; it is more hardy than either of the North American species, and although the flowers are smaller, the panicles and the number of individual flowers are much larger.

The best forms, from an ornamental point of view, are those in which the flower most nearly approaches those of the American species in size and color; and, as the seedlings show a decided tendency to revert, so far as the flower is concerned, to the Japanese parent, it will be necessary to perpetuate selected varieties by grafting. The great vigor of the seedlings of the hybrid will, no doubt, make these the best stocks for this purpose. Among a number of these seedlings sent to the Arnold Arboretum by Mr. Teas there is one in which the corolla is doubled.

If it is true that the plant is a hybrid, and there seems no good reason for doubting that it is, this tree illustrates in a remarkable manner the advantage in vigor and hardiness which the progeny resulting from the crossing of two species may obtain over either of its parents. The fact is doubly interesting, moreover, because hybrid trees, whose origin is known with as much certainty even as that of this Catalpa, are rare. Some fruit-trees are doubtless derived from crosses of nearly allied species or distinct forms of a widely-distributed species. Oaks, Walnuts and Willows, which are believed to be hybrids between related species are not uncommon, and it has been suggested that some of the varieties of *Cinchona* which produce the most valuable bark may be hybrids. The origin of such plants, however, is always veiled in doubt, and I do not at this moment recall any other hybrid tree, with the exception of *Magnolia Soulangeana* and the other hybrids between *M. conspicua* and *M. obovata*, whose history is as little doubtful as is that of this Catalpa, which seems destined, whatever its economic value may be, to become a valuable ornament in the decoration of parks and gardens.

Forcing the Gladiolus.

THE Gladiolus, when grown as a forced flower, is appreciated to a greater extent than when grown out-of-doors. Like many other flowers, it is better under the protection of glass when well cared for, as the flowers are larger, the colors purer and the spikes longer. To force the Gladiolus successfully, however, requires attention at just the right time, and its wants should always be anticipated and supplied. Here is the routine of my practice: The bulbs I forced this year were also forced last year. They were then planted February 8th, and the first twenty-five flowers were cut May 30th. This year's work began December 27th by potting each bulb in a four-inch pot, using sandy loam, without manure, and placing the bulb on the top, pressing it down to hold it without any other covering; they were watered and then placed underneath the benches of a Carnation-house until the beginning of February. At that time those plants which had grown to the height of four inches were brought to the light and again watered. Placing them close together on a bench near the light, a little water was given from time to time, retarding the top growth, and encouraging root-action as much as possible. By the 20th of the month the plants were gone over, and all those of an even size were planted together in rows about a foot apart and nine inches apart in the rows. After planting those of one size, then another batch a size less was handled. This selecting into sizes pays for all the trouble it costs in preventing strong plants from overcrowding the weaker ones. My soil is rather a heavy sandy loam, and in this the Gladioli were planted, the depth of the entire bed being a little more than four inches. The bulbs were scarcely covered even at this time, and this, I find, prevents the damping off of the plants during dull days, when they have commenced to grow rapidly, and are checked either by dark weather or by a cold spell. By the middle of March each plant was tied securely to prevent its falling over, which is generally ruinous to the flower-spike; a light mulching of stable-manure was then put on and well watered. From that time until the flowers were cut a good soaking of liquid-manure was given each week. The Gladiolus delights in abundant moisture when well along in growth, but in its earlier stages too much water is death to it.

The first twenty-five flowers were cut for Easter, or six weeks earlier than last year. The temperature was never higher than 50° at night, and during the day-time the house was ventilated whenever it could be kept above 70°. Three things I find are necessary to successfully force the Gladiolus.

(1) The pots must be well filled with roots before the plants are finally set out.

(2) The nearer the bulbs are to the surface the less liable are the plants to damp off.

(3) The bulbs must be well ripened—and if so, small ones are as good as very large ones.

Pearl River, N. Y.

John Thorpe.

Spring Bulbs.

NOTWITHSTANDING the wet season of 1888, bulbs have made a very good show in my garden this spring, and I will mention a few which are worthy of general cultivation, though as yet little known except to specialists. Among the new Tulips introduced of late years from Asia, there are four of surpassing beauty, all equal or superior in size, color and form to the very best of the Dutch early-bedding Tulips.

T. Kaufmanni is the earliest of them. Of its three varieties, figured in the *Botanical Magazine* from my garden, the yellow is, perhaps, the finest, and throws up its large flower better than the rose-colored one, which seems more tender and easily spoilt by bad weather. This is the earliest of all large-flowered species of Tulip, and one of the finest and most distinct.

T. Oculus-solis var. *Mervensis* is a real giant in flower, more than twice as large as any other form of this species, and a third larger than any Dutch Tulip known to me. It measures over six inches in diameter when expanded, and seems quite hardy; but my single bulb has not yet produced offsets. Of its origin I know but little, but it is said to have been brought from Merv by Mr. Donovan.

T. Greigi is better known, but has somewhat degenerated since I first got it, and though quite hardy, does not increase. It remains, however, one of the finest species.

T. suaveolens typica, received from Dr. von Regel also under the name of *Lanata*, is very distinct in its downy leaves, and, when well grown, is an extremely fine Tulip in size, form and color. The flower is a pure deep crimson without any eye; the height is variable, but when increased sufficiently I think this will prove one of the best bedding Tulips of the Dutch

Hybrid Catalpa × J. C. Teas.

varieties not commonly used for bedding. I find Wouwerman's Joost van Voondel in its white form, *Adelaine* and *La Remarquable* all very fine sorts. The latter I never had till this year. It is very perfect in form, and reminds me of one that I specially admired in Mr. Van Eeden's nursery at Haarlem some years ago, and which he proposed to call Mrs. H. Elwes. This is ten days earlier than any of the Van Thol Tulips, very beautiful in color, bright cerise with yellow centre, and per-

fect in form. I shall be glad to hear if it has been sent out, and if so, under what name.

Of other new or rare bulbous plants I have admired nothing so much as *Erythronium Smithi*, which seems a form of *E. grandiflorum album*. It is by far the finest of the *Erythroniums* I know, though the yellow *E. Nuttallianum*, when seen in masses as we saw it in the Yellowstone Park, runs it close.

I do not know who called it *Smithi*, but it is much larger in

flower than *grandiflorum*, with large blotched leaves flat on the ground and a tall flower-stem carrying two or three large white or pale-pink flowers. I believe it was introduced by Mr. Ware two years ago.

Of *Fritillarias* I find that the finest form of *Imperialis* is not generally known. It is much more robust and taller than the forms usually cultivated, and has flowers about three inches long. The form known in Holland as Lord Derby is something like it, but has smaller and more copper-colored flowers. The lately introduced form, *Inodora*, though variable in size and color of flowers, which are usually much smaller than those of the old Crown Imperial, is at least a fortnight earlier and is now quite over. Of other uncommon *Fritillarias* I think *F. pallidiflora* and *F. Moggridgei* are the best; the latter is perhaps only a form of the old *F. latifolia*. But when seen in large quantity there is no prettier *Fritillary* than the white *Meleagris*, of which there are many thousands in a meadow in this neighborhood, and which is easily raised from seed, though a few of the seedlings come to the usual color.

With the exception of *N. cyclamineus*, *N. Johnstoni*, and a small pretty form of *N. moschatus*, the *Narcissi* collected in Spain by Mr. Barr are disappointing, and I think we have pretty nearly exhausted the variety which exists in this genus, unless something can be done by hybridizing with the *Glenais* variety of *N. triandrus*, which is one of the most graceful and best of its tribe, though not hardy enough for a border plant.

Puschkinia Libanotica and *Chionodoxa Lucilia*, though two of the best early spring bulbs, are becoming perfect weeds with me, and seed themselves on the grass and everywhere. Of *Muscari* there is none equal for ordinary garden purposes to one which I believe was brought from Rome by the late Mr. Harper Crewe as *M. conicum*. It is not so early as several others, and not so pretty in color as *ligulatum*, but far better than most of the sorts usually grown, and a perfect weed in the rapidity with which it increases.

H. J. Elwes, in *Gardeners' Chronicle*.

Notes on Wild Flowers.

THE Showy Lady Slipper (*Cypripedium spectabile*), now in flower, is by far the finest species we have. It grows about two feet high, with numerous, large, light green leaves along the stem, which terminates in one or more—rarely four or five—large, white, pink and purple flowers. These remain fresh several days. In the right location it is not a difficult plant to grow. In sandy, gravelly, or slaty soil, plenty of peat or leaf-mould must be added. It is a lover of moisture, and does best in the shade. It is often found in the open sunlight growing naturally, but in very moist locations, and such plants are seldom as large as those found in partial shade. Too much shade, however, is worse than none. We have noticed in thick Cedar-swamps plants growing year after year in a weak, sickly way, without flowering, when if a few rays of the sun could have reached them they would have been as strong as possible.

Habenaria viridis, var. *bracteata*, and *H. Hookeri*, two of the Rein-Orchis family, are now in flower. Both are low-growing (six to twelve inches), greenish-flowered species, not showy, but grown in collections of hardy Orchids, to some extent, both in this country and in Europe. The two large orbicular leaves in the latter, lying close to the ground, from between which comes the flowering stem, make it the more desirable of the two. As seen growing, these plants are interesting, and remain green a good portion of the season, but the flowers are too near the foliage in color to be of much value. They are easily grown, and would thrive in the shade where grass would not grow.

Saxifraga aizoon is a rare northern species, more generally cultivated in Europe than in this country. The flowers are white or cream-colored, and rather pretty. Its natural location is on moist rocks, and when planted in ordinary soil in the sun it is apt to become too dry. Placed in the shade, it seems to be weak and sickly. On the whole, we do not think it desirable except for moist rock-work, where it would be quite valuable.

Draba arabisans, now in flower, is as pretty a plant, perhaps, as either *Saxifraga aizoon* or *S. Virginensis*. It grows on dry rocky banks, and would thrive in localities where few other plants would live. Its height is from four to twelve inches. It often grows in dense tufts bearing its white flowers in great profusion. We have never cultivated this plant, but believe it might be valuable in some locations, and could probably be obtained from seed better than from living plants.

Lewisia rediviva is a little, low plant, three to four inches high, from northern California and Oregon, where it is said

to grow naturally in granite sand and on ledges. Its flowers are large and showy, from one to two inches in diameter, with thin, membranaceous, light purple sepals, and nearly pure white petals. We have grown it two years in a clay loam, and it has stood the winters without protection.

The Meadow-Rues (*Thalictrum Cornuti*, now in flower, which is the taller, and *T. dioicum*, which is much earlier, and not so tall, but a prettier plant), are both more desirable for their beautiful foliage than for their flowers, though the flowers of the former are pretty. But their foliage, especially that of *T. dioicum*, is very fine, and lasts from the time it is in flower until late in autumn. It will thrive on dryer ground than *T. Cornuti*, and is a desirable plant for shaded corners where other plants would not live; while *T. Cornuti* would be more suitable for wet places.

Calochortus lilacinus, one of the many species of Butterfly Tulips, is now in flower. It was sent to us from Modoc County, California. The plant is quite small, only three or four inches high, and the flowers come from near the ground on stems so short as to be worthless for cutting. They are three-fourths of an inch in diameter, white, tinged with purple, and quite handsome. The bulbs may be wintered in dry earth in the cellar. We have not tested the hardiness of the plant. Two Columbines from Oregon (*Aquilegia formosa* and *A. flavescens*) are now in flower. The former closely resembles our common *A. Canadense* in color. It is a taller and stronger growing plant, and later in flowering. *A. flavescens* has paleish-yellow flowers, in shape much like *A. Canadense*, but not showy. Both are desirable plants and easy of culture.

One of the prettiest wild Anemones, and a hardy one, too, when once established, is the Pennsylvania Anemone, now called *A. dichotoma*. The flowers are almost pure white, and an inch or more wide. It likes a rich, moist soil, and continues in flower for a long time.

Charlotte, Vt., June 10th.

F. H. Horsford.

Orchid Notes.

Calanthe Dominii is an attractive and useful Orchid belonging to the evergreen section. It is one of the earliest hybrids, and is the result of crossing *C. masuca* with *C. furcata*. The broad, plicate leaves are deep green, and will remain in good condition until the new growths are well advanced. The scapes are erect, about two feet high and bear a profusion of mauve-colored flowers, about an inch across. This may be successfully grown in rich stove-plant soil in an intermediate temperature, and kept moist all the year round.

Vanda Batemannii. This noble species is now in flower. It is of immense growth, only suitable for large houses, as it will grow to a great height. The stem is stout, closely clasped with long, narrow, deeply channelled, leathery leaves. The racemes which spring from the axils of these are erect, stout and about six feet long, bearing a great many very handsome flowers. These are thick, dull, flesh-colored, blotched with crimson in front, while the back is rosy-purple. The racemes last nearly the whole summer, growing, and developing new flowers from the apex. The plant was introduced nearly fifty years ago from the Moluccas, and requires the most liberal treatment in respect to heat and water. The pots should be well drained and the potting material should consist of lumps of peat, chopped moss and nodules of charcoal, with a few lumps of dry cow-manure. It blooms very freely with us, and should it ever become "leggy" the head can be cut off in early summer and potted, when it will quickly become established. The old stem will produce a number of shoots, and these may be taken off as soon as the new roots appear, and will make better looking plants than when left on the old plant.

Epidendrum vitellinum is an Orchid to be commended. It flowers at a somewhat dull season, and a few spikes of its gay and unique colored flowers go a long way to brighten and bring out the sober tints of the *Odontoglossums*, with which this species should be grown. It is generally distributed through Mexico and the adjoining states, usually found growing on rocks or stumps of trees at high altitudes and under such conditions as the cooler *Odontoglossums* need, and it requires the same treatment as recommended for these. It grows freely, however, on blocks or rafts of wood, and should be kept somewhat dryer during the resting season. The clustered bulbs are ovate-lanceolate, with two acute, oblong ligulate leaves, both leaves and bulbs being of a peculiar glaucous hue. The erect racemes are often branched, and bear from twenty to thirty flowers about an inch across, the color being a vermilion-orange. The acute lip and the column is of bright yellow, while the anther-cap is red. The flowers last about two months

in perfection. The variety Majus is distinguished by its stronger inflorescence, and this is developed earlier in the season than that of the type.

F. Goldring.

Spraying Fruit-trees.

THE most important accession to recent horticultural practice is the spraying of fruit-trees with arsenical poisons for the destruction of various insects. No orchardist can afford to neglect this practice. The codlin-moth, curclio, canker-worm, tent-caterpillar and other insects are destroyed by this operation, and sometimes three or more species are killed by the same application. Experience has shown the best methods of applying the poisons, and we now know that the essential points of the operation are to use a very dilute mixture, and to apply it with great thoroughness. London Purple, when pure, is better than Paris Green, and is cheaper. A pound of

pump and one to drive and hold the hose is a profitable outfit. With such an outfit two men can spray from 250 to 300 Apple-trees, thirty years old, in about half a day. Pear-trees are treated in the same manner as Apple-trees. The mixing of flour with London Purple, in order to make the poison stick to the leaves, does not appear to meet with much favor among practical men.

Cornell University.

L. H. Bailey.

Heating Green-houses.—At the recent Convention of American Nurserymen Mr. Peter Henderson read a paper on this subject, from which we make the following extracts:

"In my judgment, when the range of glass is sufficient to justify the employment of a night watchman, say 50,000 square feet, steam has several advantages over hot water, chief of which are the exact regulation of temperature, which can be obtained by close attention, consequent economy of fuel, and the convenience of placing the heating furnaces all at one

A Japanese Garden.—See page 302.

the London Purple to 250 or 300 gallons of water is sufficient. Apply it until the liquid drips from the foliage in all parts of the tree. The apparatus should be such that the liquid will be driven with great force in a fine spray. A gallon of liquid will cover an Apple-tree twenty-five or thirty years of age.

A single spraying of Apple-trees, if the operation is not immediately succeeded by heavy rains, is usually sufficient, although a second application is always advantageous. Two or three applications should be made upon Plums, Cherries and Peaches, and I have met growers who make as many as five applications. Even five applications are much cheaper and easier than any other method of destroying the curclio, and the practice is much more effective. In young and open orchards the spraying can be well done with a machine which works from the wagon-wheel, but in large and thick orchards—those most in need of treatment—the operator must stop at each tree if the work is to be thoroughly done. A tank or cask upon a wagon, a pump with much power, one man to

point. For example: We have a range of glass where the extreme point is about 600 feet away from the boilers; it would hardly be practicable to heat by hot water at that distance. And yet for all medium and small-sized green-house establishments, whether for commercial or private purposes, we recommend the use of hot water. The size of the green-house or green-houses to be heated must determine the capacity of the boiler wanted; but the boiler being properly apportioned to the length of pipe, the following data from our own establishment, where the houses are twenty feet wide and 100 feet long, may be useful: When a night temperature of seventy degrees is required in the coldest weather, ten rows of four-inch pipe, five on each side, are used; when sixty degrees are wanted, eight rows of pipe, four on each side; when fifty degrees are wanted, six rows of pipe; and when only thirty-five or forty degrees are wanted, four rows of pipe. This is for the latitude of New York City, where the temperature rarely falls lower than ten degrees below zero. Latitudes north or

south of New York should be graded accordingly. If estimated by glass surface, about one foot in length of four-inch pipe is necessary for every three and a half square feet of glass surface, when the temperature is at ten degrees below zero, to keep a temperature of fifty degrees in the green-house. A one and a quarter inch pipe when heated by steam does almost exactly the same amount of heating as a four-inch pipe heated by hot water.

Aster alpinus albus is probably the earliest species of this genus to bloom. The flowers are produced with the early summer, and, for this reason alone, the plant is worth cultivating, but the flowers are two inches in diameter, with bright yellow discs and double rows of white ray-petals. It has been written of this plant that, in comparison with the type, *A. alpinus albus*, it is poor and difficult to cultivate. With *A. alpinus* we have had no experience, having tried in vain to obtain the true plant. But here in the open border the white form thrives and increases rapidly, making bushy plants about six inches high, which, in early summer, produce numbers of pretty white flowers on stems just above the leaves.

Gillenia trifoliata has recently been noticed in GARDEN AND FOREST as a desirable border plant; and for cutting and decorative purposes there can be no more useful one, the flowers have such a light, graceful appearance, and blend so nicely with other flowers for in-door decoration. The genus *Gillenia* contains but two species, the other being *G. stipulacea*. To the casual observer this plant, when in flower, appears to be the same as *G. trifoliata*, but on close examination the specific difference is easily distinguished. *G. stipulacea*, as the name implies, has large and well-developed stipules, and commences to flower when *G. trifoliata* is about done blooming, and so makes a good succession. It is singular that, although indigenous to this state, *G. trifoliata* never produces seed with us under cultivation, while *G. stipulacea* every year seeds freely. The seeds, if sown as soon as ripe in a shady place, germinate the second year after sowing. This may seem a long time, but, taking into consideration the fact that this genus is included in the family of *Rosaceæ*, it is not difficult to comprehend.

Silene Pumilio is one of the very best of the tufted Catchflies, and is suitable alike for cultivation in the rock-garden or open border. This plant has dense tufts of bright green foliage, now almost hidden by the profusion of pretty rose-pink flowers, the inflated calyxes of which are of the same rosy hue as the flowers. *S. Pumilio* is a native of the Alps, and succeeds well in the open border without protection. The plant may be readily increased by division, but seeds are freely produced, and these, when sown as soon as ripe, germinate the following spring, and soon form strong plants.

O.

Notes from the Arnold Arboretum.

Celastrus scandens, the Climbing Bitter-Sweet or Roxbury Wax-work, as it is known in eastern New England, is now in flower. This plant should be so well known that even a bare mention of it would be superfluous. It is a common native species, climbing high over bushes and trees; and although the small white flowers are inconspicuous the foliage is good, and the orange and scarlet fruit is so showy and hangs so late in the autumn, that this is really one of the most desirable of hardy climbing plants. It is well suited to plant where it can display its brilliant fruit, either on trellises or in the wild garden, where it will stretch over rocks or among trees and other shrubs.

Two other species in the collection are worth notice. They are *C. articulata*, Thunb. (a misprint, no doubt, for *orbiculata*, as M. Maximowicz has pointed out, *Mel. Biol.*, xi. 200), a widely distributed Japanese species, with broadly obovate, crenately serrate, membranaceous leaves. They are three and a half to four inches long, contracted at the base into a stout petiole an inch and a half long, and usually terminated by a short, broad point. The flowers are small and green, in short axillary clusters, which are quite hidden by the ample foliage. The fruit is smaller than that of our American species, but it is very brilliantly colored, and, as it is produced here in the greatest profusion along the whole length of the spur-like lateral branches, it makes a great show after the leaves have fallen, remaining fresh and bright until nearly the end of winter. *C. articulata* is a hardy and vigorous plant, growing rampantly when once established in rich soil, and then sometimes producing stems twelve or fifteen feet long during a single season, and immense masses of foliage. It is a good plant for covering quickly

rocky slopes or walls, out-buildings and other structures. It has inhabited the Arboretum for several years, having been sent here from the Parsons' Nursery at Flushing. *Orixa Japonica*, No. 1,215 of the Kew Arboretum herbarium, is our plant.

It may be well to mention here that *Orixa Japonica* (often known as *Celastrus Orixa*) is perfectly hardy here. It is a tall shrub, already some six or eight feet high, with rather slender, spreading branches, and lustrous dark green, obovate leaves. The minute green flowers, which appeared a month ago, are produced in axillary clusters. The male plant, unfortunately, is the only one in the collection, so that fruit has not been produced here. The bruised foliage and the wood are pleasantly and pungently fragrant with the odor of our Spice-bush or Benzoin. This shrub is very generally used as a hedge-plant by the Japanese of the central island.

The second exotic *Celastrus* in the collection, now in flower, is one of the Himalaya species, in which the branches are covered with pale lenticular warts, and the flowers are borne in short terminal racemose cymes. The persistent style crowning the fruit points to *C. stylosa*, to which our plant probably belongs, although I am unable to verify this determination by a reference to an authentic specimen or to a figure. This plant was received from the *Arboretum Segrezianum* several years ago as *C. paniculata*, a tropical or subtropical Indian species, with pendulous panicles of flowers. Our plant, although perfectly hardy, is a less vigorous grower than either the North American or the Japanese species, not climbing here to a greater height than six or eight feet. The leaves, when fully grown, are four and a half inches long, elliptical or ovate-oblong; they are acute, crenately serrate, and borne on rather stout petioles an inch long. The pale green or nearly white flowers are produced in terminal racemose cymes, which, in fruit, are about three inches long. The fruit is orange, crowned with the style, and rather showy. This plant, if our determination is correct, is widely distributed through the Sikkin Himalaya, and in the Khasia Hills, ascending to an elevation of 6,000 feet above the sea level. It is the least desirable of the species in the collection as an ornamental plant.

A handsome Japanese arborescent *Euonymus* received from the Flushing Nurseries is now covered with flowers. M. Maximowicz, to whom specimens were submitted last year, pronounced it to be the Japanese form of the widely-distributed *E. Europæa*—his var. *Hamiltoniana*—which is found also from Cashmere through the Himalayas, Mongolia, northern China and Manchuria, and which has been described by botanists under a multitude of names. As it grows here it is a bushy tree six feet high, with a stout trunk covered with smooth gray bark, spreading branches, terete, or slightly angled bright green branchlets, and abundant foliage. The leaves are oblong, acuminate, serrate, two or three inches long, and deep dark green. The cymes of small greenish-white flowers are axillary and dichotomous, and these are followed by four-lobed, wingless, yellow capsules, which are not particularly showy. According to Brandis (*Forest Flora of India*), whose figure (*t. 16*) represents a form with much narrower leaves than those of our Japanese plant, this variety is common in the forests of the outer Himalaya ranges up to 8,500 feet, growing, under favorable circumstances into a tree thirty to thirty-five feet high, with a short, straight trunk four to five feet round. The wood, he says, is beautifully white, compact and close grained, and used for making spoons. The Japanese plant is so hardy, it grows with such vigor, its foliage is so abundant and of so rich a green, that it promises to be a good addition to the number of small, hardy trees which can be successfully cultivated in this climate.

Spiræa Cantonensis (*S. Reevesiana* of many gardens) is rarely seen in such great beauty in this climate as it has been this season. This plant suffers generally from cold, losing much of its wood, but this year the mild winter has been favorable to it, and both the single and the double-flowered varieties have bloomed in perfection. It is not only one of the very handsomest of all the *Spiræas* which produce their flowers in flat corymbs at the ends of short lateral branches of the year, being only surpassed in beauty of flowers, perhaps, by *S. Van Houttei*, but it has the additional merit of flowering considerably later than the other plants of its class. In climates less severe than that of New England, *Spiræa Cantonensis*, especially the single-flowered variety, is one of the most beautiful spring-flowering shrubs which can be planted in the garden.

Cotoneaster tomentosa is a hardy shrub of good habit, agreeable foliage and rather pretty flowers, which are followed by showy fruit, as is the case with nearly all the species of this

genus, which is not made enough of in our gardens. This species grows here to a height of two or three feet, with upright branches, covered with elliptical, obtuse leaves, densely covered on the lower surface with pale pubescence, as are the peduncles and calyxes of the small pink flowers. The fruit is black. This is a widely-distributed plant through the mountainous regions of central and southern Europe.

Cotoneaster laxiflora is a more showy plant than the last, growing to a height of four or five feet, with slender diverging branches covered with dark-brown lustrous bark. The leaves are oblong, obtuse, smooth on the upper, somewhat pubescent on the lower surface, as are the nodding, elongated racemes of pink flowers, to which succeed showy, scarlet berries. This is certainly one of the most showy and desirable of the perfectly hardy species of this genus in the collection. The origin and relationship of this plant are rather obscure. It is possibly a form only of *C. vulgaris*, and it may have been brought originally from Siberia. According to Loudon (Arboretum, ii., 871) it was first made known from plants raised in the garden of the Royal Horticultural Society at Chiswick, from seeds sent by Professor Jacquin in 1826. But whatever may be the origin and the native country of this plant, it well deserves a place in the garden.

Syringa villosa (see GARDEN AND FOREST, vol. i., pp. 222, 520 and f. 83) has, now that the plants are thoroughly established, and of large size, flowered here more abundantly than it ever has before. It is certainly an ornamental plant of the first-class and one of the most important introductions of late years among hardy shrubs. It has, moreover, the merit of flowering late, and long after the flowers of other Lilacs with long-tubed corollas, with the exception of those of *Syringa Josikaea*, now believed to be a variety of our plant, have faded. Two quite distinct varieties of *S. villosa* occur here. The first with narrower leaves and narrower panicles of lighter-colored flowers than the second, which is of more vigorous habit, and promises to grow into a much larger plant. This last, which was raised from seed sent from Pelkin by Dr. Bretschneider, flowers about ten days later than the first. It is worth noticing that the terminal bud, which is never developed in *S. vulgaris*, grows always in this species, generally producing a cluster of flowers, so that the branch may be terminated by three instead of by two panicles. The flowers of this species, unfortunately, have not an agreeable perfume, the slight odor which they emit resembling that of the flowers of the Privet, and therefore rather disagreeable.

Vaccinium erythrocarpon, one of the "Bearberries" of the southern Alleghanies, is beautifully in flower. This is a handsome plant, and botanically a most interesting one, serving, as it does, to connect the Cranberry and the ordinary forms of *Vaccinium*—that is, it has the foliage and fruit of the Blueberries and the flowers of *Oxycoccus*. It is a tall, rather slender, divergently-branching, graceful shrub, growing sometimes in the Carolina mountains to a height of eight or ten feet. The leaves are thin, oblong-lanceolate, finely serrate with bristle-tipped teeth. From the axils of the upper ones the scarlet or flesh-colored slender flowers hang from long nodding pedicels. The fruit, which before it is quite ripe, is scarlet (whence the inappropriate name), becomes at maturity deep shining black in color, and is then much more juicy than the fruit of any other species of *Vaccinium*. The flavor, however, is insipid, and the fruit is nowhere greatly esteemed except by bears, who, when it is ripe, resort to the high mountain-tops, where this plant often covers extensive areas, for the purpose of feasting upon it. *V. erythrocarpon* is not a very easy plant to manage in cultivation. Perhaps it is not quite hardy here, although it now seems well established and to promise well for the future.

It may be of interest to note that the plants of the white-fruited Huckleberry, described in GARDEN AND FOREST (vol. ii., p. 10) and sent to the Arboretum by Mr. B. A. Westbrook, of Montague, New Jersey, are now finely in flower and promise to produce a crop of fruit.

Rosa multiflora is certainly one of the most beautiful of the Japanese plants cultivated in our gardens, and it is a matter of surprise that the natural single form is so rarely seen and so little known. The origin, in a large part at least, of the so-called Polyantha Roses, none of its descendants compare in beauty with the plant which Thunberg first made known to science a century ago. This is a stout bush with long, robust stems, arching above the middle, growing to a height of eight or ten feet and forming a broad mass of pleasant green foliage, ten or twelve feet through. The stems are round, smooth, bright green and armed with remote, broad, recurved spines, and terminated by great compound racemes, twelve to fifteen inches long by eight or ten broad, of flowers the size of a shil-

ling, the pure white petals contrasting charmingly with the golden stamens. So abundant are the flowers that the plants at this season are completely hidden by them, and as all the flowers in each raceme do not open at once, but gradually, a couple of weeks often elapsing between the opening of the first and the last, the plants are in flower for a long time. There are two forms here. One of them flowers ten days before the other; this is a less robust plant than the other, with much smaller flowers, and generally a less desirable subject for cultivation. *Rosa multiflora* should be planted in rich soil, where it will not be crowded by other plants, and where it can have sufficient room to grow naturally and spread out its branches in all directions. It is not easy to imagine a more beautiful object than a well-established specimen, planted in this way, when it is in flower. The fruit, which is hardly larger than a pea, is produced in the greatest profusion, and is rather ornamental, remaining upon the plants until the appearance of the leaves the following spring.

The Arboretum is indebted to Max Leichtlin for this plant, who sent seeds here several years ago. It has been somewhat distributed from the Arboretum among American collections, but it is hardly known yet or properly appreciated. 7.

June 12.

The Forest.

Forest Interests in Pennsylvania.—II.

THE soil of a large proportion of the mountain region of Pennsylvania was originally of good quality, strong and fertile, as compared with most of the mountain land of the northern and eastern States, and it was well adapted to sustain a valuable and permanent forest-growth. Of course, if the mountain forest-land was properly treated it would become steadily richer, would continue to increase in fertility forever. It would thus not only produce more and more timber as time goes on, but the timber growing upon it would perpetually improve in quality also. That such is not now the case does not result from any poverty or incompleteness of the natural resources and adaptations of the region, but is the effect of human ignorance and mismanagement. Much of the land is now poorer than it has been for thousands of years before, and even if it could be well taken care of henceforth—of which there is, of course, no prospect—it could produce only inferior timber for ages to come.

The principal agent in the injury and destruction of the forests here is fire. Every year vast values are totally blotted out. Timber worth hundreds of thousands of dollars is consumed. But this loss is trivial compared with the mischief of the permanent impairment of the fertility of the soil, which results from burning the forests.

The most intelligent and observing men in all parts of the state say that a very large proportion of forest fires are purposely started. In some of the mountain counties the law permits cattle to run at large for pasturage, and owners of stock set the woods on fire to promote the growth of grass. The people who gather berries are also interested in having the forests burned frequently; and fires are convenient for hunters, because they maintain and extend areas of open woods. Large tracts of valuable timber are often set on fire by men who want the job of cutting it off, as they know that it must be utilized immediately after it is burned over, or it will be worthless. Some fires result from sparks thrown out by railway engines, but the people of Pennsylvania do not believe very much in the accidental origin of forest fires in their state.

The law which permits owners of cattle to pasture them on other peoples' land should be changed. Pasturage is, in itself, fatal to the perpetuity of forest conditions, and nothing effective can be done for the preservation of the woods while cattle are allowed to run at large in them. When this arrangement for forest-pasturage operates as an inducement to set the woods on fire it is idle and useless to talk of devising means for preserving the forests unless this premium on their destruction is abolished. It is comparatively easy to obtain almost any legislation that may be desired. A little systematic and intelligent agitation is all that is required for this object. It would, doubtless, be worth while and profitable for the people of the state to undertake the care of the mountain woods, if any plan for their preservation could be made effective. Differences in details, in organization and methods would be of slight importance if the essential object—the protection of the woods from fire—could be accomplished by any system of forest guardianship.

The maintenance of forest conditions on the mountains of the state is indispensable to the permanent prosperity of the people. The woods have most important and vital relations

to the steady and equable flow of the streams which have their sources in them. If the woods on the mountains become extinct the streams will be destructive torrents in the spring season, and their channels will be dusty and wind-swept in summer, so that, as now in the West, the course of a river can be traced from afar by the clouds of dust always rising from its bed in dry weather. The soil will be washed down from the mountains into the streams, the inert clay, sand and gravel will follow, and will bury the fertile lands near the foot-hills. The area of farm land will thus be diminished more and more, and the fertility and productiveness of what is still cultivated will steadily decline.

It is in every way probable that this is what will, in time, actually occur. If existing conditions and tendencies are continued—that is, if the mountain forests are still burned as now—the time will inevitably come when there will be no trees or verdure on the mountains of Pennsylvania, and no soil. Instead of the noble and satisfying sylvan beauty which is now the pride of the state, there will remain only the wrecks and skeletons of the mountain chains, unsightly mounds and ridges, eroded by the wind (which will fill the air of the low-land regions with dust), seamed and scarred by torrents, and rent by horrid gulfs and chasms; a blasted and ruined land, the result and monument of man's incapacity.

To prevent these consequences would require the consent and coöperation of conditions and agencies which do not now exist. The processes of forest destruction which are now in use belong to and represent exactly our present stage and degree of civilization. The perpetuation and rational treatment of forests would be a feature of a stage and degree of civilization which we have not attained. The question whether we can save our forests is really the question whether a distinct and specific advance in civilization is now possible for us, and whether it can be made in a very short time. Some of the indispensable changes, to be availing, must be provided for by prompt and decisive action. But this is precisely what is least likely to be done.

Let us use a little analysis, and try thus to distinguish the essential features and conditions of the problem. Prompt, decisive and intelligent action is required, but there is nobody to take such action. The central difficulty lies in the fact that the results of destroying mountain forests become apparent, so slowly, that men are not impressed by them, do not care, are not interested about them. We are not sufficiently intelligent or civilized to understand or realize the effect or ultimate results of existing conditions and tendencies.

The prompt and decisive action which the situation requires is the establishment of a system of preliminary educational work. No efficient or successful system of forest-management is possible with our present national character and degree of intelligence. We have not sufficient thought, foresight, patience, or organizing capacity. We need in each state a considerable number of persons possessed of a degree of acquaintance and familiarity with the subject of forestry, in all its principal aspects and relations, such as very few of our people have reached. If such a journal as GARDEN AND FOREST, with its thorough, coherent and continuous discussion of forestry subjects, could be read habitually for some years in every school and institution of learning in this state, and by ten or twenty thousand of its leading citizens, we might then have here such conditions of knowledge and thought as would constitute the soil and atmosphere needed to produce a better civilization, and a practical and effective system or method of forest preservation and management might then be evolved.

J. B. Harrison,

Snow Shoe, Pa., June 10th.

Correspondence.

The Purple Beech at Throgg's Neck.

To the Editor of GARDEN AND FOREST:

Sir.—In your article of May 8th upon "The Purple Beech" you mention two notable specimens of the variety—the great tree on the Lyman Estate, at Waltham, of which you give an illustration, and the tree spoken of by Downing as growing on Throgg's Neck, Westchester County, New York, and declared by him to be the finest in the United States. You add the remark that this tree, if still alive, is probably much larger than the one at Waltham.

Thinking that the record should be completed, I have made the necessary inquiries. It appears that the Westchester tree died about six years ago. It grew on what is known as the Van Schaick Place, which was in former years owned by Mr. Thomas Ash, and was a place of resort of the distinguished

guests of the old Astor House in the palmy days of Stetson. Hence the tree is mentioned, as I am informed, by Dickens in his American Notes.

Tradition has it that the tree was brought from England about one hundred years ago. It stood in an open field with no other tree near it, and was perfectly symmetrical in form, the lower limbs sweeping the ground and "spreading about thirty feet on each side." At one foot above the ground it measured four feet eight inches in diameter, and at a height of five feet, four feet three inches.

It would therefore appear to have been no larger than the Waltham tree in the trunk, and to have had a somewhat less spread of limbs. But the measurement of these old Beeches is a very uncertain matter, from the buttressed, gnarled and embossed nature of their trunks. It is sufficiently evident, however, that these two trees were of about the same age and of substantially the same size, the Westchester tree being of the finer form.

The cause of the death of the Westchester tree is said to have been an overdose of manure. I am sceptical on this point, chiefly for the reason that some years ago the Waltham tree also showed ominous signs of failing. It recovered, however, under a course of nutrition at once set on foot by the late G. W. Lyman, which has been continued by his successor. May it not rather have been that the symptoms in the Westchester tree were not soon enough observed? At all events all lovers of fine trees must mourn its untimely end. I may add that Dr. Asa Gray stated a few years ago that the Waltham tree was the largest he had ever seen, either in this country or in Europe.

Relleport, N. Y.

George Theo. Lyman.

Peter Henderson's Plant Factory.

To the Editor of GARDEN AND FOREST:

Sir.—No title which now occurs to me would so accurately characterize the great establishment on Jersey City Heights as the one I have used as the head-line to this letter. In money value the annual sales from some of the foremost European nurseries would largely exceed, no doubt, the amount realized from the plants annually sold by Mr. Henderson. But it is probably true that the plants raised and sold here, one year with another, exceed in number those produced at any nursery in the world. This means that Mr. Henderson's business is not mainly with rare and costly plants, and that he does not take the time to prepare finely-grown specimens. His plan is rather to produce saleable plants as quickly as possible, and to market them out of the way for another lot as soon as they can be sold. With some of the plants, like *Coleus*, which root most readily, a crop can be sold every four weeks from the first of January to the middle of June. Such rapid propagation is not possible with all plants, but Mr. Henderson would not consider that he was running his establishment up to its ordinary capacity if he did not secure at least three crops a year from his entire space under glass.

Here are fifteen acres, four acres of which are under glass, devoted to the raising of plants; but this space alone can hardly be considered a measure of the productive capacity of the establishment. Every square foot is worked under high pressure. No device for saving time or labor is neglected. Improved processes are being adopted continually. Mr. Henderson is as alert to-day as he was twenty-five years ago to grasp a new idea, and the men in closest contact with him catch something of this spirit, so that a genuine advance in different points of practice is made every year. Under the complete and well-directed organization of the concern everything moves with celerity, smoothness and regularity, like a perfect machine which turns out plants by the million at the minimum cost of production. Thus it comes about that although the volume of business increases largely from year to year, there are actually fewer men on the pay-rolls than there were fifteen years ago. It should be added that the wages paid the smaller number exceed in total amount what was formerly paid, for many of the men have become so expert in some particular kind of manipulation that their services are worth a great deal more.

"It looks like slaughter," said Mr. Henderson, "to sell plants at a dollar a hundred, but it is a fact that the actual cost to us of producing these plants is often no more than thirty cents a hundred. Here are the figures: Four men will take off, make and put in the bench 10,000 cuttings a day; two men and a boy, or say three men, will pot the same when rooted in another day; three men in a day will knock the plants out of the pots and pack them in boxes. That is, ten days' work has been all that was needed to get 10,000 plants ready for market.

If we call this labor worth \$15, we can add \$15 more as a good allowance to be charged against the plants for firing and delivery, so that \$30 is a liberal estimate for the cost of the 10,000 plants. The same could be proved of some plants raised from seed—such as Asters, Balsams, Drummond's Phlox, etc., so that even with expensive structures, on land where every building lot of 100 feet by twenty-five is worth \$1,000, there is no actual loss on certain plants even at the low price mentioned when they are sold in sufficient quantities."

Of course these results can only be achieved in a large way, where the system is perfect, the labor skilled, and every motion intelligently directed. No spade is used where a plow can work. The ten acres are plowed deeply, pulverized with an acme harrow and smoothed with a disk harrow, which does finer work than any steel rake. Upon these acres, where the plants will average one to every square foot, one man constantly at work with a wheel-hoe and one day's work a week with a horse furnishes all the cultivating needed, with a little hand-weeding in the rows. To do this work on the old-fashioned plan, with hoes, would cost five times as much, and it would not be done half as well. Of course improved processes are not confined to this establishment, and many of them were not used here even five years ago. But it is true not only that improved methods are adopted here as rapidly as they are discovered, but also that many items of practice, with which every plantsman in the country is now familiar, originated here. There is no question but that the system of packing which so reduced the weight of plants, while it added to their safety in carriage, was practically begun and perfected here. Occasionally, to this day, one receives a huge box of plants still in pots, or a package in which the plants are rattling about loose, or are smothered or drowned. But perfect packing is recent, and it began here, where the plants were first knocked out of pots, wrapped in paper and set snugly, so as to carry safely for a week. It is true also that many other practical suggestions, like the "saucer system" of propagating, the snapping quality of a good cutting, and even the necessity of "firming the soil," which many another man may have known as a part of his personal experience, were first brought publicly forth and insisted upon by Mr. Henderson in some of his publications, so that while improving his own work by observation, he has done as much as any of his contemporaries, both by precept and example, to scatter the fogs of tradition and introduce simpler, cheaper and more efficacious methods in horticultural practice.

Having spoken of Mr. Henderson's writings, it is worth stating that his "Gardening for Profit" was about the first book on vegetable-gardening which was literally written out of the soil, by a man who was working with practical purpose. The intense methods of cultivation which the necessities of tilling high-priced land developed were a revelation when described in a straightforward way by one who was simply making record of his daily practice and the reasons for it. It was a lesson which many a farmer never forgot, when he learned that the market-gardeners about New York found it paid them to use seventy-five and even a hundred tons of well-rotted manure on every acre of their land—found, indeed, that their business only paid when they used this amount every year. This book has been in print twenty years, 150,000 copies have been put in circulation, and it is selling yet. A book like this does good, but it also naturally advertises its author, and, in fact, the name of Peter Henderson is as familiar as that of any other in connection with American Horticulture. He believes in printer's ink, however, and of his large catalogue alone he circulates every year 200,000 copies, at an expense for postage alone of \$14,000.

I add a list of the number of some of the more important plants sold during the year, not so much to give an idea of the volume of business transacted as to put on record the comparative demand for these staple plants in this year of grace 1889. Roses led, with a sale of 400,000 plants. The sale of Tuberoses reached 300,000, but they were not grown here. Chrysanthemums, Verbenas, and Coleus were sold to the number of 200,000 each. Then follow Geraniums, 150,000, and Alternantheras, 100,000. Ipomœas of various kinds and Dahlias, double and single, sold to the number of 75,000 each, while of Pansies and Carnations, 50,000 each were produced. Ampelopsis in variety reached 25,000, while Cannas, Echeverias and white-leaved plants like Centaurias amounted to 20,000 each. Estimating together annuals from seed and varieties on the "general list" rather more than half a million were sold, besides those named above. 3,000,000 Celery-plants is the first item on the vegetable list, with 1,000,000 Cabbage-plants and 200,000 Cauliflowers, about 100,000 each of Tomatoes and

Lettuces, 20,000 Egg-plants and 15,000 Pepper plants. Asparagus roots numbered 300,000, but these, too, were grown elsewhere, while only 5,000 plants of Rhubarb were needed. Of Strawberry plants, mostly pot-grown, 300,000 were sold; of Grape-vines, 10,000, and of Blackberries, Raspberries and Currants together, 25,000 plants.

Jersey City.

S.

Exhibitions.

The Rose and Strawberry Show of the Massachusetts Horticultural Society.

THERE is little to be said of the Rose Show held in Boston last week. It is many years since so poor an exhibition of the Queen of Flowers has been seen at her annual festival. The season has been very unfavorable for the development of good Roses. Excessive heat and constant rains have made the flowers both early and small, and they have dropped almost as soon as they opened. It is not surprising that the exhibition, under the circumstances, was not a large or a fine one. It is rather a wonder that it was as good as it was. There were few plants, or flowers besides Roses displayed, and the halls looked bare and anything but attractive. John L. Gardner, the Short Hills Nurseries and E. W. Gilmore, made small displays of Orchids. The best plant in the first collection was a well-grown, clean little specimen of *Dendrochilum filiforme*, which received a first prize for the best single Orchid. The best plant in the Short Hills collection was a very well-flowered specimen of the handsome *Trichophila crispa* from Costa Rica. The first prize for a specimen plant was taken by Mr. Gardner, with a good plant of *Gymnogramma schizophylla*, a lovely Jamaica Fern, comparatively new to cultivation, having been introduced into England as late as 1880.

Edwin Shepard & Son staged a remarkably fine collection of Delphiniums; and there were some interesting and attractive collections of wild flowers, brought from the woods and meadows by Mrs. P. D. Richards and Mr. E. H. Hitchings. The custom of exhibiting collections of wild flowers, which has grown to be a feature of all the summer shows of the Massachusetts Society, is one of the most instructive and useful things fostered by it, and has done much to make the local flora known, and its beauty appreciated.

The great collections of well-grown and tastefully arranged plants which a few years ago were always seen at the principal Boston flower-shows, and which made them the most interesting and instructive held in America, were sadly missed, as they have been of late years. The halls of this Society are not well suited for such displays, and the owners of the great gardens near Boston are tired, perhaps, of having their plants injured without any adequate return for their pains. But whatever the cause of the falling off in the number and variety of exhibits may be, the public are not the only losers, as horticultural enterprise and enthusiasm must suffer for want of healthy stimulus and friendly competition.

The first special Lyman prize for Roses was not awarded; the second went to William H. Spooner, and the third to Warren Heustis & Son. For twelve distinct-named varieties of Roses, three of a kind, Mrs. Francis B. Hayes took the first prize; W. H. Spooner the second, and Warren Heustis & Son the third. Other prizes were taken by Joseph A. White, Dr. C. G. Weld, J. B. Moore & Son and Joseph Clark.

Larger or more beautifully-colored Strawberries have not been seen in Boston. Sharpless and Belmont appear to be the favorites with Massachusetts exhibitors; and these berries were shown in great perfection. For the best two quarts, to be judged by a scale of points, the first prize was taken by Prince of Berries, shown by Thomas C. Thurlow; the second by Belmont, shown by Warren Heustis & Son, the raisers of this variety; the third for the same, shown by Isaac E. Coburn, and the fourth by Miner's Prolific, shown by Samuel Barnard. The Society's silver medal was given to Stephen Hoyt & Son, of New Canaan, Connecticut, for Yale—the "best exhibition of a seedling Strawberry introduced within the last five years, and never having taken a prize." Parry, May King, Jessie and Jucunda were shown in good condition.

Recent Plant Portraits.

ÆRIDES EXPANSUM LEONLÆ, *Gartenflora*, April 15th.

PICEA ALCOCKIANA and P. AJANENSIS, *Gartenflora*, April 15th.

FORSYTHIA VIRIDISSIMA and F. SUSPENS (figures of the fruit), *Revue Horticole*, April 16th.

Notes.

The Veitch Memorial Medal, a much-coveted honor in England among gardeners, has just been bestowed upon Mr. A. F. Barron, the well-known superintendent of the Royal Horticultural Society's garden at Chiswick. In his special branch, pomology, Mr. Barron has no superior, and his latest book, "Vines and Vine Culture," in a measure supersedes all English books on the subject.

A correspondent of a foreign journal notes that in the Jardin des Plantes, in Paris, may be seen two or three old Chinese Peach-trees which, as a rule, bear double white flowers; but among these are some flowers of a rich, deep crimson, wholly free from white markings. From a long distance, he says, these crimson flowers are conspicuous, especially when a single one appears, like a brilliant little rosette, on a twig otherwise entirely white.

In reply to Mr. Orpet's enquiry whether any one has tested the hardiness of *Heuchera sanguinea*, Mr. J. N. Gerard writes that he tried several young plants last winter in his garden, at Elizabeth, New Jersey, and all perished. It is perfectly hardy in England, and the horticultural papers there all speak of its abundant bloom this year. Mr. C. G. Pringle notes the fact (GARDEN & FOREST, i., 153) that along the northern limit of its distribution this plant is exposed to many degrees of frost.

According to an ancient superstition the Beech is never struck by lightning; and so general has been this belief that a gentleman recently thought it worth while to write to an English journal that he had been told of a lightning-shattered Beech in Ireland. Beliefs of this sort are rarely without some degree of justification in fact, and it would be interesting to know whether in this country the Beech has been observed to possess any greater immunity from electrical dangers than trees of other sorts.

A recent number of *Le Jardin*, a French horticultural paper, contained some curious pictures of large human figures, rudely carved out of Tree-fern stems by the natives of the New Hebrides. They are similar in type to the grotesque colossal figures carved in stone by the Easter Islanders, which have long been familiar to all students of barbaric art. In the museum connected with the Messrs. Veitch's great horticultural establishment in Chelsea there have been for some years past a series of vases carved from Tree-fern stems; but figures in the same material are a greater novelty.

Recent trade-reports explain that the cultivation of Tobacco has been largely introduced of late years in Borneo, and that large profits are already realized from a special kind that is known as "wrap" Tobacco, and is used for the external coverings of cigars. The production of this article in the East Indies has hitherto been entirely in the hands of the Dutch; but as it is so profitable that dividends of 100 per cent. have not been uncommon, while one company has paid as much as 152 per cent., it is not strange that English colonists should now have taken it up.

An International Horticultural Congress will be held on the 19th, 20th and 21st of August in connection with the Paris Exhibition. The main subjects which will be discussed are the following: 1. Is it possible to obtain, designedly, by artificial fertilization, certain wished-for characteristics in plants cultivated for market purposes, or in floriculture generally? 2. Is it needful, in order to obtain flowers with striped corollas, that flowers with white corollas should first be obtained? 3. Consideration of rates on railroads. 4. Revision of the Phylloxera Convention of Berne. 5. The use of chemical manures in horticulture. 6. Methods to destroy the enemies of cultivated plants (fungi, insects, etc.).

The *Gardeners' Chronicle* says that the Ginkgo is proving itself one of the best trees for street-planting in smoky cities, thriving in the most impure atmospheres and having as yet been attacked by no insect or fungus disease. In this country, so far as we have learned, no extensive use has been made of the Ginkgo as a street tree except in Washington, where of course it is not subjected to the test of an atmosphere impregnated with smoke. If it is, indeed, able to withstand the most unfavorable conditions it might be more generally adopted for it grows rapidly, its shape well adapts it for association with architectural forms, and the peculiar character of its foliage always makes it interesting to the popular eye.

The true eating Banana, or "Madura" is said to be unknown in northern countries, the varieties we import being simply those which are used in the land of their growth for cooking purposes. Many varieties of the Madura are recogni-

zed, each of which is distinct in flavor; the smaller are the more delicious and the smallest of all, the so-called "Lady-finger Banana" with a skin hardly thicker than paper, is the most highly prized. Green cooking-bananas are peeled and roasted in the ashes and eaten with butter; partially ripe ones are boiled for a few minutes with the skin on and eaten with syrup or honey; and ripe ones are sliced lengthwise and fried in Olive-oil or butter.

Mr. J. M. White, who owns a Peach-orchard of several hundred trees near New Brunswick, New Jersey, reported last week to the experiment station that one of his trees was badly diseased. Professor B. D. Halsted visited the orchard and found the sick tree readily distinguishable from its healthy neighbors. There were three main branches to the top, and the smallest of them had nearly every leaf badly distorted by "leaf-curl" (*exoascus deformans*). The whole branch was, of course, cut away and the leaves disposed of, leaving the remainder of the foliage of the tree in apparent health. After prolonged search no other tree was found in the whole orchard with a single leaf exhibiting any signs of disease. This is certainly a striking instance of an isolated case of a conspicuous and widespread fungus disease, and it naturally suggests the unanswered question how the "curl" first obtained a foothold in the orchard.

The gold medal of the Linnean Society of London has been awarded this year to M. Alphonse De Candolle, of Geneva, in recognition of his important services to botany. This medal, having on the obverse a portrait bust of Linnæus, and on the reverse the arms of the Society, was established last year to commemorate the centennial anniversary of the founding of the Society, and is to be bestowed alternately upon a botanist and a zoölogist for distinguished service to biological science, although Sir Richard Owen and Sir Joseph Hooker both received it the first year. An interesting feature of the ceremony the other day was the presence of a young grandson of De Candolle to receive the gift made to the grandfather—a future botanist, it is to be hoped, and the worthy successor in the direct line of distinguished men who for a century have made the name of De Candolle illustrious by their lives and by their service in increasing the knowledge of plants.

According to a correspondent of the New York *Evening Post*, 3,200,000 bushels of Peanuts are consumed in this country every year. They come chiefly from Virginia and North Carolina, although Tennessee also produces a small crop. "Peanuts are planted at corn-planting time; each kernel produces a running vine, like crab grass, and each root produces about twenty pods. When ripe, the plough is run through the loamy soil, on a dry day, just before frost. The nuts are dried and shocked up like corn to keep dry before housing. When marketed, they go to a cleaner, where they are put through steam-power machines and polished, after which they are graded according to size and variety. This year there is but two-thirds of a crop, and they are higher in price than since 1884. The crop begins to come into the market about the first of September. The Virginia nut is the largest and finest. The Wilmington is a smaller sort, and the Spanish nut, a still smaller variety, is one whose kernels peel perfectly clean, thus making it valuable for confectionery."

It will be new to some Americans, even though they know that Peaches are commonly cultivated under glass in England, to be told that Cherries are also grown in this manner. A correspondent of the *Gardeners' Chronicle* recently described the Cherry-house at Gunnersbury Park, where many different varieties afford fruit at different times during the season. "When the trees are started into growth," he says, "a temperature of 45° by day and 40° by night is maintained. When they are in flower plenty of air is given, and the bees are encouraged to work among the blossoms as much as possible. Scarcely any fire-heat is employed; indeed it had been employed only once or twice in order to keep out frost. At the time of flowering plenty of ventilation is given top and bottom. As soon as the fruit has set, the house is closed up somewhat, and the temperature kept quite cool until the stoning process is over, then it is kept a little closer, as when the fruit has stoned it ripens quickly. It is a little difficult to thin out the fruit previous to the stoning stage, as it is uncertain which fruit will mature and which fall. A good watering is given to the trees before they get into flower, and then water is applied with moderation until the fruit has set. Cherries appear to do best, and set their fruit more freely when somewhat dry at the roots, whether the trees are planted out or in pots, and it appears to be quite certain that all flower more freely when worked on the Mahaleb than when on the Cherry stock."

GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, JULY 3, 1889.

Mountain Reservoirs and Irrigation.

THERE are few subjects connected with the development of American civilization of more fascinating interest than that of irrigation. During all our early history it was "Something to read about," a feature of the life of far lands, oriental and romantic in all its suggestions and associations. There is, of course, plenty of hard and prosaic work in agriculture by irrigation, but there is also much that appeals strongly to the poetic and artistic imagination. The construction of canals and ditches, dams and reservoirs requires downright, immitigable toil. Not many kinds of labor are more severe or exhausting. But there are few spectacles ever beheld by man which are more impressive, or better fitted to awaken "vital feelings of delight," than the transformation, by means of irrigation, of an arid and barren waste into a fruitful and populous land. As the life-giving water invades, conquers and possesses the country its progress is like the march of a triumphant and liberating army, but there is no death or suffering or destruction in the gentle and pervading flow. It brings verdure, beauty and fruitfulness everywhere, and makes the desert to rejoice and blossom as the rose. Not many things of which men are capable come nearer the exercise of original creative power than the magical awakening of fertility where all had been inert and lifeless before, by the introduction of water into regions which had before been destitute of it.

We have great areas of arid land in the south-western part of this continent which can be made extremely productive, and capable of sustaining a dense population, by means of irrigation. The soil has all the elements of great fertility except water, and this can be artificially introduced and applied in great abundance. The rivers which have their sources in the mountain forests, which now belong to the nation, will supply water for the irrigation of vast tracts of arid land, if the water is properly husbanded, and its flow regulated by maintaining the mountain forests which now constitute the natural reservoirs for the storage of the water which sustains these rivers with equable flow through the whole year. If the

forests are removed in such a way that they are not reproduced, that is, if forest-conditions on these mountains are permanently destroyed, the great sponge which now covers them everywhere, composed of root-fibres, leaf-mould and decaying vegetable matter, will be destroyed and washed away. Then the water of the winter rains and snows will rush unobstructed down the smooth slopes, and so much of it will reach the channels of the streams in a short time that enormous floods will be immediately produced. The valleys will be ruinously inundated, and the fertile lands along the streams will be buried under the débris brought down from the hills. The experiment has been tried again and again in many parts of the world, and always with the same consequences. The extinction of the mountain forests results in the destruction of the mountains themselves, and in that of the streams which have their sources in them.

All this is well known to those who have studied these subjects, and the facts are easily accessible to any who wish to look for them. But as the work of arousing, enlightening and directing public sentiment so as to provide for the preservation of the mountain forests on our public lands is one of difficulty, some people propose that we shall avoid all this labor by surrendering the forests to extinction, and adopting the comforting notion, that as it is so hard to save them they are not really necessary. It is also to be observed that the splendor of the achievements of inventive and mechanical genius during our own time, seems to justify the most daring and audacious expectations for the future, and it is not wonderful that men should imagine that nature imposes no limitations which may not be removed or overcome. Some influential engineers in this country think so highly of their profession and its work that they even propose to disregard and reject the natural provision for guarding the sources and flow of rivers, and to substitute for the mountain forests, which are the natural storage reservoirs, a system of artificial storage reservoirs constructed with walls, dams, and embankments.

If this method is ever tried it will result in frequent and ruinous catastrophes. The recent awful tragedy at Johnstown, exhibits the inevitable consequence of all attempts to restrain and control a body and volume of water too great for the capabilities of an artificial structure. If the attempt is made to substitute the use of artificial storage reservoirs for the natural function of the mountain forests of California, and other similar regions, it will be found that either the dams and embankments must be constructed with sluice-ways so large as to permit the free passage and escape of the excessive volume of water in the time of great floods, in which case, the reservoirs would be nearly useless, and it would not be worth while to construct them, or, if the plan which is now talked about is carried out, in the construction of reservoirs large enough, really to store and preserve the water of the spring floods, for gradual distribution and use in time of drought, the breaking of such embankments is inevitable, and the valley below each reservoir will be fated to sudden desolation, with awful destruction of human life if there are people living in it. Why should we pay so dearly for the knowledge which we shall thus acquire? Why not accept now the lessons which time is sure to teach us? The advocates of the destruction of the mountain forests, and of the substitution of artificial storage-reservoirs, admit that such catastrophes will result, as fatalities now attend the running of railway trains. In the question of the preservation or destruction of the mountain forests on the lands belonging to the nation are involved the conditions of the life and welfare of millions of human beings.

Artificial storage-reservoirs will of course be necessary in some regions, as part of the provision for adequate and economical irrigation, and if they are properly designed and constructed they can be made successful while forest-conditions are maintained on the mountains and around the sources of the streams. But if the forests are destroyed no artificial structure will restrain the resulting floods.

THE will of the late Professor Reichenbach is a remarkable one, and his object in imposing the conditions which evidently appeared necessary to him in disposing of his invaluable collections are not very apparent, although a mistrust of the men into whose hands his cherished specimens would have fallen had they been made available for immediate use, was probably at the bottom of his determination to keep them sealed up for a quarter of a century. The following translation of a portion of the will, which we borrow from the *Gardeners' Chronicle*, tells the story of the Professor's desires, whatever may be the ultimate disposal of the collection:

"My herbarium and my botanical library, my instruments, collection of seeds, etc., accrue to the Imperial Hof Museum in Vienna, under the condition that the preserved Orchids and drawings of Orchids shall not be exhibited before twenty-five years from the date of my death have elapsed. Until this time my collections shall be preserved in sealed cases. In the event of the Vienna Institute declining to observe these conditions, the collection falls under the same conditions to the Botanical Garden at Upsala. Should the last-mentioned Institute decline the legacy, then to the Grayean Herbarium in Harvard University, Cambridge, Massachusetts. If declined by that Institute, then to the Jardin des Plantes at Paris, but always under the same conditions, namely, of being sealed up for twenty-five years, in order that the inevitable destruction of the costly collection, resulting from the present craze for Orchids, may be avoided."

It is certainly to be regretted that Cambridge was not selected as the first recipient. In no other country are the facilities for studying Orchids now so limited as they are in America, and there is no other—if it is fair to judge by the progress which has lately been made in the collection and cultivation of these plants here—in which a knowledge of Orchids will be so necessary or where the students of these plants could make a better use of the mass of material which Professor Reichenbach has left.

Since the above was written we learn that the authorities of the Imperial Hof Museum have accepted the bequest of Professor Reichenbach's botanical treasures, subject to the conditions imposed in the will, so that there remains no longer even the remote chance that they will find their way to this country.

A Mountain Meadow.

MOUNT Rainier, which rises to a height of 14,444 feet from the shores of Puget Sound, is the most beautiful of the mountains of the United States, as it is the most difficult to ascend, only two or three parties, previous to last summer, having succeeded in reaching the twin craters which occupy the summit. In August last, however, a party of nine men, including Mr. John Muir, the well-known student of the Cordilleran glaciers, gained the summit, and were fortunate in obtaining a large number of photographs of the mountain, and of various aspects of vegetation encountered during the journey. Among these photographs is the one that is reproduced upon page 319 of this issue. It represents an alpine meadow covered with flowers of *Erigeron salsuginosus*. We are indebted to Mr. Charles V. Piper, of Seattle, one of the party who made this memorable ascent, for the photograph, and for the following brief note, which he has promised to supplement later with a fuller and more detailed account of the flora of Mount Rainier.

"This particular meadow on which we encamped lies between glaciers of the Nisqually and Cowlitz rivers, on the south side of the mountain. It covers, probably, four square miles, and ranges in altitude from 5,000 to 7,000 feet. The meadow on the east side of the mountain, between the Cowlitz and Natchess glaciers, is about the same size and differs but little in vegetation. The other meadows on the main mountain are much smaller and, with one exception, difficult of access. The meadows on the summits of the surrounding lower mountains are quite extensive, however. The timber on the meadows is confined mainly to the crests of the ridges running up the mountain, and consists of *Abies subalpina*, *Tsuga Pattoniana*, *Chamaecyparis Nutkaensis*, and a few *Pinus monticola*.

Erigeron salsuginosus grows on the drier ground near the timber, together with the following equally abundant plants: *Orthocarpus pilosus*, *Lupinus*, sp., *Anemone occidentalis*, *Potentilla gelida*, *Valeriana*, sp., *Polygonum Bistorta* and *Veratrum viride*."

Erigeron salsuginosus is widely distributed from Kotzebue Sound and Unalaska, and along the high mountains as far south as California, Utah and New Mexico. It was first discovered by Dr. Richardson, of the Franklin Search Expedition, on the salt plains of the Athabasca. It is a handsome plant, with stout stems twelve to twenty inches high, and solitary or a few corymbosely-disposed flowers, with broad disks, and fifty to seventy purple or violet rays half an inch or more long. There is an early figure under *Aster salsuginosus* in the *Botanical Magazine*, t. 2, 942.

Testing and Introducing New Fruits.

THE following is the substance of a paper prepared by Mr. C. L. Watrous, of Iowa, for the meeting of the American Pomological Society at Ocala, Florida.

This subject has claimed much interest of late and is yearly assuming greater importance. The wonderful development of the means of communication and of transportation has brought the most distant lands nearer to us, practically, than were adjoining states a half century ago, while the growing cheapness of printers' ink has made it easier to spread the fame of a new fruit thousands of miles across land and sea than it was only a few years ago to properly advertise one in the next county.

Again, vast regions of our country with conditions like none hitherto known, have been settled by an eager, prosperous, enterprising race, determined to have the best and willing to pay for it. Furthermore, the universal custom of propagating all fruits by budding, grafting, layering, and the like—that is, by extending the life of the individual, to the exclusion of the method of sexual reproduction by the creative effort of two life germs from different individuals—has practically deprived us of all benefits from the use of the natural method of adapting fruits to new or changing conditions by seedling production, selection and the survival of the fittest.

No distance across sea or land has been too great for transportation. Neither has it been conceded that any change of latitude or of longitude present reasonable grounds for distrust of new comers.

A single glance at some laws of climatology involved in such work is all that time permits, but this glance will open vistas into the domain of Nature that no pomologist's life will be long enough to explore. It will be evident, at first thought, that all maritime regions must have many similar conditions, from the presence of the ever-changing, but also the ever-steadfast, sea. A certain degree of moisture and of warmth must always pervade the atmosphere near unfrozen water. It further appears that the western shores of all continents have softer climates than any other regions and are similar to each other; also, that the eastern continental shores bear a like climatic resemblance to each other, although less mild than either western shore; and, finally, that the eastern and western coasts of the same continent are extremely dissimilar.

The interiors of continents, besides differing greatly from any maritime regions, also differ profoundly from each other, each subject to comparatively sudden and violent changes, and each, of course, subject to laws and conditions peculiar to itself. The eastern continent is, in its northern part, a vast plain, open to all ocean influence from the west, extending, without any considerable barrier, from the most westerly cape of France to the most easterly sand-spit of China, more than 6,000 miles. On the western Continent, on the contrary, all long vistas are in northerly to southerly directions. There are narrow maritime belts on the east and on the west, soon interrupted by the Appalachian range near the eastern coast, and by many ranges on the west, including the Coast range, the Cascades, the Sierras and the lofty Rockies.

The broad interior region of this continent, known as the Mississippi region, swept by fierce winds north and south and subject to extreme electrical disturbances, is quite unlike either coast region, and also quite unlike any other known inland region of the earth. In this inland prairie region, not only do fruits and plants, natives of California or of Europe, generally fail, but also those from our Atlantic States as well. It was supposed that fruits from Russia formed an exception to the rule, but, with more extended experience, failures have multiplied and doubts gained force. At present there is not a

single variety of any fruit, great or small, of known Russian origin that has given good promise of permanent usefulness in any western state. Trials are still carried on, but with greatly moderated hopes.

It has been shown by Dr. Gray and others that the principal forms of plants of the northern hemisphere once flourished together in the region about the north pole, that thence they were driven southwards along the lines of least resistance by glacial cold; returning northwards with returning warmth and repeating these migrations till we now find regions of vegetation almost as distinctly marked as geographical boundaries on the map. Seedlings of conifers growing on the eastern slopes of the Rocky Mountains will flourish in the interior or Mississippi region, while seeds of the same species from the western slopes of the same mountains fail to produce seedlings able to live there, yet plants from the western seeds give full satisfaction in Europe, and to some degree, though a lesser one, in our Atlantic region.

A late horticultural report in Iowa showed in a certain county a Pear-orchard of 350 trees of over fifty varieties, not a tree of which had been destroyed by the late extreme seasons there, while in the second county, distant not more than fifty miles, Pears were not mentioned, and scarcely any varieties of Apples had escaped. The late geological survey of Indiana develops in that state at least seven distinct botanical regions marked by specific differences in the characteristic native plants.

In the cold and marshy north are found the plants that characterize the vegetation all the way up to Hudson's Bay, while in the south-west are those that dot the slopes and bottoms down to the Gulf. Nay more, sometimes on opposite sides of the same ravine, in a certain hilly region, may be found the uttermost outlying pickets of the opposing floral hosts.

The same laws hold in every region. In the new Stanford Arboretum, near San Francisco, subject to the unchanging Pacific, the trees of South America and of Siberia; of our Atlantic States and of Japan; of western Europe and of China, vie with each other in luxuriant growth along with those of Alaska, of Dakota and of Mexico—so writes Mr. Douglas, the Director.

The contrary exists in the upper Mississippi region, where trees of the native forests are sometimes injured by extreme seasons, and all strangers may well beware. Thus it appears that one must study his own condition to judge the limit of his reasonable faith in new fruits.

Experience has lately shown that trees from an extremely severe climate or from the far north are not, therefore, to be presumed well adapted and hardy in a climate much warmer. Partial unlikeness of environment—that is, unlikeness of some of the surrounding conditions, though neither great nor obvious, may quite easily be sufficient for utter disappointment. The wound of poor Mercutio was "not so deep as a well nor so wide as a church-door," but it was enough. Very short distances and slight changes in elevation are often sufficient to cause failure in new fruits. Moreover, it is found by trial that fruits and plants transported so far from their native habitats may thrive very well while young, but fail miserably in middle age or after producing fruit. Therefore it is found that no one can safely commend a new fruit for general cultivation in any region until it has been well tested there under all usual conditions, nor until thorough trial for a period at least equal to the usual life of an individual of that species.

Both these safe and conservative rules are persistently violated by introducers of foreign fruits—where such violations are most dangerous of all—as well as by those lightning operators who propagate, advertise and introduce their prodigies all in one and the same season, leaving the testing and the groaning to be done at leisure by the purchaser and planter.

There seems abundant reason to believe that every botanical region must be willing to undertake the task of originating, from seed and by selection, the bulk of its fruits, if success be expected. This is because health, vigor and adaptability of tree or plant can seldom be perfectly secured except by nature's process of creation and survival. It follows also that the purchaser of new fruits should inquire carefully as to the conditions of soil and climate characterizing the birth-place of the tree or plant offered for his money, because, if at its very best under one set of conditions it cannot possibly be also at its best under very different ones.

It is not sufficiently appreciated that plants are indicators of such extreme delicacy of climatic and soil differences that the finest instruments of men are clumsy beside them.

Is it too much to say in the light of experience that no region can reasonably hope for as good results from the plants of any other region on earth as from selected individuals from abundant seedlings produced in that very region

and subject to all its peculiarities. It seems to me that the proposition needs no argument, but that an attitude of distrust and caution towards all fruits of distant origin is the duty of every planter.

Upon every fruit-grower is equally laid another duty; that of annually planting some seeds from his best fruits, that the course of nature be kept clear for the perpetuation of a race of successful fruits, for the changed times and changing conditions in which his posterity must exist.

Foreign Correspondence.

London Letter.

I DO not remember to have seen the London parks and gardens with such a poor show of flowering shrubs as they have this season, and the same complaint comes from all parts of the country. This result is attributed to the last wretched summer, when the tree and shrub-growth was too luxuriant to form flower-buds. Notwithstanding the dearth of shrub-bloom, the public parks here are just now delightful; the glass-houses have given out their millions of bedding-plants to adorn the lawns. Ever since March the public gardens have glowed with their parterres of gorgeous bulbs, and the late Tulips are only just past. I agree with your remarks in a recent page of GARDEN AND FOREST, that Tulip-planting is an expensive luxury, considering how short their flower season is. But we are trying to reduce the expense here, for not a few bulb-growers are of the opinion that as fine bulbs can be grown in England as in Holland, and if in gardens where bulbs are planted extensively they can be grown to perfection, they must be cheaper than imported bulbs.

The Royal Horticultural Society has lately had a busy time, and it really seems that the old Society is becoming re-invigorated. No stranger who saw the magnificent exhibition the Society held a few days ago in the Temple Gardens (which is almost in the heart of the city of London) would have supposed that this show was organized by a Society which a few months ago was considered in a hopeless condition. Nowhere in the world could such a display be seen, especially of Orchids, which were contributed from the richest collections. Among amateurs I need only mention the names of Baron Schroeder and Sir Trevor Lawrence, while the trade was worthily represented by Messrs. Sander, Low and others. Such Orchids as *Odontoglossum Alexandra* were displayed by the thousand in one mass of graceful bloom. Then there were hosts of Cattleyas, Lælias, Cypripediums and all the popular genera of Orchids, besides numerous varieties that could only come from the Schroeder and Lawrence collections. In the presence of these banks of Orchids, glowing with splendid colors and most graceful in form, one is hardly surprised that the world of flower-lovers worship Orchids, at any rate, for the moment. But this comprehensive exhibition represented other classes of plants grown to perfection. There were pot Roses six or eight feet across from the Cheshunt Nurseries, similar to those that grand old florist of the past, Charles Turner, showed year after year at Regent's Park.

These fine examples of cultural skill did not excite the admiration of the crowd so much as the group of huge pot-specimen Clematises shown by the Worcester nurseries. These plants were balloon-trained, ranging about six feet high and some three or four feet through, and were masses of flowers, some of which were quite a foot across. These varieties were all of the Lanuginosa or early-flowering section, and comprised in their colors all shades of purple and mauve, besides snow-white. I need not give the names, as they are the standard sorts to be found in good Clematis lists. Since Jackmann, of Woking, ceased showing Clematis nothing has been seen in London to compare with these. There are no better climbers for the green-house at this season than these large-flowered Clematis, and they continue to bloom until the smaller-flowered *C. Jackmanni*, in its endless varieties, come in flower next month. For the lovers of hardy plants there was abundant entertainment in this show, for Ware, of Tottenham; Paret, of Cheshunt, and others put out their full strength, and showed us what a show border-plants can make when potted and grown specially for exhibition. Pæonies of the Albiflora, and other herbaceous species; Poppies, Pyrethrum, Pansies and a whole host of other things which at this season make open-air gardens so gay, made the flowerless lawns at the Temple gay in a few hours. Pot-culture of hardy plants has not been much practiced, but there is a great deal in it, and it is only from experience that we can tell which are most suitable for the purpose.

Hardy shrubs were represented by Mr. Anthony Waterer,

who contributed from his Knap Hill nurseries a bright group of new hardy Azaleas, all highly-bred seedlings, which are very different from the old sorts of Ghent Azaleas. But I must give you a special note about this most important race of new Azaleas. Messrs. Veitch showed a good many interesting things in the way of shrubs in bloom, but there was nothing that calls for notice here except the Japanese Maples, which are fast becoming so popular for green-house adornment. They are hardy in a good many places in England, but they must, on the whole, be termed half-hardy shrubs. The most attractive green-house flowers here were the Begonias, single and double, from Messrs. Laing and Messrs. Cannell, two firms who have done most to improve and popularize Begonias. Some say that they are getting the blooms too big. This may be so from an artistic standpoint, but ask the amateur, who is forever striving to produce the biggest Begonia-bloom as he is the biggest Gooseberry. Messrs. Cannell claim to have beaten the record with their flowers six inches across, looking more like double Hollyhocks than Begonias. The market-men, too, were in evidence at this grand show, and none more worthily represented this section of gardeners than Mr. May, who is chiefly a Fern-grower, and has raised so many of the beautiful new varieties. He carpeted a large area of the turf with his Ferny growth, which in every instance was the perfection of cultural skill.

W. Goldring.

New or Little Known Plants.

Spiræa Van Houttei.

THIS is by far the handsomest of all those *Spiræas* which produce their flowers from the extremities of short leafy branches of the year, and one of the very handsomest and most desirable of all hardy flowering garden-shrubs. According to a writer in the *Revue Horticole* (1866, p. 269), it was raised by a French nurseryman, Monsieur Billiard, of Fontenay-aux-Roses, from seed of *Spiræa aquilegifolia*, a form of *S. trilobata* with which we are unacquainted. Its relationship with the Siberian *S. trilobata* is evident; it is, however, a much more free-growing plant, attaining in good soil a height of six or eight feet, and forming, with its spreading and gracefully arching branches, a wide bush as much through. The foliage is somewhat paler, especially on the upper surface, than that of *S. trilobata*, the flower heads are broader and much flatter, while the individual flowers differ from those of the Siberian plant in their larger size and in their color, which is pure, clear white, while those of the parent plant are greenish white.

Cultural Department.

Cultivation of the Pecan.

THE Pecan is cultivated quite extensively now in the southern States, and it may be found growing on river-banks from Indiana to Texas. Although the tree is well known for its delicious nuts, which constitute an article of considerable commerce, it has not been cultivated systematically for profit until recently, except in a few localities in Texas and Mexico.

The tree is a species of Hickory (*Carya*), and grows tall and slender, with a very hard wood. In early days it was held in high estimation in the south on account of its beauty, and many an old plantation is now marked out by a fine growth of these trees. When the trees are confined in the forests they shoot up fifty or sixty feet without branches, but when standing alone they attain a height of from sixty to ninety feet, with straight, symmetrical trunks, and expand into well balanced, ample heads of bold, handsome, pinnated foliage.

The Pecan-nuts which come from the southern States are from an inch to an inch and a half long, smooth, cylindrical, pointed at the heads, and thin-shelled, with the kernels full of delicately-flavored meat. The demand for them in this country and in Europe far exceeds the supply, and owners of land in the south bordering on river-bottoms would do well to plant it with the thin-shelled variety of Pecan. This is being done now more or less in many of the states, and plantations or groves of Pecans are annually set out. It is an important question, not yet satisfactorily decided, whether they will not pay much better than either Oranges or Lemons. In Florida there are many acres of low, rich hummock-land, aptly called here

"flat-woods," which cannot be put to any profitable use until it has been thoroughly drained. Such drainage, owing to the nature of the soil, is an expensive undertaking, and it is doubtful if, in the end, the land would prove thoroughly dry during rainy seasons. But these "flat-woods" would make fine places for Pecan-groves. The trees do not seem to mind an overflow of water around their stems, for many of the best groves found in Texas and Mexico are situated on rich bottom-land that is often inundated once or twice a year. The low "flat-woods" can be obtained for a trifle, and the cost of a Pecan-grove is thus materially lessened. In the case of Oranges and Lemons the land to be selected must be of the best, and the prices are usually correspondingly high. Land along the river-bottoms and bayous all over the southern States is comparatively cheap, owing to destructive overflows of water, which may rise any season and flood the fields. Rice and Sugar-cane are about the only crops that can be made to thrive here, and it is not always desirable to grow either one of them along river-banks or in flat-woods.

The prospect, therefore, is that much of this waste land must be taken up by Pecan-groves, which will well repay the planter eight or ten years after the trees are put out. Several of the young groves that were planted two or three years ago in low flat-wood, as an experiment, are now doing finely, and from present indications they will repay the owners.

The period of waiting for a Pecan-grove to bear fruit is long, and often this proves a serious drawback to the cultivation of the trees. The time after planting for the trees to begin to bear so that they will pay expenses has been placed variously from ten to twelve years. The first few years the trees grow slowly, but as they increase in size and age their growth becomes rapid. Their bearing also increases, and the crop nearly doubles itself every year or two.

It is not desirable to raise the tree from seed, as it is not likely to be as good as the seed. Young nursery-trees are the best, or if one has time he can raise his own trees from the seed, and then bud them with the large, paper-shell variety. This is the most successful way here of propagating the Pecan. After the trees are once started they need little or no care. An occasional plowing between the rows and general stirring of the soil would tend to improve their growth; but such labor is really unnecessary. The trees, however, do not stand transplanting very well. They should be put in the place at first where they are intended to grow. If the land is not too low and wet, vegetables can be grown successfully between the rows of trees. Some persons plant the trees thirty or forty feet apart, but fifty or seventy feet is better. When the trees once begin to bear the only expense attached to the grove is the cost of picking, packing and shipping the nuts.

Fort Meade, Fla.

Geo. E. Walsh.

Celery Growing.

THERE is little doubt but that the method of growing Celery, which is practiced from Baltimore southward, could be profitably extended further north, particularly in private gardens and where space is valuable. I refer to the plan of growing it in beds five feet wide and of any desired length. Celery kept where it is grown is certainly superior to that which has been lifted, and when grown in beds it can be covered and kept through winter, which is impracticable in single rows.

In planting these beds we use a board six feet long and one foot wide. A garden-line is tightly stretched along one side of the bed, and the square end of the board is kept parallel to this line, so that the rows run straight across the bed one foot apart. Notches are cut on the edges of the board six inches apart, beginning six inches from the end, making eleven notches. In using the board it is laid perpendicular to the line, as before described, and the planter, standing on it, sets a plant at each notch on both sides of the board, and so continues the whole length of the bed. All that is now necessary is to keep the bed well cultivated until it is necessary to add some earth to keep the leaves erect. The earthing is done with a pair of boards ten inches wide and about seven feet long, a foot or more at each end being tapered to form a handle. In using these boards they are set on edge between two rows of plants, and kept nearly upright by pegs stuck in the ground on the outside at each end. Two men work together standing one on either side of the bed, and shovel the soil from the space left on the sides of the bed, placing it between the boards until level full. Then grasping the handles at the ends of the board they bring their upper edges together with a few sharp raps, then each man throws up the end of the board in his left hand and catches the one in his right, inserting it in the next row of plants.

The soil is thus left standing in a sharp ridge between each row of plants. After setting up these ridges between each row the boards are laid aside and the men "handle" the celery. Beginning at the middle of the bed each man grasps a plant with his left hand, holding the foliage erect, while with his right he pulls down the ridge of earth and packs it tightly around it. After the whole bed has been "handled" in this manner the boards are again used and fresh ridges are set up between the rows, so that the plants stand in little trenches and are drawn up more erect. As the plants get above the ridges and are inclined to spread the earth is again pulled down around them and another set of ridges set up. As the season gets cooler the earthing is continued as fast as the tops of the plants get above the ridges, care being taken at the same time to carry up a bank of earth a foot thick on each side of the bed. When hard freezing is evidently at hand, say late in November northward, and in mid December in Virginia, the entire bed is covered with a thick layer of earth rounded up so as to shed the rain. Forest leaves are then banked thickly over all, and corn-stalks or bean-poles laid on to keep them from blowing off. At the north a temporary board roof over the bed, packed underneath with leaves or straw, I should suppose would exclude frost. Having the bed covered in any convenient way, it is easy to get at it in winter, and the labor

Palms is good, fresh seed, and this, in the case of some species, is difficult to procure, on account of the long ocean voyage, during which the seeds invariably lose much of their vitality unless very carefully packed. It will be found that some species suffer much more than others from this cause. *Kentia Balmoreana*, for example, apparently, decays much more rapidly, than *Kentia Forsteriana* when packed in precisely the same manner and sent at the same time.

The seed of that most useful Palm, *Areca lutescens*, though easy to germinate, does not keep well, and, consequently, it should be sown as soon as possible after its arrival, and if it is fresh it will germinate in three or four weeks, and may be potted off at the end of three months.

Among the Palms in general use probably the easiest and quickest to germinate is *Livistonia Chinensis* (or, as more generally known, *Latania Borbonica*). Seeds of this species, under favorable conditions, germinate in about two weeks after planting, and are ready to pot off in two months' time.

Cocos Weddelliana is one of the easiest of its family to raise from seed, though not always making so good progress after the first potting, owing to the fact that the long, stiff tap-root, which is made during the first growth of the seedling, is very brittle, and is, in consequence, frequently broken or otherwise injured in potting. This gives the young plant a severe check;

Fig. 117.—*Spiraea Van Houttei*.—See page 316.

is much lighter than earthing up single rows and then lifting and storing the plants.

Celery should be set in the beds early in July for late fall use, and from the middle of July to the middle of August for winter and spring use. That which is intended to keep during winter should not have any earthing beyond the first handling until the last of October. White Plume Celery is especially adapted to bed-culture, but the Sandringham and Golden Heart are our favorites.

Seedling Palms.

THE greatly increased use of Palms for house decoration and also for filling conservatories, is being met by a corresponding increase in the number of seedling Palms raised from year to year in the establishments of many of the leading florists. That this branch of the business may be overdone in the near future is an opinion freely expressed by some florists, but as the public knowledge of the great utility of these plants becomes more general, it may reasonably be expected that the demand for well-grown plants will quite equal the supply for some years to come.

It is not, however, to the commercial side of Palm-growing that I propose to call attention, but rather to give some general remarks in regard to their culture.

The first requisite to success in the raising of seedling

and, if accompanied with a slight excess of water, such an injury often causes the death of the seedling.

The Kentias are rather slower in germinating, and sometimes take from six to eight months for the operation, and besides this it is seldom that more than fifty per cent. of the seeds prove good. This fact, coupled with that of the comparatively slow growth of the young plants, undoubtedly has much to do with the high prices at which good plants of this species are sold.

The soil for Palm-seeds should be rather lighter in composition than that in which established plants are grown, and may consist of equal portions of peat and light loam, with sand enough to make the mixture open and easy to drain, the latter point being worthy of attention, for when the soil is allowed to become too wet many of the seeds are sure to rot.

The seeds may be planted in either pots, pans or wooden boxes, an objection to the latter being their liability to breed fungus, the earthenware vessels being therefore found the most satisfactory, and for convenience four to six inch pots are preferable. As a steady bottom-heat is essential for the rapid germination of Palm-seeds, the pots containing them should be placed in the propagating house or some similar structure, and plunged in cocoa-fibre or coal-ashes, the cocoa-fibre being the better conductor of heat of the two, and also cleaner to handle.

Care should be given to watering, to keep the soil damp without making it sodden, until the seedlings have developed

their first leaves, after which water may be given much more freely without injury to the plants. As to the time for potting off, it will be found best with most species to wait until the second leaf begins to push up, but with some of the free-growing sorts, such as *Areca lutescens* and *Livistonia Chinensis*, it is not necessary to prolong the time to this extent, and plants may be potted as soon as the first leaf is fully expanded; but they should in any case be kept in a warm house and shaded from the direct sunlight until they are well established.

Orchid Notes.

Cattleya Mossiae.—Ever since the flowers of this grand Cattleya first developed themselves under cultivation they have been the admiration of all beholders. Some fifty years have elapsed since its introduction, and where Orchids are grown it is invariably found occupying a prominent position among the other species. It is by no means a difficult plant to grow. The flowers are very showy and durable and most remarkable for their great variation in form and color. There are two beautiful white forms of this Orchid, but, like the majority of white-flowered Cattleyas, they are extremely rare. These are *C. Wagerii* with large flowers, having a yellow blotch on the labellum, and *C. Reineckiana*, a variety with pure white sepals and petals and a broad, rich-purple labellum and yellow throat. The flowers of *C. Mossiae* are borne on stout stems, four or five together on each, and they measure, individually, six or eight inches in diameter, with broad rosy sepals and petals, and a lip large and exquisitely fringed. They make their appearance during the months of May and June, and if removed to a cool temperature will remain four weeks in good condition on the plant. After the flowering period is past the plants that require it should be repotted before root-action begins. If this is not done at the proper season, the most careful cultivator may break or injure the roots in potting and thereby check the plant for a considerable time. The usual compost given to Cattleyas will suit this species, that is, good fibrous peat with a little sphagnum, and ample drainage, and during the period of growth an abundance of air and moisture.

Lælia majalis.—Mr. Charles Carpender, of New Brunswick, New Jersey, is the possessor of some remarkable specimens of this Orchid. On a recent visit to this collection I observed a plant carrying numbers of its enormous flowers, which in many instances measured seven inches in diameter, their broad lips beautifully penciled with fine purple, forming a pleasing contrast with the lilac color of the sepals and petals. This is one of the largest-flowered Orchids in cultivation. It is somewhat objected to on account of its shy-flowering habit. The plants here noted were attached to wooden blocks and suspended well to the light where a plentiful supply of air reaches them at all times. After the bulbs are fully grown a thorough rest is given to the plants by placing them in a cooler and drier atmosphere.

Summit, N. J.

A. Dimmock.

Raspberries.—The variety of this fruit which is best for the market is seldom the one for the home-garden. A red raspberry, like the Brandywine, which is so dry and firm that it keeps its shape and bright color in transportation and produces large crops, will suit the market-grower, but in our home-garden we want better fruit—we want a raspberry of good size and full of juice, such a berry as the market-grower cannot handle. It is a great misfortune for private gardeners that nearly all the efforts at so-called improvements in the Raspberry have been in the direction of getting a large cropper and a good shipping fruit, so that quality and juiciness have been largely sacrificed. Among all the new Raspberries we have none to compare in quality for home use with Brinkle's Orange, Fastolf, Franconia, Hornet and others of the old tribe, which nurserymen have almost ceased to grow, because every one in planting follows the lead of the market-men.

For a combination of good qualities for home use the old Hornet is still unsurpassed, and with me has always been as hardy as any of the newer red varieties. Herstine is close to it and rather more productive. Brinkle's Orange is unsurpassed in flavor, but very tender. But in our gardens hardness is a minor consideration. It is a small job to bend the canes down late in autumn and throw a few shovelfuls of earth on them after the old canes have been cut out. I plant them four by six feet and tie to a single wire stretched about four feet from the ground. If space is valuable, and this seems to be too much to occupy, it can be utilized by Cucumbers planted in the row between the Raspberry-plants about the time the fruit is ripe; and the winter-supply for pickles can thus be easily grown, for

the shade of the canes will not interfere with the Cucumbers.

I have said nothing about the Black Cap Raspberries. Those who like fine fruit do not care for them, and, from sad experience, I know that, owing to their abundant seeds, Black Caps are dangerous if eaten too freely by children. B. R.

Albemarle Co., Va.

Manure is the leading topic of inquiry among all classes of farmers and gardeners. The values of certain substances, in fact of almost every substance, are still mooted points. We are only beginning to learn in this direction. But something is accomplished when we know what we are talking about. "Manure is plant-food" is a poor definition; "manure is a promoter of plant-growth" is better. One definition contemplates the use only of the elements of plant-growth, employing potash merely as so much potash, and nitrogen as so much nitrogen; the other admits of the mechanical improvement of soil and food for the plant at the same time. Our knowledge of the use and treatment of stable manure is yet imperfect. But we no longer hold to the notion that manure applied in the fall leaches away and is lost, or that its essential elements vaporize. On the contrary, we know that the best results come from application in the fall, and the more vegetable matter the soil contains the more complete will be the retention of the soluble ingredients. In barn-yards the soluble materials may pass into the underlying soils or be carried down gutters, but in compost piles which are four or five feet high, or even less, it is doubtful if the rain-fall of any season is sufficient to wash away the elements of fertility. But we do not recommend composting manure; there is no necessity for such an operation. But the refuse of the garden, the vines of Squashes, Potatoes, Tomatoes, the trimmings of Cabbage, Celery, and vegetable refuse, become valuable when composted. Of commercial substances, no doubt wood-ashes, finely-ground bone and nitrate of soda are the best for the gardener. But ashes are often of doubtful history, and should be purchased cautiously.

Weeds.—I never saw a good gardener who knew or cared much about weeds. In fact, ignorance of weeds is commonly a proof of good gardening. It matters not whether certain weeds are ten per cent. bad or ninety per cent. bad; they all succumb to good culture; all perish by the same process. When we all come to realize that we till for the good of the crop and not for the sole purpose of killing weeds, we shall have no occasion to study the tares, for they will never find the chance of growing. But some people cultivate only when the weeds force them to do so, and here the credit accrues to the weeds. Weeds are oftener a blessing than a curse. Even Virgil knew this.

L. H. Bailey.

Cornell University.

Spiræas.—One of the finest herbaceous Spiræas is *S. Aruncus*, or Goat's Beard. It is indigenous to the Alleghany and Catskill Mountains, and is cultivated considerably in European gardens, where it is used in groups on lawns with fine effect. It is a plant of noble habit, and in rich soil, with plenty of water, its panicles of cream-white flowers develop into magnificent proportions. *S. astilboides* is a recent addition to the list of garden-plants, as it is also one of the best. It resembles *S. Aruncus* in many respects, but the latter, under liberal treatment, often grows five feet high, while *S. astilboides* does not exceed two feet. The flowers are similar in color, and have the same massive appearance, and for forcing it is far superior to *Astilbe Japonica*. *S. palmata* is perhaps the brightest-colored species of all. Its large corymbose panicles of brilliant crimson flowers make it one of the most striking and effective species in cultivation. We have never been so successful with this plant as during the past season, when it was planted in low, marshy soil with *Iris Kämpferi*, where it thrives luxuriantly. *S. lobata*, or Queen of the Prairies, is a native species, and well worthy of cultivation. There are, apparently, two forms of this plant—one having much darker-colored flowers than the other. The better of them rivals *S. palmata*, with its bright rose-colored flowers, and has also a delightful fragrance. *S. filipendula* is a distinct plant, with large loose cymes of white flowers on stems two feet high, with the leaves flat on the soil. There is also a double form of this species much dwarfer in habit and with very beautiful double flowers. We have also a tall-growing Spiræa from Japan, the name of which we have never been able to ascertain. It grows six feet high, with large whitish flowers, the whole plant resembling a gigantic *S. ulmaria*. This plant makes an excellent plant for the back row of the flower-border. All of the above are desirable garden-plants, and are at their best just now, adding considerably to the attractions of the garden.

Passaic, N. J.

A Meadow on Mount Rainier.—See page 314.

Notes from the Arnold Arboretum.

Lonicera Iberica, or the species which is known by that name in gardens, is the latest of the bush Honeysuckles in the collection to flower. It is a stout shrub, with upright branches covered with light gray bark, which separates readily into thin scales. The leaves are small, barely more than an inch long, short-petioled, ovate-cordate, or sub-rotund, contracted at the apex into a short point. They are dark, dull green, with a few scattered hairs on the upper, and pale on the lower, surface, which is densely covered, as are the shoots of the year, with a short pubescence. The flowers are bright yellow, an inch long, the corolla covered on the exterior with scattered hairs. The fruit is scarlet and conspicuous. This is a perfectly hardy plant, which, owing to the lateness of its time of blooming principally, has considerable value for the

decoration of the garden. It is a native of the Trans-Caucasian country.

A number of the so-called Chinese Honey-suckles are now in flower. They all belong to one species, however, and are all—that is, all the plants found in our gardens—Japanese, and not Chinese. These plants have long been cultivated and are familiar in some form or other to all persons who have ever had anything to do with a garden. The true name of this plant is *Lonicera Japonica*, and it was discovered a century ago by Thunberg at the time of his journey in Japan. The most familiar form of this plant, or rather the form which was until the last few years most frequently met with in gardens, is a slender climbing plant, with pubescent, reddish stems, dark green leaves, with rather conspicuous red veins, and long tubular, slender corollas, pale red on the outside, yellow on the interior, and always fading yellow. This is the *Lonicera flexicaulis* of many old gardens. There is an excellent colored figure of this form in the "Dendrologia Britanica," t. 117, under the name of *Lonicera Chinensis*. Another form of this plant differs from the first in the color of the flowers only, which are white, fading to yellow, and in the absence of the red tinge on the stems and the veins of the leaves. This is sometimes known as *Lonicera brachypoda*. The showy yellow-leaved Honeysuckle which has appeared so generally of late years in gardens and which is known as *Lonicera brachypoda*, var. *reticulata* and as *L. brachypoda*, var. *foliis aureo-reticulatis*, is a variety, merely, of this same species. Another form which has been quite generally distributed of late in American gardens as *Lonicera Hallii*, so named because it was first sent to this country from Japan by Dr. Hall, is perhaps the most beautiful of them all. It flowers about ten days later than the other varieties; the leaves are broader, rather paler, and more densely covered with pubescence. It is a strong-growing plant, and will cover a large space in a single year with its flexible, twining stems. These various plants look quite different as they are seen growing side by side, but they all have characters which unite them. The flowers are in pairs at the end of a long (or sometimes quite short) common peduncle, upon which just below the flowers are two large leafy bracts, which are almost identical in shape with the true leaves, although they are much smaller, and generally not more than half an inch long. The corollas have slender hairs of the same character upon their exterior surface. The fruit is black and the same in all; the flowers all fade yellow, and all possess the same delicious fragrance, which is most powerful in the evening; and upon all these forms, although rather more commonly upon the golden-leaved variety, a few leaves grow near the base of the stem, with the margins deeply cut and lobed like those of a White Oak. *Lonicera Japonica* has escaped from gardens to the woods in some parts of the southern

States, and has become well established, and practically naturalized. It is very largely planted in the middle States, where it is certainly one of the very best vines for covering buildings or rocky banks, or any rough waste spots over which it is desirable to spread a thick mantle of brilliant foliage and fragrant flowers. Here in New England this plant is not quite hardy, and is often killed back during severe winters, but as it flowers on the branches of the year, this killing back only serves to develop the growth of stronger shoots, and to retard, a little, the flowering time. Here the leaves fall in January generally, after having remained perfectly fresh and green during the autumn and early winter; further south the plant is evergreen, the old leaves remaining upon the branches until the appearance of the new crop in the spring. The branches keep on growing until stopped by frost, and, as flowers are produced upon these new growths, the plants are generally in

bloom all summer long. *Lonicera Japonica* is a widely-distributed plant in Japan, Formosa and in China, from Peking to Shanghai, and far into the interior. Its tenderness in this climate seems to point to a somewhat southern origin for the plants now in cultivation; and it would be an interesting and probably a valuable experiment to test plants of this same species raised from seed gathered at Peking or at some other northern station, where the climate resembles that of our extreme northern states.

Lonicera Etrusca is in flower. It is a very pretty, slender, graceful plant, with twining stems, ovate-obtuse leaves, which are pubescent on the under surface, the lower on short petioles, the upper pairs joined together. The flowers are delicately fragrant with long, slender corollas, purple without and yellow within. They are arranged in verticillate many-flowered heads, of which there are generally two or three at the end of each branch. It is a native of southern Europe, and although a very pretty plant, less desirable, perhaps, for general cultivation than the more robust and showier *L. Periclymenum*, the Woodbine of English gardens.

Viburnum molle is now in flower. It is a southern plant, only just reaching New England on the islands of Nantucket and Naushon. It is a stout shrub very like our common *V. dentatum* in habit and general appearance. The young shoots, petioles and cymes are, however, covered with stellate pubescence, and the leaves are rather more crenately-toothed and rather longer than those of *V. dentatum*. Like all our native *Viburnums*, with the exception of *V. lantanoides*, it takes kindly to cultivation, and like them all, it is a desirable garden-plant. It is only because these beautiful plants are "natives," a word which, when applied to a plant, has come to mean with some people common or homely, or because they are not known at all to persons who plant gardens, that they are not esteemed at their true value.

The Dwarf Huckleberry (*Gaylussacia dumosa*) is an ornamental plant, which, like many of its relatives, may wisely be transferred to the garden, where it should just now be covered with its pure waxy-white flowers. It is found growing naturally in low situations, generally in sandy soil, and never very far from the Atlantic sea-board. Generally a low plant, it may be seen sometimes four or five feet high. The leaves are green on both surfaces, thick and rather shining when fully grown, tipped with a point, and covered with the resinous dots peculiar to our deciduous-leaved Huckleberries. The nodding bell-shaped flowers are large—a third of an inch long—pure white and very abundant; and these are followed by large, showy black fruit, which has little but its beauty to recommend it, as the flavor is insipid and very inferior to that of the common Black Huckleberry (*G. resinosa*). The Dangleberry (*G. frondosa*) is a handsome garden-plant also. It is taller than the other Huckleberries, being found sometimes five or six feet high, with slender spreading branches. The berries, which are oblong and blunt at the apex, are pale and glaucous on the lower surface. The handsome white globular, bell-shaped flowers hang in loose slender racemes, on rather long drooping pedicels. The fruit is large and showy, dark blue, covered with a white bloom, and sweet and edible. This is the most ornamental of our Huckleberries as a garden-plant; and like the others not difficult to establish in the garden, if a little care is taken in lifting the plants in the woods.

Euonymus radicans, as the climbing Japanese evergreen *Euonymus* is generally called, is gradually, as its value becomes better known, working its way into popular favor. It is really a valuable plant in this climate, where the Ivy is not hardy, and where no other climbing plant with evergreen foliage can be grown in the open air. *Euonymus radicans* grows very slowly when it is first planted, but being once well-established it grows, never rampantly, but with some rapidity, and will climb, with the aid of its stem-roots, to a height of twenty or thirty feet. It will cling to masonry, but it seems to prefer to grow over the stumps or trunks of trees (as it does naturally in the forests of Japan), and an old stump covered with its dark green, lustrous foliage is certainly a beautiful object. The leaves are small, but as the plants grow older they increase in size, especially on the young shoots, and are then sometimes two inches or more long. There are varieties of this plant in cultivation with white-marked and yellow-marked and blotched leaves, but none of these are as handsome or as vigorous as the green-leaved form. *Euonymus radicans* is believed by botanists to be a form of the evergreen *E. Japonicus*, and it is said by M. Maximowicz, who has studied these plants, that he has never seen flowers of this variety. This year they have appeared in this neighborhood in several different gardens, and a figure of them has been prepared for GARDEN AND FOREST.

June 18th.

J.

The Forest.

Forest Interests in Pennsylvania.—III.

AT present very few, even of the friends of forestry or of the people in this country who are more or less active in efforts for forest-conservation, adequately understand the necessity of this preliminary work of the diffusion of knowledge and propagation of just ideas relating to forestry subjects. We need to work on long lines for objects which lie far ahead, but we have not the intellectual quality or temper which would enable us to do this. I am aware that it is a question among students of history and civilization, whether such an advance in national character and action as I have here referred to is ever consciously brought about, by men who plan and intend such a result, and organize and direct the action which is necessary to secure it. Some think that all advances in civilization come without having been thought about or intelligently aimed at by anybody, but I incline to the opposite opinion, to the view that most of man's steps forward have been taken because somebody foresaw the need for them, and felt an impulse to work to prepare for them and to urge others to do the same. I think that with ten years of work for that object, and the expenditure of one or two hundred thousand dollars, we might bring about such a condition and education of the public mind in this country as would render possible effective work for the perpetuation and successful management of our forests.

But we are probably not yet civilized enough for this in our country. Even the best races of men usually learn very slowly the things which are necessary for national success and prosperity, and nations acquire wisdom by the severe discipline of suffering and loss. Very likely we may not learn in any other way the importance of our forest interests in our national housekeeping.

Yet there is more of encouragement to hope for the beginning of real growth here in Pennsylvania than anywhere else in our country. The public men of the state are becoming much interested in forestry subjects; the State Forestry Association is doing a useful work, and its organ, *Forest Leaves*, attracts the attention of many persons who had not before thought of this topic. But the most favorable condition which I have anywhere observed is the superior character of a large proportion of the people of the mountain regions of the state. In some districts most of them are of German origin, and one constantly hears the dialect known as "Pennsylvania Dutch." These people constitute one of the most valuable and promising elements of the state's population. I have been much impressed by the frequent evidences of poetic feeling and a real sense of natural beauty among them, such as I have not found among the natives of mountain regions in any other part of the country. They have the old-fashioned virtues of industry, veracity, hospitality and silent verity. I know of no other class of laboring people who work so many hours of the twenty-four as they. Many of their children and young people have fine natures, and they are certain to be numerously represented hereafter among the foremost men of the state and of the nation. They know a great deal about the woods, and think about them, too. A writer in GARDEN AND FOREST last year made a most sensible suggestion regarding these people which I am glad to quote in this report. "Some plan for taking care of these woods ought to form part of the education of the people of this part of the country. They are hard-working, sensible men and women, with a great deal of character; most of them poor. How can they be reached and taught what they need to know and think of and practice in regard to the forest interests of their region, and the best ways of managing their own woodlands?" Some kind of educational work regarding forests and tree-culture should be constantly maintained among them, and among all classes of the people of the state.

This state should have a Commissioner of Forests and Rivers, who should be not only a well-trained engineer, but a man of superior mind, with what military men call "an eye for country," who could hold the entire river-basin and watershed system of the state in his brain. He should have supervision of the location of buildings along the streams of the state, and of the construction of dams and reservoirs. The complex conditions of our modern life require more comprehensive co-operation and direction in matters pertaining to the general welfare of our densely-populated communities than we have hitherto practiced. The individualism which insists upon the right of every man to build his house where he chooses, and which permits corporations to construct dams and reservoirs without restriction or supervision, is barbaric,

and is not adapted to an advanced state of civilization. In connection with other lessons of the recent awful tragedy in this state, it should be kept in mind that the plan of destroying the forests which constitute the natural reservoirs for the water of the mountain regions of California and Colorado, and of constructing enormous artificial reservoirs for the storage of this water for irrigating purposes, is being pushed forward with much energy. If it is carried out, catastrophes resembling the one at Johnstown will be inevitable. The advocates of the plan admit that calamities resulting from the breaking of reservoirs and dams will occur, and compare the liability to such disasters to the liability to accident which now attends the running of rail-road trains. There is no reason to suppose that engineering ability will ever enable us to dispense with the natural function of mountain forests in storing water and regulating its flow.

Recent Publications.

The Industries of Japan; Together with an Account of its Agriculture, Forestry, Arts and Commerce. By J. J. Rein, Professor of Geography in the University of Bonn. Illustrated. New York: A. C. Armstrong & Co., 1889. (Translated from the German.)

Five years ago Professor Rein published a large volume which, in its English translation, bore the title, "Japan, Travels and Researches," and was universally accepted as the most thorough and scientific treatise of its class. In the present book he extends and completes the account of his researches which, it may be explained, were prosecuted at the cost of the Prussian Government. He is conscious, he modestly says in the preface, that all he can offer is "only patchwork," notwithstanding many years of care and labor; that all subjects are not treated with equal fulness, and that the pictorial arts of Japan, in especial, are but meagerly treated. Nevertheless, the book is a marvel of painstaking thoroughness in almost all its parts, and is more systematically arranged and clearly written than is customary in a work from a German hand. Here and there one finds an ambiguous or awkward expression, but it seems due not to the author himself but to a hasty translator or careless proof-reader.

About half of the large octavo volume is devoted to agriculture and forestry and the industries dependent upon them, the other half being absorbed by artistic industries, trade and commerce. The general condition of Japanese agriculture is passed in review, its food-plants are separately considered and then what are called its "plants of commerce;" cattle-raising and silk-growing are described; the forests of the country are passed in review, and the nature and uses of the various kinds of Japanese woods explained; and then follows a chapter on gardening and another on the acclimatization and extension of Japanese ornamental and useful plants in Europe. There is scarcely a page in any of these chapters from which we might not quote with profit to our readers; but, of course, their chief value lies in that systematic completeness to which no citation of special parts can do justice. Unlike most writers who speak of industrial and commercial facts, Professor Rein has a scientific knowledge of botany, and everything he reports is thus of great interest to the student of plants as well as to the student of economic conditions. In speaking of any plant of commercial value he is careful to note its place in the botanical systems, its relation to allied plants in other lands and its aspect to the eye; and then he follows it through the industries in which it is of service, explaining processes of manufacture and final results with equal care. Seven closely-printed pages are given, for example, to the Camphor-tree (*Cinnamomum camphora*), and from them we learn the geographical distribution of the tree, its nature and habits as seen at home and as affected by the climate of different European regions where it has been introduced, the size and aspect of conspicuous individuals in Japan, the processes by which gum-campor is produced (with a picture of the apparatus used), the uses to which it is put by the Japanese, and the commercial results of the industry. The Tea-plant and the industries dependent upon it are treated in a most thorough and illuminative way; and fruits, vegetables and condiments, leguminous plants, dye-plants, oil-producing plants, drugs, and many other groups are as carefully described.

In the forestry chapters Professor Rein refers back to his earlier volume with regard to certain general facts. Yet those he gives are sufficient to explain with great clearness the nature and aspect of Japanese forests, facts of geographical distribution, and the difference between the wild and the cultivated woodlands of the country. The chief building-woods, he says, are furnished by *Cryptomeria Japonica*, *Abies firma*,

Pinus densiflora and *Pinus Thunbergii*. It is highly probable, he thinks, that all the forests which furnish these woods, "and also those of *Chamæcyparis* and *Thuyopsis* have been planted since experience has shown that their self-propagation, like that of most conifers, is difficult, and wherever a Pine-forest disappears its place is usually filled by Blackberry-bushes, Wild Roses and other almost worthless deciduous plants." These trees, other useful sorts, like *Castanea vulgaris*, several deciduous Oaks, the evergreen *Quercus cuspidata* and some others less widely known, for example, the so-called "Screen-Fir," (*Sciadopitys verticillata*) "are raised from the seed in nurseries, as with us, and the seedlings transplanted after two years' growth. The cultivation of the plants during these two years, as well as the laying out of the plantation, is very carefully managed and based on all the teachings of past experience. There is also no lack of printed instructions with all necessary illustrations. The ground chosen for such a plantation is prepared as thoroughly as for a fruit-tree nursery or a tea-garden, and is well enclosed with a light, Bamboo-hedge from three to six feet high, which does not cut off light and air. In snowy districts a further protection is provided in winter in the shape of a straw roof, . . . and in case it becomes necessary to shelter the young plants from the cold, . . . straw fastened to a Bamboo-framework is spread over them. The greatest care is also observed in taking up the young seedlings, cutting back their perpendicular roots, making ready the plant-holes with the hoe, and planting again in the ground laid out for the new forest. I did not find, however, that our system of planting in rows was very much adhered to; much more regard was had to the nature of the ground, and to the peculiar taste which has a dislike for systematic regularity on a wide scale except where it is necessary, as in agriculture. The cultivated forests of Japan are seldom very large. Poor, gravelly soil, fixed dunes and other sandy districts are, as a rule, devoted to the above-mentioned Pine-trees. . . . The other species of cultivated conifers need a deeper and better soil, which is to be found only in the plains. They are sometimes found, however (as the *Chamæcyparis* and *Thuyopsis*), on the lower gentle slopes of mountains. In case the soil here is too stony and unfruitful, the Chestnut is planted, while the Oak is better adapted to the saddles and hollows. It is seldom, however, that forest cultivation of any kind goes higher than 3,000 feet." Many interesting facts are given with regard to the cultivation of different kinds of trees in different districts, and the economical or religious reasons which cause a demand for special kinds of wood. "The Bamboo-groves may also be ranked as cultivated forests. They serve the most manifold purposes, making an agreeable diversion in the landscape, and are especially frequent on the boundaries of the larger cities, where great use is made of the cane. . . . As is more carefully noted in Volume I., the deciduous forest of Japan, in contrast to the dark Pine-forests and to our own woods with their few species, is made up of a great mixture of large numbers of trees and bushes in all stages of growth. It is exceptional, and generally due to special cultivation, when we find Chestnuts and the varieties of Oak forming separate plantations. Creepers and climbing plants, parasitic and rooted Ferns are seen in greater variety and of larger growth than with us. . . . The most common constituents of these forests are Oaks, Beeches, Hornbeams, Maples, Birches, Horse-chestnuts, Magnolias, Aralias, Walnuts, Elms, Planes, various *Rosaceæ* and, in moister places, Ashes and Alders." The Japanese deciduous forest, Professor Rein explains, is, however, "not at all a primeval forest. It may here and there even be a plantation on what was once a field, but it has the stamp of a thoroughly natural growth, and is left to itself and renews itself. The woodman visits it with his axe, it is true, but only for the sake of the most valuable and scattered timber, such as *Magnolia hypoleuca*, *Stuartia monadelphæ*, *Actinidia volubilis* and some others, and this does not in any way affect the settled character of the forest. This is accomplished by means of thorough destruction by forest fires." When these occur the place of the trees is taken by a "brushwood in which the Fire Weed (*Epilobium angustifolium*) springs up here and there, as in our burnt forest-grounds, and stiff Bamboo-grass (*Phyllostachys bambusoides*), and in high, damp places also the *Polygonum cuspidatum* more than eight feet high. The forest generally takes on its original character by degrees and after a long time." Of course these brief citations give but a glimpse at the interest which the forestry chapters of Professor Rein offer to the general reader. The multitudinous facts of scientific import must be sought by the student in his own pages.

In the chapters devoted to gardening we find brief descrip-

tions of the different sorts of Japanese pleasure-grounds and lists of the plants most commonly used to adorn them. No page is without its interest and significance, but Professor Rein speaks with less enthusiasm than most travelers of the effects beloved by Japanese gardeners. He does not seem to accept their point of view and recognize that it is thoroughly artistic although quite unlike the European point of view. He sees little but a painful artificiality in Japanese attempts to make pictures of wide landscapes on a miniature scale—he sees only the process and not the illusive effect upon which a Japanese eye would dwell. With regard to the methods employed for dwarfing plants and the extraordinary results achieved he gives some interesting facts. "To produce a slow growth they choose particularly small seeds from a poorly developed individual plant. Frequent cutting back has been found even more effective, also planting in pots of insufficient size. Twisting the twigs and stems in a horizontal spiral direction has the same effect, and the refrigeration of the ground and roots by evaporation, using porous pots. Grafting is often also a means to this end, *i. e.*, it serves to check natural development. It is employed especially in the many varieties of *Acer polymorphum*, and is usually effected according to the oldest methods known to gardening—grafting by approach, as it is called. Some of the results obtained in Chinese and Japanese gardening in dwarfing species are very surprising. Kämpfer relates that he once saw growing together in a small box, four inches long, one and one-half inches broad and six inches high, a Bamboo-cane, a Pine-tree and a blooming Plum-tree. The price of this group of dwarfs was nearly £100—an evidence of the difficulty and tediousness of the accomplishment, and also a token of the high estimation of such abnormal forms. Whoever visits a Japanese art and trade-garden in spring will notice in company with these dwarf forms yet another kind of popular plant-maiming which is usually practiced on the Mume Plum. Young and blooming shoots from stumps, four to twelve inches in height, are wound about these or bent over them umbrella-fashion. Often the trunk is cut down even to the ground so that the small blooming offshoot looks like an independent tree." The great number of plants with variegated leaves, produced in Japan, is likewise noted by the author, with wise advice as to the danger run by European gardeners in introducing them profusely into their plantations. He speaks also of the fact that the Japanese do not like to separate flowers from their stems and gather them in bunches, admiring far more their individual beauty under natural conditions—"lovely blossoms and leaves on their stem or slender twigs, the Iris and the Lotus-flowers on its long stem." But he adds that "one would scarcely suppose that under such circumstances there could be such a thing as 'the art of arranging flowers' in set pieces;" thinks that the art which goes by this name depends too much upon the forms of vases and other receptacles, and seems to deplore the fact that "the arrangement and coloring of bouquets is not understood by the Japanese." This very fact is usually cited with admiration by visitors to Japan, and once again Professor Rein shows a lack of sympathetic artistic instinct. But this lack should not, of course, be weighed in the balance against the numerous gifts and merits which his volume, as a whole, reveals, and we can heartily recommend it to all who desire a knowledge either of the natural products of Japan or of the industries dependent upon them. Its greatest value springs from the fact that these two subjects, so often disassociated in print, are considered together, and, are systematically, clearly and fully set forth in their mutual relationships.

Periodical Literature.

It is pleasant to find that our architectural journals are turning their attention to the allied art of landscape-gardening. The connection between the two arts is so close as to be of vital importance to the welfare of both; and we hope that many architects will inwardly digest the excellent articles on "Landscape-gardening and its Relations to Rural Architecture," by the late J. A. McKenzie, and recently published in *Building*. The first chapter is devoted to the general principles which underlie the subject. To quote from it at length would merely be to repeat what has already often been said in these columns; yet it can hardly be too often repeated that while we have comparatively few good landscape-gardeners in this country, we have some of the very best; that an intelligent demand for more will surely create a supply; that no body of men can "promote this demand with greater influence than architects," and that "they are really interested in its promotion as much, if not more, than any others." The writer

does not over-state the case when he says that to start to lay out a place without some comprehensive preliminary scheme is as great a piece of folly as it would be to essay to "erect a mansion piecemeal, room by room or wing by wing, ignoring the general appearance of the whole structure when completed; each individual section as it is constructed may be perfect, but the *tout ensemble*, unless by some happy and remote accident, will, to a certainty, be a failure, lacking coherence and harmony." A significant paragraph is likewise the following: "One reason for the hesitation of owners to seek the assistance of experts when about to lay out their properties may be traced to the damage done by the innumerable so-called landscape-gardeners, who generally combine with their professional (?) work the more appropriate and modest calling of 'jobbing gardener.' If these are the specimens from whom any one deducts his opinion of landscape-gardening, no wonder he is disgusted and prefers to do the work himself or allow his gardener to do as he pleases. For these men never think it worth while to prepare a design, and the result is that where they do not entirely obliterate what natural beauty the place possessed before their ruthless spades started to work, they wholly fail to grasp the opportunities for enhancing those beauties and natural effects which have really stared them in the face. And their work usually runs into enormous expenditure in proportion to what is done; for, owing to their gross ignorance, useless work is often executed, and work done has as often to be torn down and executed afresh." Truly, it is not such men as these whom we have had in mind in claiming, so often, a wider and franker recognition of the claims of the landscape-gardener to be the architect's-helper on equal terms. It is the thoroughly trained and experienced artist who should be chosen; and any proprietor who really desires to find him can do so without a great deal of trouble. As the lamented writer says, the fact that make-believe artists have any standing in the community is simply because their employers are not "as appreciative of the difficulties of landscape-gardening as they are of those of architecture." His second chapter is devoted to a systematic consideration of the various tasks which the landscape-gardener must execute, such as choosing the location of buildings, grading, forming carriage approaches, roads and walks, managing lakes and waterscenery, planting, and treating small properties and suburban lots; and with regard to all points wise advice of a general sort is given. "As to the future of landscape-gardening in this country," the author remarks towards the end of his valuable sermon, "there can be no doubt; there are already substantial signs that a taste for it has taken hold of a considerable class of country residents. What is wanted is to extend that taste and develop it and interest all property-owners in its cultivation." And we may conclude with another brief quotation, which concisely expresses the gist of the whole matter: "The question is often asked, What is really the proper work of the landscape-gardener? The answer is, Everything that is done to a property which will in any way alter its appearance comes naturally and properly within his scope."

Correspondence.

Unappreciated Trees.

To the Editor of GARDEN AND FOREST:

Sir.—He who plants a tree, of any kind, is almost always so certainly a public benefactor, that it appears ungracious to find any fault with him; nevertheless, I feel like quarreling with park-superintendents and landscape-designers, as well as with the less pretentious planters, for their indifference towards certain of our most beautiful indigenous trees.

The Beech, *Fagus sylvatica*, unites the sturdiness of the Oak, the shapeliness of the Maple and the dignity of the Elm. It is the cleanest limbed of all trees, its smooth ash-colored bark being almost unbroken from base to summit. No tree has a denser or a richer foliage than the Beech, and its buds are nearly as beautiful as its perfect leaf; long, tapering and pointed, with a ruddy tinge, perceptible even in midwinter. Standing a little distance off and in the right light, the body of the tree upon a winter's day appears suffused with a faint blush, which, upon the approach of spring, becomes a full coral tint, such as fringes the afterglow of a November sunset. The Beech is a tree of remarkable symmetry, preserving the same proportion in trunk, limb and leaf. It is persistent to one type, always and everywhere a thoroughbred.

The Yellow Birch, *Betula lutea*, has the fineness of limb and of foliage which distinguishes all the Birches, but its chief attraction is the thin, film-like pellicle or scurf-skin forming the outermost part of its bark. This fine covering peels partially off from the trunk and larger branches, remaining

attached thereto in dainty waves and ringlets, flaxen-colored, with a kind of satin finish. Those parts of the surface from which the pellicle does not loosen often take on a metallic lustre, of a shade between that of nickel and of brass. This apparel of the Yellow Birch varies with different specimens, appearing to be most perfect upon those well exposed to the sun during the period of their early prime.

Both these superb trees are unique, and beyond comparison with all other trees in the beauty of their bark. They are as attractive without their foliage as with it, since its loss makes their special feature more prominent. If it were in my power I should, instead of building for my fellow citizens a cathedral or a university, buy and lay out for them a park which should be set wholly with the Beech and the Yellow Birch. Whoever shall bring those two ornaments of our woods into the same favor for shade-trees as the Elm and Maple, will do more toward nourishing among us the spirit of beauty than if he were to import and donate to his countrymen the gallery of the Louvre.

Thus much for my deciduous favorites. But no less do I complain of the scant regard paid to the most graceful of evergreens—our native Hemlock, *Tsuga Canadensis*. This noble conifer has not the majestic port and solemn beauty of the White Pine, but it surpasses that monarch in general comeliness, and has in its order no other peer. The delicacy and richness of its foliage, bright green upon the upper and glaucous upon the under surface, is excelled only by the Club Mosses. The Hemlock is lithe and elastic, and its limbs are wind-proof, and it is the least disposed to rust or to the attack of insect pests of any of the conifers. Besides these qualities, the Hemlock has a special facility of adaptation. It can be a stately tree, a wide-spreading shrub, or a most effective hedge-plant, as you choose to make it. Yet, in place of this matchless evergreen, we have imported the coarse Norway Spruce, and the still coarser Scotch and Austrian Pines, as our grandfathers imported the miserable and short-lived Lombardy Poplar, than which they could have found nothing more unsightly among our entire native flora.

Poughkeepsie, N. Y.

Alfred H. Peters.

Insensibility to Certain Odors.

To the Editor of GARDEN AND FOREST:

Sir.—It is well-known that certain persons are color-blind, that others are "note-deaf," or unable to appreciate the difference between musical and unmusical sounds, and that some are entirely deficient in the senses of taste and smell. But I think it is not so generally realized that many persons whose sense of smell on the whole seems as keen as that of the average man, are powerless to perceive certain special perfumes. Delicate odors, like that of the Pansy, are naturally those with regard to which this deficiency is most often found. But some years ago I discovered that a friend, sitting near an avenue of European Lindens, the perfume of which was almost overpowering, could not perceive it at all, though as regarded other scents his sense was normal. Afterwards I found the same insensibility to the perfume of Linden-blossoms in other individuals. My sister declares that she can perceive in the great flowers of the green-house *Datura* no odor whatever except a certain earth-like smell proper to growing things in general, and I myself cannot realize that *Olea fragrans* deserves its name even to the faintest degree. Yet we are both susceptible to even the faintest perfumes of other flowers. I have no trouble with Orange-blossoms, so similar in scent, I am told, to those of *Olea fragrans*, and as to the *Datura*, the odor is so strong to me that I know a blossom is in the house the moment I enter the front-door, and can hardly sit in the room with one. This total deficiency of sensibility in certain directions is a different thing from that dislike to certain odors, agreeable to most people, which is more often recognized. I should like to know whether any of your readers can cite other instances, and whether there is any scientific explanation of facts which seem so odd.

New York City.

Temperature and Germination.

To the Editor of GARDEN AND FOREST:

Sir.—Referring to Mr. Allen's observations on the slow germination of corn in cool temperature, allow me to recall some very careful trials to determine the lowest germinative temperature for Indian Corn, the results of which have been published in full in the Report of the New York Agricultural Experiment Station for 1884 and 1885, and a partial summary in the "Proceedings of the American Association for the Advancement of Science," Vol. XXXIV. As the figures are inter-

esting, I may again put them on record in GARDEN AND FOREST.

When the apparatus was maintained within the extremes of 37° and 42° F., a sample of Dent Corn germinated in 430 hours, and one of Flint Corn in 460 hours.

Within the variation of 41°–43.7° F., samples of various varieties of Dent Corn germinated in 233, 233, 401, 401, 479 and 521 hours respectively; of Flint Corn, 331, 331, 498 and 498 hours respectively; of Pop-corn, 378, 378 and 498 hours respectively; of Sweet Corn, 452, 498, 479, 498, 616, 616 and 521 hours respectively.

South Framingham, Mass.

E. Lewis Sturtevant.

Another New Palm.

To the Editor of GARDEN AND FOREST:

Sir.—While visiting a few of the south keys of this state, Mr. R. D. Hoyt, of Bay View, noticed large specimens of what appeared, at first sight, to be *Thrinax argentea*, but on closer inspection were found to be totally unlike this common Palm. Leaves and seeds were sent to botanists of this state for identification, but in their lack of suitable botanical works could not determine it. We recently found the description of *Thrinax excelsa*, Grisebach, to correctly apply to these specimens, many of which, eighteen feet in height, grace the tropical jungles of a few of the keys east of Key West. Thus another beautiful addition is made to the Palms of the United States.

Manatee, Fla., June 24th.

E. N. Reasoner.

Recent Plant Portraits.

SKIMMIA FOREMANI, *Gardeners' Chronicle*, May 4th; a form, according to the raiser for whom it is named, derived from *S. oblata* of gardens, fertilized with the pollen of *S. fragrans*, and thus not a hybrid, but merely a form of *S. japonica*; but in Dr. Masters' opinion this statement of the origin of this plant is open to some doubt; and it is possible that *S. Fortunei* had some part in its parentage.

ANOIGANTHUS BREVIFLORUS, *Gardeners' Chronicle*, May 4th; a Cape bulb formerly referred to *Cystanthus*, but now considered by Mr. Baker the type of a distinct genus. The flowers are yellow, with a short tube and spreading perianth-segments. It is recommended as a cool green-house spring-flowering plant.

CHRYSANTHEMUM MAXIMUM, *Gardeners' Chronicle*, May 11th; a hardy perennial plant, native of the Pyrenees and of Switzerland, which, if "cultivated properly," says the Rev. C. Wolly Dod, by whom this plant has been distributed, "that is, by being pulled to pieces and re-planted within a fortnight of Michaelmas every year in rich soil—it is quite a 'sensational plant.' The flowers sometimes measure four inches across."

CHRYSANTHEMUM LACUSTRE, *Gardeners' Chronicle*, May 11th; a native of Portugal.

Botanical Magazine, June.

SOBRALIA LEUCOXANTHA, *t.* 7,058; one of the largest-flowered of this beautiful genus, closely related to *S. macrantha*, from which it differs by the smaller limb of the lip and the pure white color of all parts of the flower, except the disk of the lip, which is orange. It is a native of Costa Rica, whence it was introduced into cultivation by the Messrs. Sanders, of St. Albans.

ENKIANTHUS CAMPANULATUS, *t.* 7,059; a native of northern Japan, and described as a small deciduous-leaved tree, with small, dull-red, pendulous, ball-shaped flowers. The genus *Enkianthus*, of which six or seven species, distributed from the eastern Himalaya to northern Japan, are known, is very closely related to *Andromeda*, the only technical difference being found in the seed-coats. *E. campanulatus* has been introduced into England, where it is perfectly hardy, by the Messrs. Veitch. It may be expected to flourish in all our northern States.

SPATHOGLOTTIS INOIDES, *t.* 7,060; a graceful terrestrial Orchid, a native of Nepal and Sikkim, of gregarious habit and with large, nodding, bright golden-colored flowers. It is easily cultivated in pans of sphagnum and peat, and blooms at midsummer.

ANGRÆCUM GERMINVANUM, *t.* 7,061; this very handsome species was discovered in 1886 by Lion Humbot, a collector of the Messrs. Sanders, in the interior of Madagascar. The plant from which this figure was made flowered at Kew in the spring of 1887, and again last spring, and is apparently the only specimen of the importation of twenty plants which survived. The stems of this beautiful and very interesting species are twelve to eighteen inches long, with alternate distichous, spreading, very thick and bright green leaves one and a half to two inches long, sessile, sub-cordate or half-clasping at the base.

The flowers are pure white and solitary, on short, slender axillary peduncles. The sepals and petals are two to three inches long, narrow and pendulous, and the lip is broad, quadrate, with rounded angles, and an inch across, the anterior margin suddenly contracted in the middle into a subulate filiform, recurved tail an inch long. This is one of the handsomest of recent Orchid introductions.

SOLANUM PENSILE, t. 7,062, a native of Guiana and of Brazil, and, although long known to botanists, a recent introduction into gardens, having been sent to Europe first in 1887. It is a tall, slender, unarmed, climbing plant with purple flowers very much like those of *S. Dulcamara*, except that they are produced in loose, spreading, terminal panicles. It requires the temperature of the tropical stove-house.

Notes.

The *California Florist and Gardener* has been merged into the *Pacific Rural Press*.

Mr. John Taylor, the well-known Rose-grower of Bayside, Long Island, cut 60,000 buds of the Madame Cusin Rose from 200 running feet of glass between July 1st, 1888, and February 1st, 1889.

A competent observer writes of the land which has been acquired by the City of Wilmington, Delaware, for a park, that it is "a most refreshing place." It is in the main a piece of rocky woodland, through which the Brandywine flows.

Eighteen thousand Japanese Orange-trees have been planted in one orchard in the southern part of Monterey County, California, and native gardeners have been imported to care for them. They are now in their second year, and the experiment promises to be successful.

The Pennsylvania Horticultural Society has accepted the offer of Messrs. Strauss & Co., of Washington, D. C., to bestow a prize of \$300 for the best twelve cut blooms of the new Souvenir de Wooton Rose, and will award the prize at a meeting of the Society in January or February next.

Over 3,000 different species of plants have been grown in the rock-garden of the Royal Botanical Gardens in Edinburgh. A list of 1,408 was published by the curator of the Gardens in the transactions of the Botanical Society for 1887-'88, as having flowered during 1887 and being not mere botanical curiosities but well selected species of plants suitable for rock-gardens and such as intending planters would do well to inspect.

It has been stated in this journal that the pamphlet entitled "Observations on the Treatment of Public Plantations" was prepared by Messrs. Olmsted and Harrison at the suggestion of a land-improvement association, the Park Commissioners of this city and the Torrey Botanical Club. We have received, however, authentic information that the Torrey Botanical Club offered no suggestion, and took no action whatever in relation to the questions discussed in the report.

Mr. T. S. Brandegee has recently returned to San Francisco from a long botanical journey in Lower California, devoted principally to the neighborhood of Magdalena and Marguerita Island and Comander, where he collected about 400 species. Later collections in the centre of the peninsular, and near San Quintin, bring the number up to 800 or 1,000 species. Mr. Brandegee on his arrival at San Diego was married to Mrs. Curran, the accomplished botanical curator of the California Academy of Sciences.

Dr. F. S. Gould, of Montecito, near Santa Barbara, California, has recently received from Italy 600 young Olive-trees of the best Italian varieties for the production of oil. They are the Cucco, Correggiolo, Frantoio, Morinello, Morchiajo and Palazzuolo. The plants are budded on seedling stock, and are two to four years old from the bud. The plants arrived in California after the three-months' journey in excellent condition, having been carefully packed, the roots of each plant separately, in a straw jacket.

Arrangements have been made under which persons who desire to attend the Convention of the Society of American Florists, in Buffalo, next month, can procure return tickets for one fare and a third. Delegates will pay full fare to Buffalo, and receive a certificate to this effect from the station-agent where the ticket is purchased, and this certificate, when signed by the Secretary of the Society, will be good for a ticket at one-third of a full fare. All the railroads east of the Missouri have practically entered into this agreement. Tickets will be good for three days before the Convention and the return tickets for three days after its close.

There is an Ash-tree standing in the little village of Cuantlan, north of the City of Mexico, which is believed to have been planted there not long after the conquest. The trunk measures at the ground thirty-three and a half feet in circumference, and the shade cast by its branches at mid-day, when the sun is just over it, covers a circumference of 335 feet. This great tree, and the other large Ash-trees, which are a conspicuous feature of the vegetation of the Valley of Mexico, are probably all *Fraxinus pistaciifolia*.

At the Arnold Arboretum, a new insect, a species of *Coccid*, has become quite noticeable and abundant on the trunks and branches of certain Elms during the past two or three years. It is doing considerable injury to young trees, and seems to be a very difficult insect to exterminate. A full record of its habits and origin has not been published yet, but it is supposed to be an importation from Europe and to be known to European entomologists. A further account of the insect and its injuries will be given in a future number of GARDEN AND FOREST.

The English Government is helping in the work of establishing a system of botanical stations throughout the smaller West Indian Islands. The first station established was at Grenada, and it has grown into an attractive, as well as useful, botanic garden. The station at Dodds, in the island of Barbadoes, has distinguished itself by first succeeding in raising Sugar-canes from seed, and has done other valuable work with regard to the sugar industry. At Santa Lucia is another station which distributes useful plants among the islanders. Other posts are to be established by order of the Secretary of State for the Colonies at St. Kitts, Nevis, Dominica and Antigua, and they will receive assistance from the Botanical Department at Jamaica. One great point in the extension of these stations is that through the Jamaica establishment the resources of Kew can be made available in the remoter parts of the Archipelago.

In an address on "The Dahlia," recently delivered before a horticultural club, and reported in the *Garden*, Mr. T. W. Girdlestone says the plant was originally found growing in sandy meadows in Mexico, 5,000 feet above the sea, by Hernandez, a physician to Philip II., of Spain. It made its first appearance in Europe at Madrid, where *Dahlia variabilis* was flowered from seed in 1789, the grower naming the plant after Andreas Dahl, a Swedish pupil of Linnaeus. Lord Bute was then Ambassador at Madrid, and in the same year—just a century ago—Lady Bute sent seeds to the Royal Gardens at Kew, and thus first introduced the plant into England. Lady Holland also sent home seed from Spain in 1804, and among the plants raised at Holland House were the first two seedling double varieties seen in Europe. It was long supposed that these were literally the first double Dahlias, but it appears that figures of both single and double flowers had been published in an old work on the natural history of Mexico, printed in Rome in 1651. One of the double varieties with a yellow disk and violet ray-flowers there bore the name Cocoxochitl. Perhaps we, too, have the same flower, but fortunately under another name. About the year 1800 serious attempts were made in France to introduce the tubers of the Dahlia as an article of food, but the public seemed to prefer to consider it a purely ornamental plant.

The largest tree in Great Britain, and one of the most famous, is the Cowthorpe Oak, in Yorkshire, which is believed to be some 1,500 years old. When Evelyn wrote his "Sylva," in the seventeenth century, its circumference at the ground was seventy-eight feet, but later, earth was banked up around it, which covered some considerable projections and reduced its girth. At the beginning of the last century its branches overshadowed an area of half an acre of ground. The top or leading branch fell at some unrecorded date, curiously slipping down into the hollow trunk where it remained. In the last century one of the main branches which was blown down proved to be ninety feet in length, and yielded five tons of timber. When carefully measured by Dr. Jessop in 1829 the girth of the tree at the ground was sixty feet, and at a yard above forty-five feet; the chief remaining limb was fifty feet long and its circumference eight feet, and the height of the tree was forty-five feet. It was then hollow to the top. For many years saplings raised from this tree were sold in pots by the villagers for as much as a guinea apiece. It is now a venerable ruin, but most picturesque in its decay. It stands in a green paddock, carefully protected from injury, with its ancient limbs supported by props. An idea of its size may be gathered from the statement that at least forty persons can stand within its cavity, and that its circumference is greater than that of the Eddystone Lighthouse, which was confessedly designed on the model of an Oak.

Railroads and the Adirondack Reservation.

DURING the last session of the legislature at Albany a bill was introduced to prevent railroads from crossing any of the forest-lands owned by the state. The bill at once met with strongly-organized opposition, was amended so as to destroy its efficiency, and ultimately was killed outright. It was evident that some powerful corporations were anxious to get at the hard-wood forests which had hitherto been preserved because they were practically inaccessible. The great bulk of the pine and spruce has been cut already, or is doomed to early removal, because this timber can be floated down the small streams to mills and markets. These conifers, however, form a comparatively small portion of the forest, and if the hard-wood trees were left standing the advantages which the people of the state gain from the forests would still remain. It is true that the waste from the evergreens is too often left in the woods by the lumberman, and this is an invitation to fire, which may consume the standing timber, but it is possible to prevent these conflagrations or to hold them in check.

But when a railroad penetrates the recesses of a hard-wood forest its destruction is absolutely certain. These roads are often constructed for the avowed purpose of stripping the land of its timber, and stripping it clean. Besides this, they necessarily increase the danger from fires, not only by kindling them with sparks from locomotives, but by multiplying the number of loggers, and squatters and hunters, who light camp-fires along their course. That it was railroad interests which killed the bill alluded to, and killed it because they were meditating an immediate invasion of the forest through the state-lands is evident from what has happened since the legislature adjourned. According to a careful statement in *The Tribune*, of this city, no less than four railroads—one from the north, one from the south, one from the east, and one from the west—have already begun, or are about to begin, extensions of their lines into the very heart of the Reservation, so as to reach the best blocks of timber which still remain in the North Woods.

The Northern Adirondack Railroad, which runs south-

ward to Paul Smith's, is now pushing onward through a region of dense forest to Tupper's Lake. It is built primarily as a lumber road, and it means the extinction of this forest. The Carthage & Adirondack Railroad has been extended eastward this summer almost to Cranberry Lake; and, besides its purpose as a lumber road, its connection with iron works will incite more charcoal-burning, an industry which obliterates every vestige of a tree when it is conducted on the methods prevalent in the Adirondacks. The Delaware & Hudson Canal Company, having recently acquired the Adirondack Railroad, propose, it is said, to extend it northward across the Wilderness to unite with the Northern Adirondack Road. At all events, the extension is now surveyed as far north as Long Lake. Finally, the Chateaugay Railway, coming into the Wilderness from the east is planning to stretch on beyond Saranac, its present terminus, to Lake Placid. West of Lyon Mountain is a dense, hard-wood forest which is now owned for twenty-four miles by this Chateaugay Company, and through this it is proposed to cut a swath six miles wide, three miles on either side of the track, taking every stick for charcoal, and leaving behind a verdureless desolation. After the charcoal kilns have swallowed up the last available bit of wood, the chips and branches are gathered into heaps about the stumps and fired, until everything inflammable is consumed, including the thick mat upon the forest floor, which can only be felted together by the slow processes of Nature carried on through centuries. This means not only death to every green thing, but to every hope of renewed forest-growth for generations to come. The reason offered for this effacement of all life is that it insures protection to the adjacent forests owned by the same company. Sparks from their locomotives will fall into no tinder, and tourists will kindle no camp-fires after the charcoal-burners have left the land. The entire strip will be as bare and barren as so many miles of sand upon the sea-coast.

The only way to protect the Adirondack Woods from being utterly swept from the face of the earth is for the state to acquire the land in fee-simple. Something beyond this is, no doubt, essential: an administration which is above the mutations of party politics; a policy which is adapted not to temporary conditions, but which looks forward to results in the far future; an educated public sentiment which will tolerate no ignorance nor inefficiency in the men who have executive authority over the Reservation and which will insure abundant moral and financial support to worthy officers—but, after all, the state must own the land, and the sooner it begins to acquire a title the better. No doubt it would be wise to begin with moderation—that is, with a comparatively small appropriation and a maximum limit of price per acre. But a beginning should be made, and the public spirit and intelligence of the state should organize itself to enforce a judicious administration of the trust.

A writer in the *London Lancet*, in reviewing Mr. Henry Gannett's paper, in which the ground was taken that the forests upon the mountain ranges in our western States and Territories had the effect of decreasing the supply of water available for irrigation, and therefore that the sooner they could be wiped out of existence the better it would be for the country—a view which we have already shown could not be substantiated by any scientific data—says:

"He (Mr. Gannett) admits that land under tillage retains its moisture better than land not so treated, and that woods equalize temperatures and air currents and act as water reservoirs. But some of his divergences from the popular view are surely inadequately reasoned out; for example, that the great superficial area made up by leaves favors evaporation and sends back to the air a large proportion of the rain which, unintercepted, would go straight to the soil, which is thus impoverished of its due supply of moisture. To this objection Ebermayer can rejoin that evaporation in the forest is two and a half times less than outside it; nay, Clavé makes it as much as five times less. If we take into account the protective covering of the soil caused by the leaves that have been shed

upon it, then, compared with the evaporation from the free or woodless ground, we get a diminution of more than eighty per cent. ! The practical question, however, lies not so much in the increase or diminution of the rain-fall as in its distribution."

Some Old American Country-Seats.

III.—BELMONT.

BEYOND Fresh Pond the road from Cambridge to Waverly ascends a gentle swell of smoothly-surfaced upland, enters the shade of arching Elms and presently discloses on the right hand a green lawn of an extent that is uncommon near Boston. The ground has a beautiful form. It descends a little from the road towards a gentle hollow which holds a small pond, and thence it rises very gradually, and with many slight irregularities of slope, to the wood which bounds the scene at the north, and to the house at the north-west. The western border of the open ground is a wood of native, deciduous trees through which the approach road goes to the house. In many places the grass runs in between the surrounding groves, so that only the lower or eastern boundary of the lawn appears in the least degree formal or stiff. A few Hickories rise in the midst of the grass. They are quite in keeping with their surroundings, but this cannot be said for the group of White Pines, or the two or three Norway Spruces, or the big Larch encircled by old plants of *Arbor-vitæ*, which are the companions of the Hickories in the open ground. Our picture, (page 330) taken from a point near the little pond, shows only the upper half of the lawn and but one of these incongruous trees, the Spruce, which appears behind the two Hickories in the foreground. This Norway is a fine specimen of its kind; its lower limbs rest upon the ground on all sides, but it should never have been planted where it is, for its formal shape is quite the opposite of every shape around it and attracts the eye to itself at once in a way which confuses the effect of the otherwise harmonious scene. The stiffly circular clump of *Arbor-vitæ* is a still more obtrusive object. Thoughtless planting like this has too often injured scenes which nature made harmoniously beautiful, and to which nature would gladly add more and more of character and beauty if she were helped and not thwarted by man.

The house is approached through a wood of trees which arch overhead to form a handsome informal avenue within which the road curves very gently; but as the whole length of the road is visible at once from the beginning, it had better have been made straight. At the house is a wide gravel space for the accommodation of waiting carriages, and here a junction is made with the service road, a branch of which leads to the stable. Thus all the necessary gravel spaces are provided at this one side of the house, so that the grass is free to sweep up to the very walls on two sides—a point of great merit in the plan. The fourth, or north, side is occupied by a walled kitchen-court and laundry-yard.

The house is a substantial structure of brick, with verandas built of stone. Its rooms command a view of the ten acres of lawn on one hand, and of the interior of the wood on the other. Over the tops of the trees at the foot of the lawn appears the shining dome of the State House on Beacon Hill, five miles away.

A broad walk leads eastward from the house to a point of view which commands Fresh Pond and the intervening diversified farms. Six Purple Beeches stand in a row beside this path near the house, but formality ceases at the view point, and the walk wanders off along the brink of the gentle eastward slope, passes among scattered Oaks of large size and around the small deer-park, and after sending off a branch to a knoll which offers a yet wider prospect over the Mystic River basin, returns to the rear of the garden.

Our picture on page 331 shows a part of the Oak-wood on the eastern slope. The trees are fairly well exhibited, but the gracefulness of the undulations of the ground surface at this point is scarcely suggested.

The garden behind the house is an enclosed square measuring 300 feet each way, level, and formally divided by broad gravel paths, as shown upon the plan. A conservatory and two long graperies, behind which are the potting-sheds and plant-houses, front upon the northern side of the garden, while two Peach-houses and many well-trained Pear-trees occupy the east and west walls. Most of the ground is smoothly grassed. There are two large masses of *Rhododendrons* mixed with similar shrubs; at the sides are long beds of perennials and foliage-plants, and grouped upon the grass near the angles of the walks, are specimens of such trees as the Flowering Magnolias, the Red-flowering Horse-

chestnut, the Weeping Elm, the Swamp Cypress, the Ginkgo, the Oriental Spruce, the Swiss Stone Pine, and the Mountain Pine (*P. Mugho*). Such specimen plants are certainly quite in place in a formal garden intended to be decorative. They should, however, be chosen for their appropriateness, and grouped with due regard to the effect upon their neighbors. The Mountain Pine just mentioned is too roughly picturesque to appear in a garden like this where elegance is the end and aim.

A glance at the sketch-plan will explain the arrangement of the numerous minor buildings and enclosures of the estate. The completeness of the equipment is remarkable. There are buildings for all purposes—they are not all named upon the plan—and elaborate facilities for the growing of everything from the Parsnip and the Potato to the Chrysanthemum and the Orchid. The land company which is now in possession has cut off the farm lands, but offers the remaining parts for sale quite intact. These lands made a country-seat, at least, as long ago as 1800, when the owner was a brother of Commodore Preble. One of the daughters of the house married Mr. Nathaniel Amory, who became the next owner, and he sold the property to Mr. R. D. Shepherd, and he to Mr. J. P. Cushing. Mr. Cushing spent many thousand dollars every year upon the place and made it, thirty-six years ago, the most famous seat near Boston. Mr. S. R. Payson, the last owner, maintained and increased this fame.

To-day the place possesses something of that priceless and poetic charm which so distinguishes the Gore Place and the Lyman Place; it is felt in the deer-park and among the Oaks, but the spell is not so potent, nor does it pervade the whole scene, as at Waltham. To define the difference is a little difficult, but it is in part accounted for by the fact that a certain unavoidable suspicion of display attaches to this place—to the great expanse of clipped lawn, the specimen trees, and the elaborate gardening. On the other hand, the gardening and the specimen-planting is generally good in its way, and it is placed where it belongs: namely, in the garden, and not in the landscape.

Boston.

Charles Eliot.

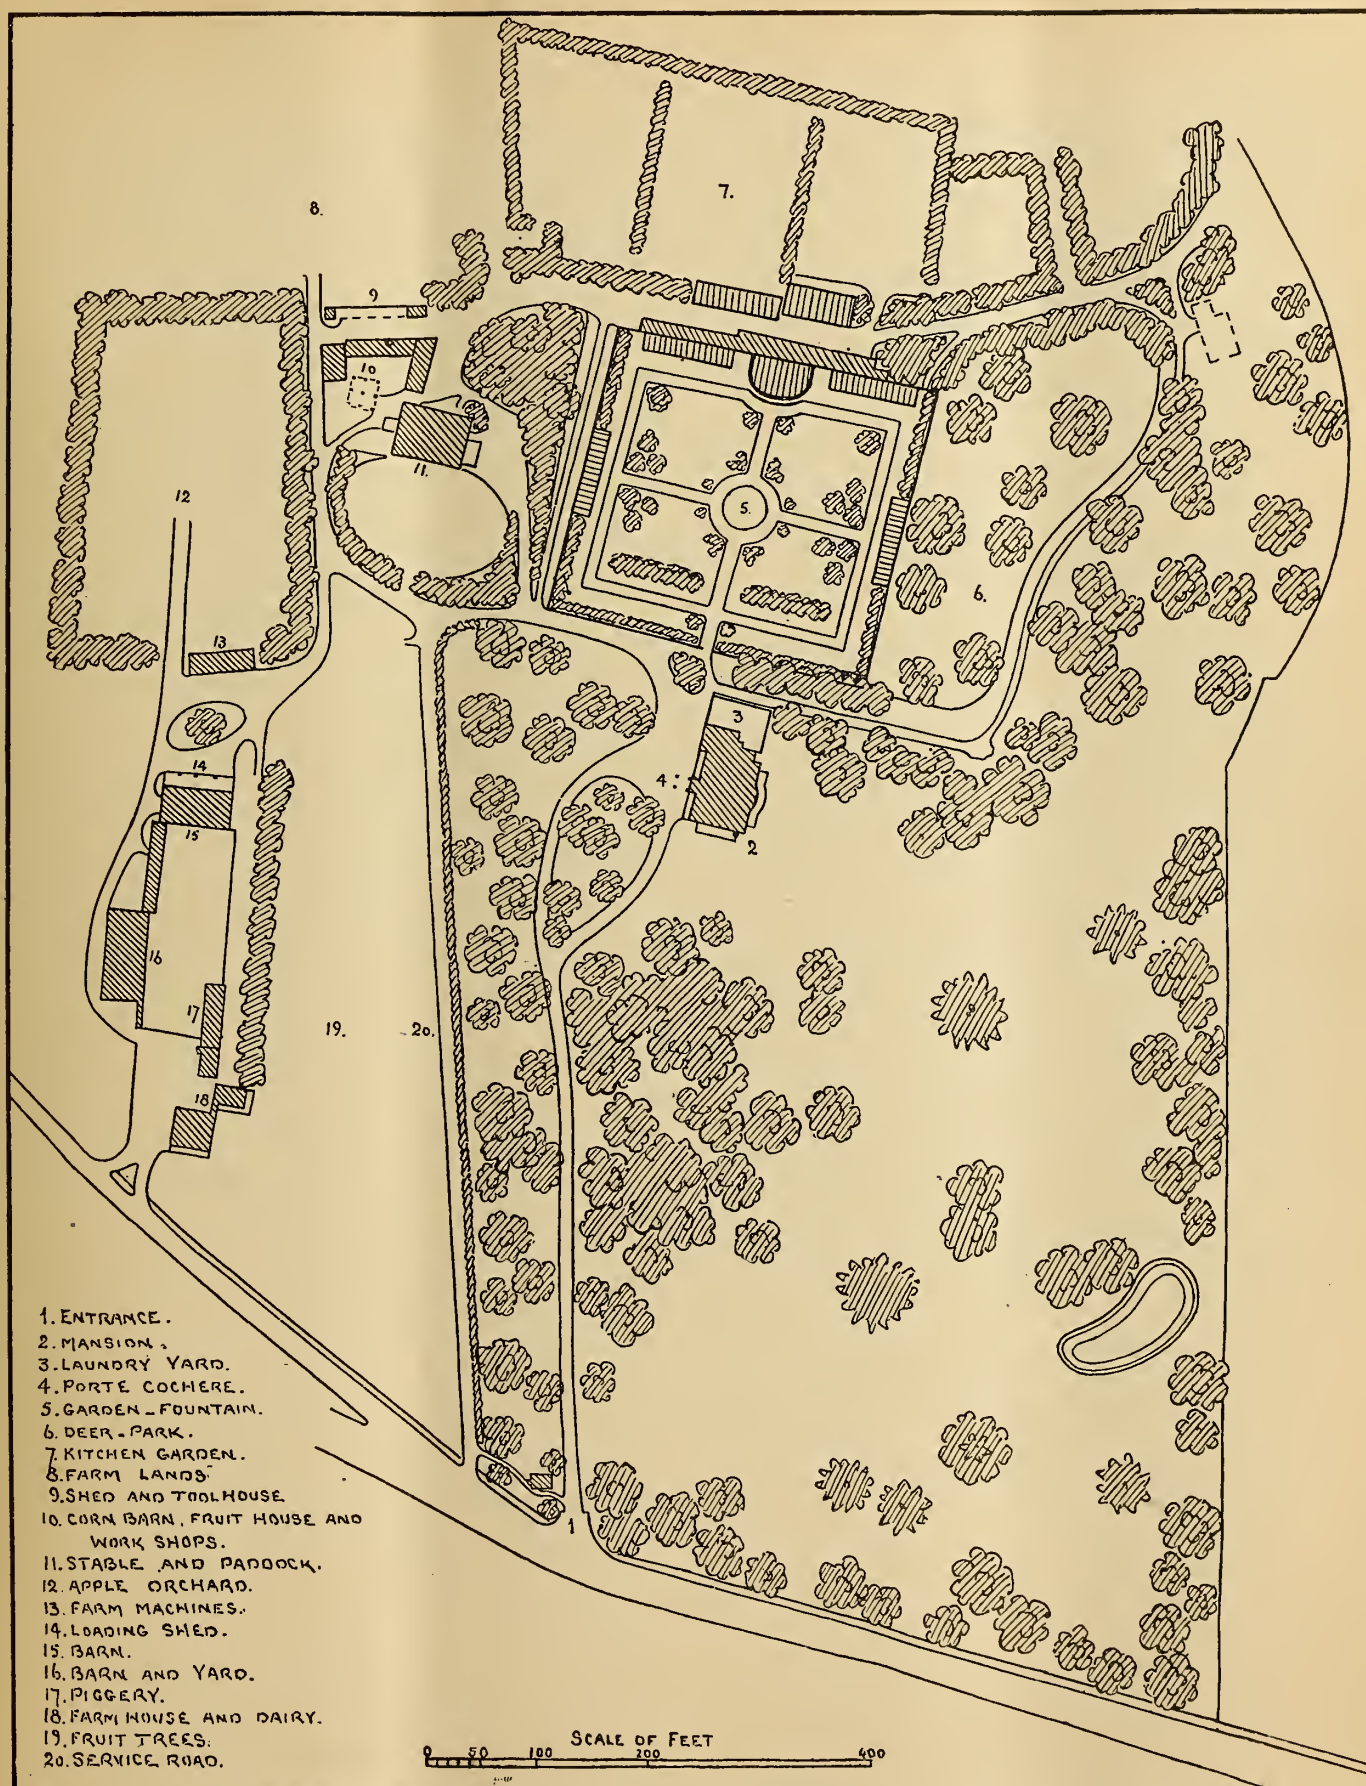

A New Race of Lilacs.

THERE may be found in some gardens still a very old variety of the common Lilac under the name of *Syringa azurea plena*. I do not know the origin of this plant. It produces small panicles of clear-colored flowers in each of which there are a number of corollas arranged one within the other. It is a teratological curiosity, but as an ornamental plant quite destitute of value, as the rare flowers are quite hidden by the foliage. This variety, as the flowers have no stamens, and the pistils are either abortive or so hidden among the numerous corolla-lobes as to be beyond the reach of insects, does not produce seeds naturally. But it will sometimes seed with the aid of artificial fertilization; and seeds secured in this way produced the first of the double-flowered Lilacs introduced during the last few years.

It is eighteen years since this plant, artificially fertilized in my nursery with pollen of various Lilacs, bore a few seeds, which afterwards germinated. Some of the best varieties of *Syringa vulgaris*, such as Ville-de-Troyes, Sanguinea, etc., were selected as pollen-parents in this experiment, and the pollen of *Syringa oblata*, a species remarkable for its early flowers and for the brilliant coloring of its foliage in autumn, was also used. The characters of this species, to which an article recently published in GARDEN AND FOREST has called attention, were transmitted to one of the seedlings derived from this cross. This was first sold under the name of *Syringa hybrida hyacinthiflora plena*. The term "hybrida," which is found still on the catalogue of the Maison Lemoine, was used to show that this plant is a true hybrid between two species of *Syringa*.

Syringa hybrida hyacinthiflora is already out of flower, although the flowers on most of our Lilacs are only just opening; and in autumn it is exceedingly ornamental, with its brilliant red foliage. The panicles of flowers are large enough, although the corolla-lobes of the double flowers are narrow and reflexed. But the production of this plant was a step in the right direction.

The other seedlings from this first crop of seed showed no trace of the blood of *S. oblata*, but there were some of them which were handsomer than *S. hyacinthiflora plena*. The best plant of this set was sent out under the name of *S. vulgaris Lemoinei*. The thyrsus of this plant is eight inches long, and covered with lilac-blue double flowers, with numerous imbricated corolla-lobes. A number of other good varieties were in the set differing from *S. vulgaris Lemoinei* in the shape of the flowers, in their color, in the color of the flower-buds, or in the

Sketch Plan of Belmont.—See page 326.

shape and size of the thyrsus. These varieties are Renoncule, Rubella Plena, Mathieu de Dombasle and Le Gaulois. An attempt was made as soon as these different varieties flowered to get seeds from them, and the old *S. azurea plena* was dis-

carded as a seed-bearer. The best single-flowered varieties with flowers of different shapes and colors were used to cross with the new double-flowered race, and pollen from the flowers of *S. Chinensis*, even, was tried; but this last experiment pro-

duced no results. A new set of seedlings was obtained from the second cross, and among them were some very remarkable and beautiful plants. From this sowing came Alphonse Lavallée, Michel Buchner, President Grévy, Pyramidal, M. Maxime Cornu, etc. Here we have, in addition to the form and color of the flower, remarkable variations. The corollalobes in one variety are round and flat, resembling a Ranunculus; they form in another a globular head, with the lobes all incurved; in another they are all reflexed, and in another they are crumpled.

I will not give now a detailed description of each of these varieties; and it need be said only that we are constantly experimenting with double-flowered Lilacs, and that each spring-time sees a new set of flowers produced, with forms and colors entirely unknown before. Nearly all the shades of color found in the flowers of single Lilacs have been produced already in this new race. Shades of blue are represented by A. Lavallée, Michel Buchner, President Grévy and Léon Simon. The darkest reds appear in Comte Horace de Choiseul and La Tour d'Auvergne; a delicate rose in Virginité; and we have now obtained a variety with large, pure blue flowers. This has not been sent out yet, but it will appear next week at the Exposition in Paris.

Nancy, April 18th, 1889.

Entomological.

Cut-worms.

THIS is the popular and expressive term usually employed to designate the larvæ of certain species of the Lepidopterous family, *Noctuidæ*, and it is based upon their practice of eating off young plants at the level of the ground. The more succulent the plant, the greater the danger from Cut-worm. Usually the complaints come in just after plants are set out, and I myself have seen a field of young plants set out one evening cut off to the extent of fully one-half by the next morning. The explanation is simple: many of the larvæ of *Noctuidæ* are hatched in the autumn and hibernate about one-third or one-half grown. They are voracious in spring, and, after a cleared spot of ground is planted, the only vegetation on it must suffer. Other larvæ hatch early in spring and feed on grass, weeds and whatever may be on the ground until it is cleared for the garden plants. Then the enforced fast until vegetation returns to their neighborhood makes them dangerous to whatever is set out. They are nocturnal in habit, lying hid just under the surface of the ground during the day, and feeding at night. In the morning they can be most usually found at or near the base of the plants cut off by them during the night.

Various means have been tried to keep them from the plants—lime, salt, gas-tar and a variety of other repellants have been employed, all with a variable, usually small, degree of success. Later, as the habits of the worms became better known, traps were prepared for them. Holes were driven with a dibble, around the newly-set plants, and the Cut-worms wandering about fell into them, and, being unable to climb up the smooth sides, perished there. Traps were set in the form of chips and short pieces of board, which proved convenient hiding places for the larvæ, and there they could be readily found during the day and destroyed. Still later, balls of grass and succulent leaves were scattered about the fields, and there the worms congregated, and were easily destroyed during the day. Most recently, the grass balls were poisoned, by being soaked in a pail of water into which a tablespoonful of London Purple had been stirred, and the Cut-worms were thus killed without the labor attendant upon a daily visitation of the lures. The trapping system with the aid of poisoned lures has, on the whole, proved most satisfactory; but, as in the case of all applications of insecticides, the element of time is a most important factor, and in many cases really determines success or failure.

There is comparatively little success from lures placed after a field has been set out and where vegetation has started, since the worms will prefer young, growing plants, to the lures, and after the larvæ become full grown and ready for pupation, lures, of course, fail in attracting more than a very few belated specimens. The proper time for a Cut-worm campaign is indicated by what has been said in the previous part of the paper. Just after the ground has been prepared for the crop to go in it, and while it is clear and free from vegetation—if possible only a day or two before planting—the poisoned lures should be spread about liberally, and the vast majority of all the Cut-worms in the prepared ground will be attracted and destroyed. It is, of course, not likely that the destruction will be complete, but the percentage of plants lost will be very much lessened, and will be insignificant in comparison to the damage that would have been otherwise caused. It has quite frequently

happened that fully-grown larvæ have been sent me, and, after recommending lures, I received word that they did not attract. The explanation in such cases has been given: the larvæ were ready for pupation and their work had ceased. Lures are always successful in proportion to the lack of other vegetable matter in an infested field; and they are more successful when used early in the stage of growth than when the larvæ approach maturity. For the readers of this paper the species of Cut-worm is not important. They have all similar habits, and the same remedy is applicable to nearly all of them—certainly to all cutting plants at the level of the ground.

Foreign Correspondence.

London Letter.

THERE was a bright display of flowers at the last meeting of the Royal Horticultural Society, but a conspicuous absence of new Orchids, although this date was fixed for Mr. Harry Veitch's paper on "The Cultivation of Orchids." Such Orchid fanciers as Baron Schroeder and Sir Trevor Lawrence do not give the public a treat very often, and, considering the risk that attends the transportation of Orchids in flower (in most cases of enormous value) for a journey of thirty miles, it is not surprising that these two staunch supporters of the society do not show more frequently. Among the few Orchids sent yesterday was a remarkable group of some two dozen specimens of *Epidendrum vitellinum majus*, every plant carrying tall branched spikes of large orange-vermilion flowers. Rarely, indeed, has such a perfect group of this Orchid been exhibited, and it is evident that the grower has hit upon the peculiar treatment this Mexican species requires. I could not ascertain how long the plants had been imported, but the bulbs seem to have been home-grown. If Mr. Partington can show this same group in such perfect condition five years hence, he might well lay claim to being the champion grower of this fastidious plant, which, though it grows well for a time, is, like *Cattleya citrina* from the same country, not to be depended upon for a great number of years. *Cattleya Mossia Schroederiana* was shown fairly well, but I fail to see much distinction in this variety, so named, from many others one could single out of a large collection. It has certainly a large, fine flower, and there is a delicacy about the lilac-mauve tint of the broad sepals, but the lip is not nearly so richly adorned with gold and purple as many unnamed forms I have lately seen.

Amongst a collection of Tea Roses from the well-known Tea Rose-grower, Mr. Prince, of Oxford, was the new white sport from the old Souvenir d'un Ami, which is named Souvenir de S. A. Prince. Mr. Prince catalogues it as "Undoubtedly the finest white Tea Rose offered to the public of late years, as it possesses all the good qualities of Souvenir d'un Ami combined with a more robust growth." This advertisement is endorsed by our best Rose growers, some of whom sat on yesterday's committee when a first-class certificate was proposed for it and carried unanimously. It is indeed a lovely Rose, rivaling the favorite Niphetos, with even greater depth and substance in the flowers, its snowy petals set off by the broad, deep-green foliage. The other Tea Roses from Oxford included some perfect blooms of two of the loveliest Teas that Mr. Bennett has put into commerce. These are Princess of Wales and Princess Beatrice. The former has a strong resemblance to Comtesse de Nadaillac; indeed, as the blooms were ranged side by side it needed a second look to discern the difference. Another Rose of quite a different stamp that is worthy of note is Paul's Single White, a most valuable addition to our list (never too long) of hardy climbing Roses. This one has pure white flowers, nearly three inches across, produced plentifully on slender branches that have a decided rambling tendency. When I first saw it I thought it was a large form of the Rocky Mountain *Rubus deliciosus* until I saw the foliage.

The chief task of the floral committee centred in singling out the best varieties of Pæonies, Pyrethrums and Delphiniums from a magnificent collection of flowers occupying a space of 500 square feet shown by the great raisers of these plants, Messrs. Kelway of Langport, a favorable spot in wild Somersetshire. For large size of bloom, for delicacy of tint and for fragrance, no hardy flower, except, perhaps, the Rose, can equal these double Pæonies, which have all originated from the flimsy single European and Chinese species. The best varieties grown, as Kelway sends them to town, have blooms as big as a child's head, a solid mass of petals, with a delightful blending of soft tints. Usually there is a central tuft of small petals surrounded by a row of broad or guard petals of a different color, and one of the best examples of this is in

a sort called Princess Irene, which won an award of merit. The centre is creamy-white, the guard petals pale pink, and the fragrance that of a Tea Rose. Other sorts I picked out as good were Princess Christian, pale pink; Mrs. Chamberlain, soft blush pink; Prince George, deep crimson and Baroness Schroeder, delicate pink. These comprised the cream of a large number of new varieties, every one of which was a vast improvement on old sorts. There were a good many single-flowered sorts shown, but these found no favor with the committee, in fact I don't think that single Pæonies will become popular, for the æsthetic people who made the single Dahlias popular do not seem to see beauty in a flimsy, single Pæony. The typical *P. albiflora*, however, with its cup-like flowers, snow white, incurved petals with a golden centre-tuft of stamens is very beautiful.

Pyrethrums, like the double Pæonies, are quite modern flowers, and both single and double sorts take the public taste; the double flowers because they last so long in perfection, the single ones because of their gracefulness. Kelway had many new varieties but only a dark crimson flower named Pericles won an award; not because the others possessed no merit, but the committee did not recognize the novelties as improvements on older sorts. There were some beautiful white double sorts and glowing crimsons, and one was almost a yellow, though we hardly need yellows much in Pyrethrums, seeing that we have the best of golden-yellows in annual Chrysanthemums which flower at the same time. Everybody thought the Delphiniums, or perennial Larkspurs, were wonderfully fine. Some of the spikes were two feet high, and massive in proportion. Their colors ranged from pale blue to reddish-purple, and some had showy, white eyes, which made the spikes very attractive. Four sorts were voted awards of merit, their names being Faust, Orbit, Regalia and Ardite. I will not attempt to describe their distinctive features, as it cannot be done. These Larkspurs, well grown, reach six to seven feet high, and a few masses of these appropriately placed create about the finest effect one can have in a June garden. Moreover, if cut down immediately after flowering, which is about the beginning of July, they will throw up flower-spikes in autumn again if well treated with water and manure. They are gross feeders, and will repay occasionally dosing with liquid manure, not too strong, but weak and frequent. The best soil for them is a sandy loam, and in a sheltered situation.

There were a few new Begonias sent by Messrs. Laing, the Begonia-raisers, and one, because of its persistency of bloom, as well as its large size of flower and delicate color, obtained a meritorious award. It was called Mrs. Joseph Chamberlain. Its flowers are single, five inches across one way, with white petals broadly margined with pink. A first-rate new Fuchsia also won the committee's approval. It was called Dorothy Fry. It has large, single flowers, crimson sepals and a snow-white corolla, very floriferous and of excellent habit. Among other plants worthy of note was *Verbascum Olympicum*, a large hardy biennial Mullein with broad and long leaves of a grayish-green arranged in a huge tuft from which arises the much-branched flower stems about six feet high, covered thickly with bright yellow flowers. It is a very showy border plant, and one of the finest of the numerous group of large Mulleins. It is quite hardy here, and would be, I think, in America, if protected the first winter. It is a first-rate plant. *Rhododendron calophyllum*, one of the Himalayan group with large white flowers borne in clusters, was admired by many, though unfortunately it is only in large conservatories that it and its congeners can be grown successfully.

In his paper on Orchid-culture Mr. Veitch reviewed the history of the art from Philip Miller's time, when the Vanilla was the only exotic Orchid known in Europe, till the present day. He contrasted the difficulties under which our forefathers labored, owing to the want of knowledge as to the natural conditions under which Orchids grew wild, with the present system of culture when we have tolerably precise information of the conditions we have to imitate. Notwithstanding the marvelous results we obtain now, the essayist considers that we have a great deal to learn, and that our knowledge and practice will be progressive. Without entering upon the details of culture, Mr. Veitch asserted that successful Orchid-culture must depend upon carrying out a few main principles, the chief of which is abundance of light, ventilation with the minimum of artificial heat. The speakers in the discussion which followed, including Sir Trevor Lawrence, Baron Schroeder, Sir Charles Strickland, Dr. Masters, Mr. Dyer and Mr. Morris, all corroborated the correctness of the principles laid down by Mr. Veitch, and one related a fact in regard to a certain fine specimen of *Vanda cærulea* which for

some years won for itself much glory at the London shows, because it had received cool treatment from its cultivator, but when it was sold and sent to America it died the year after, presumably on account of being warmly treated. Some discussion arose concerning the future means of naming Orchids, since Dr. Reichenbach is dead. The director of Kew has intimated that he is willing to put the establishment of Kew at the service of orchidists in this respect, and, considering that the Kew Herbarium is rich in material and embodies Lindley's full Orchid collection, it is hoped that not much inconvenience will result from the action of the professor who, in his eccentric will, stipulates that his herbarium is to be sealed up for twenty-five years. The chief regret is that the Reichenbach collection contains so much material that we cannot hope to be collected again, especially the fragments that were contributed to it by travelers who sought Orchids in untrodden regions, but could not gather living plants.

Cultural Department.

The Strawberry Season of 1889.

THIS spring Strawberry plants appeared to have wintered well, and early indications seemed favorable for a fine crop of fruit; blossoms were abundant, the fruit apparently well set, and frequent rains seemed to furnish all requisite moisture, but as they began to ripen the blight or brown rust put in an appearance with more fatal effect than usual. Few varieties escaped entirely, although some were less seriously affected than others. I find that among amateurs as well as among market growers there are many who do not know what is meant by this term "blight," and when asked if they are troubled with it, reply in the negative. It appears in brown spots on the leaves, stems and fruit-stalks, destroying the circulation; the stems and calyx die, and the fruit ripens prematurely, with a poor, indifferent, and sometimes bitter, flavor. The mildew that sometimes effects the foliage is an entirely different thing. This rust, or, as generally called, blight, has troubled me for years. Last year I planted my Strawberries on entirely new ground, in the hope to escape this scourge, but it was of no avail; some varieties were so badly affected that they were picked but once, and this season it was nearly as bad. Some varieties are seemingly more susceptible to its attacks than others, and I have thought that this might be due to impaired vitality resulting from cultivating a variety a long time, but I find new varieties, young and vigorous from the hands of the originators, are sometimes as readily affected as the older sorts. I have some of the new varieties now on trial that have been introduced during the past two years, with the usual accompaniment of testimonials and praises in the superlative degree, that are absolutely worthless here on this account. One of these, in-particular, sent to me for trial a few years ago, gave much promise for productiveness, and last year I gave it the best possible chance by planting it on the ground where Strawberries had never been grown. But the rust developed to a greater extent, if possible, than on any others. It is an entire failure, and I infer that the liability to attack is due to a constitutional weakness, rather than to the age of the variety.

My old favorite, the Downing, the best berry, taken all in all, that I have ever grown, and the one I have grown longer than any other, has become so seriously affected that it must go. I gave all a spraying with sulphate of copper this season, but the application did no good, possibly because made too late. Last fall I happened on a bed of Downings on new ground three miles from here. They were so vigorous and healthy I hardly recognized them, and I felt hopeful that the owner would be able this season to show the Downings as I used to grow them. But I found later, to my disappointment, the enemy had found them also, and I have concluded to surrender my favorite and confine my planting to such as seem to possess greater power of resisting the fungus.

As soon as I discover a variety which seems to have any special liability to this disease it is at once rooted out, lest it become a breeding-place of the fungus. This scourge is annually spreading, and it is only by such caution that we can hope for any relief. The mycologists of the country are said to be studying the disease, but as yet no satisfactory remedy has been reported.

The first ripe berry I picked (May 30th) was from the Pearl, and the following day the Jessie yielded its first specimen. Of the former I formed a very favorable opinion last season, and another year's experience confirms this view. The berry is handsome, perfect in shape, conical, very uniform in appearance and of good size; the calyx is easily removed, and the

quality is very good. It compares favorably in all respects with the Jessie. The Jessie may possibly produce a few larger berries, from a tendency to irregularity not shown by the Pearl, but, in other respects, it shows no superiority here. It shows, also, a tendency to uneven ripening not seen in the Pearl. Both have a liability to blight to some extent, but I shall retain them as leaders for another season. Prince (Durand's) is the standard of excellence for quality by which others are judged. It is not quite as productive as is desirable, but it makes up in quality for its shyness in bearing. It rusts some, but I hope this tendency will not be so apparent when its more susceptible neighbors have been discarded. Jersey Queen, the Prince's twin-sister, is more vigorous and robust in habit and produces larger berries, more of them, and of more acid flavor. It rusts somewhat, but I shall keep it a little longer.

Sharpless, the largest of all and the most deformed, is not very productive, and rusts and rots so badly that it must go.

article is looked upon as an extortion. The fraudulent baskets, five of which will hardly hold four honest quarts, have also an influence in depressing prices, for not one buyer out of ten observes the scant measure. The way to get the highest satisfaction out of this luscious fruit is to grow it well at home. If that is not possible, then buy only freshly-picked berries grown near at hand.

Montclair, N. J.

E. Williams.

Some Hardy Ferns.

OF the many species and varieties of Ferns (over forty) in New England, nearly all are desirable for cultivation. All are hardy, that is, against cold weather, and many of them may be grown as easily as any of the hardy plants. The beauty of their foliage, which lasts with most of them, from early spring until it is killed by frosts in autumn, and even through the winter with a few which are evergreen makes them invaluable as hardy, ornamental plants. There are, about most

Belmont.—See page 326.

Davis, a reproduction of Sharpless, shares the same fate. Jewell, which made such a splendid record with Mr. Augur, its originator, and promised well here, rusts so badly that another season closes its career with me. Gold, Dewey and Acme are discarded this season from the same cause. Atlantic follows, and the worthless Cahanse. I have petted and coaxed these varieties in vain attempts to develop their good qualities and they utterly fail to respond.

Belmont proves unproductive here and ripens unevenly, otherwise it would be a very desirable kind, as it possesses size, quality and good looks. I shall retain it in place of Sharpless, another season, at least. Cumberland Triumph is a good-enough family berry, but its capricious fruiting and liability to blight renders it uncertain. Burt, sent out last year as likely to supersede the Wilson, proves more healthy and desirable than that old variety ever did with me. It remains healthy so far, but seems lacking in productiveness. The fruit is of fair size, solid, and so acid that it makes an unusual demand upon the sugar-bowl. Ohio looks and tastes so much like the Champion as to suggest the suspicion that it is the old variety rechristened or reproduced. Louise, sent out last season, has thus far shown no quality that encourages a hope that it will prove an acquisition on my soil.

The most promising of the new varieties I have yet tried is the Bubach. The berries are large, bright, smooth and handsome. It appears to be both vigorous and productive—two desirable features in a Strawberry—and the quality is fair to good.

If quantity and vigor alone were wanted I should name the Crescent as a most satisfactory variety, but amateurs generally want something a little better. Strawberries, owing to their delicate texture, ought to be grown very near the point of consumption, and consumers who would secure the very finest flavor should never buy a berry that has been carried far or picked long. While our markets are supplied with stale fruit grown hundreds of miles away, bruised by transportation, and so far on the road to decay that it must be sold at once, it will be difficult for local-grown fruit to command prices that will afford profit to the producer. Consumers have become so used to low prices that two or three cents' advance for a fresh, superior

country homes, bare shaded corners, too shady for grass to grow, where these Wild Ferns would thrive and might be permanently established. One of the most desirable species is the Ostrich Fern (*Onoclea Struthiopteris*). The plant varies much in size, according to location. The finest specimens we have seen were growing in the bottom of a cool, half-shaded ravine. The fronds were fully five feet in length by ten inches wide, and of a beautiful light-green color. It is an easy plant to grow in either sun or shade if in moist soil, and it may be planted in spring or autumn. Another valuable Fern often found with the Ostrich Fern, but a rarer kind, is *Aspidium Goldianum*. This beautiful Fern grows nearly as tall as the former, with broader fronds, often a foot or more in width and of a darker green color. It is usually found in the shade and likes a moist, sandy or gravelly soil.

The Cinnamon Fern (*Osmunda cinnamomea*) and *Osmunda Claytoniana* are both valuable species, with large, broad fronds, often over five feet high. They are not difficult to grow in moist soil and will thrive in either shade or sun.

The Royal or Flowering Fern (*O. regalis*) is the prettiest of the three with finer, and more divided foliage, quite distinct from the others in its general appearance. Its height is from two to four feet. We have in Vermont a finer form with narrower foliage which English dealers sell as *O. gracilis*.

Phegopteris hexagonoptera, one of the Beech Ferns, is a small plant six to ten inches high, with triangular fronds of a light-green color. It is an easy Fern to grow in half-shaded corners. *Phegopteris polypodioides* is somewhat like the preceding, with smaller and darker fronds and grows in dense tufts. It is readily established in moist, shady ground. *P. Dryopteris* the most common of the Beech Ferns, is a delicate little plant seldom over six inches high with triangular fronds four to six inches wide. It does best in peaty soil along the borders of swamps, but it can be grown in any moist and shady corner.

Woodia Ilvensis is a little low Fern growing in tufts seldom more than six inches high. The fronds are chaffy and hardly an inch wide. It is generally found on exposed rocks, but may be grown in moist, shaded soil. It is a valuable Fern for the rockery.

The Maiden-hair Fern (*Adiantum pedatum*) is one of our prettiest species, and larger numbers of this are exported to Europe than any other. It grows in tufts, about a foot high, and fine, strong clumps of it are very beautiful. It is not a difficult plant to grow, but should be set in autumn.

Asplenium Trichomanes is one of the prettiest of the smaller Ferns and not difficult to grow. It is found in tufts on shaded cliffs, but we have grown it in moist, loamy soil in the shade. It is a fine plant for sheltered corners of the rockery.

The common Wood Fern (*Aspidium marginale*) is a pretty plant and its fronds are evergreen. The plant is generally about eighteen inches high, and grows naturally on rocky hill-sides, in the shade, and in low woods. It can be successfully grown on any ordinary soil in the shade.

The Walking Leaf (*Camptosorus rhizophyllus*) is a low, evergreen Fern, growing in dense mats or tufts on shaded rocks. In the right location it spreads very rapidly, but it needs shade. We have seen it successfully grown in the shade in fine, loamy soil with ordinary culture, but for its best development it needs a light, moist soil.

Orchid Notes.

Lalia Amesiana.—This most beautiful and rare hybrid is now in flower with us. It is the result of crossing *Cattleya maxima* with *Lalia crispa*, and is a great improvement upon both. In habit it much resembles *C. crispa*, though by no means so strong. It is a robust, free-growing kind, producing four to five flowers on a peduncle, though larger plants may produce more. They are about six inches across, the narrow, white sepals tinted with purple, which is more intense on the broader undulate petals. The lip is beautifully crisped with a pale margin, while the front lobe is a rich purple which is extended into the throat. This species is of recent introduction, and is as scarce as it is beautiful. It is named in compliment to Mr. F. L. Ames, of Boston.

Brassia verrucosa is an old and well-known Orchid which produces many-flowered racemes of curious flowers with attenuated sepals and petals of pale green, dotted near the base with dull purple. The spreading lip is white, marked with the green, wart-like excrescences which give the specific name to the plant. It is a native of Guatemala, and is particularly easy to grow in open soil of peat and moss, the temperature of the intermediate house suiting it best. At this season of the year its flowers—though by no means showy—are welcome, and their grotesque appearance always attracts attention. There is a strong-growing variety with superior flowers called *Grandiflora*.

Dendrobium moschatum is a very strong-growing, evergreen species introduced from India more than sixty years ago, and formerly to be seen in nearly every garden, where stove-plants were grown. The best grown plants I have yet seen were trained to the roof of one of the old-fashioned stove-pits, and subjected to the strong, dry heat of a brick flue. Under this treatment the immense bulbs were thoroughly ripened, and produced every year a tremendous crop of bloom which hung from the roof like bunches of grapes. Of late years this old plant has had to give way to newer and more showy kinds, and is now seldom seen. The bulbs are very stout, six to eight feet long, furnished with oblong, ovate, leathery leaves. The flowers are produced in pendant racemes about a dozen in number, usually from the sides of the leafless bulbs. They are about four inches across, creamy-buff suffused with rose; the slipper-shaped lip is pale yellow, ornamented with two large blotches of dark purple. They last about a week. This is one of the easiest Orchids to grow, preferring strong heat and abundance of water during growth. A long rest with good exposure to sunlight will insure abundance of flowers. If pot-bound, liberal applications of liquid manure will be beneficial.

Anguloa Clowesii is a Colombian Orchid found at medium elevations, and does best when treated as an intermediate. A compost of peat and loam with chopped leaves, with plenty of sand, suits it, and so do an abundance of water and air during growth, and a long and somewhat dry rest. It is a large-growing kind with oblong, ovate bulbs and plicate leaves about two feet long. The scapes are produced from the base of the young growths, and bear a single, large, Tulip-like golden-yellow flower, with a pure white lip and very fragrant.

Kenwood, N. Y.

F. Goldring.

Savoy for Winter.—For home use the coarse Drumhead class of Cabbages should be discarded for the more delicate Savoy. The Netted Savoy is best, but the American Drumhead Savoy is larger and fairly good. I set the plants generally upon a strawberry-bed after the fruit has been gathered, burying the strawberry-sod deeply with a large plow. Then a heavy coat of fine stable-manure is spread over the plowed surface, which is harrowed lightly, and rows are cut to set the plants three feet apart each way. In all late summer crops in the garden it is better to spread the manure on the surface after plowing, and keep it there by shallow culture. It thus serves the double purpose of a fertilizer and a mulch. If stable-manure is not to be had good raw-bone or bone-black superphosphate, at the rate of about 1,000 pounds per acre, is the best substitute. As soon as the plants recover from the transplanting, cultivation should begin, and the surface should be kept constantly stirred. There is an old superstition that Cabbage must not be cultivated during dog-days, but the only time when cultivation should be suspended is when the leaves are wet with dew or rain. To keep off the Cabbage caterpillars we use Pyrethrum, the *Pieris rapa*, which come first. The later enemies are the larvæ of *Plusia brassica*, which generally come in larger numbers, and are so much more difficult to destroy, that of late years we have given up the fight, and try to encourage such a rapid growth of the plants that the caterpillars cannot keep up with the increasing heads. For this purpose we use nitrate of soda, mixed with superphosphate, scattering about 100 pounds per acre at two applications, just before working the plants. Its effects are wonderful in promoting a rapid growth, and we generally succeed in outwitting the worms and making a crop in a good season. Here we defer planting our Winter Cabbage until late in July, to avoid the Harlequin Beetle. This insect has not been troublesome in the north yet, but here it is the worst mid-summer pest we have on Cabbage. Every leaf attacked withers as though fire had passed over it. North of Virginia Winter Cabbage had better be planted the first week in July.

W. F. Massey.

Orchids in New Jersey.—Although small in comparison with the area of many other states, New Jersey possesses a surprisingly rich flora of its own. Its shady hill-sides and extensive swamps are peculiarly adapted to the growth and reproduction of the various members of the Orchid family indigenous to the eastern States. I have found places in shady woods where *Cypripedium pubescens* and *C. parviflorum* were found covering acres of ground, the fragrance of their flowers being especially noticeable. This I have never found so pronounced when plants were grown in gardens. These two plants are found growing in clumps together here, and it would appear

Oak Woods at Belmont.—See page 326.

as if the one might be a minor form of the other. *Orchis spectabilis* is plentiful in the same locality, and so are *Habenaria Hookeri* and *H. orbiculata*, all thriving luxuriantly in the rich vegetable mould, the result of ages of growth and decay. *C. acaule* grows on lower levels, and appears to thrive best in a

drier soil. Just what this plant needs to keep it in cultivation we have never been able to ascertain. During the past few days I have found whole colonies of *Pogonia ophioglossoides* and *Calopogon pulchellus*, the former noticeable for its exquisite sweetness and the richly-marked lip, while the *Calopogon* could be distinguished at a long distance by its purple flowers, an inch and a half in diameter. If these two plants were exotics how they would be sought and appreciated. The same may be said of *Cypripedium spectabile*. This plant is found near Lake Hopatcong, and is said to be quite plentiful, though we never had the good fortune to find more than a few plants. *Habenaria fimbriata*, *H. virescens* and *H. lacera* are now in flower. The two latter have inconspicuous green flowers, and are often passed by unseen. In July and August the orange-colored *H. ciliaris* will be at its best. I shall never forget the impression made by the first glimpse of a swamp of many acres tinged over with the bright golden-yellow of the Fringed Orchis. The plants were found growing literally by the thousand, and showed considerable variation in the color of their flowers. *H. tridentata* and *H. psycodes* are also found at the same place and time. I have seen quantities of *Arethusa bulbosa* that were collected near here in New Jersey, but tried in vain to learn the locality, and although it is quite plentiful in some parts of the state, it has never been my good fortune to find it. Last year I found one plant of *Habenaria rotundifolia*, which is rarely seen so far south. This year I sought it again, having carefully noted the spot, but it was gone. Some zealous collector had probably found it and taken it away.

Passaic, N. J.

O.

Scabiosa Caucasica is a first-rate hardy perennial, with beautiful flowers of a fine shade of blue, and should be more commonly grown. Frequent complaints are made that it is a difficult plant to establish, but with proper care it will grow vigorously in any deep border. Probably the failures result usually from careless shifting of seedlings, which, even in a young stage, have a long tap furnished at the lower end with fine feeding roots, which one is apt to strip off if not careful in breaking out of the seed-bed, the result of which is total failure of the plants to grow in their new quarters. It is well in planting seeds of this plant to use a good depth—say six inches—of light soil, so that the fine roots may have full run and be readily lifted without stripping.

Tridax bicolor, var. *rosea* is a pretty new composite introduced to cultivation in 1888 from north-eastern Mexico. It is a half-hardy annual, forming a neat, erect, much-branched bush about two feet high. The flower heads are borne well above the ovate foliage singly on long footstalks, and are from half an inch to one and three-quarter inches in diameter, of a pleasing rose color, the disk florets being yellow. It is very floriferous, continuing in bloom till frost. The typical *T. bicolor* has the ray florets pure white.

Border Carnation, Paul Engelheart, is a variety discovered in a cottage garden by the well-known amateur, Mr. Engelheart, and introduced last year. It is a very vigorous variety, with strong, wide leaves, the flowers being of a rich shade of deep crimson, fragrant and plentiful, borne on stout, erect stems, only eight to nine inches high, and requiring no stakes, a merit which will be appreciated by any one who has had to do with garden Carnations, which are mostly of lanky growth, and if unstaked or staked are usually equally unsightly. Among the series of Carnations in my border this neat dwarf variety is certainly the most sightly and satisfactory. It is to be hoped that we may be able to secure other colors with some habit.

Elizabeth, N. J.

J. N. Gerard.

Notes from the Arnold Arboretum.

SOME of the small-fruited Vines are attractive and useful ornamental plants. There are three east-Asiatic species found in gardens in this country, although they are not at all well known, and there is everywhere, judging from the different names under which these plants have been sent to the Arboretum from European gardens, the greatest confusion about their names, which are often interchanged.

The first of the three species to be considered is *Ampelopsis heterophylla*. This is a widely distributed, but not very variable, plant from Manchuria, Mongolia, and through China to Japan. It is a vigorous and hardy climber. The stems attain here a height of ten or twelve feet or more, with ovate or slightly-lobed leaves, or sometimes deeply three or five-lobed with deep, broad sinuses, the bases rounded, cordate or almost truncate. They are smooth above; the under surface of the mid-rib and primary veins covered with stout hairs. The flower-cymes are corymbose, long-stemmed and widely

branched. The fruit is the size of a pea and bright blue when ripe.

There is a Japanese variety with variegated foliage, often found in gardens, under the name of *Vitis Sieboldii*. This is the *V. elegans* of Koch, and the *V. vinifera foliis variegatis* of Neubert. The leaves of this form have deep, broad sinuses. The north China variety with slightly lobed leaves, somewhat cordate at the base or those near the end of the stems, with three or five broad lobes, is *Ampelopsis humulifolia* of Bunge, figured in the *Botanical Magazine*, t. 5, 682. It is the *Vitis Reliiana* and the *V. orientalis* of Hort. Kew; at least plants of this species have been sent to the Arboretum from Kew under these names.

The second species is *Ampelopsis serjaniæfolia*. This is a very distinct and ornamental species, easily recognized by the broad wings on the leaf-stalk between the leaflets. It is a native of north China and Japan, and has been described under half a dozen different names. It has smooth, rather slender branches climbing here eight or ten feet high, palmately five- (or rarely three-) foliolate leaves, with narrow, trilobed and incisely cut leaflets, dark green and lustrous on the upper and somewhat paler on the lower surface. The cymes are dichotomously divided, and the fruit is small, the size and shape of a pea, pale violet-blue with darker blue spots. It is the *Cissus viticifolia* of Siebold and Zuccarini, the *Vitis pentaphylla* of Miquel and the *Ampelopsis napæformis* and *tuberosa* of Carrière.

The third species, *Ampelopsis aconitifolia*, of north China and Mongolia, may be distinguished from all the Vines of eastern Asia by its nankin-colored fruit. It is a slender plant, with three to five-lobed leaves, which are often divided into three to five palmately disposed leaflets. The leaves are cuneate at the base, sharply and unequally dentate, dark green and glabrous on the upper surface; the lower paler and hairy on the mid-rib and primary veins. The cymes are long-stemmed and several times dichotomously branched. The fruit, rather larger than a pea, is nankin-colored.

There is a form in which the leaflets are divided into narrow, acuminate lobes, which is as hardy and even more ornamental than that with broader leaflets. It is the *A. dissecta* of Carrière; and it is this variety upon which, according to Panchon, in the Monographs of DeCandolle (v. 2, 459) the species was first established by Bunge, and which was found by the Abbé David in Mongolia.

Cissus Japonica, a native of Japan, the East Indies and Australia, with immense tuberous roots, and annual stems climbing four or five feet high, has stood uninjured in the open ground during the past winter, and appears to be perfectly hardy. It is rather a botanical curiosity than an ornamental garden-plant.

Two of the small-fruited North American Vines are admirable garden plants also. *Ampelopsis indivisa* is the species most commonly found in gardens. It is a high-climbing, glabrous vine with ample, heart-shaped, coarsely-serrate, rather thin leaves, and small, loose panicles of small flowers; the fruit about the size of a pea. It is a common plant along the banks of streams from Virginia and the Ohio southward, where its graceful branches may be seen draping tall trees and hanging down over the water. It is perfectly hardy here, and perhaps the best plant of its class in this climate.

Ampelopsis bipinnata is a more ornamental species, with twice pinnate or ternate leaves, the leaflets sharply cut-toothed and small obovate fruit. It is a more southern plant than the last and is not, unfortunately, quite hardy here, although in the neighborhood of New York it succeeds admirably. Less vigorous than *A. indivisa*, it is rather inclined to be shrubby in its habit of growth.

Clematis Eriostemon is one of the hardiest and most satisfactory plants of this genus here. It produces long, woody stems destitute of tendrils, sometimes eight or ten feet long. The stem leaves are pinnate, with three pairs of lateral, entire, oval, three-nerved leaflets, and a terminal leaflet often lobed and long petioled. The leaves on the flowering shoots are sessile, simple and entire. The dark-blue flowers are long-peduncled, about three inches across, and appear in succession during two or three months in the greatest profusion, completely covering, sometimes, the plant from a point near the ground to the extremities of the stems. The origin of this charming plant, which was first described under this name by Decaisne in the *Revue Horticole*, 1852, p. 341, with portrait, is entirely unknown. M. Lavallée, who introduced an excellent figure of it in his "Les Clématites à Grande Fleurs," suggests that it is, perhaps, of American origin, but this is hardly possible. It is an old inhabitant of gardens, where it has been cultivated as *C. Hendersoni*, *C. Chandleri* and *C. Poizati*. In

England it has been considered a hybrid between *C. viticella* and *C. integrifolia*. But whatever its origin, it is a far more desirable plant in this climate than any of the more modern and now more fashionable, larger-flowered varieties, which, with few exceptions, have here proved themselves short-lived and very unsatisfactory.

Correspondence.

Forests and Civilization.

To the Editor of GARDEN AND FOREST :

Sir.—I have recently asked several of the thoughtful men of our country for some expression of their interest in forestry subjects, and have just received the following letter from Professor C. E. Norton, of Harvard University :

"Dear Mr. Harrison :—The strange, hideous, barbaric spectacle which the rush to Oklahoma has presented during these last weeks affords the clearest proof that the work in which you are engaged, of endeavoring to rouse the conscience of our people to a sense of the prevalent misuse and waste of the natural resources of the country, is of prime, national importance, not only from the material but also from the moral point of view. Were the proper use of these resources understood there would have been no such scene of savage struggling to gain possession, by fair means or foul, of the fancied advantages which this territory, now for the first time open to settlement, is supposed to offer.

"It is now many years since the late eminent George P. Marsh, in his most interesting and instructive work on 'Man and Nature,' demonstrated the fact of the calamities and desolation which had fallen upon many once fertile regions of the earth through the ignorance and reckless disregard of man, in dealing with the soil, of the laws by which its permanent resources for human support are maintained and replenished. His demonstration fell for the most part upon deaf ears. Never has the waste of what should be the permanent, inexhaustible fund of a nation's prosperity been exhibited on so wide a field as in our own country during the past twenty years. We have been living like spendthrifts, flinging away treasures slowly accumulated during the past without consideration of the rights and interests of future generations or recognition of our responsibilities toward them. We have used the goods of Nature as if we were sole and absolute owners of them. We have behaved like fraudulent trustees. A people can only justify its claim to be called civilized by so using the free gifts which it has received from Nature and its own predecessors as to transmit them undiminished and improved to its successors.

"All good men, all men who love their country and who desire that the democracy of America should set an example of rational, manly, intelligent and moral national life, must desire your success, as the agent of the American Forestry Congress, in the work which you have undertaken.

With the highest regard, sincerely yours,

"Cambridge, Mass.

C. E. NORTON."

I should like, with your permission, to write a series of notes on forest interests and affairs in this country, with allusions to contemporary journalism, literature and life. There is always occasion for vital and discriminating discussion of these subjects, and the need of it increases of late. For many years I have observed the course and methods of action of the people of the United States in their treatment of their forests and woodlands, and have studied the disappearing woods themselves, in nearly every part of our country, with deep interest in the relation of the forests to our national civilization and development. I remember many years ago when I began to talk of this relation, even men of a high degree of general intelligence often asked, "What have forests to do with civilization?" Since the establishment of this journal the idea has been more definitely presented, and such a relation has been generally recognized in the discussion of forestry subjects in these pages, but the idea is still unfamiliar and needs further development.

It is not wonderful that people do not readily receive the notion of such a relation, for the popular ideas of civilization, and of nationality itself, are extremely nebulous, incoherent and inadequate. A nation should be a vital unity—a population organized for intelligent co-operation for the attainment of worthy practical ideals. The sentiment of nationality, or what is called by that name in our country, is still superficial and indefinite, with little vital relation to the present time, and our national life is in great degree inorganic, made up of scattered nuclei, and without common direction. We are wanting in some of the elements which are necessary to the persistence

of national individuality. Our "magnificent vitality," to use the phrase of the centennial orators, lies all abroad, and is, thus far, not able to come to time, or to get down to the serious business which requires our attention. The principal adequate and manly thing which we have done as a nation, the fighting out of the great controversy over slavery, though inevitable, was largely of the nature of an accident, something apart from the natural and essential continuity of our national life and history.

The Civil War has already become, to a great extent, a part of ancient history. Its lessons have little relation to the needs of our time, and the fact that "we put down the Rebellion" does not render it certain that the problems of the present and the future will solve themselves, or that the enemies which now threaten our national prosperity and success will be frightened out of our path by the shouts with which we celebrate past triumphs. We may have a splendid destiny before us, but it will not be the product of our present national temper or character, nor the result of the methods which now prevail in our national house-keeping. Nothing splendid lies along the roads upon which we are now mainly traveling.

As to civilization, it does not appear that those who talk of it most boastfully have thought much about what it is, in what it consists, or how it may be maintained and carried forward. They never have anything definite to say about it. The popular optimism may have a basis in reality, but its prophets have no liking for scientific methods of inquiry. They are either incapable of analysis, or they regard facts with contempt. If our people had the idea of nationality, and a definite perception of what constitutes civilization, they might be brought to see clearly the relation of the nation's forests to its development and welfare.

There is a great deal of talk about forestry in this country, but I cannot find out that we have much of the thing itself. Forestry is an art, and it can be learned only by practicing it, and it can be practiced only where there are forests to be administered or cared for. The art has not been practiced in this country. The only forests in which it could be illustrated and practiced, and thus learned, are neglected, outrageously abused, and as rapidly as possible destroyed, so that we have here no means, material or opportunity for training young men in a real knowledge of forestry. We have some admirably equipped dendrologists, but forestry in the United States is a matter of talk, of Arbor Day oratory and essays at Forestry Congresses. We shall build nothing valuable on a basis of unreality, and to clear the ground of misconception and illusion is usually a necessary beginning for any serious work or real advance.

J. B. Harrison,

Cor. Sec. American Forestry Congress.

Franklin Falls, N. H.

The Choice of a "National Flower."

To the Editor of GARDEN AND FOREST :

Sir.—It has not seemed to me that the question of a "national flower" for the United States, so widely discussed in the press, had a very serious interest either for patriots or for flower-lovers. Of course, if we could choose and bring into general use a floral emblem of the right sort, it would conspicuously enrich the sentimental side of our lives; and, of course, it behooves every patriot as well as every lover of Nature to regard this side. No one questions that a flag is a precious, indeed an indispensable, national possession, or can fail to see that ours is all the more valuable because of the symbolic significance of its stripes and starry field. The utility of such an emblem as the eagle is also plain, for we must have some device to serve in a coat-of-arms and to ornament a multitude of "official" articles. If a flower could be added to the flag and the eagle it would serve more than one end they do not meet, and would be especially valuable as an element to introduce into our decorative art. What a blank would be left in the art of France were the Fleur-de-lis expunged! What a boon would it be to the American decorator had he some such consecrated type ready to his hand!

Nevertheless, the current discussion has seemed without much point, for, discuss as we will, how are we to choose our flower? There is no prince to hand it over to us, already encircled with a halo of significant associations; it seems most improbable that any popular assembly, charged with the settlement of important national affairs, will put the question to a vote, and such an assembly is our only substitute for the personal ruler of old. A flower might have been selected when the flag and the eagle were chosen; and chance may some day give us one, in some great national crisis, when we are thinking least about it. But to choose deliberately by "popular" voting, and then to impose the choice upon a nation so

immense and so widely scattered over different soils and under different skies—this seems, indeed, a hopeless effort.

Being hopeless—or seeming so to me—your readers may wonder why I speak of it at all. And yet I have a reason for speaking, the reason implied when I said at the outset that a national flower would be a valuable possession could we get one of the right sort. By this I mean that, even if it were perfectly easy to choose a national flower and bring it into universal use, it would be of next to no value if it were of the wrong sort; and the fact is important because, of the four flowers thus far “ahead at the polls,” only two have any claims to be considered of the right sort. These four are the Golden-rod, which seems beyond all others to be the favorite; the Mayflower, which comes next; the Sunflower, and the Mountain Laurel.

In the many discussions and exhortations which I have read upon the subject, and in the reports of the preferences of famous individuals, there has been much mention of sentimental associations as dictating this choice or that, and also of facts of distribution and general familiarity. These questions have their importance, of course, but it seems to me that the primary consideration is an artistic one—has regard to the serviceableness of the proposed form as a type or model for artistic variation. Let me try to explain what I mean by taking each of the four favorites in turn.

The Golden-rod, in some of its protean shapes, is very widely distributed throughout the United States, and familiar enough to be beloved by all Americans; and though it grows in other countries it does not grow in Europe (unless as introduced in gardens), except in the higher parts of Switzerland. It has no associations, therefore, which unfit it to be our national emblem; and it is a good flower to wear on the person as a badge—individual, bright, pliable, graceful and lasting.

The Mayflower is likewise a characteristically American plant, with relatives in Asia but none in Europe. As regards sentiment, it has perhaps a higher claim than any of its rivals. Was not the first Pilgrim ship called the “Mayflower,” and does it matter to the short memories of men that the name did not denote our Epigea, but undoubtedly the English Hawthorn? But the Epigea is a poor flower to wear—charmingly pretty when grown or even when massed in a large dish, but ineffective as a little spray—stiff in habit and very perishable; and, while it is very familiar in the eastern States, it is unknown “out West,” and therefore has but a half-claim to adoption as a national flower.

The same lack of universality affects the claims of the Mountain Laurel. From North to South, eastward of Kentucky, it is very familiar, but our occidental regions know it not. Yet it is another true American, seen in Europe only in gardens; and it is a good flower to wear, while its ever-green leaves, with a distinctive character of their own, would be available at all seasons.

The Sunflower, like the Golden-rod, grows everywhere in our country, varying in different localities, but keeping its essential character throughout; and it is nowhere a native of the eastern hemisphere. But cultivation in this case has largely undone the favor which Nature did us in making this flower our own. It is so commonly grown in Europe to-day it can hardly be called a true American. What would the “*æsthetes*” of England say did we exalt the Sunflower to be national emblem? And should we not feel like English *æsthetes* instead of American patriots, did we go about with a Sunflower on our bosoms? Seriously, whenever an American sees or hears of Golden-rod, Kalmia or Trailing Arbutus he thinks of his own country and of nothing else; but the case is very different with the Sunflower, and I think the difference seriously invalidates its claim to be adopted as an emblem of the United States.

Let us look now at the adaptability of these flowers to the designer's purposes. What we want is that it can be used, like the Lilies of France, on everything which man's hands can ornament; from a coin to a button, from a pennant to a carpet for the White House, from the capital of a column in a public building or the pedestal of a hero's statue to the binding of a copy of the census.

Of what account, now, is the popular Golden-rod for such purposes as these? To be rightly used in art a flower must be conventionalized, and to be conventionalized each head or blossom must have individuality and, so to speak, architectonic dignity. The flower of the Golden-rod has no individuality, when we stoop to study it; isolated from its fellows it looks precisely like numerous other flowers of the vast family of the *Compositæ*. And, moreover, we never do isolate it; the Golden-rod as we think of it is not a flower but a panicle of many minute heads, and to separate them would be to ruin

the type, even had the heads each a more special character. The character of Golden-rod comes, in short, not from its flowers but from the way they grow; this loose, irregular way cannot be reproduced in strictly ornamental art; and a single little head used alone would look no more like Golden-rod than like Aster or Fleabane. Then the foliage of Golden-rod, while it varies very much in different species, is never really beautiful or individual or well adapted to use in the arts.

The Mayflower is a little better, yet it is by no means a good flower for the artist. It is not strikingly individual; it is ineffective; it is weak in form and somewhat trivial; it lacks the two indispensable qualities—dignity and special character.

The Sunflower is a cousin of the Golden-rod, and one of its great heads resembles in large the tiny head which we scarcely notice as such in a *Solidago*. But this increase in size and distinctness makes all the difference in the world as regards use in the arts. A Sunflower is a flower meant to be seen alone, and it is so formal, so massive, so stately that it could admirably serve every purpose of the designer. But the same unfortunate fact again confronts us. Modern “*æstheticism*” has made this flower its own, and so frequently reproduced it, with more or less artistic felicity, on a myriad objects of the most trivial sort, that it would seem absurd for the American decorator now to seize upon it, and for the American people to try to read into his reproduction any sign of patriotic meaning. Sunflowers on the base of a hero's monument or around the capital of a post-office column—the artistic effect might be admirable, but the sentimental effect would be entirely different from the one we desire. A generation ago we might have made this flower our emblem and rejoiced in its use. I fear it is spoiled for the purpose to-day.

But something still better is left us in the Kalmia. Here is a plant which neither art nor sentiment has touched as yet, but which seems to have been created for the artist's hand. Its leaves are so like those of the Laurel, which from time immemorial has been an artist's favorite, that its popular name has sprung from likeness; they are fine in outline, solid in aspect, and beautifully grouped, on the stem, needing but a trifle of arrangement to fit them for the weaver's or the carver's use.

Still more beautiful, infinitely more individual, is the flower of the Kalmia in every stage of its growth. Look at the conical bud with its deeply-cut, symmetrical flutings, the admirable contrast between the upper and the lower portions, and the ten strong points where they meet; see how architectonic it is, whether viewed sidewise or foreshortened from the top. Look at the half-expanded blossom, where to these sculptural beauties are added the wide, deep, simple indentations of the lip; and look at the expanded blossom, a beautiful five-pointed star, with ten radiating stamens running each to its deep little cleft; and if anything beyond the artistic excellence of the form is asked, examine the artistic beauty of the color-markings. How easy it would be to conventionalize this blossom, seen from the inside or the outside, and how beautiful it would be, in paint or tissues or carvings, when thus conventionalized. Conventionalizing, indeed, is hardly the right word—Nature has done the artist's work in this case; the flower could be almost literally copied and be systematic and dignified enough. A temple frieze might be made as nobly beautiful with a Kalmia pattern as with the Lotus of the Egyptians or the Honeysuckle of the Greeks, and with far less deviation from actual portraiture. So, too, on woven stuffs it might be as effective, almost, as the *Fleur-de-lis* of France, and again with much less change—for the *Fleur-de-lis* has been changed so greatly that we cannot be quite sure whether it really means an Iris, as is generally thought, or some other related flower. Indeed, I can think of no flower which in its various stages offers so many quite admirable types for artistic treatment as the Mountain Laurel. Turn back now to the Golden-rod and the Mayflower, compare them with the Lotus or the Honeysuckle or the *Fleur-de-lis*—what must the verdict be? It is, or should be, a decisive verdict against them both as proper to be chosen for a national emblem. Why did the Violet of the Napoleons never impress itself upon national sentiment like the Valois Lily, and never enter into national art? Why was the place it should have held in art taken by the Napoleonic bee? Simply because it was not susceptible of artistic treatment. It is pretty, but it has no dignity; it is graceful, but it has no “form” in the artistic sense, no architectonic, sculptural character. This the Kalmia has. If the fact is not so immediately apparent in its case as in the case of the Lotus or the Iris, it is because the blossom is smaller and few people notice characters which are not boldly thrust upon their eyes. But size means less to the artist than “form,” “character,”—and no flower in the world has these in greater perfection than the Mountain Laurel.

If, then, we really want a national flower, and if there is really a way to decide upon it, could not the one deficiency of the Mountain Laurel—the fact that it is not universally distributed throughout our country—be overlooked because of its manifest superiority in other points? The Great West has taken much that pertains to national life from the East. Could it not be persuaded to take a national flower as well?

New York.

M. G. Van Rensselaer.

Squirrels and Conifers.

To the Editor of GARDEN AND FOREST:

Sir.—Several correspondents of GARDEN AND FOREST, whose opinions are certainly entitled to consideration, hold the red squirrel responsible for cutting off and scattering the twigs of the Norway Spruce. The red squirrel does a good many curious things, apart from the heinous offenses he perpetrates upon his larger black and gray cousins.

In the cases cited it may be that owing to the mildness of the past winter the red squirrels were more active than usual, and having exhausted their supply of nuts, turned more particularly to the Spruce cones for food. The squirrel does not dislike a cone when he cannot get his nut. Indeed, the nurseries would be without the *Sequoia gigantea* to-day were it not for the squirrels, who cut the cones off from the Californian big trees, the seeds of which were otherwise unobtainable. Thoreau refers in several instances to the squirrel's manner of plucking and stripping a Pine cone. "He does not prick his fingers, nor pitch his whiskers, nor gnaw the solid cone any more than he needs to. Having sheared off the twigs and needles that may be in his way (for, like a skilful wood-chopper, he first secures room and verge enough), he neatly cuts off the stout stem of the cone with a few strokes of his chisels, and it is his. To be sure, he may let it fall to the ground, and look down at it for a moment curiously, as if it were not his. But he is taking note where it lies, that he may add it to his heap of a hundred more like it, and it is only so much the more his for his seeming carelessness."

This would bear out the theory of several of your correspondents, were it not for three reasons—the torn or mangled, not cut, appearance of the tangled twigs; the many fallen twigs beneath trees where no cones, or hardly any cones, exist, and the scattered twigs in masses where there are no squirrels in the near vicinity. These scattered twigs are repeatedly noticed beneath the Norway Spruce during early spring, and late in April they might have been seen in quantities on my neighbor's lawn beneath his patriarchal Norways. The same state of things is observable in the case of the White Pine. As the red squirrel works by day, he would be seen, and if not seen he would be heard were he the spoiler in these instances. It is to be noticed, moreover, that the trees underneath which the scattered twigs exist most numerous stand most exposed to the wind, and that the side of the tree facing the west is noticeable for the quantity of dried and bruised twigs upon the tree.

If we consider for a moment the fury of the wintry gale, especially when the limbs of the tree are coated with ice and lashed one against the other for hours, the cause of the scattering of the twigs and needles will, in most instances, I think, be apparent as due to high winds, and not to a rodent's tooth.

Rochester, N. Y.

George H. Ellwanger.

[We have received several other letters on this interesting subject; but it may be well to refer the writers to the original article on page 111. It was there stated that squirrels, both gray and red, had been seen to cut off the small twigs of the Norway Spruce in order to get at the terminal and lateral buds (not the cones), the heart of which they dextrously extracted. Examination of the twigs on the ground last winter showed that in cases where the buds appeared sound the heart had been neatly taken out.—Ed.]

To the Editor of GARDEN AND FOREST:

Sir.—Will you kindly inform the readers of your journal what is the proper treatment for the beautiful *Rosa multiflora*, described in the notes from the Arnold Arboretum, on page 309, and especially whether this plant should be cut back to induce free flowering.

Boston, July 1st.

W. W. C.

[*Rosa multiflora* should be planted in rich soil, where it can have plenty of room to spread its graceful, arching branches without being interfered with by other plants. Young, stout shoots produce the best flowers, and their development should be encouraged by cutting off the

flower-clusters as soon as the flowers have faded, and by shortening in the branches at the same time to induce the growth of lateral shoots. Old branches should be removed entirely after they have flowered during two or three years, to make room for more vigorous ones which will spring up from the roots of well-established plants. A plant of this species, generously treated, may be expected to grow six or eight feet high and ten feet through, and to be completely covered with flowers at the blooming period.—Ed.]

To the Editor of GARDEN AND FOREST:

Sir.—I am glad to see GARDEN AND FOREST calling attention to the importance of preserving our national and state parks. The State of Wisconsin, in 1882, set apart some twenty or more townships in what was then Lincoln County as a state park. The scenery is bold and rugged. It is a land of heavy timber and lakes and running water—its natural features finely adapted to the purpose to which it was devoted. But last winter a bill was introduced near the close of the session to allow the Pine-timber to be cut, and to destroy the native beauty of the tract. I am glad to say that the bill failed. It was, however, a fair warning to the friends of forestry and state parks to be on the alert, for similar attacks will, no doubt, be organized year after year.

Recent Plant Portraits.

LÆLIA DIGBYANA MOSSIÆ, *Gardeners' Chronicle*, May 25th; "decidedly one of the most remarkable, and with equal certainty one of the most beautiful of the hybrids raised in the great Veitchian establishment by Mr. Seden." A hybrid between *Cattleya Mossiæ* and *Lælia Digbyana*.

CATTELEYA SKINNERI, *Gardeners' Chronicle*, June 1st; the portrait of a remarkable specimen with 200 expanded flowers.

PSORALEA PINNATA, *Gardeners' Chronicle*, June 1st.

PUCCINIA SCHRÆTERI, *Gardeners' Chronicle*, June 1st; this is the Fungus which is doing much damage among the Narcissus in some English gardens.

"It is sufficient to say that *Puccinia Schræteri* is closely related to *P. malvacearum*, the deadly pest of Hollyhocks; and the life-history of the fungus of Narcissus agrees with that of the Hollyhock. Many species of *Puccinia* have a Uredo, or young condition, but no Uredo is known for either the Narcissus or the Hollyhock fungus. Neither has any æcidium condition been recorded for either; this being so, the readers of the *Gardeners' Chronicle* will understand that the spores of the Narcissus fungus germinate as soon as they are mature upon the host-plant, and produce at once new pustules of spores. The fungi to which the Narcissus fungus belongs produce many generations of spores in one season, and so make great havoc in gardens, as every one acquainted with the history of the Hollyhock disease knows only too well. Diseased plants should, of course, be utterly destroyed, if possible, but no amount of burning or burying will get rid of all the minute spores which are produced in hundreds of thousands upon every affected plant. The new arrival is not confined to one species of Narcissus; it has been recorded on *N. poeticus*. The fungus may be considered a very threatening one, but time only can show whether it will spread in Britain as did its ally, *P. malvacearum*."

ÆSCULUS SINENSIS, *Gardeners' Chronicle*, June 8th; a native of northern China, and a still imperfectly known species. The figure is from a specimen of the flowers produced in the establishment of M. Van Volxem, of Brussels, where it is probable that this tree has flowered for the first time in Europe.

CATTELEYA WALKERIANA, *Gartenflora*, June 1st.

CYPRIPEDIUM NITENS SUPERBUM (*C. villosum* × *C. insigne* Maulei), *Le Moniteur d'Horticulture*, June 10.

CHRYSANTHEMUM ULIGINOSUM, *Gardeners' Chronicle*, June 15; a hardy, decorative, autumn-blooming plant with large, white flowers.

AMORPHOPHALLUS TITANUM, *Gardeners' Chronicle*, June 15; this, the largest known of all the Aroids, has recently flowered for the first time in Europe, in the Victoria House at Kew. It is to be gathered from our English contemporary that Dr. Beccari discovered this wonderful plant in western Sumatra. "The tuber dug up by the doctor measured nearly five feet in circumference, and was so heavy that ten men could scarcely carry it. From this tuber only one leaf is produced; but what a leaf, to cover an area of forty-five feet in circumference."

The leaf-stalk is ten feet high, divided at the top into three branches, each as large as a man's thigh. The flower spadix is six feet long, and, altogether, this must be considered one of the vegetable marvels of the world.

BOUGAINVILLEA GLABRA, *Revue Horticole*, June 16.

Notes.

The first prize for cut blooms of double Lilacs at the Paris Exposition was taken by Messrs. V. Lemoine & Son, with flowers of twenty seedlings named and unnamed, and including the double white variety.

The programme for the Botanico-geographical exhibition which, as we have already announced, will be held in Antwerp during the summer of 1890, may be obtained from Monsieur Charles de Bosschère, Lierrelez-Anvers, Belgium.

According to the *Pacific Rural Press*, California has produced two new Roses of undoubted excellence this year. One, introduced by J. H. Sievers, is known as Rainbow, and the other, yet unnamed, was raised by E. Gill, of Oakland.

Mr. H. H. Rusby, well known as a botanist from his explorations in southern New Mexico, and later in South America, has recently been appointed Professor of Botany and Materia Medica in the New York College of Pharmacy, in this city.

A correspondent of the *Country Gentleman* writes that he once heard Dr. William Darlington, the well-known botanist, express the wish that the Tulip-tree (*Liriodendron tulipifera*) might be selected as our national emblem, both leaf and flower being distinct and beautiful.

A very interesting hybrid Philadelphus, lately bloomed at Nancy. It was produced by crossing *P. microphyllus*, the beautiful dwarf species with deliciously fragrant flowers, which is a native of the mountains of southern Colorado and New Mexico, with *P. coronarius*. The plant has been named after its originator, *Philadelphus hybridus Lemoinei*.

Among the bush Honeysuckles, *Lonicera Ruprechtiana* is now by far the most striking. Its abundant bright scarlet fruit, carried gracefully on arching branches, would make it one of the most desirable of hardy shrubs, even if it were not beautiful in general habit, foliage and flower. Its single fault is that the flowers lack perfume.

Cladrastis Amurensis, the Old World representative of our Yellow-wood, is blooming most abundantly this year, and as the specimens grow older the tree becomes more attractive. The foliage is very clean, the shape of the tree neat, and the spikes of flowers are fragrant and yield abundant nectar, as is proved by the constant hum of the bees, which visit this tree in great numbers.

English horticultural journals describe a splendid display of Tulips lately in bloom in the garden of Lord Arlington, at Crichton House. Twenty-four large beds were filled with about 15,000 bulbs, Crimson King and Yellow Prince being the only varieties used. This is but one sign among many that we have noted of late to prove that there is a growing tendency in England towards more simple and effective arrangement of bedding-plants than those which have hitherto prevailed. In the parks of London the Tulips are said to have made an especially attractive appearance this year, "although individually the flowers have not been so fine as in some seasons. . . . The advantage of having distinct beds of one color over indiscriminate mixtures of several shades is most conspicuous."

Mr. Roosevelt, consul of the United States at Bordeaux, recently reported to our Government concerning the wine production of France during the year 1888. He announces a considerable increase over the amount credited to 1887, and explains that the fact is due to the introduction of American vines as stocks. The vineyards of the south of France were the first to suffer from the ravages of the phylloxera, and their owners were the first to test the value of American plants. A large number of vines on American roots bore for the first time in 1888, and so successfully that the most steadfast doubters were converted; a large demand for seedlings immediately followed, and the nurseries have been already exhausted. Preparations are being made to meet the growing demand as quickly as possible, and, according to Mr. Roosevelt, the future is not very distant when the vintages of former years will again be equalled.

A recent number of the *Illustrirte Gartenzeitung*, of Vienna, quotes from Monsieur Charles Joly, Vice-president of the Horticultural Society of France, a description of three enormous trees

which stand in the south of France. One is a Stone-pine (*Pinus Pinea*), the stem of which is two metres in diameter—which means nearly twenty-two feet in circumference—with a crown of foliage that measures twenty-six metres in diameter. Another is a very old Olive-tree at Villefranche-sur-mer, between Nice and Monaco, which seems to have formed part of an ancient orchard, as it has several neighbors of almost equal size; the diameter of its trunk, at a metre above the ground, is the same as that of the Pine just referred to. And the third is a still larger Olive, which stands in the "*domaine de St. Eulalie*." The circumference of this trunk is no less than eleven metres. Its head was greatly injured by a severe frost in 1820, but since then has developed afresh into a compact, spherical shape.

We have more than once referred to the fact that greater simplicity in the planting of flower-beds was becoming the rule in England, much to the enhancement of the effect of private gardens and public parks. Another instance may be quoted from a recently published description of this year's Tulip-planting in Alexandra Park, Manchester. Here there were twenty-eight large circular beds, each filled with a single variety of Tulips, about 300 plants to a bed. Prosperpine, Dussart, Potter, Crimson King, Rosa Mundi, Queen of the Violets and Chrysolora were the varieties used—seven in all—making four beds of each. The contrast of their colors, which was carefully considered in disposing the different beds with relation to each other, was sufficient to produce a very brilliant effect; and it may be noted that the beds themselves were placed where such formal arrangements are well in keeping—fourteen on either side of a long, straight path which runs from the terrace to the principal drive.

An interesting article recently published by Mr. Percy E. Newberry, in the *Pharmaceutical Record* of this city, upon "The History of Medicine in Ancient Egypt" says that some fifteen vegetable remedies are mentioned in a Papyrus preserved in the Leyden Museum, while the so-called "Berlin Medical Papyrus," which dates from the eighteenth dynasty, mentions more than fifty such remedies, "from herbs and fruits to sawdust and chips of Cypress and Sycamore." Mineral remedies were, of course, also largely used; and while many incantations and conjurations were thought to aid the physician in his work, still the manuscripts reveal no dependence upon "hocuspocus or gibberish." On the contrary, the well-known Egyptologist, George Elvers, writes that the famous Papyrus which bears his name and was published by him "shows that it was possible to write in the sixteenth century, B.C., complex receipts, and that the physicians understood how to administer with care the medicines prescribed." Many such receipts are written on the papyri, and some of them, says Mr. Newberry, might well be used to-day for the indicated purpose. Castor-oil, Senna and Caraway-seeds are among the vegetable remedies that were then employed in much the same way as they are to-day.

The park of Holwood House, which lies about fourteen miles from London, on the road to Uckfield, and was formerly the home of William Pitt, is famous for its magnificent trees of many kinds. But there can be none among them more interesting than a double tree recently described in the *Garden*. It is formed of an Oak and a Yew which were originally planted close to one another and the young stems of which were, perhaps, bound together. A "natural graft" was thus produced; the two trunks united and, though a clear line marks the junction of their different barks, there is now but a single trunk of perfectly normal outline, which at three feet above the ground girths nearly twelve feet. The height of the Oak portion is thirty-five feet, and its branches spread fifty-four feet, while the Yew portion is fifteen feet in height with a spread of thirty-six feet. Up to about five feet above the ground, where the Oak sends out two great branches, the Yew seems to absorb nearly one-third of the diameter of the trunk, although it is impossible, of course, to tell how far inward its wood extends. Each of the main branches of the Oak girths more than four and one-half feet and "as they grow in opposite directions . . . and in bow-shape have an appearance that is as peculiar as it is unusual in tree-growth." The Yew stem almost encircles one of these branches and is completely amalgamated with it, "the barks being level and as if inarched at the point of junction." Such a twin growth would be remarkable in any trees of different species, but is doubly striking when one is a deciduous and the other a coniferous tree, and we can well understand that "when viewed from the public path, which is only eleven yards distant, these combined trees present a most curious and unusual appearance, particularly when the Oak is destitute of leaves, as the co-mingled, deciduous and evergreen branches are then most noticeable."

The Treatment of Road-sides.

THE planting of trees along all highways is usually insisted upon as a public duty by persons who take an active interest in matters which pertain to rural improvement. The first work undertaken by village improvement societies is most frequently road-side tree-planting. The activity of Arbor Day is apt to expend itself in the same direction, and very often the work is commendable from every point of view. A long, straight, level avenue with a row of Elms, or Sugar Maples, or Tulip-trees on either side set on smooth turf at regular intervals, is always beautiful. No nobler approach to a stately mansion can be conceived of than such an avenue. As an introduction to a suburban park, or the extension of the main street of a country village, especially when it leads to some object of adequate dignity, such an avenue is always satisfying. But in an open, hilly country, road-sides are not always improved when bordered by a formal line of trees. To one standing on an eminence, slender lines of foliage following the winding of various roads across the landscape would rarely be pleasing, and to one traveling on such roads the constant shade and the unvarying repetition of a tree on either side at equal distances would be still more displeasing.

It does not follow from this that the planting of trees along country highways should be discouraged, but it should be remembered that trees can be agreeably disposed in various ways, and that in many cases an occasional group of trees at a cross-road, or a single tree here and there at desirable points by the wayside, will prove more attractive than a monotonous row on either hand in which each tree is precisely fifty feet from its neighbor. It should be remembered, too, that shrubs and vines, and even humbler growths, should have a place on a road-border as well as trees, and there are many road-borders where they are of much more importance than trees. These thoughts have been suggested by a letter which is published in another column of this issue. This letter will enable any one to realize how trifling an outlay of labor and expense is needed to transform the hot, raw gravel-slope of an excavation or embankment into a sweep of

verdure, which becomes purple and fragrant with bloom in its season. An unsightly gully filled in with brush to guard against a more serious wash-out becomes in its turn a bower of beauty under the directing hand of one who thinks it worth his while to render such service to the wayfarer. We have heard of a piece of road on Long Island which is bright with flowers in their season, through the thoughtful care of the gardener of a large estate near by. We know a mile of country road which grows more attractive every year because a little care is taken to introduce the flowers and shrubs and vines which flourish naturally in that region. Marsh Marigolds and Cardinal flowers have been made at home by the outlet of a way-side spring. Houstonia and Bloodroot bloomed this year where they were unknown before. The thickets are fringed with an increasing variety of Ferns, and Club Mosses are now creeping among them. Even in winter the hedges of wild Roses and the berries on the Red Alder show how a road-side can be brightened by a few hours of attention in a year.

It is hardly to be hoped, however, that every land-owner will be persuaded to take such an active and intelligent interest in the treatment of road-sides. The energetic pathmaster would think it beneath his dignity to plant shrubs or sow flower-seeds to help cover over the seams and scars left by man in the track of all his "improvements." But, fortunately, he need put himself to little trouble in all the hill-country east of the Alleghanies, at least, for Nature, if left to her own kind offices, will at once begin to clothe the desert made by man. No artificial planting can be more attractive than the natural thickets which would fringe almost every road in New England and the Middle States, if they were only allowed to grow. In many places, it is true, such growth would be out of place. Smooth turf running from the wheel-way to, or under, the fences inclosing fertile fields is always attractive. In the rougher country, however, the natural border of shrubs and trees and festooning vines is generally worth preserving. The Thorns and Dogwoods and Viburnums, the thickets of Elder and Hazel, the Bitter-sweet and Clematis and Moon-seed climbing over all—the flora of the world has no more beautiful plants than these and a hundred more which spring up of themselves and flourish until some one with a zeal for "trimming up" attacks them with grubbing-hoe and brush-hook. And when the vines are stripped from the fences, and the brush all cut, gathered and burned, the road-sides are thoroughly cleared, it is true, but a desolation of rocks and ashes is all that is left in exchange for the fragrance of flowers, the beauty and coolness of green leaves, and the melody of the birds among them.

It is a comfort to note that road-borders of native shrubs are being used more and more in the best park-work. Nothing can be more effective than the shrubbery on either side of the drive through the Arnold Arboretum, not only as an appropriate cover for hill-sides where Myrica, Sweet Fern and other low-growing shrubs take the place of turf, but for the distinct purpose of fringing the road. These shrubs are proving themselves no less useful or appropriate along the smooth, broad and well-kept wheel-way than they are in remote by-ways among the hills. Indeed, it is difficult to imagine how the hard, stony gutter-line beside the road-bed could be more agreeably broken than it is by the Wild Roses or Red-root that occasionally stray across it, or how any other shrub would take the place of the Sumachs banked above one portion of the drive. Every one of these shrubs would grace a palace garden, and yet when they modestly appear along a rural highway they are mowed down to "improve the appearance" of the country. If there is no reason to look for any general and organized effort to beautify our country road-sides, let us hope at least that overseers of the highway may in time be induced to refrain from expending labor and money to destroy the native shrubs and vines and trees which clothe so many waysides with beauty as with a garment.

These are native to New England

Notes Upon Some North American Trees.—I.

THE last catalogue of the trees of this continent (exclusive of Mexico) was published in New York in 1885, in a work entitled "The Woods of the United States," intended as a guide to Mr. Jesup's collection of woods in the American Museum of Natural History. This was a condensation, with a few unimportant changes, of the more detailed catalogue of our trees which I had published the year before in the ninth volume of the Final Reports of the Tenth Census of the United States. Since this catalogue was written I have had the opportunity of studying, for the first time in the field, many of our trees during different journeys undertaken for the purpose, especially those found in the extreme southern portion of Florida and in the valley of the lower Rio Grande; and to examine in European herbaria, type specimens of many of the old species. A large number of correspondents, moreover, in different parts of the country have continued to favor me with information bearing upon this subject. Questions of nomenclature, too, are now, perhaps, more than ever before occupying the attention of botanical students; and although the subject is perplexing enough in some cases, I cannot any longer delay a discussion of the names which should be applied to our trees, as the first volume of the new "Silva of North America," which has engaged my attention pretty continuously during the last ten years, will not, it is to be hoped, be much longer delayed, the plates for the illustrations for nearly three volumes being already engraved. It is therefore desirable to print now such changes, from the Census Catalogue, as fuller information than was available when it was written appears to make desirable both as a record of facts and for the purpose of calling out criticism, which, as well as any facts about our trees, it is needless for me to say, will be welcomed from all quarters. I shall now take up, therefore, the Catalogue as it was published in the Census Report, and briefly note such changes as it now seems necessary to make in it. The numbers prefixed to the species are those of the Census Catalogue.

4. *MAGNOLIA CORDATA*, Michx. —Michaux's specimens preserved in the *Museum d'Histoire Naturelle*, in Paris, upon which Richard founded this species, have leaves which are not at all cordate, and are clearly that form of *M. acuminata*, with broadly oval, rarely cordate leaves, more or less pubescent on the lower surface, and rather small, yellow flowers, which Dr. Mohr has found in central Alabama and I have collected on the Blue Ridge, in North and South Carolina, and which Michaux, as his own labels, still attached to the Paris specimens, show, considered to be *M. acuminata*.* I have already proposed for this form, and for the plant known in gardens as *M. cordata*, the name of *M. acuminata*, var. *cordata* (*American Journal of Sciences and Arts*, 3 ser. xxxii., 466). No wild form, it must be said, has been found just like the one, of unknown origin long preserved in cultivation, which has small, canary-yellow flowers, broadly oval and, occasionally, slightly cordate dark green leaves. Two specimens of this variety may be seen in the Harvard Botanic Garden, where they were found already well-grown trees by Professor Gray in 1842 when he assumed control of the garden. The plant so often spoken of by Michaux in his journal as *M. cordata* was *M. Fraseri*, Walt.

5. *MAGNOLIA UMBRELLA*. —Linnæus first named this plant *M. Virginiana*, var. *tripetala* (*Species Plantarum*, 536), and in the second edition of the same work *M. tripetala*. Lamark, twenty-eight years later (*Encyclopédie Méthodique*, iii., 644), proposed for it the name *M. Umbrella*, quoting Linnæus' name as a synonym, but giving no reason for discarding it. The Lamarkian name was taken up by De Candolle (*Systema*, i., 452), the sentence "petala oblonga concava 9-12 (nec 3 ut vult nomen Linnæanum)" explaining his reason for so doing. Many botanists, nota-

bly Professor Gray in all his works, have followed Lamark and De Candolle in discarding the Linnæan name, which was based upon the three broad reflexed petaloid sepals of this species, which, as they are not strictly petals, make it, perhaps, inappropriate. But in natural-history nomenclature it is now well nigh universally acknowledged among working naturalists that a name cannot properly be changed because it happens to be inappropriate. The inappropriateness of the name, moreover, in this particular case is certainly not great enough to warrant its disuse; and I should therefore propose to take up for this species the name *Magnolia tripetala*, L.

13. *CLUSIA FLAVA*, L. —This plant has been considered a native of Key West on the strength of a specimen collected by Dr. Blodgett more than fifty years ago. It has now entirely disappeared from the island, and has never been seen on any of the neighboring Keys, so that it may be supposed that Nuttall, who published Dr. Blodgett's discoveries, mistook in the case of this plant, as he did in that of *Terminalia Catappa*, also included in his supplement to Michaux's *Sylva*, a cultivated for an indigenous plant.

17. *TILIA AMERICANA*, var. *PUBESCENS*. —Professor Gray (*Proc. Am. Acad.*, new ser. xxii., 305) has pointed out characters ("smaller and mostly thinner leaves, distinctly pubescent beneath, yet often glabrate in age; floral bract usually rounded at base, except the uppermost; fruit ovoid, usually lightly costate") which seem to separate this plant specifically from *Tilia Americana*. The oldest name connected with it is *T. Caroliniana*, of Miller (*Dictionary* 204), but, as Professor Gray has suggested (*l. c.*), Miller's characters point to *T. Americana*, as do those of Wangenheim and Marshall, who followed him in the use of this name. Aiton's name, *Tilia pubescens*, will, therefore, be most safely retained for this tree.

19. *BYRSONIMA LUCIDA*, HBK. —This plant, as it appears on the Florida Keys, is a low, slender shrub, rarely attaining a height of six feet; and I have now no reason to believe that it ever becomes a tree. I should propose, therefore, to drop it from the North American *Sylva*, unless it is known to become arborescent in the West Indies.

C. S. Sargent.

The Sumachs.

ALL the Sumachs, as the plants of one section of the genus *Rhus*, of eastern North America are popularly called, are plants of great ornamental value, and if they do not now play a more important part in the decoration of American gardens, it is because they are seen so commonly along the borders of the highways or upon rocky slopes, that they are not supposed to be worth a place in the garden or upon the lawn. In Europe they are often planted; indeed, in the countries of central and northern Europe no exotic plant, with the exception, perhaps, of the American Locust (*Robinia Pseudo-Acacia*), and its varieties, is planted so commonly, or is so generally admired, as the Staghorn Sumach. They are all plants of good habit, with bold and handsome pinnate leaves. The flowers, which are small and greenish-white in color, are not, in themselves, showy or conspicuous, but the great terminal panicles in which they are clustered are striking, from their size and are conspicuous objects. The panicles of fruit, which is a small, dry drupe, covered with scarlet hairs, give great beauty to the female plants in the autumn, for the Sumachs are dioecious, or mostly so—that is, they produce, ordinarily, male and female flowers upon different individuals. The foliage of all the species turns to an intense scarlet color during the month of October, when some of the most beautiful effects of American autumn-coloring are produced by the great masses of these plants, often found spreading over the rocky hills of the New England and middle States.

There are three species of Sumach in eastern North America:

The Staghorn Sumach (*Rhus typhina*) is the largest of them in the northern States, and the one most generally cultivated in Europe. It reaches sometimes the size and habit of a small tree, thirty or thirty-five feet high, with a trunk eight or ten inches in diameter at the base. This, like the branches, is generally more or less crooked or contorted; it is covered with a light brown bark, separating sparingly into very thin, flakey scales. The young branches are stout, forked, entirely

*The two specimens in Herb. Michx. of *Magnolia cordata* are labelled in Michaux's handwriting, the first "*Magnolia acuminata* florib. flavis;" the second "*Magnolia lutea*, fol. acuminatis florib. luteis, collines, territoire de Squirrel's Creek."

destitute of spray, generally crooked, and covered with a dense velvety-pubescent—a character which has gained for this plant its popular name, from the supposed resemblance of the branchlets to the young horns of the stag. The leaves are two to three feet long and are composed of from eleven to thirty-one pairs of lanceolate, serrate, sharply pointed, sessile leaflets, dark green on the upper and pale on the lower surface. This species flowers in New England during the third week of June; the fruit begins in August to assume the scarlet color, which it retains throughout the autumn and long after the leaves have fallen.

The Staghorn Sumach is found from New Brunswick to Minnesota; it is very common through the northern States, and extends southward along the Alleghany Mountains to upper Georgia and to central Alabama and Mississippi. It is found growing in nearly all soils, but requires a deep, rich and rather moist loam, in order to develop its full beauty and best size. The wood of the Staghorn Sumach is light, brittle and coarse grained, of a yellow color streaked with green; the bark and leaves are rich in tannin and are somewhat used in dressing leather and, domestically, for dyeing cloth yellow; and the whole plant contains a copious resinous, milky juice. Our illustration upon page 343 will give an idea of the value of the Staghorn Sumach in ornamental planting. It is from a photograph of a broad mass—about eighteen feet high and fifty feet long—of these plants, growing upon the borders of one of the most carefully planted lawns in the United States, where it is by no means, the least attractive object among the plants gathered from all the temperate parts of the world associated with it. The Staghorn Sumach is valuable in ornamental planting when grown in a mass and kept compact by occasional shortening-in of the vigorous upright branches, as in the group which serves as the subject for our illustration. It can be planted, too, with admirable effect, as a single specimen upon the lawn; and from the habit, common to all the Sumachs, of spreading rapidly from underground shoots, it is one of the best plants for clothing rocky banks, railroad-cuts, and other rough places, where it is desirable to hold the soil from washing and to shade the ground. The Staghorn Sumach can be increased from seed; but a supply of young plants, and this is true of all the species, can be obtained more quickly by cutting up pieces of the stout roots into lengths of two or three inches and planting them in rich soil in nursery rows. Vigorous young plants, of a size suitable for permanent planting, can be attained by this method in a year.

Rhus glabra, the Smooth Sumach, is a smaller plant than the Staghorn Sumach, never reaching to the size and habit of a tree, and rarely exceeding a height of ten or twelve feet. It is a broad, spreading, handsome bush with irregular branches, which are smooth and often somewhat glaucous. The leaves are composed of thirteen to thirty-one pairs of lanceolate-oblong, sharply pointed, serrate, sessile leaflets, which are glaucous on the lower surface. The greenish-white flowers are borne in broad, thyrsoid panicles, eight to ten inches long, and are not open until the middle of July, or two or three weeks later than the last species. The fruit resembles that of the Staghorn Sumach. *Rhus glabra* is found from eastern Canada to Washington Territory, extending south to Georgia, Texas and New Mexico. It is a common and generally distributed plant, being commonly seen along the borders of woods and farm inclosures, or covering dry and barren fields and rocky hills, sometimes almost to the exclusion of other plants. As an ornamental plant it is as valuable as the Staghorn Sumach, except that it never attains the size of that plant; and it can be propagated and used in the same way. There is a variety with deeply incised leaflets (var. *laciniata*), discovered many years ago in Chester County, Pennsylvania, which is often seen in gardens.

Rhus copallina, sometimes, at the north, called the Dwarf Sumach, is the last of the three species popularly called Sumach in the United States. The name of Dwarf Sumach is appropriate enough in the northern States, where this species is only found upon dry and, generally, barren soil, and where it grows to a height of only a few feet. In the southern States, however, especially in the neighborhood of streams in the valleys situated about the base of the high mountains of Tennessee and Carolina and along the borders of the rich bottom-lands of southern Arkansas and western Louisiana, it becomes a round-headed tree, sometimes forty feet high, with a tall, straight trunk, ten or twelve inches in diameter at the base, and is the largest of all the North American *Rhus*, with the exception of the south Florida and West Indian *R. Metopium*.

The branches and leaf-stalks of *Rhus copallina* are downy, and the leaves, which are composed of nine to twenty-one

pairs of oblong or ovate-lanceolate, serrate, or of the entire leaflets oblique or unequal at the base, may be readily distinguished from those of the other species by the broad wings which occur on the petiole between the leaflets, and by their lustrous upper surface. It is the latest of the species to flower. They do not appear in New England until the middle of August, and the fruit is ripe a month later.

The panicle of the male or sterile flowers is twelve to eighteen inches long, its stem and branches quite downy; while that of the female flowers is shorter, three to six inches long, with less downy stem and branches. The fruit is somewhat compressed, ovoid, dark, vinous-red, with scattered gray dots when ripe, the clusters not upright as in the other species, but more or less pendulous from the ends of the more slender branches. The leaves, although smaller than in the other species, are beautifully bright and lustrous, and in the autumn turn, not scarlet, but to a deep, rich claret color. Although less often planted than the Staghorn Sumach, this is, perhaps, the most ornamental of the Sumachs, and few shrubs or small trees can be used upon the lawn or in great masses on rocky hill-sides with better effect. The fact that it will thrive and spread rapidly in dry and sterile soil increases its value.

The genus *Rhus*, of which more than a hundred species are now recognized by botanists, is widely distributed through the extra-tropical portion of the northern hemisphere, especially in eastern Asia and in eastern North America. In Europe this genus is confined to the southern and south-east portions of the continent, where four species occur; it is found in the Andean region of South America, in the East Indies, and abundantly in tropical Africa, south of the equator, and in the Cape region. Eight or nine species in addition to the true Sumachs are found within the limits of the United States, over which the genus is widely and very generally distributed. Four of these species—the so-called Poison Ivy and the Poison Dogwood of the East, the Poison Sumach of semi-tropical Florida, and the Poison Oak of the Pacific States—contain a milky juice, which is exceedingly poisonous to most persons touching these plants. S.

A New Zealand Forest Scene.

PERSONS familiar only with the dwarf Ferns of the temperate parts of the earth, have but a faint idea of the magnificence of the arborescent forms of these plants, which are often conspicuous features in the tropics, and which outside of the tropics are found only in some parts of Australia, in Van Dieman's Land and in New Zealand. Tree Ferns are often inhabitants of conservatories, but they must be seen in their native forests, clothing the forest-floor with a gigantic undergrowth, and producing an effect of vegetable richness and grace which no pen can describe, before all the effects of beauty they are capable of displaying can be realized. The illustration upon page 343 of a New Zealand forest scene, with one of the large Dicksonias in the foreground, serves to give an idea of the peculiar vegetation of that region. Tree Ferns are pretty generally distributed through the warmer parts of the tropics of the two worlds. Some of the species attain a height of trunk of more than sixty feet, with a crown of fronds twenty or thirty feet across.

Foreign Correspondence.

London Letter.

THE chief event in the London horticultural world this week was the great summer exhibition of the Royal Botanic Society in their Regent's Park Garden. There is much reason for the popularity of these shows, as they are delightful displays of flowers and fruit in a delightful garden, which I have always looked upon as Robert Marnock's masterpiece in his half a century's work of landscape gardening. It is, in a great measure, due to Marnock's original arrangement of the permanent exhibition ground in these gardens that the shows are so popular. In no other place that I have seen is the possible arrangement of exhibition plants so far removed from primness and formality. The ground surface under the great tent is undulated in such a graceful and natural way that it wears a totally different aspect when bedecked with plants and flowers from the matter-of-fact arrangement of breast-high benches generally seen at flower-shows. The plants look better, too, on grassy mounds than on anything else, so that the whole scene is fresh and natural. This grassy-mound arrangement can obviously only be carried out where the exhibition site is permanent, but in all public gardens where shows are held there should be a fixed spot, and, if laid out in a tasteful way, it might

be made attractive throughout the year. Although the Botanic Society's show-ground is a model in its way it has faults, the chief being the narrowness of the pathways, which should never be less than twenty feet wide, in order to avoid unpleasant crowding. The width of walks is generally governed by the size of the tent, but if this is constructed on the ridge and furrow principle (which is decidedly the best) it costs comparatively little to extend it so as to render the locomotion of large crowds pleasant. There is in this country an ample scope for more picturesque grouping in flower-shows, and since they have ceased to be the attraction for the million that they once were there is the more necessity for novelty in arrangement.

The great gatherings of this Society afford a good indication of the prevalent fashions in floriculture. For years, and until recently, the chief features of the shows were the monster stove and green-house plants trained in perfectly symmetrical shapes, which were, of course, admirable examples of patient skill and good culture. This was the fashion for half a century; the present fashion dictates otherwise. The trained plants seen at London shows to-day are mere apologies for the elephantine specimens that once paid visits to every important exhibition up and down the country. We get, however, more variety in shows now, and the prevalent taste runs in the direction of Orchids and hardy flowers. It does not even pay exhibitors to build up those marvelous mushroom-headed specimens of show-Pelargoniums; for there is no demand for them since the advent of more easily-grown plants like the Begonia, for instance. There is an ever-increasing demand for all classes of showy, hardy plants, the great delight of those who cannot afford, or do not care, for the trouble of green-houses. At this show there was ample material for every class of visitors, and the open-air flowers won, perhaps, the most attention. Of the two great groups of bulbous Irises, the English (*Iris xiphoides*) and the Spanish (*I. xiphium*), with their graceful flowers of an infinite range of hues, the Spanish Irises are the greatest favorites, as they are smaller and their colors are more æsthetic. The ladies seem to admire most the bronzy-hued sorts and those that show odd mixtures of yellows and purples. They have been the chief florists' flower for the past three weeks, and they are seen in every flower-shop done up in all kinds of ways. The quantities of this flower that are poured into Covent Garden from the Channel Islands and the warm counties are prodigious. The Langport Pæonies, Irises and Pyrethrums, about which I wrote you last, were as pure as ever, and I do not remember to have seen such a marvelous array of Roses so early in the season. The new rival to Niphetos, Souvenir de S. A. Prince, was shown splendidly, and won additional honors by being certificated. Two other prominent Roses, which were in perfection of bloom, were Mrs. John Laing and Lady Mary Fitzwilliam, the latter a Rose that will become as popular as La France.

I shall not attempt to go into the details of the multitudinous exhibits, as there was but little novelty about them; indeed, there was a conspicuous absence of absolutely new things, for most of the so-called novelties sent up for certificates had been shown before the Royal Horticultural Society, which is the recognized authority for adjudicating upon novelties. One always sees a large collection, at these shows, of "new plants," because exhibitors know that the judges are less critical than the committee of the other society, though, of course, a certificate granted by the Botanic Society does not carry the same weight as one from the other. As instances of what are recognized here as new plants I need only mention that certificates were granted to *Lilium Hansonii* and *Lilium Martagon album*, both old plants, now having been in cultivation for years. Orchids were a strong and most attractive feature, and a grand display was made by the Duke of Marlborough, who now possesses one of the richest collections of Orchids in England, while the trade-growers were represented by the two veteran firms—Low, of Clapton, and Williams, of Holloway. It is getting late in the season for Orchid bloom, but the exhibitors had evidently "held back" for this show, as some of the specimens which would ordinarily have been past a month ago were in grand condition. The leading Orchids were *Cattleya Mendeli* and *C. Warneri*. Masdevallias, especially *M. Harryana* and its many varieties. *Epidendrum vitellinum majus*, *Odontoglossum vexillarium*, *O. crispum* (*Alexandra*), *Lælia purpurata* and various species of Cypripedium. The leading collections were composed of huge specimens, and consequently represented old varieties, and the first prize group shown by the well-known gardener, Mr. Douglas, was perfection in all points. There were, however, a good many so-called specimens to be seen which were

nothing more than several plants of a sort massed together in large pots. "Made-up plants" are not bona fide specimens, and, as there is no skill required in producing them beyond that of cunningly fitting the pieces together, they should not be allowed to compete for prizes for specimens.

Not the least attractive exhibit was that from the famous Sawbridgeworth fruit-nurseries, consisting of fruit-trees—Peaches, Nectarines, Cherries, Plums—in pots, in the most vigorous health, and bearing fine crops of fruit. This system of pot-culture has for many years been a leading feature of these nurseries. The late Mr. Rivers originated the idea of orchard-house culture, and after showing what good results can be obtained and publishing a book on the subject, his system is practiced throughout the country, especially in small suburban gardens where there is no space for wall trees. Mr. G. F. Wilson, the great Lily amateur at Weybridge, has an orchard-house fixed on the Rivers' principle, in which he grows superb fruit, though the trees are stunted and only from five to six feet high. Most of the trees have not been potted for years. The secret of success lies in administering liberal supplies of manure as top-dressing.

London, June 20th.

W. Goldring.

New or Little Known Plants.

Vitis palmata.

THE figure of *Vitis palmata*,* Vahl, upon page 341, appears to be the first which has been published of this handsome plant. Its history is interesting. It has been cultivated in the Jardin des Plantes at Paris for more than a century, having been introduced, it is supposed, by one of the French missionaries, who were the first European travelers through the valley of the Mississippi. It was first described by Vahl (*Symbolæ Botanicæ*, iii., 42) from the cultivated plants and a few years before the elder Michaux discovered it on the banks of the Mississippi, the Cumberland, Tennessee and other streams during his visit to the Illinois country in 1795. He failed to recognize the plant, which he had no doubt seen growing in Paris, and proposed for it the name of *V. rubra* on account of the bright red color of the young branches. This name however, was not mentioned in Michaux's Flora, in which work the plant was merged into *V. riparia*; and it was not rediscovered until the autumn of 1882, when Mr. H. Eggert found it growing abundantly upon the banks of the Mississippi opposite Alton, and Dr. Englemann was able to establish the identity of Michaux's plant with that of the Paris Garden, and to point out its true specific characters.† Seeds of *Vitis palmata* were sent to the Arnold Arboretum in January, 1883, by Dr. Englemann, and the plants raised from them are perfectly hardy, and now flower and produce fruit every year. They possess no little decorative value, and in a collection of climbing plants grown for ornament this vine should find a place. It flourishes in ordinary garden soil, and is easily multiplied by cuttings or by seed. Our figure is from a specimen in the Arboretum.

C. S. S.

Amorophophallus Titanum.

THE flowering of this gigantic Aroid at Kew, for the first time in Europe, is an event full of interest to botanists and horticulturists. Compared with it, the *Rafflesia*, *Victoria regia* and *Aristolochia Goldiana*, all giants among flowers, are small and almost commonplace. There is no known plant that approaches it in size and magnificence, and, I am sorry

* *Vitis palmata*, Vahl., *Symb.*, iii., 42.—DC. *Prodr.*, i., 637.—Englemann in the *Bushberg Cat.* (1883) 17; *Bot. Gazette*, viii., 254.

† *Vitis riparia*, Michaux., *Flor. Bor. Am.*, ii., 231 in part.

to be compelled to add, in the power and disagreeableness of its foetid odor. The discovery of this Aroid, in Sumatra, was made by Dr. O. Beccari, a well-known botanist and traveler, whose explorations in New Guinea, Borneo and Sumatra have

done so much to enrich botanical and horticultural collections. To him we are indebted for a knowledge of the wonderful Myrmecophilous plants, two of which, *Hydnophytum* and *Myrmecodia*, are in cultivation at Kew. He also sent home

living plants of *Bulbophyllum Beccari*, whose enormous leaves and massive inflorescence are unequaled by any other Orchid. This plant also flowered at Kew in 1881, and it is noteworthy that the odor of the flowers was almost as powerful and repellent as that of the *Amorphophallus*. In the account forwarded by Dr. Beccari to the *Gardeners' Chronicle* of his discovery of the Aroid in 1878, he stated that he found it growing side by side with a *Rafflesia* (a model of this wonderful parasite is in the Kew Museum), and that the tuber when dug up was five feet in circumference, and so heavy that two men could scarcely carry it. The solitary leaf was composed of a stalk as thick as a man's thigh, and ten feet high, whilst the blade was many times divided, spreading umbrella-like, with a circumference of forty-five feet. This is a little larger than the leaf borne by the Kew plant last year. The dimensions of the tuber, however, when measured in March of this year, were equal to those of the specimen described by Beccari, and it weighed exactly fifty-seven pounds. From this we entertained the hope that a flower would be developed at Kew this year, and the hope has been realized to the fullest extent. Less than a month ago the bud was sufficiently developed to enable us to see that it was a flower-bud, not a leaf-bud; at that time it was cone-shaped and about a foot high. From this it grew in height at the rate of about three inches a day, till it attained a height of nearly seven feet. The spadix is now five feet long, nearly a foot wide, club-shaped, with irregular depressions, and colored pale greenish-yellow. It stands erect in the middle of the huge bell-shaped spathe, which is three feet deep, three feet eight inches across the mouth, the margin wavy and deeply-toothed, with numerous parallel ridges on the outside. Its color is pale green, mottled at the base, almost white on the upper part, whilst inside it is a deep vinous purple with a sheen of bluish color. The whole is elevated on a stalk fifteen inches high and six inches in diameter. It is impossible to convey in words any correct idea of the stateliness and massive grandeur of this huge inflorescence. The expansion of the spathe took place to-day (21st June), and at once the house where the plant stands was filled with an odor exactly like that of putrid fish. Flies of all kinds were attracted by the smell, and buzzed about the spadix in great numbers. We cannot guess how long the flowers will remain fresh, but already crowds of people are attracted to the house by the reports in the papers concerning this plant.

Kew obtained a seedling of this *Amorphophallus* from the Florence Botanic Gardens in 1879, and this has been grown in a moist tropical house until its leaf faded, which usually occurred late in Autumn. The tuber was then removed from the soil, well washed, and at once placed in a pot filled with moist silver sand. Whilst at rest it was kept in a stove temperature. As soon as the bud showed signs of pushing the tuber was replanted in strong, well-manured soil, and kept perpetually moist. During the last four years the plant has been grown over the tank containing the *Victoria regia*, its pot standing an inch or two in the water. The gigantic leaf with its noble proportions has been annually a feature of this house, so that even apart from its enormous flowers, this plant is worth growing for its leaf alone.

There have flowered at Kew this year, in addition to this titanic Aroid, the following giants of the same order, viz.: *Amorphophallus campanulatus*, *A. virosus* and *Godwinia gigas*. These all have very large inflorescences, tall and handsome foliage, large tubers, and an unpleasant odor. The last is certainly a drawback, but it is more than counterbalanced by the wonderful proportions and extraordinary character of the flowers themselves.

Kew.

Cultural Department.

Summer Pruning.

PRUNING is one of the most important points of garden practice. When judiciously pruned, a shrub or tree can be held at almost any size or changed to almost any form; and, besides this, a tree or shrub can be made much more productive of fruit and flowers. On the other hand, improper pruning will not only weaken the vigor of a plant, but may destroy all its beauty of outline, and at the same time hinder the production of flowers and of fruit. The shearing of a tree or shrub into some formal shape, as of a cone or hemisphere, may have a proper place in some styles of gardening; but, in general, it may be said that the clipping of trees or shrubs into any set form is radically wrong. I have seen many good collections of shrubs ruined because each one was cut into a shape to resemble all the rest. In this way all individuality is lost, whereas the object of pruning should be to develop what-

ever beauty each plant possesses on the lines of its natural growth. It is utterly impossible to secure any fine effects in large shrubberies where each individual is trimmed after the same pattern. Evidently the true way is to encourage each one to make the best of its natural graces, and then to arrange this infinite variety of form into a harmonious picture.

If we prune for the purpose of increasing the flowers of a shrub or tree, we must prune different species and varieties at different seasons of the year; but surplus wood and suckers can always be thinned out during the summer season, and wounds which are cut clean in midsummer will heal more quickly than those made in frosty weather. Maples, Birches, Yellow-woods and many other trees bleed copiously when their branches are cut in the spring, but they heal over more quickly if pruned while in full leaf. Again, shrubs which bloom on wood made the previous year, of which the early *Spiræas*, *Forsythias*, *Honeysuckles*, *Viburnums*, *Syringas*, *Philadelphus* and *Deutzias* are examples, should receive their chief pruning soon after the flowers have fallen. This will encourage a growth of young wood with flower-buds for the following year. Of course, when these shrubs are cut back in early spring before flowering, the flower-buds are sacrificed. On the other hand, shrubs like *Hydrangea paniculata*, *Desmodium penduliflorum*, *Hibiscus Syriacus* and others, which flower on the new growth, bloom more abundantly when cut back severely in early spring. But even in this case the surplus wood should be thinned out during the summer.

With anything like an extensive collection of shrubs constant attention must be given to pruning during the whole growing season, and this is especially true where coarse-growing shrubs and those of delicate habit are planted together. If this is neglected the less robust plants will soon be smothered out by their vigorous neighbors. Many shrubs are pruned too much. If a healthy young plant is carefully pruned at the outset, allowed plenty of room, with all the cross branches cut away to admit light and air, and all the old flowering wood shortened in after bloom and the over-strong shoots stopped, at midsummer, it will not only retain all its natural beauty, but this beauty will be increased, and it will be full of flowers the next year. After the branches of large shrubs have been thinned out, stronger shoots should be pinched back with the thumb and finger, for this will hasten the growth of flowering-buds. Many trees and shrubs can be made to produce flowers and fruit at a smaller size than if they were left to themselves or pruned only in the winter or spring. This summer pinching also helps to ripen up the wood, and leaves it in good condition to withstand the cold. I have known trees which were tender, when left to grow naturally, to endure our winters fairly well when the wood had been properly stopped by pinching it in summer. This is especially true in wet seasons, when the branches often continue to grow until the frost kills them. Apples, Peaches, Plums, Filberts and many other trees can be made to bear when quite small if the new growth is stopped once or twice in the summer. I now have Peach-trees five or six feet high which are loaded with fruit, the result of pinching back in summer. While trees are growing vigorously the flower-buds do not form well, but by this summer pinching the flow of the sap is checked and the buds are developed. Many plants also ripen their fruit better when the strong shoots above the fruit have been stopped. Young trees can be easily trained with very little use of the knife when they are taken in time, the surplus buds rubbed off from the lateral branches and the branches properly pinched back. In short, summer pruning is useful and indispensable for the removal of superfluous branches in the middle of the tree or shrub, and for the shortening-in of all over-vigorous branches and such as interfere with the native symmetry of the tree; and by thinning out the weak and misplaced branches additional nourishment is supplied to those that remain.

Arnold Arboretum.

Jackson Dawson.

The Vitality of Seeds.

MOST books on horticulture contain tables showing the number of years that the seeds of garden plants remain "good"—that is, retain their germinating strength substantially unimpaired. These tables, compiled by different writers, do not quite agree; yet they are not widely discrepant. Of late, our agricultural experiment stations have been engaged in testing the vitality of seeds sent out by dealers; and these reports show a considerable amount of difference. It is, unquestionably, a wide-spread practice among seedsmen to mix old stock with new; and in some conspicuous cases this has been shown, by the station experiments, to have been carried

Forest Vegetation in New Zealand.—See page 339.

very far, so that nearly or quite half of some stocks had entirely lost their power to grow.

In the case of those seeds which hold their vitality substantially unimpaired through a considerable number of years, this mixing of the remainders of one year with the fresh stock of the next is unobjectionable. To do otherwise would be foolishly wasteful, and, if insisted on by buyers would unnecessarily enhance the price. But to sell dead seeds, or seeds the vitality of which is weakened by keeping, is a dastardly wrong. On this point there can be no mistake. I believe that any one who will make a study of seeds, with a glass of a moderate magnifying power, will, in many cases, be able thus to judge very closely of their quality. But every gardener should procure his stock of seeds early enough to be able to test them in good time, although, fortunately, there is now a

large and increasing number of seedsmen in this country who never wilfully send out inferior seeds.

In regard to the keeping of home-grown seeds, so that their vitality shall be as well maintained as nature will allow, there are some necessary points to be observed. The first is, that they shall be well ripened. This is a nice point, and one not always easy to secure—in fact, impossible, except by making successive cuttings. That they should be well and promptly dried, cleaned and secured from attacks of vermin is obvious; but the duration of their continued vitality is very much affected by the after care. They should be kept dry. This is more important than the question of light, temperature or ventilation. My own experience of now many years has not convinced me of any positive disadvantage from exposure to the air or to low degrees of temperature. In fact, many seeds retain their vitality better in open barrels and boxes, or in bags, than in tight packages. Warm this valuable chiefly as a security against dampness. Many times I have found seeds good that had repeatedly endured a cold of 40° below zero; but dampness will very quickly destroy them. Light bleaches or darkens them; the color of seeds is rarely maintained unchanged for any considerable time.

T. H. Hoskins.

Orchid Notes.

Cattleya granulosa.—Several nice strong plants of this striking species are now producing their flowers here with great freedom. One gets so accustomed to look upon all *Cattleyas* as being represented by the numerous gorgeous-flowered forms of the labiate section that it is quite a relief to meet with such a contrast to them as that presented by the species now under consideration.

C. granulosa belongs to a very distinct section of the genus typified by *C. guttata*. It has been cultivated in English gardens now for nearly fifty years, having been introduced, it is believed, from Guatemala in 1840 by Hartweg, who at that time was collecting in tropical America for the Horticultural Society of London. Notwithstanding the fact that it has been under culture so many years, it is a neglected Orchid in many collections, although well-grown plants when in flower present a type of beauty difficult to match, and one which should entitle this species to more respect.

The plants are characterized by their slender, terete and jointed stems, nearly of the same thickness throughout, except at the base, where they are slightly narrower, and clothed

A Group of Staghorn Sumachs on the Border of a Lawn.—See page 338.

with silvery membranous sheaths. At their apex are two oblong-lanceolate, deep-green leaves, from between which arises a stoutish peduncle bearing from three to eight flowers, each about four inches across. The sepals are oblong acute, the two lateral ones being falcate; the petals are nearly similar, but broader and wavy on the margins of the upper half. Both sepals and petals are of a shining coppery-green color, handsomely spotted near the edges with crimson-purple. The two lateral lobes of the lip meet over the top of the column; they are creamy-white outside and lined inside with rows of crimson-purple dots, which become very thick on the recurved tips; the middle lobe, which expands into a crisped emarginate limb in front, has the surface traversed by irregular granulated lines of deep crimson-purple, radiating obliquely from the central purple lines which run from the base. It is from these granulations, or papule, as they are now called, that the plant received its specific name from Dr. Lindley.

About two months ago there was another very handsome *Cattleya* in flower, namely, *C. Schofieldiana*, which, from a botanical point of view, must certainly be looked upon as a magnificent variety of *C. granulosa*, although it is much superior in every way to that species as far as the grandeur of its flowers are concerned. In character of stem, leaves and growth *C. Schofieldiana* is similar. The flowers, however, are half as large again as those of *C. granulosa*, and are of a rich tawny yellow, suffused with a coppery tinge, and thickly covered with large crimson spots. The large lip is very beautiful, the surface of the middle lobe being covered all over with deep crimson-purple raised dots, as in *C. granulosa*. *C. Schofieldiana*, which is a native of Brazil, flowered for the first time in England in the autumn of 1882 with Mr. G. W. Law-Schofield, of Rawtenstall, near Manchester, in compliment to whom it was named by the late Professor Reichenbach.

Both of these plants thrive well in pots, which must be well drained. They should stand well above the rims in a compost of rough fibrous peat, which may have a little charcoal added, so as to render it not only more porous, but also to prevent it from becoming sour. Owing to the slender nature of the stems care must be taken not to let the plants get too dry during the resting season, otherwise they are liable to shrivel—a misfortune which could not be easily rectified. During the time of growth an abundance of water may be given judiciously, and as much light as possible, so long as there is no danger of their being scorched by the heat of the sun. This is necessary to enable the plants to ripen their growths, without the proper development of which it would, of course, be impossible to expect good flowers.

St. Albans, June 7th, 1889.

John Weathers.

Phalænopsis Culture.—The best-grown collection of these plants in England is that of Mr. Parlington, of Cheshunt, whose gardener, Mr. Searing, has met with the most surprising success in the cultivation of these oft-times "miffy" plants. I saw them last week. Imagine *P. grandiflora*, *P. amabilis* and *P. Schilleriana* with from eight to eleven leaves each, and some of the leaves measuring sixteen inches long by four and a half inches wide. No spot, no bad health in any shape. The spikes bear as many as sixty flowers each. The house in which these plants are grown is a lean-to, with an aspect full south, and it is twelve feet high at the back by four feet high in front. Mr. Searing allows the sun to shine upon his plants in early morning, and again in the afternoon. He ventilates very carefully, but never keeps the house shut up close. A dressing of salt is given to the gravel in the house, both on the stages and in the path. This is done several times in the year, and Mr. Searing attributes much of his success to this. It is difficult to imagine how salt thus applied can have any effect on the health of the plants, as salt does not evaporate. Still, the proof of the pudding is in the eating, and there may be something in this salt dressing after all. I am told that collectors always find the strongest and healthiest *Phalænopsis* within reach of an atmosphere affected by the sea, and we know that the genus is generally confined to small islands. There does not appear to be anything but the salt in Mr. Searing's treatment that would account for his wonderful success. His plants are in teak baskets, well-drained, with a little sphagnum about the roots. The strongest plants are placed over pots half-filled with charcoal, and into these the roots have grown most vigorously. In winter only sufficient water is given to keep the moss alive, and in summer the plants are kept fairly moist at the roots. Mr. Searing does not disturb his plants at the roots, but simply removes the dead moss in spring and replaces it with living. Mr. Herman Wendland, whose knowledge of Orchids, and especially of Orchid collections, is exceptional, was filled with astonishment when he saw these plants.

Kew, England.

W.

Notes on Wild Flowers.

Habenaria orbiculata, one of the Rein Orchis family and now in flower, is an interesting plant. The leaves (a pair of them) are nearly round, lying flat on the ground, and are often ten inches broad. They are dark, shiny green in color, and from between them comes the flowering stem, ten to twenty inches high, with its loose raceme of almost white flowers. Its natural home is in the shade of Spruce and Hemlock. It can be grown without much trouble in moist, well-drained soil in the shade if leaf-mould is placed about its roots. It is a desirable plant for its curious leaves as well as for its interesting flowers.

Habenaria dilatata, also in flower, is a valuable plant for artificial bogs, but it can be grown in ordinary soil in a moist, shaded place. It grows from one to two and a half feet high, with a dense spike of pearly-white flowers, six inches to a foot in length, which are deliciously fragrant. Another species of this genus, almost identical in its general appearance with *H. dilatata*, except that the flowers are greenish-white and not fragrant, is *H. hyperborea*. The two species grow together, and it is difficult to distinguish them when not in flower.

The Hare-bell (*Campanula rotundifolia*) is quite interesting, now that the little blue, bell-shaped flowers are open. The natural location for it is in rocky soil, and it is a valuable plant for the rockery. It will, however, thrive in any ordinary soil. The plant grows about a foot high, often higher, with an abundance of fine, grass-like leaves along its stems.

Two desirable plants now in bloom are the Tickseed (*Coreopsis lanceolata*) and the Golden Ragwort (*Senecio aureus*). The former grows about two feet high with large, bright yellow flowers often two inches broad, on long stems, several from each plant. The plant remains a long time in bloom and is easy of culture. The flowers of the Golden Ragwort are smaller, but in dense heads or umbels, of a bright yellow and very pretty. It is a variable plant according to its location. The most showy form is found in low, wet meadows, along the borders of swamps. It takes easily to cultivation, and may be grown in moist upland soil.

One of our most desirable bog plants is the Side-saddle Flower, or Pitcher Plant (*Sarracenia purpurea*). Its pitcher-shaped leaves, when grown in the sun, are of a rich purplish color, three to six inches long, usually full or partly filled with water, and the single purple flower is nodding on a stem a foot or more high. The plant requires wet soil, and seems to prefer peat or muck. We have grown it in wet clay-loam, but the leaves seem to be sickly and the flowers dwarfed. Another pretty bog plant, but one which we never have tried to grow, is *Pyrola rotundifolia*, var. *uliginosa*, one of the Shinleaf family. Its spike of reddish-purple flowers is very showy—the most showy of any of this genus we have seen. It is found in cold bogs, and, probably, would not thrive except on a boggy soil.

Charlotte, Vt.

F. H. Horsford.

Narcissus for Borders.—Among spring-flowering plants *Narcissus* take a foremost place. The many species and varieties now in commerce are perplexing, to say the least, to the general cultivator, and it has occurred to me to note a few of those that may be relied on to succeed and increase under ordinary garden treatment. The first to bloom here is always Golden Spur. This is a bright yellow variety, and in my opinion superior to Emperor. Golden Spur is fully expanded a week before any other kind, and increases rapidly. Next in order of flowering is *N. princeps*. This is a form of *N. Pseudonarcissus*, and is well named. Sir Watkin, the largest of all with us, produces noble flowers and foliage, and doubles the number of its bulbs every year. *N. bicolor Horsfieldii* is the best known of the bicolor section, and should be grown in every collection, the bright yellow of the corona being a beautiful contrast to the paler yellow divisions of the limb. Of *N. poeticus* and its varieties, we can strongly recommend the variety *Ornatus*, which flowers two weeks earlier than the type, while *N. poeticus plenus* flowers two weeks later. The type and these two varieties give a supply of flowers lasting over a month. Orange Phoenix is, perhaps, the best of the double varieties, combining, as it does, two shades of yellow in a charming manner. Of all the varieties of *N. incomparabilis*, none, perhaps, excepting Sir Watkin, are superior to the type. The best time to plant *Narcissus* is as soon after the foliage dies down as possible, and before the bulbs commence to make new roots in fall—that is, in September. Home-grown bulbs are, we find, preferable to the imported ones, which need a season or two to get established. Choice kinds of *Narcissus* should be lifted about every three years; the soil enriched, and the bulbs replanted, for this gives them

an opportunity to fully develop, and insures plenty of good flowers. We plant six inches deep, cover the bulbs with two inches of soil, then give a sprinkling of manure and fill in the soil. If the manure is brought in immediate contact with the bulbs they are liable to rot. By adopting the above plan we find the rains provide the young roots with the full benefit of the manure used. This remark applies also to most of the Lilies, for which many people are averse to use manure; we find, however, that the main feeders of the Lilies are the roots produced between the surface of the soil and the top of the bulb.

Passaic, N. J.

E. O. Orpet.

Orchard Notes.—During July many fruit-trees can be budded. A strong bud, if it takes well, is as good as a graft. Just as the longitudinal growth stops is about the time to bud, although the operation can be successfully performed at any time before the sap ceases to flow.

Sometimes the work of looking for borers about the base of fruit-trees is forgotten. The first inspection should have been made earlier than this, and a later one should follow. A keen-pointed knife and a piece of stiff wire will now dislodge the grubs. Cherries budded on Mahaleb stock are failing, largely on account of the borer at the root. Purchasers should procure trees worked on the Mazzard.

Clapp's Favorite is a valued early Pear for family use, but is not greatly prized for market, on account of its lack of keeping qualities. But the fact that its large, beautiful fruit can be gathered in this latitude by the 10th of August makes it desirable.

The Home Acre. By Edward P. Roe. New York: Dodd, Mead & Co. 1889.

Mr. Roe's "Success with Small Fruits" has long been familiar to thousands of readers, and the present little volume will be found another store-house of useful information, so pleasingly conveyed that it will doubtless instruct and profit many whom more strictly scientific treatises would repel. It is a series of papers, collected from the periodicals where they were issued before Mr. Roe's death, dealing with the problems which confront the owners of suburban places. "The area of land purchased in such places," says Mr. Roe, "will depend largely on the desires and purse of the buyer; but about one acre seems to satisfy the majority of people. This amount is not so great that the business man is burdened with care, nor is its limit so small that he is cramped and thwarted by line fences. If he can give to his bit of Eden but little thought and money he will find that an acre can be so laid out as to entail comparatively small expense in either the one or the other; if he has the time and taste to make the land his playground as well as that of his children, scope is afforded for an almost infinite variety of pleasing labors and interesting experiments." The taking title of the book thus expresses its exact purpose, as giving counsel not to the professional horticulturist but to the amateur with modest funds but a genuine love for out-door work and beauty. Yet it is essentially practical in scope, dealing not at all with the culture of flowers, but, in its successive chapters, with Tree-Planting, Fruit-Trees and Grass, the Garden (as a useful rather than an ornamental spot), the Vineyard and Orchard, the Raspberry, the Currant, Strawberries, and the Kitchen Garden. The advice given with regard to the selection and planting of trees is sound in substance and clearly conveyed. Good counsel of a general sort relates to the preference that should be given to native over foreign species—a preference, of course, which need not mean narrow exclusiveness, only, when the Norway Spruce is mentioned, we should have been glad had its unsuitability to the climate of our Eastern and Middle States been expressly set forth. Speaking of Grape-culture, Mr. Roe insistently recommends that, where birds are destructive, songsters should not be shot, but that the bunches should be protected by mosquito-netting bags, as is the constant custom in Germany, or by cheap paper-bags with the lower corners cut off to admit of the easy passage of moisture. And, he adds, "clusters ripen better, last longer on the vine and acquire a more exquisite bloom and flavor in this retirement than if exposed to light as well as to birds and wasps. Not the fruit but the foliage of the Grape-vine needs the sun." With regard to keeping grapes after they are cut, Mr. Roe says that few of the early sorts will last long, but that some of the later ones can be preserved a considerable time in boxes stored where the temperature is cool, even and dry, and that "some of the wine-grapes . . . will keep under these conditions almost like winter-apples. One October day I took

a stone pot of the largest size and put in first a layer of Isabella grapes, then a double thickness of straw paper, then alternate layers of grapes and paper until the pot was full. A cloth was next pasted over the stone cover, so as to make the pot water-tight. The pot was then buried on a dry knoll below the reach of frost and dug up again on New Year's Day. The grapes looked and tasted as if they had just been picked from the vine."

Correspondence.

Forests and Civilization.

To the Editor of GARDEN AND FOREST:

Sir,—We might have had some real forestry here in the State of New York if we had been sufficiently advanced in the art of living; if we had had the interest in the public welfare and the perception of our obligation to coming generations, which are necessary to the development and persistence of civilization. The entire Adirondack Wilderness should have been held permanently in the possession of the state. Then a real school of forestry could have been established somewhere in the woods, and young men could have been trained in the practice of this art, and they could have been employed in the care of the forests and woodlands of other portions of the country. The whole tract of 8,000 square miles was originally heavily wooded. The timber could have been cut off as the trees matured, and, of course, should have been so cut off. Nothing could be more absurd than the notion that trees should never be utilized or removed. Whenever a tree has come to its best it should be cut down, and its wood applied to some useful purpose, so as to obtain its value, and in order to provide for a succession of generations of trees, and thus for the permanent life of the forest.

If the Adirondack forests had been thus intelligently managed and administered they would now have been for a long time yielding an increasing revenue to the people of the state. The whole population would have been greatly benefited by the reduction of taxation. Every man and woman in the state would have been richer to-day—would have had more of the means of subsistence and of comfort and happiness than at present. Every child in the state would have been born to a better inheritance, and into more favorable conditions than now. The forests would have been better now than ever before, and they would have gone on increasing in value to the people of the state, with the increasing density of population, and on account of the exhaustion of the timber-supply in regions fit for agriculture.

The Adirondack region is not fit for agriculture. No part of it is suitable for any other than forest-conditions, and these should have been maintained forever. It is indeed impossible to disturb these conditions very extensively, or to remove the forests permanently, without destroying the region itself and annihilating everything that makes it of any value. I doubt if an instance of more obvious and complete adaptation of a region to a special and particular use can be found in the whole world. Nature made this region for the permanent and everlasting growth of forests, and this sole and exclusive adaptation to a most important function should have been recognized.

As I said years ago,* if the Adirondack forests could be saved by legislation, one of the best possible measures would be "An Act for the Discouragement of Agriculture in the North Woods." The lumber-business is not by any means the only destructive agency at work here. Tens of thousands of acres, entirely unfit for any use but forest-growth, have been stripped of trees, and by cultivation and pasturage have been rendered incapable of reproducing the only crop for which the land ever had any adaptation. It is strange—if anything in human folly is strange—to see so many people persist in the effort to "farm" where the soil is so meagre, and the country so high and cold, that no profitable return for their labors is possible. The thin film of soil disappears after a few years, leaving only the bare, inert sand or gravel, and as most of the "farming land" here is rolling or hilly, the slopes soon begin to break down and wash away. Great gullies are formed, which grow wider and deeper every year, till vast waterless tracts of shifting sand, or of clay and gravel, varied only by rock-ledges and boulders, stretch before the unhappy traveler where once grew noble forests fed by perennial springs.

I have carefully studied the lives and work of farmers in nearly every part of our country—from the Atlantic to the Pacific coast, and from Canada to Mexico—and I have found nowhere else conditions so forlorn and forbidding as here in northern New York. The local histories of the regions adjoining the Wilderness abound in stories of the hardships of

* In the New York Tribune.

the early settlers of those counties, especially of those endured by the women of those times. The hardships continue with little mitigation, but as few people are interested in contemporary history, there is no record or observation of these miseries.

The region was meant to be let alone. It has no natural fitness for agriculture. It is pitiful to see the scanty growth of vegetation which the farmer's toil produces here cut off by frosts in both spring and autumn, and, in many places, even in the middle of summer, while in the southern States of this country there are millions of acres of fertile soil lying untilled beneath most genial skies. The effort to farm these inhospitable lands has also been the source of a large proportion of the fires which have destroyed so much of the remaining forest. Land is cleared by being burned over, and in a dry time the fire extends from the fallow to the woods, despite the best efforts to keep it within bounds, and it is a common saying in the woods that such a conflagration is often a convenient accident for the farmer, as he plants corn the next spring in the burned woods without any clearing whatever, and raises a crop in the ashes. A great deal of the "farming land" here has been brought into cultivation in this way. It is all, from beginning to end, a most wasteful and suicidal process, and the inevitable end, the ruin and disappearance of the soil itself, is speedily reached. Man has no power to create a new world. He has not yet learned how to take care of the one which he inherits, but his ability to wreck and exhaust it is very great. The accumulation of the soil of the planet, out of which must come everything that supports human life, civilization and happiness, has been the slow, patient process of vast and unimaginable periods of time, and it has been chiefly the work of vegetation. While the forests stand on these mountains, the soil out of which they spring grows perpetually richer, and it would continue to do so forever if man had yet become a rational being. Each year's leafage as it grows and falls wins and deposits for us a little more of the precious material out of which all things human are fashioned, lifts another slight increment from the dark province where all is inert and lifeless, up into the light, and starts it on its shining way to the realm where it shall take its part in the play of consciousness. The stones are thus changed to bread. But since man began his work in these regions he has blotted out, over great areas, the results of millions of years of Nature's patient toil, and has brought back and re-established here the hard and forbidding conditions under which she began her processes of vegetable growth, and it will require great cycles of time again to redeem and recover these vast tracts of scorched and desolate stone.

Moirs, New York, May, 1889.

J. B. Harrison.

Roadside Adornment.

To the Editor of GARDEN AND FOREST:

Sir.—A striking feature may be added to roadside adornment by sowing the seeds of wild flowers where grass does not readily take root, there being many plants that thrive where it does not. For instance, if a road is cut through a knoll of sand and gravel, as frequently occurs, the rugged surfaces give little encouragement to grass, while the Lupin finds them altogether congenial. Beside giving a mass of purple bloom in May, the pretty foliage of this plant covers the ground throughout the summer. No other sowing than the first is needed, as Nature has provided for the dissemination of the seed by the bursting of the pods.

The owner of a sandy way has obtained very satisfactory results by gathering seeds from the great variety of flowers bordering the railroad track (that bounds his farm on one side) and scattering them broadcast beside the highway. Among these Lupin predominates, but *Lithospermum hirtum*, Vetch, Wild Pea of several varieties, Cone-flower, Butterfly-weed, Painted Cup (*Castilleja coccinea*), Golden-rods in great variety, and the persistent little Harebell, all follow along in their season. A troublesome wash-out along this roadway that was filled with brush and other unsightly material, to prevent farther encroachments of the water, has, by skilful planting, been changed into a place of beauty.

Basket Willows screen it from the road on the lower side, and higher up along the slopes are set Purple Lilac, Red Cedar, Bladder Nut, Scarlet Maple, Whitewood and Osage Orange; Sassafras springing up of itself.

Any surplus of the flower-garden was transferred there. Yards of crimson Boursault and yellow Roses trail over the brush and flower in their season, and in the vicinity low Scotch and native Roses flourish. The Lemon Lily and Iris add, too, their brightness to the scene; and all these trees and plants thrive without care or attention.

This spot is a favorite nesting-place for birds, and I am in-

clined to think the Roses owe their freedom from the pests that infest the gardens to the presence of these active neighbors.

Kliuger Lake, Mich.

Dorcas E. Collins.

The Newtown Pippin.

To the Editor of GARDEN AND FOREST:

Sir.—Referring to the note of Mr. J. J. Thomas in your issue of May 26th I would state that the Newtown Pippin—by which he means, I suppose, the Newtown Pippin of his "Fruit Culturist" and the Green Newtown Pippin of Downing's Treatise—is one of the most obscure Apples in California, while the Yellow Newtown is generally considered our best winter Apple. In several hundred reports from Apple-growers, which I have secured as a basis for tabulation of varieties in "California Fruits, and How to Grow Them," which I now have in press, the Green Newtown Pippin was approved by a single grower in a single county, while the Yellow Newtown is reported favorably from every county from which I secured reports, and nearly all counties have been heard from. The data presented in this work of the popularity of different varieties here are interesting for comparison with the tables of the American Horticultural and other societies representing eastern experience.

College of Agriculture, Berkeley, Cal.

The American Beech.

To the Editor of GARDEN AND FOREST:

Sir.—I have never seen a more noble or beautiful tree than an American Beech growing on the Luce Farm, in the town of Riverhead, and within a quarter of a mile of Long Island Sound.

Soon after the Revolutionary War the entire head was cut from this tree to make a brush-harrow. Not discouraged by this rude treatment it threw out seven branches, equidistant, in various directions, forming a beautiful and symmetrical head. Its trunk, two feet from the ground, is ten feet in circumference; its height to the branches, eight feet; the circumference of four of the larger branches is respectively, six, six, five and a half and five feet, and they extend from thirty-six to thirty-eight on either side, giving the head a diameter of seventy-four feet. The ends of the branches nearly touch the ground and turn up with a graceful curve. The outline of the top is regular and massive and beneath the branches is a beautiful camping-ground, where a party of one hundred or more would be perfectly protected against sun or shower.

Floral Park, N. Y.

C. L. Allen.

To the Editor of GARDEN AND FOREST:

Sir.—I have often heard complaints that the Crown Imperial does not flower well, and perhaps the method that has given me fine blooms for the last fifteen years may interest some of your readers.

When the stem-leaves fade I cut the stalk to within six inches of the ground, and when convenient (some time in July) dig up all the bulbs with the earth about them, and put in its place rich mould from a frame or old hot-bed. I plant the bulbs again immediately in a layer of this mould, covering with the same, and treading it down firmly. In December I cover the bed with some litter, and good flowers are sure to come in spring. The place where these Crown Imperials grow is well open to the sun in early spring, but later in the year is heavily shaded by a spreading Ash tree.

Cambridge, Mass.

J. M.

Dosoris.

To the Editor of GARDEN AND FOREST:

Sir.—It would be difficult to find a more desirable situation for country homes than the north shore of Long Island, with its frequent bays cutting deeply in between well-wooded hills, behind which fertile farm-lands roll away in endless variety of surface. Every bluff is breezy with coolness from the Sound, and on either hand is a diversity of pleasing prospect across green fields or glittering waters. Along this shore, close to the mainland and hardly twenty miles from the City Hall in a right line, lies the Island of Dosoris, a portion of an old estate which has borne that name for nearly two hundred years. The original title was derived from the Matinecock tribe of Indians, and in 1668, under a patent granted by Sir Richard Nicolls, the first English Governor of the province, it passed into private hands, and in 1693 "it was owned," says the record, "by John Taylor, who died seized thereof, leaving his surviving daughter and heir-at-law, Abigail, who subsequently intermarried with the Reverend Benjamin Woolsey, and the title was therefore, by deed of lease and release, conveyed to him, and the trust from that circumstance acquired

the name of Dosoris—*dos uxoris*." Some sixteen years ago the island was bought by Mr. Charles A. Dana, who at once began the systematic planting which has made it one of the most interesting gardens in the country. The entire island, about forty-five acres in extent, is now one garden, and is maintained throughout as a garden, the pasture and forage lands being on the neighboring mainland.

Mr. Dana's collection of trees and shrubs and herbaceous plants has grown year by year, until it rivals in richness the most complete private collections of the world, and yet the island is much more than an arboretum or a plant museum, for the planting has been disposed with reference to some fine old trees which already stood about the house, and to the belt of forest which already fringed the island, so as to bring out and emphasize the natural beauties of the place. The house, with broad, hospitable, vine-shaded piazzas, stands on high ground, and from one side the prospect is over a stretch of perfect lawn, with glimpses of the open waters of the Sound between the trees, to give life and light to the picture. On the other side the most attractive view is down a long slope and through a vista of rich foliage towards the bridge which unites the island to the mainland. A sea-wall is built all around the island, and it is draped and festooned with Matrimony Vine, our native Bitter-sweet, a Japanese species of the same genus (*Celastrus articulatus*) and *Periploca Græca*, which are planted on the top, and relieved by an upright growth behind them of *Eleagnus*, *Tamarix* and some species of *Prunus*. On the banks, exposed to the lashing of storms, are set such sturdy trees as Locust and Red Cedar, while the Waxberry and Beach Plum have proved perfect shrubs for such a position, extending down to high-water mark, and hiding the dry sand and gravel of the bank with a mantle of luxuriant leafage. Within this trim circumference, in every shrub-border and group of trees and flower-bed, the universal health and vigor of the vegetation bear witness to the skill and intelligence with which the garden is cultivated and cared for, and over all is the charm of perfect neatness and order that is absolute.

To give a list of the garden treasures of Dosoris would be to make a catalogue of the trees and shrubs of ornamental value that flourish in this climate, but some idea of the richness of Mr. Dana's collection can be gathered from such statistics as these: Of Oaks there are 29 species and varieties; of Hickories, 7; of Walnuts, 6; of Maples, 39; of Magnolias, 15; of Pyrus, 13; of *Prunus*, 20; of Lindens, 11; of Aralias, 7; of Cornels, 12; of *Euonymus*, 12; of Rhus, 8; of *Spiræas*, 33; of *Viburnums*, 20; of *Berberis*, 12; while 2,700 plants of *Azalea* indicate the abundant way in which many species and varieties are used. The figures relating to conifers are still more remarkable when the slender success which usually attends their cultivation in this region is considered. Of Pines there are 38 kinds; of Spruces, 21; of Firs, 23; of *Chamaecyparis*, 17; of Junipers, 16; of Thujas, 20; of Hemlocks, 10; and so on. Mr. Dana considers one secret of his success with conifers to be the unsparing use of the knife. He makes repeated extirpation of the leader to cause a full and vigorous growth of the lower branches and certainly some of the specimens which have been habitually pinched back are objects of singular beauty. This is notably true of some Nordmann Firs, a Cilician Fir and a Cephalonian Fir, which have been subjected to this treatment for a long series of years.

Besides the general assortment in the fruit garden there are 400 dwarf, espalier and cordon trained Pear-trees, with Apple, Plum, Cherry and other fruit trees trained in the same way. Figs, German Medlars, Filberts, with other rare fruits and nuts, are cultivated, and this year an unusually heavy crop of Madeira Nuts will be produced. Japanese, Spanish and American Chestnuts and Chinquapins are also grown. In the two acres of vineyard sixty varieties of Grapes are found including many of Rogers Hybrids, which are the most favored here. Between the rows of grapes and in the young orchard as well as in an independent garden are seven acres where every sort of vegetable is grown and all new varieties are tested as soon as they are sent out, many of them, indeed, being sent here before they are put on the market. In connection with the garden is a Mushroom cellar, eighty feet long, a structure built tunnel-fashion, where fresh Mushrooms can be gathered from October until May. The green-houses are arranged in compartments for Roses, for tropical plants, for winter-flowering stock, and a second range consists of a propagating house, a cool house for plants like *Calceolarias* and *Pelargoniums*, a Fern house, and a vegetable house while some 250 sashes are used for frames and hot beds.

It was my good fortune to be one of a small party who visited these well-appointed grounds last week upon the invita-

tion of Mr. Dana, whose hospitable habit it is to give a day among his trees now and then to guests who take an interest in them. To go through this collection, or as much of it as it is possible to see in a day, under the guidance of its owner and of Mr. Wm. Falconer, for many years head-gardener of the place, is something like a liberal horticultural education, but apart from very general facts, like those given above, it is difficult to make a selection of topics that might prove interesting to your readers. As an item of seasonable interest it may be worth recording that among trees in flower, on the 11th of July, I noted the *Kœlreuteria*, our eastern *Catalpa* (the western species was out of bloom) *Catalpa Kœmpferi* and many of the Lindens. Of shrubs in bloom the most striking to me was *Stuartia pentagyna*, with its large, pure white blossoms. The Japanese *Stuartia Pseudo-Camellia*, whose flowering caused some sensation in England last year, has bloomed here for several years, but had gone out of flower. Next were three species of *Hypericum*—*H. Kalmianum*, *H. prolificum* and *H. aureum*, which last would be a perfect shrub if the old flowers, withered and brown, did not remain so long amid bright golden blossoms in their prime. *Hydrangea paniculata*, also in flower, seems to me more graceful than its more widely-known variety, *Grandiflora*. Other shrubs in bloom were *Spiræas* in variety, dwarf Horse-chestnut, *Lespedeza bicolor*, *Ligustrum Iboti*, *Buddleia recurvifolia* and *B. Lindleyana*, *Grewia parviflora*, *Symphoricarpos occidentalis*, Trumpet Vine, and the Chinese *Wistaria*, which was showing its second crop of flowers. Among the gayest of other plants in bloom were Cannas, Montbretias, Perennial Phloxes, Clematises of several species and varieties, Silphiums, Rudbeckias, Statice, Hollyhocks, and all seasonable sorts of hardy perennials with annuals in countless varieties, since every novelty in this line is grown and tested. In the flower-garden the annual and perennial Poppies, Larkspurs, Canterbury Bells, Sweet Williams, Foxgloves, Stocks and other early bloomers were being cleared off and replaced with *Gaillardias*, *Coreopsis*, *Mignonette*, *Gladiolus*, *Zinnias*, *Marigolds* and other plants, which, as a second crop, will make a bright display of flowers before and during autumn.

Of conifers, besides the specimens named above, which seemed conspicuously beautiful, I noted a glaucous form of the Atlas Cedar; a *Sequoia gigantea*, probably the finest on this side of the continent; a Japanese Hemlock of wonderful grace; a remarkable specimen of *Pseudolarix*; a Numidian Fir, which seems to me one of the noblest of its class; a Douglas Spruce, not quite as large as some specimens I have seen, but unexcelled in form and in the soft texture and color of its foliage. *Eleagnus longipes*, a fruiting branch of which you figured in GARDEN AND FOREST last year, was loaded with fruit which was relished by all. There is little doubt that by careful selection this relative of our Buffalo-berry could be made to produce a valuable dessert or culinary fruit. Not far away from the *Eleagnus* stands a most effective bed of grasses, with an immense mass of *Arundo donax* in the centre, eighteen feet high, varieties of *Eulalia* and *Briza maxima*, ranked about it according to their various stature, and the whole bordered with *Stipa pinnata* and *Pennisetum longistylum*. Noteworthy groups of shrubbery were made up of several different species of the same genus as of *Spiræa* and *Viburnum*, and one mass of *Rosa rugosa* alone, twenty-five feet square, must have been an imposing spectacle when in bloom. The Rose season was over, but the pink, ever-blooming Bourbon Rose, Mrs. Degraw, was loaded with flowers, and it was pronounced by both Mr. Dana and Mr. Falconer the best garden Rose in the entire collection. The bewildering profusion of vines I thought noteworthy. Woody and herbaceous, tender and hardy, they were clambering and twining, wherever there was a support to cling to and a handful of soil for root-room.

"You must use a good deal of fertilizing matter to feed all these plants so well," said one of our party to Mr. Dana.

"One year I bought 5,000 loads of stable-manure," was the reply; "but my ordinary annual supply is about 1,500 loads, brought here from New York by schooner."

Besides this, quantities of sea-thatch, forest-leaves, lawn-cuttings and the like are collected for mulch, which is more largely and systematically used here than in any other garden which I have visited. The theoretical value of mulching, both in summer and winter, is admitted by all, but it is demonstrated here in actual practice, for the principle which controls every operation here seems to be that whatever is worth planting is not only worth planting in the best manner possible, but it deserves the very best after care that can possibly be given to it.

New York, July 15th.

S.

Notes.

Syringa Pekinensis flowered this year in the Arnold Arboretum probably for the first time in cultivation.

The flower of the giant *Amorphophallus*, described in another column of this issue, remained open but a single day, when the expanded spathe again closed about the spadix.

In regard to the hardiness of *Heuchera sanguinea*, Mr. A. H. Fewkes, of Newton Highlands, Massachusetts, reports that it passed the winter safely in his border. It made stout plants in rather light soil, flowering freely. It received the usual covering of leaves given to other plants in the same border.

Market-gardeners in England sometimes add to their profits by cultivating hardy flowers among their vegetables. For example, in a Cornish market-garden recently described in the *Gardeners' Chronicle*, a growing demand for Wallflowers had induced the owner to plant four acres of them, on ground the first duty of which was to produce Potatoes. As soon as the Potato crop is up the young Wallflower plants are inserted, "much in the same way as Broccoli and Mangels were planted a few years ago."

Kœlreuterias are blooming most abundantly this year and it is noticeable that on some trees the flowers are of a much brighter yellow than they are on others. There is a marked difference, too, in the time of flowering in different individuals—some being ten days earlier than others. Any well grown Kœlreuteria is a striking object when in full flower and these trees have an especial interest from the fact that they are covered with showy flowers after the great majority of trees and shrubs are past their bloom.

The Prairie Rose (*R. setigera*) is slowly finding its way into American gardens and few persons see its corymbs of large, deep rose-colored flowers without feeling that it is superior to the double flowered climbing roses, like Queen of the Prairies, which have originated from it. It is the only American Rose with climbing stems and is one of our most beautiful climbing plants. Its foliage is handsome and less liable than that of the garden hybrids to attacks from insects and its beautiful flowers appear in great abundance after the general Rose season is past.

In a private letter, Mr. F. L. Temple, of Shady Hill nurseries, now in Europe, states that the most interesting flowers he saw in England were the Pyrethrums, and he was surprised to find that plants so little known and grown at home were, next to the Rose, the most popular ones in English gardens in June. The best double varieties are as good as the finest China Asters in autumn, and they are admirable for cutting. Among the named single varieties, Melton and Mrs. Bateman Brown were noted as the best, while Captain Nares, Mont Blanc, Flora, Haage & Schmidt and M. Barrall were among the finest double sorts.

Mr. Andrew S. Fuller finds that the green Cabbage-worm is discouraged by the following treatment: Two quarts of coal tar are put into an open vessel which is set in the bottom of a barrel and the barrel is filled with water. In forty-eight hours the water is impregnated with the odor of the tar although the tar is not dissolved in it. The water is then sprinkled abundantly on the Cabbages and the odor penetrates every portion of the head, killing or driving away the worms. As the water evaporates no stain nor odor remains on the cabbage. The same quantity of coal tar can be made to impregnate several successive barrels of water.

The great Rose Shows of England this year have differed altogether in quality from the exhibitions generally held when collections of Hybrid Perpetuals and of the Tea-scented varieties were only to be found. For the late exhibitions, collections were invited of Moss and Provence Roses, of hybrid Chinas, of Bourbons, of Noisettes, of Single Roses "of decorative value," of climbing Roses, of Polyantha Roses and other classes. The season there has been favorable for the production of these flowers so that the display of bloom has been remarkable, while the public interest in all matters relating to Roses and Rose-culture seems to be more profound than it ever was before.

According to the *Pacific Rural Press* the cool, moist climate and filled in, sandy soil of San Francisco are peculiarly adapted to the best development of the Fuchsia, which has grown in popularity since the day it was introduced until plants are found thriving in every unlikely nook and corner. On some residence streets there is scarcely a yard or strip of shaded ground which does not boast of beautiful specimens. Doorways and windows are shaded, stone walls and board fences covered and foundations hidden—in fact, some yards are entirely filled, so that the Fuchsia plays an important part in the

city's decoration and there are many single specimens there that would do honor to any part of the world.

In response to a request by the Board of Park Commissioners of the City of Omaha, Mr. H. W. S. Cleveland has prepared a report upon a system of parks adapted to that city. Mr. Cleveland gives some sound advice as to the desirability of broad, tree-planted avenues or park-ways and of systems of small parks for American cities. It is his counsel, also, that land be secured outside the present business part of the city for a park large enough to furnish the relief of seclusion from city sights and sounds and the refreshment of rural scenery. He considers that for this purpose 500 acres is the smallest area that would be required in one body, and that an equal area will in time be needed for another park in some other direction from the business centre of the city.

A new disease of the Irish Potato has been discovered by Professor J. Lamson Scribner at the Experiment Station at Knoxville, Tennessee. The disease first appears in numerous small pimples, each surrounded by a slight depression. In advanced stages the pimples and their depressed borders occupy the entire surface of the tubers, which become much shrunken. The skin is broken over the point of the pimples, giving them a grayish color. The Potatoes gradually become reduced in size, dried out of shape, and finally are very dry and hard. The cause of the disease was shown by microscopic examination to be thread-worms or nematodes, which were present in great numbers, the largest of them being about one-fiftieth of an inch in length. Nothing is known of the history of this parasitic Potato-eel, so that no remedial treatment can be suggested. Many of these parasitic nematodes pass a period of their existence in the ground, so that it is probable that they were introduced into the University farm from infected seed—for an infected tuber would be certain to carry the worms to the new crop, thus perpetuating the disease.

One of the most interesting of the old homes of America is Dungeness on Cumberland Island which lies off the coast of Georgia just north of the Florida boundary-line. The southern portion of the island, together with the estate of Mulberry Grove on the mainland, was presented by the state of Georgia to General Nathaniel Green as a recognition of his services in the Revolutionary War. He resided at Mulberry Grove, but, says a recent writer in the *Evening Post*, he planned a country-house on the island, "laid out the garden which afterwards became so famous for its tropical fruits and flowers, . . . and cut through the forest of Live-oaks those grand avenues which now form the wonder and delight of Dungeness." After he died in 1786, the house itself was built by his widow who subsequently married Phineas Miller, of Connecticut, and it became her permanent home. Its foundations rested upon an immense shell mound, a relic of Indian habitation, which was levelled to form a terraced base nearly an acre in extent, and it was of great size and dignity, containing some forty rooms. "A wide lawn lay before the house with its shades of Palm and Live-oak. On the south was an Eden-like retreat—the famous Dungeness garden. It comprised twelve acres enclosed by a massive wall of Coquina and was entirely devoted to tropical fruits and flowers. The garden fell by terraces to the creek. On the terrace nearest the house was a luxuriant growth of Crape-myrtle, and Sago Palms. Below it was a broad terrace divided by an avenue of Olives. A thick-set hedge of Mock-orange separated this from the lower garden, which was devoted to flowers and in which was a similar avenue of Olives. The garden was more particularly famed for its Roses though all varieties of flowers were cultivated. East of the garden was an Olive-grove of 800 trees brought from Italy, which attained a flourishing and profitable growth. Beyond, in the broad fields, 400 negroes toiled to raise the Sea Island Cotton and Sugar-cane that yielded the revenues of the estate. If the guests wished to ride there were the long dim avenues of the forest and the eighteen-mile-long beach. If they wished to sail, bright waters that seem especially provided for the yachtsman surrounded them; to hunt, they found an abundance of bear, deer, wild turkeys and water-fowl in the forest which even now covers much of the island." Dungeness was burned during the Civil War in a Christmas frolic of the negroes who were then in undisputed possession. It lay ruined and deserted for years, but was bought a few years ago, with half the island, by Mr. Thomas Carnegie of Pittsburgh who erected a modern villa on the old site, reclaimed the lawns and gardens from their wildness, and eventually added the northern half of Cumberland to his estate. The lawns in this climate are always green, and Orange-trees, Palmettos and a host of other sub-tropical plants group with the Live-oaks in splendid confusion. But the Live-oaks themselves are the great feature of Dungeness.

What is a Sycamore?

IN an article called "Popular Errors," not long ago printed in a St. Louis newspaper, and thence copied into an eastern journal, the following paragraph appears:

"Another error in the application of names is noticeable in the vegetable world. This is with regard to the so-called Sycamore. The true Sycamore (*Acer Pseudo-platanus*) grows only in England, or, at most, in the British Isles. Our tree—*Plantanus occidentalis*—should be called Buttonwood. The true Sycamore is as worthless as Buckeye or Horse Chestnut."

It would be hard to find more errors combined in a single paragraph than appear in this one, which was intended to set wrong things exactly right, even if the mistake of printing *Plantanus*, instead of *Platanus*, be credited to the printer rather than the author.

Mistakes and confusions are, however, the very essence of popular plant-naming, and it may therefore be worth while to explain what is the right use of the name Sycamore, and to trace the steps by which it has come to be applied to three entirely different trees—*Ficus sycomorus*, *Acer Pseudo-platanus* and *Platanus occidentalis*.

Not the second, but the first of these, is the "true Sycamore." It is a tree of the Fig Family, very common in Palestine, Egypt and Arabia, where it grows to a great height, extends its branches over a wide area, and is much prized for the shade it affords. Its Figs are sweet and delicate, although it is not the species commonly cultivated for fruit. Its wood is light, but very durable, and was largely employed in ancient times. The mummy-cases of the Egyptians, and those wonderful sculptures in the round which have been found in the tombs of their earliest dynasties, were made of it. The name Sycamore is a combination of the two Greek words, *Sykon*, a Fig, and *Moron*, a Black Mulberry, and emphasizes the fact that the leaves of this Fig-tree resemble those of a Mulberry. This, then, is the Sycomorus of the Romans, the Sykomoros of the Greeks, the Sycamore of the Bible, the "true Sycamore" for all time. The most famous specimen now existing is perhaps that one not far from Cairo, which is

believed to be more than two thousand years old, and is pointed out to travelers as the tree under which the Virgin and Child reposed during the flight into Egypt.

Acer Pseudo-platanus is a species of Maple. Although commonly called in England simply the Sycamore, it should be called the Sycamore Maple, the qualifying word merely explaining the likeness of its leaves to those of the true Sycamore. The statement that it grows only in the British Isles is far enough from the truth; for, while it is a native of the continent of Europe, and is found growing wild in many places there, especially in Germany, Austria, Switzerland and Italy, the first mention of it as growing on British soil is in Turner's "Herbal," printed in 1551, and all subsequent writers either deny or question the fact that it is indigenous to that soil. Nor is it a "worthless" tree, for its wood is much used in the delicate work of the makers of musical instruments, as well as for many other purposes. Pliny makes especial mention of three species of Maple among many which he believed to exist. One of these is undoubtedly the Sycamore Maple, and it seems to be the Maple mentioned by Virgil, as he speaks of the stature and strength of the tree and the durability of its wood. The confusion of its identity with that of the true Sycamore must have begun very long ago, for Evelyn, in the seventeenth century, mentions the fact that religious persons had then long been accustomed to plant the Sycamore Maple near their homes in the mistaken belief that it was the Sycamore into which Zacharias climbed to see the Saviour pass. For the same reason, its significance in old treatises on the language of flowers is "Curiosity." This tree has been much planted of late years in America, but is never called the Sycamore—always the Sycamore Maple.

Platanus occidentalis is the principal American representative of *Platanus orientalis*—the Plane tree of modern Europe and of ancient writers. In Europe the name Sycamore is never given to a Plane tree, but in America it seems to have been thus applied from early times, for the younger Michaux, writing early in the century, cites it as an accepted name, others being Buttonwood, Cotton-tree and Water Beech. According to him Plane trees were called Sycamores only in the Western States; but now-a-days, at all events, they are so called in many eastern districts. The fact appears to be that the English who had miscalled a Maple because of its striking, if superficial, resemblance to the true Sycamore, similarly miscalled the *Platanus occidentalis*, when they emigrated to America, because of its resemblance to the Maple they had left at home. The right name for the western as for the eastern *Platanus*, is the Plane tree; but Buttonwood is a perfectly legitimate, and, indeed, excellent name, as it has not been applied to any other kind of tree and is picturesquely descriptive of the fruit of the Plane. Water Beech is, of course, a patent misnomer, and Cotton-tree is not appropriate, and leads to confusion with Cottonwood, a species of Poplar.

Classic writers constantly refer to the Plane tree, and it was one of the most highly-prized trees of the more temperate parts of the Orient. On a Plane tree in Phrygia Marsyas was hung to be flayed by Apollo. Under a grove of giant Planes on an island off the Lacædemonian coast the youth of Sparta met for athletic exercises, and Pausanias mentions a Plane in Arcadia which was then said to be 1,300 years old and to have been planted by Menelaus. But the most famous Plane tree of antiquity was, perhaps, the one in Lycia, which so delighted Xerxes by its size and beauty that he caused it to be encircled with a collar of gold and delayed a whole day beneath its shade—a fact to which contemporary critics are said to have largely attributed the defeat of his expedition. The so-called "Seven Brothers" are seven huge and magnificent Planes which stand on the shores of the Bosphorus, as they stood when, in 1096, Godfrey de Bouillon and his Crusaders encamped in their vicinity, and are estimated to be at least 1,500 years old. The most famous Plane of our western world, if we may associate renowns so dis-

similar in duration, is the one which stood and perhaps still stands on an island in the Ohio River near the mouth of the Muskingum, which was measured by Washington in his early days and again by Michaux twenty years later, when its circumference was found to have but slightly increased and to be forty feet, four inches at five feet from the ground. It is a pigmy, however, in comparison with one of the Seven Brothers, which, it is stated measures 150 feet.

In Scotland, we are told, the Sycamore Maple is frequently called the Plane tree, and thus the cycle of confusion is complete.

The name we have been discussing is sometimes spelled Sycamore and sometimes Sycomore. Both spellings are permissible, but, although the use of the *o* seems more logical, in view of the derivation from *Sykon*, the *a* is preferred by the best modern English authorities. Most of them do not associate differences in spelling with different significations, but we have found it stated in one horticultural dictionary that the *o* should be used in writing of the true Sycamore, and the *a* in writing of the Sycamore Maple. In modern foreign tongues the *o* is universally employed, and in colloquial French we find the same mistake as in colloquial English—*Sycomore* being constantly used in the stead of *Erable faux-platan*—Sycamore Maple.

How to Mask the Foundations of a Country House.—I.

NOTHING is more essential to the beauty of a country-place than that the foundations of the house should be properly connected with the ground from which they spring. The house should look as though it belonged where it stood and could not be moved to another spot without detriment; and all the devices of the gardener at a distance from its walls will not give it this appearance unless the walls themselves seem integrally united to the soil.

The first step towards the production of this effect must be taken by the architect. Not very many years ago a broken, irregular site was considered, in this country, undesirable for building on, and, when it could not be avoided, was often levelled that the foundations might be made as mechanically symmetrical as possible. But of late our architects have realized the folly of neglecting the chance to unite a house well with its site and at the same time to secure individuality and, possibly, great picturesqueness, and have seen that it is still more foolish to spend time and money in destroying such a chance when it cannot be evaded.

When the slopes of an irregular site are gentle and devoid of stones a beautiful result can be achieved by respecting their undulations, laying more or fewer courses of masonry according as they fall or rise, and bringing the grass up to the walls in an uneven, billowy, yet not too broken line. No better example of such treatment can be found than in the Public Library at Quincy, Massachusetts, a work of Richardson's which has been familiarized by repeated illustrations. When the site is rocky and when local stone can be used, rough-faced, for the foundations, as charming a result of a more strikingly picturesque kind can be achieved, as we see in Richardson's Public Library at North Easton—where the rock-like turret seems almost to have grown naturally from the rocky hillside—and in many cottages along the north shore of Massachusetts Bay, built by Mr. Emerson and others. To have levelled such sites as these would have injured the house as greatly as the grounds about it. Now the two are in harmony and each helps the effect of the other; while as the formation of such sites is never twice alike, each home has that most desirable of qualities—individuality.

But even in cases where Nature has given the architect a good chance to blend his work with hers something more is needed to make the union seem perfect; and this is doubly the case when the site is flat and the house must stand like a box upon a floor. Some simple arrangement of terraces may then be used with advantage if there is a difference of level between the spot where the house stands and the adjacent street or pleasure-grounds. But always something more is necessary—always the planter must be called in to help the architect whether Nature has helped him much or little.

Nature has helped him most, of course, when the site is very broken and rocky. Then the planting of a few vines against the walls may often suffice to bring them into a close enough

union with Mother Earth. It is a pity, however, that when vines are relied upon to do this service, a single kind should so often be chosen for repeated planting. A little thought in the selection of different kinds which harmonize, yet contrast, would produce a far more beautiful effect. It is well on a city house to let Wistaria or Japanese Ivy alone clothe the walls. Here there is no question of uniting site and walls, and we do not want variety or picturesqueness in a street facade even though it be a very wide one. A symmetrical architectonic effect should be preserved, and for this purpose a Wistaria trained on two or three wires stretched to the roof or a close covering of Japanese Ivy is better than would be an intermingling of two or more different kinds of foliage. But on a country house, especially of the irregular, picturesque kind we most often build, the presence of a single sort of vine produces an undesirable monotony. In some parts it will look best to have a vine which clings very closely to the walls; in others a more massed and freer growth will be preferable; and contrasts of color, density and habit in the clothing foliage will add immensely to the general effect.

But when the vines are once planted they should not be allowed to grow at their own sweet will. A house is not like a ruin or a cliff or a blasted tree where the wilder and more erratic the growth of the creeper the more charming and appropriate is the effect. It is (or should be) a work of art to which all its immediate surroundings are subordinate; and as its prime end is to give its owners comfortable shelter, it should always present—no matter how great its picturesqueness—a neat, orderly, well-tended aspect. Its vines, therefore, should be intelligently pruned and trained—not allowed to run ragged yet not forced into unattractive, unnatural stiffness. They should be pruned, but the fact that they have been pruned should not be apparent. Nor should they ever be allowed to cover a house entirely or to so great a degree that its architectural character is concealed—unless, indeed, this character be such that it deserves a shroud. To build a solid lower story of stone and then allow it to be entirely hidden, even during half the year, by a dense growth of foliage, is surely a mistake. Not only is the beauty of the stone-work concealed, but the effect of the upper stories, based, apparently, upon a substructure of fluttering leaves, is unsatisfactory to the eye. Vines enough may be grown to beautify the walls in the highest possible degree and unite them well with the ground and yet spaces be reserved, below as well as above, where the constructed surface shall appear—spaces which will indicate the character of the walls as a whole and thus prevent the eye from questioning the stability of any part. It is a good plan, also, to train some vines so that they spread over portions of the ground and thus make the transition between the soil and the wall seem still more natural. A mass of Honeysuckle, for instance, running out over rock or grass for a little distance is a very beautiful object, and its bloom will seem even more profuse in this than in an upright position.

The Art of Gardening—An Historical Sketch.—VII. Persia (continued).

IT is noteworthy that even princely Persians did not confine themselves to enjoying parks and gardens but shared in their creation. Strabo says that after the active exercises of the day were over young Persian noblemen were taught to plant trees as well as to forge armor and weave hunting-nets. When the Spartan Lysander visited the "paradise" of Cyrus the Younger at Sardis, he said: "I look with astonishment on all these trees on account of their beauty, but am still more astonished at the art of him who measured out the ground and arranged them for you." Cyrus, on hearing this, "was delighted," and said: "It was I, let me tell you, Lysander, that measured out the ground and arranged all the trees myself; and there are some of them that I planted with my own hands. Whenever I am in health I never dine until I have put myself into a perspiration by pursuing some military or agricultural occupation, or by contending for superiority in some exercise of a similar nature." Lysander may well have been surprised; despite the active temperament of the Greeks they left manual toil to their slaves, and to hear agricultural coupled with military exercises, as similar in dignity and interest, must indeed have been a novel sensation.

What now were the gardens of these Persians who created them on so extensive a scale and valued them so highly? In speaking of the parks of Bazarra, where Alexander hunted lions, Quintus Curtius says:† "A spacious wood in which

*Xenophon, *The Economist*.

†Life of Alexander.

numerous unfailing springs give cheerfulness to the scenery is selected, encompassed with a high wall, and interspersed with towers for the reception of the hunters"; and some writers have believed that this brief account describes the character of Persian *paradeisoi* in general—that they were merely portions of ground which Nature herself had made beautiful, carefully protected from hurtful alterations. But Plutarch is careful to relate that the park in which Artaxerxes permitted his soldiers to despoil for firewood stood "in the midst of a region naked, and without trees"; and if these special words imply, perhaps, nothing more than a natural oasis in a wilderness, there are others which more definitely indicate the arts of cultivation and arrangement. Plutarch says of the park which Tissaphernes named for Alcibiades—a true *paradeisos*, not a mere garden—that it contained "salubrious streams and meadows," but also "pavilions and places of retirement royally and exquisitely adorned"; and wherever in ancient times there were buildings that could be thus described, the adjacent landscape must likewise have been "royally and exquisitely adorned"—not left in the wild graces of nature. It is only in modern days that men have failed to perceive that the essence of beauty is harmony; that the essence of harmony is the likeness in fundamental character of one thing to another; that architectural beauty and the untouched beauty of nature, though equal in value, are dissimilar in character; and that each must be accommodated to the other if a satisfying general effect is to be the result. No Egyptian, Assyrian, Persian or Greek would have allowed the virgin forest or the untended champaign to come up close to the walls of temple or palace. In the park at Celænæ where Cyrus the Younger reviewed 13,000 troops, there were of course vast open spaces; yet through the middle of it, says Xenophon, ran the river Mæander. "Its springs issue from the palace itself, and it runs also through the city of Celænæ." A park which lay between palace and city, and a river which ran from beneath the palace itself, certainly imply some degree of formal, architectural treatment.

Several passages which I have already quoted show that trees were extensively planted by the Persians. Nor was it only in situations where they could not possibly have grown by themselves, as in city streets and squares, for the parks which Cyrus the Younger formed during his journeys were "stocked with everything good and valuable that the soil will produce;" and the scene where Lysander expressed his astonishment at Cyrus's personal prowess in tree-planting was the famous *paradeisos* at Sardis. This last-named incident, I may say in conclusion, gives us decisive proof that in such great parks a portion of the planting, at least, was done in a strictly formal way. Lysander admired not only the beauty of the trees, but "how regularly they were planted, how straight the rows of them were and how elegantly all the rows formed angles with one another."*

At "Shushan the Palace," as described in the book of Esther Ahasuerus held his great feast in the "court of the garden," which was hung about with embroidered draperies. The Persians used columns profusely, although the Assyrians and Babylonians did not. Ahasuerus has been identified with Xerxes, and in the splendid palace of this king at Persepolis may still be seen a wide, unwalld space with various groups of stately columns, sometimes called the "summer throne-room," which may well have been planted like a garden and used for feasts and audiences. Or, if "Shushan the Palace" means Susa, here also may be traced the remains of a similar court-yard.

In short, we may conclude that in Persia the art of gardening meant a combination or alternation of formal with natural-seeming arrangements. Symmetrical court-yards, regular plantations and stone-walled canals gave harmony to the neighborhood of buildings and formed adjuncts to such magnificent terraces and external stairs as we see at Persepolis, while more distant parts of the domain were left in their natural state or merely beautified without losing their character; and cultivation was everywhere carefully practiced. Are not these facts? And must we not deeply regret that we know so

little about the parks of the Persians? One can hardly imagine a more interesting relic of antiquity than a plan of a *paradeisos* could it be recovered—preferably, perhaps, the plan which would show us how Cyrus arranged his pleasure-ground at Celænæ so that he could hunt wild beasts within its limits yet review a great army in safety, and so that it formed a harmonious setting for the palace with a river flowing from its base.

When Pliny wrote in his "Natural History" that "the first Plane-trees that were spoken of in terms of admiration were those which adorned the walks of the Academy at Athens," he had in mind only Greece and Italy. He must have been familiar with Herodotus' story of the giant Plane that so delighted Xerxes near the borders of the Hellespont, when he was marching towards Greece, that he lingered for an entire day beneath its shade—imperiling his expedition by the act—decorated it with a golden circlet and left an officer of rank to serve as its guardian. In explaining the different varieties of Palms, Pliny says: "The most famous of all are those which, for the sake of distinction, have received the name of 'royal' Palms because they were preserved solely by the kings of Persia. These used to grow nowhere but at Babylon, and there only in the garden of Bagoas, the eunuch; . . . this garden was always carefully retained within the precincts of the royal court." Anecdotes like this help us to divine the almost passionate love that the Persians had for trees; and so many plants now familiar in European lands have come from Persia that we may fancy its gardens rich with a variety of beautiful blossoms as well as with those odorous shrubs the cultivation of which was rendered necessary by a profuse employment of perfumes and unguents.

New York.

M. G. Van Rensselaer.

Notes Upon Some North American Trees.—II.

21. *PORLIERA ANGUSTIFOLIA*, Gray.—This is a common plant on the dry plains of the lower Rio Grande valley, where I have observed it in Texas and Mexico. It is everywhere a low, upright shrub, with thickened stems, which are rarely six feet high. It cannot in any sense be considered a tree, and must be dropped from the Silva.

22. *XANTHOXYLUM AMERICANUM*, Miller.—Although this plant may be grown in gardens into a small tree with the aid of skillful pruning, it does not appear to become naturally a tree anywhere, and it should be dropped from the Silva.

23. *XANTHOXYLUM CARIBEUM*, Lam.—The proper name of this south Florida tree, which was first described by Nuttall (*Sylva* iii, t. 85) as *X. Floridanum*, is still in doubt. It has been referred to the West Indian *X. Caribeum*, which is said to be prickly, while the Florida plant is quite unarmed. It differs, also, in some minor characters from the description of Lamark's plant. Professor Gray doubtfully proposed to call the Florida tree *X. Caribeum* var. *Floridanum* (*Proc. Am. Acad.*, new ser. xxiii. 225), but it will be necessary to examine authentic specimens of the different West Indian species before this question of nomenclature is settled.

XANTHOXYLUM EMARGINATUM, Sw.—This handsome plant was collected by the late Dr. Garber in 1877 on Virginia Key, in Bay Biscayne, Florida. It has not been seen elsewhere in Florida, where it is probably exceedingly rare. It was not found by Mr. A. H. Curtiss, who has carefully explored the flora of the Florida Keys, and I failed to detect it anywhere on the shores of Bay Biscayne, to which I have made three separate journeys. Professor T. C. Porter, who has placed, most obligingly, his specimens in my hands, informs me that Mr. Garber left no notes upon this plant, which both Macfayden and Grisebach speak of as a tree or shrub. It may, perhaps, properly therefore find a place in the North American Silva. More information of its habit of growth, and of the size which it attains is, however, desirable. I am quite ignorant of the character of the bark of this plant, of the nature of the wood which it produces, and of the situations and soil in which it is found. Professor Porter calls my attention to the fact that some of the leaflets on the Florida specimens are obtusely pointed, the others emarginate as described by Swartz and by Grisebach, who gives (*Fl. Brit. West Indies*, 137), under *Tobinia emarginata*, the full synonymy of this species. A specimen

* "A person of high spirit and honor, naturally a king though fatally prevented by the harmless accident of post-geniture, not only a lord of gardens but a manual planter thereof, disposing his trees like his armies in regular ordination. . . all stories do look upon Cyrus as the splendid and regular planter." These words occur in "The Garden of Cyrus," a curious and interesting treatise by the famous seventeenth century writer, Sir Thomas Browne. The essay, however, like many of its time, is but loosely connected with its title. Accepting Cicero's statement that the regular rows and angles which Lysander admired in the plantations of Cyrus meant an arrangement in "quincunxes"—in a succession of patterns like that on a five-spot of cards—Sir Thomas passes into a rambling dissertation, finding, as Coleridge said, "quincunxes in heaven above, quincunxes in earth below, quincunxes in the mind of man, quincunxes in tones, in optic nerves, in roots of trees, in leaves, in everything."

collected on the Island of New Providence by William Cooper in 1859, is preserved in the Herbarium of Columbia College. This plant is apparently widely distributed through the West Indies.

HELIETTA PARVIFOLIA, Benth.—Dr. V. Harvard detected this plant growing very abundantly as a shrub on the bluffs of the lower Rio Grande, on the Texas side of the river (*Proc. U. S. Nat. Mus.*, viii. i., 515); and I found it near Seralvo, south of the river, where it is a slender tree, twenty or twenty-five feet high, so that it should find a place in our *Silva* in *Rutaceæ*, immediately after *Xanthoxylum*.

KÆBERLINIA SPINOSA, Zucc.—This plant, which is widely distributed from the valley of the lower Rio Grande to San Luis Potosi and to Chihuahua, must be included among the North American trees. It is often shrubby in its habit of growth, especially in Texas, but sometimes becomes truly arborescent, with a straight, erect trunk, six or eight feet long, and a round, compact head. Its place in the Catalogue is in *Simarubæ*, immediately before *Simaruba*.

30. *AMYRIS SYLVATICA*, Jacq.—I follow Professor Gray (*l. c.*) in referring our south Florida tree to *A. maritima* of Jacquin. The exposition of the confused synonymy of this plant will be found in the paper cited.

32. *XIMENIA AMERICANA*, L.—I have never seen this plant growing as a tree. It is common on all the south Florida Keys as a spreading shrub, sometimes with stout, nearly prostrate stems ten or twelve feet long, and eight or ten inches in diameter at the ground. I propose, therefore, to omit it from the *Silva*.

ILEX MONTICOLA, Gray.—This species was not included in the Census Catalogue. It is a widely-distributed plant through the Appalachian Mountains from New York to Alabama, generally as a low shrub, but I have seen it on the slopes of the Blue Ridge, both in North and South Carolina, especially near Highlands in Macon County of the former state, growing as a tree thirty or forty feet high, with a clean, straight trunk ten or twelve inches in diameter. It should find a place in the *Silva* immediately following *Ilex decidua*, Nutt. (No. 36).

38. *CLIFTONIA LIGUSTRINA*, Spreng.—Mr. Watson has pointed out (*Bulletin Torrey Botanical Club*, xiv., 167) that the oldest name for this plant is *Cliftonia nitida*, Gærtn, fil. (*Fruct.* iii., 247, t. 225, f. 5).

40. *MYGINDA PALLENS*, Smith.—This, it now appears, is a shrubby species, and should therefore be dropped from the North American *Silva* and replaced by *Myginda integrifolia*, Lam, as I have pointed out in the *Botanical Gazette* (xi., 313). This last is the *M. latifolia* of Chapman's "Flora of the Southern States," and was early confounded with *M. pallens* in American herbaria. *M. integrifolia* is truly arborescent upon Key West, where it is abundant and reaches a height of twenty or twenty-five feet, with a straight, slender trunk, often six inches in diameter. The fruit is two-celled, although sometimes one-celled by abortion. *C. S. Sargent.*

Platanus occidentalis.

OUR western Plane (*Platanus occidentalis*) is the largest deciduous tree of the American forests. It rises sometimes from the deep, alluvial soil deposited over the margins of streams in the valley of the Mississippi, to a height of a hundred and forty feet by actual measurement, with a tall, straight shaft, fourteen or fifteen feet in diameter. One of these large trunks appears in our illustration upon page 354. Such trees were common many years ago, in the valley of the lower Ohio and in those of its tributaries. Now they are rarely seen. The disturbances of natural conditions which always follow man into the wilderness are bringing to the forests in all our western country their inevitable consequences. When the surroundings of an old tree, which may have grown undisturbed through centuries, and which left undisturbed might have continued to grow through other centuries, are once invaded by man, its subsequent history

is generally short. The picture of another old Plane-tree and its characteristic surroundings, on page 355, shows what the fate of these forest giants is likely to be. An old tree which has grown always among other trees, and has been supported by its fellows, when suddenly deprived of this support, must soon die. Either the first severe gale will blow over the tall, badly-balanced trunk with all its weight of branches at the summit, or it will die gradually as the tree in the second picture is dying from the sudden exposure to the full sunlight of the trunk and branches, which were developed in the shade of other trees. The danger from wind is increased in the case of the Plane-tree, by the fact that these very large specimens, like the individual which appears in our illustration on page 354, are entirely hollow for a long distance above the ground. It is probable that these very large Plane-trees will disappear entirely, and that at the end of another century, and perhaps much sooner, such great trees as excited the wonder and fired the imagination of the early travelers on the Ohio, the Cumberland and the Illinois will be entirely unknown. The specimens which are now large will have died naturally, or prematurely through the interference of man, and younger trees must, in the future, be sacrificed to the demand for the wood which this tree yields, and which has lately become esteemed and is already largely used for many purposes.

Our two illustrations are made from photographs taken by Mr. Robert Ridgway in the valley of the White River, in southern Indiana—a region once famed for the beauty and varied character of its forests and for the great size attained by its individual trees.

Foreign Correspondence.

London Letter.

AT the last meeting of the committee of the Royal Horticultural Society, new Roses were the leading features of the exhibition, Mr. William Paul having a dozen or more novelties. Only two of them, however, were commented upon—Pink Rover and Duchess of Albany. The first is a climbing Bourbon, with flowers of the size and form of the old *Souvenir de Malmaison* and with the habit of *Gloire de Dijon*, vigorous and of a decided climbing habit. The delicate pink of the large, full bloom is very pleasing, but as the committee are very cautious in certificating new Roses before their true character is known, Pink Rover must be seen again and again. The Duchess of Albany is simply a sport from *La France*, differing from it only in color, being several shades darker, and some rosarians do not think this a desirable variation, as one charm of *La France* is its delicate pink hue. For all that the Duchess has its admirers. The best of the other novelties from William Paul included *Magenta Queen*, a bright magenta flower of good form and substance; *Hero of Waltham*, similar to but lighter than *Beauty of Waltham*; *Spenser*, in the way of *Baroness Rothschild*, but with more substance in the flower; *Salamander*, a good, deep crimson, and *Marchioness of Lorne*, a very free bloomer, said to be a capital garden Rose. There was also a lovely little Moss Rose called *Waltham Pet*, with white flowers and pink centres, a suitable companion for *Little Gem*. *Sappho*, the fine Tea Rose certificated some time ago was shown well, the singular nankeen-yellow tint being fully developed in the open air. *Medea*, a new Tea in the way of *Madame Caroline Kuster*, may be heard of later on as a good addition to the pale yellow group.

The chief among the other exhibits shown at this meeting were hardy flowers, as on the last occasion, the *Pæonies*, *Pyrethrums* and *Delphiniums* from Kelway, of Langport, and the *Lilies* from Ware & Barr being remarkable. Orchids are dropping off now conspicuously, and yesterday there were only half a dozen shown, the most noteworthy of these being two new hybrids from Messrs. Veitch, raised by their indefatigable foreman, Mr. Seden. One of these was *Zygocolax leopardinum*, raised between *Colax jugosus* and *Zygopetalum maxillare*. It is, therefore, a bigeneric hybrid, assuming that the *Colax* is a true genus. The hybrid resembles the *Zygopetalum*, both in habit of growth, in size and form of flower, but differs in color. The lip is of a very deep plum-purple, the sepals olive-green copiously spotted with cinnamon-brown. Though interesting to Orchid fanciers, it possesses no special merit to the general cultivator. The other hybrid was *Masdevallia Ellisiana*, a cross between *M. Harryana*

and *M. ignea*. It reminds one of *M. amabilis*, but has quite the form of flower of *M. ignea*. The color is intermediate. If it proves a winter bloomer, as *M. ignea* is, it will be a good addition to cool Orchids. There were two varieties of *Cattleya* shown, both having the lateral sepals feathered with deep purple on a pale mauve ground. One was called *C. Mendelii Hallé*, which had in addition a very brilliant labellum, and *C. Gaskelliana Sunray*, which differed from the ordinary forms only by the feathering. The very remarkable *Dendrobium Stratiotes*, from the South Pacific, was shown in flower, and, as it has seldom been seen, it created some interest. Like *D. taurinum*, to which group it belongs, it has peculiarly shaped flowers produced on short spikes from the last year's growths. It has narrow, whitish sepals, and the two petals are pinkish and stand erect, and, being twisted, remind one of the horns of an ibex. The labellum is beautifully adorned with rich purple reticulations on a pure white ground. It is among the most beautiful and distinct of all *Dendrobiums*.

Lilies of all kinds are just now in perfection, and among the great number shown were not a few new or uncommon varieties. The white form of *L. Martagon* was shown in grand condition by Mr. Ware, with stems a yard high, carrying conical spikes of pure white blossoms. Though an old sort, this is still rare, and, as it is so beautiful, it is the desire of all hardy plant-lovers to possess it. Another form of *L. Martagon* which I do not remember to have seen before was *Punctatum*, which has whitish flowers spotted with crimson, but it is not nearly so effective as the white or the blackish-crimson variety, *Dalmaticum*. Several American Lilies were shown, and of *L. pardalinum* there were some interesting forms. A hybrid between *L. pardalinum* and *L. parvum*, and named *L. pumilum*, was sent up as a new plant, but as it has not the noble beauty of the one or the pretty form of flower of the other, it was not considered worthy of an award. Of *L. parvum* there was a beautiful variety with scarlet flowers like those of *Fritillaria recurva*. It was named *L. alpinum*, but was evidently only a form of *L. parvum*. Of the lovely *L. Parryi* from the Rocky Mountains there were some fine specimens from the open border, some bearing four to five flowers on a stem. The rich canary-yellow of the fragrant blossoms renders it already a much-talked-of plant, and it is likely to prove a hardy and vigorous grower. There was a greatly admired group of *L. auratum* and other Lilies intermixed with dwarf plants of Japanese Maples. The elegant foliage of the Maples quite disguised the rigid stems of the Lilies, and with their different shades of green produced a charming effect. A very noble and handsome Indian Lily was shown by Messrs. Low, of Clapton, and the committee were unanimous in awarding a first-class certificate to it. It was named *Lilium Wallechi*, var. *superbum*, it being finer in all respects than the typical form. The plant shown had a stem about six feet high, clothed from top to bottom with long, narrow leaves, and surmounted by two flowers about nine inches in length, trumpet-shaped and of ivory whiteness. It is, unfortunately, not hardy, but will prove a superb plant for the green-house. This is the second Indian Lily Messrs. Low have introduced recently, the other being *L. Nepalense*.

Messrs. Veitch showed a fine gathering of flowering branches of some choice, hardy shrubs, including the very elegant *Zenobia speciosa* and its variety *pulverulenta*, both first-rate American peat shrubs. The variety is most popular because the glaucousness of the leaves go so well with the pearl-white flowers which look like magnified Lily-of-the-Valley flowers. *Styrax Japonica*, which is quite hardy as a standard here, was again shown in abundant bloom. Its flowers are an inch across, pure white with yellow stamens, reminding one of the old green-house climber, *Solanum jasminoides*. *Leptospermum baccatum*, similar to, if not identical with, *L. scoparium*, is also hardy at Coombe wood, though a native of Australia. It is scarcely showy enough in flower to recommend it to general cultivation, though the specialist in trees and shrubs will be delighted with it. W. Goldring.

"Having disposed the masses of trees, shrubs, etc., with reference to the general effect of the whole scene, we come now to the finishing touches of decoration—flowers.

"From the general love of flowers and their increasing varieties, we frequently see the breadth and repose of the lawn sacrificed to them. In a flower-garden, properly so-called, they hold undivided sway, and are at liberty to cover the whole surface and to assume every variety of form that fancy may dictate; but when flowers are admitted to the dress ground we have been considering, they must be amenable to the laws of composition, otherwise they injure the scenery they are intended to adorn."

W. S. Gilpin, 1832.

Cultural Department.

California Lilies.

EIGHT distinct species of Lilies are native to California, besides varieties. They are *Lilium Columbianum*, *L. Humboldtii*, *L. pardalinum*, *L. parvum*, *L. Parryi*, *L. maritimum*, *L. Washingtonianum* and *L. rubescens*. No other country in the world is so rich in these floral beauties, except Japan. Their range is from the sea-coast of Mendocino County to the edge of perpetual snow in the Sierras. Old Shasta's sides are the home of several species.

I have found *L. Humboldtii* in the rich alluvium of the upper Sacramento Valley, and *L. Parryi*, one of the most beautiful, is a native of the high mountains of San Bernardino and San Diego Counties.

As a collector I have taken many thousands of the bulbs of six of these species from their native homes, and have grown all but *L. Parryi*. In the soil in which they flourish and the manner of root-growth they vary greatly. Briefly it may be said that *L. maritimum*, *L. pardalinum*, *L. parvum* and *L. Parryi* are bog lilies with running or rhizomatous roots; that *L. Humboldtii* and *L. Columbianum* are native to rich, clayey soils, and that *L. Washingtonianum* and *L. rubescens* rot easily in cold or wet soils, that they are true bulbs, and that they thrive in well-drained soil of leaf-mould mixed with disintegrated sandstone or gravel.

L. pardalinum, often called Tiger Lily, by the country people, is the most easily grown of all. It has an erect stem with many long, lanceolate, pale green leaves, in whorls. The flower is large and showy; the petals, bright crimson at tips, orange dotted or blotched with black at centre, and recurved to the stem. There are few more brilliant sights than a well bloomed plant of this Lily. The root is hardy and little subject to rot. It prefers a rich sandy mould, but adapts itself to varying conditions. In a shaded pond I saw fine specimens on the mould on old logs, the fibrous root running down into the water. They were six to seven feet high with the finest of blossoms. In the rich mould below mountain springs, or in the alluvium on the banks of small streams, they grow to perfection. I have seen them doing well in sandy soil which in mid-summer was as dry as a brick. In cultivation I have seen the best results from planting in a sunken barrel filled with sand well mixed with leaf-mould or bog soil. It should be kept moist, not wet, and is better in the shade. The bulbs should be planted about four inches deep. Under such conditions strong plants grow five to seven feet high, with an abundance of bloom. Once planted, the roots should be undisturbed. They spread rapidly increasing in geometrical ratio. The bulb of this year throws out two growing roots this fall, each of these throws out two next fall, etc. When the clump gets too thick, the soil can be taken off and the smaller roots removed without disturbing the ones to be left. I have seen clumps of four or five hundred in the wild state, the produce of one bulb. Both leaf and flower of *L. pardalinum* have wide variations, and three or four varieties are named, but it is hard to lay down a dividing line, as the varieties run into each other.

L. Californicum is a variety with narrow leaves, and a brilliant flower; the tips of the petals a rich crimson and the dots small. Var. *puberulum* has paler flowers and broad leaves. The English florists have found a clear yellow form which they call *L. Warei*, but I have never been able to secure a specimen.

L. maritimum is one of the rarest in cultivation; this is for a double reason. The bulb is difficult to handle, being particularly liable to decay when disturbed. Then, too, its range of growth is limited. It grows in and around peat bogs, on the coast of Mendocino County—rarely farther north or south. It is seldom seen farther than two miles from the ocean. The surface of these bogs is dotted with clumps of Ferns and Azaleas. Around the bogs is a waste of gray, ashy-looking sand, densely covered with Heath, Cypress and Pines. On the edges of the bogs, the Lily is a dwarf, often blooming at three or four inches. In the bogs it roots itself in the tufts, and becomes a lovely plant, five feet high with ten or fifteen fine blossoms. The leaves are dark glossy green, and the blossom crimson. At Ukiah I have grown it easily in a reclaimed swamp in the shade. The soil is of vegetable matter and always moist. In the same situation *L. parvum*, *L. pardalinum*, *L. Columbianum* and *L. Humboldtii*, as well as the Japanese *L. auratum* make a vigorous growth, and, what is not usual for the latter, strong bulbs. At Ukiah there is little fog, and there are days in the summer when the thermometer will register more than one hundred degrees.

Lilium Parryi is similar to *L. pardalinum* in leaf and bulb, but the bloom is lemon-yellow and very fragrant. Of its

Platanus occidentalis.—See page 352.

cultivation I cannot speak, but believe it easy of culture under the same conditions as *L. pardalinum*.

L. Columbianum is *L. Humboldtii* in miniature. The bulb is small and compact. The stalk is two feet or so high, and the flowers true lily-shaped, the petals recurved. In color it is a light orange-yellow dotted with dark spots. This Lily has for its native home the plains of the Columbia River. It is easy to grow in cultivation only needing a well drained loam and ordinary moisture.

L. Humboldtii's bulb is often a pound in weight and very compact. The stalk is strong and stiff. The leaves are arranged in circles or whorls and are many in number. Eight or ten blossoms to the stalk are not unusual. These are of a reddish orange with round dark spots. Ordinarily this Lily will grow to a height of three or four feet. The finest specimen it has been my fortune to meet grew in the debris by the side of a Sierra stream. It was over eight feet high and had an enormous bulb. This Lily increases by seed only, in its native state, and where the natural conditions happen to be exactly suitable it is found in great numbers. I took over eight thousand good bulbs from one place some years ago. It was on a hillside in volcanic soil, where years ago the gold miners had cut the timber. I had spent the previous week in hard travel-

ing to find five hundred. I once found fine bulbs of *L. Humboldtii* in an Oak-grove near Chico. They were doing splendidly in the black adobe of that section. In cultivation, this Lily will thrive in clay loam or sandy loam. In hot sections it does better planted in the shade. It needs to be planted six inches to a foot deep, and will give the grower value received. High up in the Sierras above the pine-timber on those grand slopes covered with a mixed growth of Wild Cherry, Manzanita and Ceanothus, *L. Washingtonianum* finds its most congenial home. The soil is loose, decomposed granite and mould. The snow lies very deep in the winter and is late in melting. It keeps the bulbs moist in their early growth, and when it is gone they make a very rapid growth, often blooming six or eight weeks after the snow has melted. The stalk grows up from three to five feet, densely leaved in whorls, and with from five to twenty-five flowers, pure white and with a most delicious fragrance. I have seen places fairly white with this Lily and the air heavy with perfume. The bulb is large. I have bloomed it at Ukiah, but find it rather harder to bloom than any of the other native Lilies. I believe, however, that it is grown quite successfully in England. It should be given a loose soil and abundant moisture during the growing season.

Lilium rubescens is like *L. Washingtonianum* in every particular excepting that the flower blooms out pure white blotched with purple, and gradually gets darker till it is of rich ruby color, hence its name. Similar as the two Lilies are in habit, their native home is very different. *L. Washingtonianum* is a Lily of the high Sierras, *L. rubescens* of the Coast Range. It is found in the Red-woods close to the coast, on shaded hillsides in sandstone gravel, and on high ridges in the chapparal. The finest I have ever seen in numbers were on a chapparal ridge in a soil of gravel mixed with mould, the ordinary chapparal soil. The bulb grows deep and has abundant moisture in winter and spring, but in the summer such places get very dry. A friend of mine grows and blooms them readily in half barrels filled with sand and mould and placed in the shade. The first essentials with them is perfect drainage and a loose, porous soil. Of all our California Lilies it is the most beautiful, and of all Lilies it is the most deliciously fragrant. A flower will per-

fume the leaves of a book for months, and a well grown plant is the admiration of all beholders.—*Carl Purdy in California Florist*.

Orchid Notes.

Motions of Orchid Flowers.—Of all the numerous Orchids exhibited at the recent show of the Royal Horticultural Society, held in the Temple Gardens, in London, none proved such a centre of attraction as the remarkable little *Bulbophyllum barbigerrum*, exhibited by the President, Sir Trevor Lawrence. It was, indeed, difficult to get near the plant at all, such a crowd of visitors was there, all eager to obtain a sight of the curious little plant, whose beautifully fringed labellums were continually in motion. Curiosity, perhaps, prompted many people to see it; indeed, it was this that first drew my own attention. Whatever could it be which held together that cluster of people over whose shoulders others were trying to peep? "Why, it's alive," said one, and, on getting a little closer, the cause of the commotion became apparent. There was a curious little plant in a basket of some six inches in diameter, bearing a short, drooping raceme of reddish-purple flowers, each of which had a smallish lip margined with numerous long hairs, the whole nearly an inch long, perhaps,

and these were continually popping up and down in the most remarkable fashion. "The delightful little athlete," the *Gardener's Chronicle* calls it.

Being somewhat curious to know the cause of these singular movements, and being fully aware of the delicate hinge by which the lip, in this genus, is attached to the column, I carefully watched it for some seconds, and soon concluded that currents of air were the cause of disturbance; a conclusion abundantly confirmed by a gentle puff of the breath, which caused an unusual amount of commotion. So the exercise of the little "athlete" is of quite a passive nature, after all.

It appears to be some curious provision for securing fertilization of the flowers, the movements of the labellum probably serving to attract the attention of curious insects.

The singular little *Masdevallia muscosa* is, perhaps, still more remarkable. It appears from an account which has recently been published, that the lip of this plant is sensitive, and has a movement as definite as that of the remarkable *Dionaea muscipula*, or "Venus' Fly-trap." The habit of the plant is almost that of the well-known *M. Harryana*, but smaller, the flowers standing some six inches high; light yellow in color, the tube of the sepals short, the lip long and protruding, and much narrowed behind. When the flower opens the lip hangs pendulous underneath, but when an insect alights on the lip, and touches a small cushion-like disc, situated some distance from the apex, the lip suddenly shuts up tight against the column, moving through an angle of 80° or 90° in two seconds. The *Masdevallia* is not as bloodthirsty as the *Dionea*, for the insect is not tightly boxed in, nor does the plant forthwith proceed to devour and digest its victim. There is a way of escape between the two petals and the face of the column, but the insect can scarcely fail to carry away the pollen-masses in making its exit, and there can be little doubt that on visiting a second flower it comes in contact with the stigma, and thus fertilization is effected.

This is not all. The plant regularly goes to sleep at night—that is to say, it closes up tight—but positively refuses to sleep in the daytime; for two hours in a dark cellar are reported to have made no impression on it. The slightest touch with a hair on the sensitive cushion causes the lip to close suddenly, but after a short time it gradually opens again. Another remarkable point about the plant is that the peduncles are completely covered with greenish-yellow moss-like bristles, which have been well compared to those of a Moss Rose. There is no climbing up some other way. Ants have been observed to make the attempt, but eventually had to give it up in disgust. It is supposed that this is the particular use of these bristles, to keep away robber-insects. Those who would pay their respects must come in a legitimate way, and alight on the flower itself. Quite a little chapter of romance; but one would suspect that the insect goes away with rather mixed feelings after its first visit. *Calypso*.

London.

The genus *Brassia* derives its name from Mr. William Brass, who, towards the end of the eighteenth century, was sent as a botanical collector to Cape Coast and the surrounding districts by Sir Joseph Banks. There are several species known, but owing to the dingy color of the flowers of most of them, there are only a few which present sufficient beauty to entitle them to the consideration of the cultivator. Both *B. maculata* and *B. verrucosa* are now freely flowering here. The former is the oldest representative of the genus, of which it is the type, having been first made known to cultivation in 1806, when it was discovered in Jamaica. It has dark green, ovoid, compressed pseudo-bulbs, surmounted by a pair of spreading strap-shaped leaves. From nine to twelve flowers are borne on erect, arching spikes, about two feet long, which spring from the base of the pseudo-bulbs. The yellowish-green sepals are linear-lanceolate acute, and channelled on the front surface, the lower portion of which has several dark, dull purple blotches; the incurved petals are similar in shape and color to the sepals, but are only about half as long, and the dull purple blotches

are not so dense, having the ground color showing through in minute spots. The cordate acute lip is large and conspicuous; it is recurved at the apex, and the creamy-yellow surface is sprinkled over with purple-brown spots, while at the base there are two short orange-yellow ridges or crests. The specific name of *Maculata* was suggested to R. Brown, who first described this plant in "Hortus Kewensis," by the spots or blotches on the flowers, but it might be here mentioned that the flowers of all the species are more or less spotted in a similar manner.

B. verrucosa resembles the preceding species in habit, but has thicker pseudo-bulbs, somewhat furrowed and ridged, and narrower leaves. The sepals are about five inches long, pale yellowish-green, with a few dark reddish-brown spots at the base; the petals are only about two inches in length, of the same color, but more thickly covered with spots. The anterior half of the pandurate-cuspidate lip is pure white, abruptly changing to greenish-yellow on the lower half, which is studded with conspicuous green warts—a characteristic from which the plant received the specific name given by Dr. Lindley. This species flowered for the first time in England in April, 1840, in the nurseries of Messrs. Rollison, at Tooting, who had received plants of it from Mexico. Since that time, however, it has also been collected in Guatemala.

I might mention here that a few weeks ago at a London sale I noticed a fine specimen of this species which bore seven erect, arching spikes about two and a half feet long, each having from fourteen to eighteen flowers, which collectively presented a most striking appearance.

The culture of *Brassias* presents no particular difficulty. They will succeed either in well-drained pots or baskets,

Platanus occidentalis.—A Characteristic Western Scene.—See page 352.

although the former seem to be more generally used. A compost of rough, fibrous peat suits them best, and during the summer months, when the plants are making their growths, they should be watered frequently and thoroughly. During the winter months very little water is required to keep the pseudo-bulbs plump and fresh, but care should be taken not to withhold it until the plants begin to shrivel. The winter temperature during the day should be about 65° or 70° Fahr., sinking five or six degrees lower at night. In summer the night temperature should not be allowed to sink below 65° Fahr., while in the day it may rise from 70° to 80° Fahr.

John Weathers.

Odontoglossum Alexandra.—Only of late years has the finest form of this beautiful Orchid been introduced. Among the early importations the majority of the plants consisted of the variety with very narrow, thin-petaled flowers. These are now rapidly giving place to the broad, round-petaled type, which, during the past seven years, has been imported in considerable numbers. Mr. Frederick L. Ames, of North Easton, Massachusetts, has some very remarkable specimens in luxuriant health, with broad, deep-green foliage and stout well-formed pseudo-bulbs, from the base of which I recently observed no fewer than 200 spikes carrying massive blossoms well shaped and, in many instances, beautifully marked, spotted and fringed. In this wonderful display I noted the scarce *O. Wilckeanum*, carrying dozens of its striking yellow and brown flowers, *O. luteopurpureum*, *O. Pescatorei*, bearing on many-branched stems a profusion of lovely white blossoms, and several handsome plants of *O. vexillarium*, with six to eight richly-colored flowers on a spike. A fine specimen of *Oncidium macranthum*, with a spike measuring seven feet in length, was carrying many of its enormous olive-brown and bright yellow flowers, and specimens of the bright scarlet *Masdevallia Harryana*, helped to make this a paradise of Orchid flowers. The plants here noted occupied a structure facing north, the back wall being covered with moss and ferns, which are kept continually moist, maintaining at all times an atmosphere full of humidity, which is one of the necessities of successful cultivation. *O. Alexandra* is of easy culture and grows freely during the spring months, but during July, August and September great care must be taken to provide cool quarters, or the intense heat of this season will prove detrimental. Where extensively grown, north houses have proved the best for this Orchid, being cool, airy and light. While growing they delight in abundance of air and water, and when the flowering season is past they should be re-potted in a mixture of peat, sphagnum and decayed leaves, in equal proportions. Of all *Odontoglossums* grown few equal this for purity and durability of blossom, and when grown, as it is here, it must prove valuable as a florist's flower.

Planting Roses for Winter Bloom.

THIS operation is an important part of the work in many establishments at this season, and demands the exercise of great care and judgment. Careless planting is doubtless responsible for many failures that are attributed to other causes. The benches or beds having been prepared for planting by being refilled with good soil, in which has been mixed a proper proportion of good manure, some air-slaked lime should be added if the soil is inclined to be clayey; and if the soil is very dry when brought into the houses it will be found better to give it a good watering the day before beginning to plant, so that it will be moist enough to work nicely. The plants to be set out should be well watered a few hours before they are turned out of the pots, this being very necessary, from the fact that when the old ball of earth is dry at the time of planting, it will be found almost impossible to get it wet afterward without making the entire bed sodden, and a poor start, followed by a weak and unsatisfactory growth, soon shows the effect of this error. This point of having the plants moist at the time of transplanting is one of especial importance, and is essential to the welfare of the future crop of flowers.

It will also be advisable to leave the plants in their pots until they are actually needed for planting, as the tender young roots are easily injured if exposed to the direct rays of the sun for even a short space of time. In planting, the soil should be pressed firmly around the plant without breaking the ball, after which a good watering should be given so as to settle the soil. If the weather should prove very hot and dry at this time a light shading on the glass will be beneficial to the young plants, but it should be removed as soon as the Roses become established in their new quarters. For several days

after planting it is well to keep the house a little closer in regard to ventilation, gradually increasing the amount of air admitted as the plants take hold of the new soil, but always bearing in mind the fact that Roses are not stove-plants, and will not flourish if kept too hot.

As a preventive measure it is best to give the plants a dusting with sulphur after planting, as the germs of mildew are frequently present at this season, and awaiting a favorable opportunity to attach themselves to the young growth of the Roses, and this will at once check and disfigure it. It should be remembered that young Roses recently planted are not in a condition to assimilate large quantities of manure, and it will therefore be found best to defer heavy mulching or other application of strong fertilizers until the plants have become better established.

Holmesburg, Pa.

W. H. Taplin.

Notes on Wild Flowers.

Actæa spicata, var. *rubra* (Red Baneberry), is one of the early spring flowers. The chief beauty, however, of the plant is in the ample spike of cherry-red berries, which are now ripe. The foliage is also a handsome dark green. The plant will thrive in moist soil in either sun or shade.

Phlox pilosa is nearly past flower. It is one of the best of the hardy Phloxes, and remains a long time in flower. It is a slender plant, nearly a foot high, with large heads of rose-pink flowers. It takes readily to cultivation, and will thrive in any ordinary soil.

Asclepias incarnata (Swamp Milk-weed) is just beginning to bloom. It is a desirable plant for cultivation, and may be found in many of the wholesale lists of European nurserymen. It grows nearly three feet high, usually bearing several heads of rose-purple flowers. The plant is easily grown in ordinary soil.

Bloomeria aurea, a plant belonging to the Lily family from southern California, is now in flower. It grows nearly a foot high, bearing at the top a dense umbel of pretty yellow flowers half an inch or more in diameter. These flowers do not all open together, and the plant is a long time in flowering. We have had the best success with this plant when set in autumn and covered with leaves to protect it from frost.

Rudbeckia hirta (Cone-flower), although too common in many of our meadows, is a more showy plant when in flower than the rarer *R. laciniata*. The plant is generally about two feet high. The flowers are darkish yellow with a dark purple centre, and are often nearly three inches wide. It will thrive in any ordinary soil, and, when stimulated by cultivation is very fine.

Calochortus albus, var. *paniculatus* (Butterfly Tulip), is one of the finest of this genus. The plant grows from six to eight inches high, bearing several showy white flowers nearly an inch wide. Another pretty species is *C. pulchellus*, with numerous bright yellow flowers a little more than half an inch wide. The flowers of both remain fresh several days. They are both Californian plants and need to be protected from frost. We have had better success in wintering them in the ground and protecting with a covering of leaves than in the cellar. They like a warm, well-drained, loamy soil.

Brodiaea laxa and *B. ixoides* are both natives of California. The former is a slender plant hardly a foot high, bearing a loose umbel of large, showy blue flowers, which remain fresh several days. The latter has smaller flowers, yellow with a darker stripe, several on a plant. Its height is about the same as the first. Both need protection from frost, or should be wintered in dry soil in the cellar.

Charlotte, Vt., July 2.

F. H. Horsford.

Two Good Hardy Plants.—A recent issue of the *Gardeners' Chronicle* contains excellent figures of two fine hardy plants, *Chrysanthemum maximum* and *C. lacustre*. There has been much confusion about the names of these plants since their first introduction. We received from a well-known English firm *C. lacustre* as *C. maximum*, but were subsequently informed that the so-called *C. maximum* was the true *C. latifolium*, the former being a totally distinct plant, and so it has proved. Now, it appears that the name *C. latifolium* is not correct and must be replaced by *C. lacustre*. It is to be hoped that the two species are properly defined at last, since both are showy and desirable border plants. The true *C. maximum* is of somewhat spreading habit, the flower-stems attaining a height of eighteen inches. The flowers are two inches in diameter, with yellow discs and white ray petals of good substance and very suitable for cutting. *C. lacustre* is much taller when treated liberally, having erect shoots three or four feet high surmounted with flowers similar to those of *C. maximum* but

much larger, with the edges of the petals recurved. This plant is a native of Portugal, but has lived out here during the past two winters without protection. *C. maximum* is a native of the Pyrenees and near the Stelvio Pass, so that we may reasonably expect it to prove hardy in our eastern States, since Stelvio Pass is 9,100 feet above the sea and the highest carriage route in Europe. Now, that the Marguerites are so much used for floral decoration, both the above plants should find favor with growers, as both are eminently suitable for cutting purposes.

Symphandra Hoffmanni is the name of a new and very beautiful Campanulaceous plant, which was figured and described last year as flowering at Kew for the first time, and is now flowering freely in the grounds here, and proves to be a valuable plant for the border. It grows about two feet high and is much branched, forming a compact plant, which has for some weeks been covered over with a profusion of large pure white cylindrical bells, reminding one forcibly of *Campanula nobilis*. Other species of this genus are biennial and *S. Hoffmanni* may also prove so, although it offers, at present, no indications of that character. But even if it is, seeds are produced in abundance and these germinate readily. Our plants were raised last year and planted in rich, moist soil, and there they wintered safely without any further care, and they are now covered with flowers and buds that promise to maintain a succession of bloom until frost.

Passaic, N. J.

O.

Roses in Open Ground.—So far this has been a very peculiar season for these plants. Most of the Hybrid Perpetuals did well at blooming time, but they do not appear to be making much growth since, and all kinds of destructive larvæ are preying upon them. Of the newer varieties the best, so far in this locality, has been Mrs. John Laing. Though not of a very hardy constitution, its pale-pink color, fine form and delightful fragrance make it a very desirable variety, and it is a splendid autumn bloomer. Earl of Dufferin is a grand Rose of a deep bright crimson, very fragrant and of a good constitution. Lady Helen Stewart is another first-class Rose, with a good, vigorous constitution. Ulrich Brunner, though not particularly new, nor yet generally planted is pleasing in shape and color. Queen of Queens has again proved one of the best bedding Roses, of a pale shaded-pink color and very attractive in every way. To my mind, however, the best Rose of this class introduced to this country this year is Gloire de Margottin. It is the clearest bright red yet introduced, very fragrant, a strong grower and a Rose that pleases every one who sees it. Last of all is that grand Rose, Madame Gabriel Luizet. With its satin-pink color and unsurpassed fragrance it has few equals, and it should be in every garden no matter how small. If it were my fate to be deprived of every Rose but one for growing in the open air, I should choose this one above all others. It is still producing some good flowers, and will continue to do so all summer at intervals. The monthly or everblooming Roses are not growing very well in this section, except where extra good, strong plants were put out early.

Summit, N. J.

John N. May.

The Vegetable Garden.—It is not too late to plant Lettuce, Spinach, Turnip, Corn Salad, Kale and many other vegetables, but to secure double crops the soil must be full of plant-food from frequent applications of fertilizers in former years. Cucumbers, Melons, Lettuce, Egg-plant, Spinach, Onion and many other crops demand hearty and constant food for their best growth. This can be illustrated more plainly when the crops are maturing than at any other time, for this truth is then brought home with convincing power if the crops do not promise a good reward for the labor given to them. If, on a close inspection, a growing crop seems less vigorous than it should, there are reasons for the failure. The soil may have been too compact, too dry or too wet; but lack of fertility is, four times out of five, the cause of backwardness. And the remedy should be applied at once, in the form of some high-grade commercial fertilizer, especially prepared for garden crops. This application is valuable now in any backward garden. Scatter it along near the growing plants, and hoe or dig it into the soil with as little injury to the roots as possible. If not too long deferred, this treatment will effect a striking change in color and vigor of growth.

Hampden Co., Mass.

W. H. Bull.

Fine Flavor in Fruit.—As the period for the ripening of large fruits is approaching, it may be well to remind inexperienced cultivators of the importance of high culture for the development of the finest quality. Some years ago, two St. Ghislain Pear-trees bore fruit so unlike that they would not be

recognized as the same variety. There was almost no similarity in flavor. One tree, bearing poor fruit, stood in a thick grass sod; the other, with excellent Pears, was kept well cultivated. Early Pears, as well as early Peaches, on crowded trees, which ripen first on the tree, are much inferior in flavor to those which come later. The first are grown so thickly on the branches that they cannot sufficiently mature; those which ripen later, after the early portion of the crop has been removed, have plenty of space to develop their fine quality. Hence the great advantage of early thinning. Take the Summer Doyenné Pear, for instance. Those which are first ripe on densely crowded limbs are about half the size of those which ripen last, and strikingly inferior to them in quality. So with early Peaches—the last scattered ones on the tree are commonly observed to be greatly superior in flavor to the first which ripen. These facts teach the importance of good cultivation and of thinning the fruit on crowded trees, both of which operations will always repay the grower in large, beautiful and excellent fruit, instead of small, knotty and flavorless specimens.—*Country Gentleman*.

Periodical Literature.

THE most interesting articles in the June number of the Kew Bulletin of *Miscellaneous Information* are the following:

Jamaica Cogwood.—This has long been known as one of the most valuable woods produced in the forests of Jamaica, and in the flourishing days of Jamaica sugar-planting it was everywhere in demand for framing mills and for the cogs of machinery. It is durable in water, and tough, hard and heavy. But although this wood has been used for centuries, and the trees which produced it almost exterminated, it is only now that their true name and botanical affinities have been made out. It was long supposed to be a Laurel and then a Ceanothus, but at last sufficient material has been obtained to enable Professor Oliver to make out that the Cogwood-tree is a *Zizyphus* (*Z. Chloroxylon*), a genus not represented before in the Jamaica flora.

Cocoanut Coir from Lagos.—Large nurseries of young Cocoanut plants have been established by the Colonial Government of Lagos, and seedlings are distributed at very low rates, with the view of making the cultivation of this plant in the colony as general as possible. Samples of the fibre recently sent, experimentally, to London, owing, perhaps, to defective methods of preparation and shipment, have not been very well spoken of by experts.

A Wheat Pest in Cyprus.—A report upon a species of *Tinea*, an insect destructive to wheat crops in Cyprus.

Patchouli.—An abstract of an article entitled the "Cultivation and Curing of Patchouli and its Adulterations," from the *Journal of the Agricultural and Horticultural Society of India*, a portion of which we reproduce here:

The plant yielding the perfume known as Patchouli is usually stated to be indigenous to the Malayan Peninsula, but there appears to be no evidence that it has been met with in the jungle, except in places where it could be clearly traced to some old cultivation.

It is grown and much esteemed by the aboriginal tribes of Perak and Pallang, and is met with at an altitude of nearly 5,000 feet amongst the Sakais of the mountains, far away from any Malayan villages.

The leaves are made into garlands and worn round the waist by the women, and bunches of them are often stuck into their bamboo ear-rings. They are also mixed with other leaves and flowers and formed into ornamental bunches, which are hung up and used in some sort of demon worship or propitiation.

Patchouli is a very shy flowerer, so much so that by the natives it is said never to flower, and a dealer, who has grown and bought it for the last thirty years, has never seen or heard of such a thing as a flower or fruit. Mr. N. Cantley, in "Notes on Economic Plants," says: "Plants raised from seed are reported to grow well but to have no scent, but retain it when produced from cuttings. I have not been able to verify these statements, but it is well known that plants do sometimes play tricks of this kind—Sandal-wood frequently." If this report was obtained from native sources it, probably, only represents another way of saying that the plant hardly ever bears seed.

The cultivation of Patchouli is carried on almost exclusively by the Chinese in the Straits Settlements. They do not grow it on a large scale, but a man will plant a patch of perhaps half an acre or an acre at a time. The land is trenched and thrown up into long beds either four feet or eighteen inches wide. The former of these will take two rows of plants, and

the latter only one. The plants are put two feet apart along the rows. The planting is done in the wet season, and the cuttings, which are about a foot long, require careful shading with leaves until rooted, or they will get withered and die, the plant being a delicate one, and very susceptible to the heat of the sun.

The first cutting of the crop is made in about six months after planting, by which time the Patchouli will have reached a height of two to three feet, and two other cuttings are made from the same plants at intervals of about six months. At the end of this time the old roots are dug up, the land re-trenched and fresh cuttings planted.

No reliable information as to the yield per acre nor the cost of cultivation is accessible, but it must be rather high, as the land has to be thrown up into beds, manured and carefully weeded and the cuttings shaded, and, if dry weather sets in before they are rooted, they have to be watered until established. The plant seems to flourish best under slight shade, but, probably, the production of oil is less in that grown under shade than in that grown out in the sun, though the yield of leaf would be greater. It is often planted on new land between Coffee, Nutmegs and other permanent crops, and is said to pay all the expenses of clearing and planting, leaving the permanent crop as clear profit.

The plants are cut down near the ground when they have reached a sufficient size, one stalk only being left to each bush. The Patchouli is then laid out in the sun to dry in the daytime, and put under cover at night and on the approach of rain. When thoroughly dry it is done up into bales, and sold either to dealers in the leaves or to the distillers. In this state it fetches about six dollars a hundred pounds.

The dealers cut it up and separate a great quantity of the larger stalks, and, according to its freedom from these, it is classed as first, second or third quality. The best consists of leaves only, and is valued at \$20 to \$24 a hundred; but, owing to the labor involved, this quality hardly pays to prepare. The second quality is composed of leaves and young shoots with little of the heavier stalk, and ranges in price from \$13 to \$15 a hundred. The third quality contains less leaf and more stalk, and fetches about \$10 a hundred.

The best quality of all would be produced by picking from the plants the leaves and tops of the young shoots, and drying these in the shade, but it is doubtful if it would pay. Prepared in this way thirty-six pounds of green leaves produce ten pounds of dried Patchouli.

Large quantities of the leaves of a plant known by the Malayan name of Ruku are often mixed with Patchouli. The botanical name of this plant is *Ocimum Basilicum*, L., var. *filosum*. A Chinaman recently bought the whole of the Ruku growing wild in a Coconut plantation in Province Wellesley, and twenty-eight tons of the dried herb were collected and taken to Penang to be used for the adulteration of the more valuable Patchouli. European dealers prefer to buy the plant just as it is cut, when it is easy to see if it is adulterated or not, but if the leaves are bought it is very hard to detect the imposition. The leaves of another plant are also often mixed with Patchouli. This plant (*Urena lobata*) is called *Perpulut* by the Malays, and is to be had in any quantity for the trouble of collecting it.

The dried Patchouli is put into a large copper cylinder fitted with a perforated false bottom and mounted on trunnions. Through one of these steam enters from a boiler and is conducted by a tube beneath the false bottom. The remaining trunnion is also hollow, and the steam under a ten-pound pressure, after passing through the leaves, passes out by it and into a worm immersed in a tube of water in the ordinary way.

One hundred pounds of the dried Patchouli, just as it is cut, yields from eighteen to twenty-two ounces of essential oil, and a sample free from the heavier stalks yields about double that amount. By an ordinary still not more than one-half of the oil can be extracted. The green leaves yield little or no oil, and therefore it is necessary that they be dried before being subjected to the process of distillation. The oil is of two varieties, the one being sage green, and the other the color of medium-colored sherry.

Sometimes the one color is in greater demand than the other, but the prices are the same for both. At present the price in Penang is about fifty cents per ounce. Both kinds of oil when fresh are limpid and quite fluid at ordinary temperatures, but at 40° F. they become rather thicker, but remain bright and clear. The golden-brown oil has a specific gravity of 9580 at 85° F., and the green oil a specific gravity of 9578 at the same temperature.

Oil has been kept for ten years in a bottle with a loose stopper, when it becomes of a dark brown color and of a syrupy

consistency. The scent of this old oil, however, is little inferior to fresh, though not quite so powerful. This bears out the statement in Ure's Dictionary of Arts, that "the essential oil of Patchouli is one of the least volatile of any known, hence it is one of the most persistent of perfumes from plants."

Mr. N. Cantley, Superintendent of the Botanical Gardens, Singapore, says: "Plants of Patchouli have been in demand for experimental planting, and a good number have been supplied. Pickled leaves are now selling at \$12 per hundred. The plants grow freely with but little care, and should figure among colonial products." This statement, although correct as far as it goes, gives a mistaken idea of the circumstances of the case. The production now is quite equal to the demand, which seems to be very limited, consequently the market is soon glutted, particularly with the oil. Unless, therefore, the use of the leaves and oil could be very materially increased, there seems to be no prospect of profitably cultivating it on a large scale.

Correspondence.

Forests and Civilization.—III. The North Woods.

To the Editor of GARDEN AND FOREST:

Sir.—It now seems probable that a great World's Fair, or International Exposition, will be held in the City of New York in 1892. If this is done a complete and well-arranged exhibition of the wood-products of this country should be one of the chief features, and the fair should be used as an occasion and means for stimulating public interest in forestry, tree-culture, landscape art, the management of parks and public grounds and related subjects. There should be an elementary department for the benefit of the good people who like to see trees smothering each other to death, and who think it is a crime to cut a tree down under any circumstances. As some savage races like harsh noises better than music, so some persons appear to feel as much pleasure in an ugly tree as in a beautiful one.

Such an exhibition of forest-products, as a part of an International Exhibition which will be visited by intelligent and thoughtful men from all civilized lands, can be made highly interesting and serviceable, and the friends of forestry in this country should at once begin to consider plans to secure its completeness and success. Some preparatory action looking to this end will probably be taken by the American Forestry Congress during its session at Philadelphia in October of this year.

One of the most important and useful features or adjuncts that could be connected with such an exposition would be an exhibition of the Adirondack region itself, as an actual, concrete illustration of our treatment of one of the most remarkable forests in the whole world. There should be arrangements for excursions, for visitors to the Fair, through different parts of this mountain region, and especially across the great tracts that have been destroyed by fire. It would be an interesting lesson to intelligent European visitors. They might write for their own journals descriptions of what they see, which if republished here would be valuable as criticisms from independent sources; and some of our own people who think that no very serious injury has been wrought here might bring their theories regarding the value of forests, as natural storage reservoirs for water, into a little closer relation with facts if they would take the trouble to come and look at the country.

When in Washington last winter I met a number of gentlemen connected with one of the departments of the Government, who asked me if the impression which is produced by the report of the New York Forestry Commission for 1885, regarding the denudation of Adirondack hills, is not an exaggeration of the facts. This is the report of Messrs. Sargent, James, Shepard and Poucher. It was based upon a more careful and thorough examination of the condition of the entire Adirondack region than had ever been made before, and all its representations are of the most moderate character. Most of them are far within the limits of the truth. The photographs, of course, exhibit faithfully the scenes which they represent. Nobody can question that fact, but the Washington people thought there were probably but a few places like those which are shown in these pictures, and that those were tracts of small extent, so that the aggregate denudation is really, they supposed, of but slight importance.

The truth is that the tracts represented by these photographs are so extensive as to constitute an important proportion of the whole Adirondack region. There are hundreds of such places as that which is shown in the picture called "An Adirondack Farm," facing page 5 of the Report. The soil was never fit

for cultivation. Now it is exhausted and ruined, and the inhabitants are starved and dwarfed in body and mind. The pictures of the Indian River country, and of the Hudson River above North Creek, exhibit accurately the desolation of regions of appalling extent. The one showing the appearance of the denuded hills of the Hudson watershed, following page 14, represents precisely as it was at that time the condition of broad hill-tops and slopes which were once covered with glorious forests. I looked at these hills a few days ago. Their appearance has not changed perceptibly in five years. The pictures are still accurate. I wish that these pictures, or photographs of similar places, could be reproduced in GARDEN AND FOREST. Making allowance for geological differences they would show what will yet be seen in Pennsylvania and other mountain forest-regions of our country, unless a great and almost impossible change is speedily wrought in the character and habits of the people of our country.

Years ago I wrote from here: "Last week I rode through the 'Schroon Country' with a man who has probably done as much as any one to desolate this whole region. From Minerva, past Pottersville, Schroon Lake, Schroon River (Roots Hotel), and on along the Elizabethtown road past Dead-water to the new road that leads through the forest to Smith Beedy's, we traveled all day long through a blighted and hopeless land. As league after league of utter desolation unrolled before and around us, we became more and more silent. At last my companion exclaimed: 'This whole country's gone to the devil, hasn't it?' I asked what was, more than anything else, the reason or cause of it. After long thought he replied: 'It all comes to this—it was because there was nobody to think about it, or to do anything about it. We were all busy, and all somewhat to blame, perhaps. But it was a large matter, and needed the co-operation of many men, and there was no opening, no place to begin a new order of things here. I could do nothing alone, and my neighbor could do nothing alone, and there was nobody to set us to work together on a plan to have things better; nobody to represent the common object. Why did not you come along to talk to us about it years and years ago?'"

During the last two days I have passed over the same ground. The aspect of the country is the same, except that the gullies in some places are deeper and wider, and where there is clay or sand the erosion increases. Where there is life there is change, but these dead regions, hills of bare rock, and valleys of desolate sand are little changed from year to year. Extensive tracts here will be much the same a century from now.

I hope all the visitors to the great World's Fair in 1892, who are interested in forestry subjects, will come and see the "Schroon Country," taking the route I have indicated. Minerva is reached by stage or buck-board from North Creek, which is at present the northern terminus of the Adirondack Railroad. If the people of the State of New York would visit these regions they might, possibly, come to feel a more intelligent and vital interest in their own possessions in the North Woods, and in the great river which has its sources here, and which is so necessary to the prosperity of the cities at its mouth. At present everything indicates that when the Adirondack region is completely ruined, if not before, the people of the State will at last awaken to a sense of its value, and will then, perhaps, take steps to obtain possession of it. It will cost vastly more then than it would now, and its value will be fatally impaired for centuries to come.

The Adornment of Gardens.

To the Editor of GARDEN AND FOREST:

Sir.—Kemp, in his "How to Lay Out a Garden," a little volume brimful of excellent suggestions, says: "Gardening and architecture, like all the fine arts, have much in common—and that department of architecture which belongs more exclusively to the garden has especially a great affinity with gardening in its broader principles. In fact, there is much more relation between the two than is usually admitted, or than the ordinary products of practitioners in either art would at all justify us in believing."

I confess to a great admiration for those stiff, formal, geometrical gardens so prevalent in England during the eighteenth century, and whose disappearance was in great measure due to the writings of Addison, Pope and Walpole, and to the hands of Bridgman and "Capability" Brown. There was a direct, harmonious connection with the architecture of the day—they were stately and full of dignity, like the grand lords and ladies that walked in them. William Howitt thus pleasantly

discourses in his "Rural Life of England": "It has been the fashion to cry down all gardens as ugly and tasteless which are not shaped by our modern notions . . . yet the old French and Dutch gardens, as the appendages of a quaint, old house, are, in my opinion, beautiful. They are like many other things, not so much beautiful in themselves as beautiful by association—as memorials of certain characters and ages. If the taste of the present generation had been that of all past ages, what could there have been in the gardens of our past kings, nobles and historical characters to mark them as strongly and emphatically as they are now marked?"

In a modified way, these old gardens were those of our fathers in New England. They served to awaken associations with the past, and with very distant shores, which were still dear to them.

And they yet have their place. In the small public squares of cities and of the larger towns, in contracted suburban bits of ground where variety and irregularity are out of question, and in connection with the pretentious square or rectangular colonial house of the present taste—all that goes to make up the mathematical garden—would, if judiciously carried out, be extremely pleasing—for its novelty, if for no higher reason.

The proper and appropriate adornment of the architectural garden could not be mistaken. Its rectilinear gravel walks with its edgings of Box-wood, its statues, fountains, vases, formal trees and quaint topiary-work were, each and all in keeping with the symmetrical laying-out and with the adjoining buildings. Such, however, is not the case with the style of the present day. Incongruity is too often displayed. As examples, we may cite the disposal of fruit-trees among those of a strictly ornamental character; the cultivation of vegetables in the flower borders; the representation, in the surface of a lawn, of some inanimate object by means of variegated plants; the use of ornaments in a style different from the architecture of the house—not only immediately about but attached to the building.

This applies especially to rustic work. Not that I would by any means decry the æsthetic use of any object or material, however humble, but it must be in harmony with all that surrounds it. And this leads me to speak briefly of the material used in the construction of the suburban dwelling, a matter of the more importance if it has any pretensions to architectural beauty. Wood has long held its ascendancy among us for this purpose, chiefly on account of its cheapness, and in a measure for sanitary reasons. It must, however, soon yield to stone or brick, as the tastes of the people improve. To a man of correct taste and judgment the idea of the want of solidity in the wooden house is unpleasant, especially, if as is generally the case, the appurtenances of the garden and adjoining grounds, such as terrace walls and steps, balustrades, pedestals, vases, etc., are made of the same material. Downing, who did much to improve the public sentiment in all that relates to such matters forty years ago, says: "In point of taste a house built of wood strikes us the least agreeably, as our pleasure in beholding a beautiful form is marred by the idea of the frailness of the material composing that form. . . . The strength with which it strikes a European accustomed to solidity and permanence in a dwelling, is the best proof of the truth of our remark."

The Cranberry Gall Fungus.

To the Editor of GARDEN AND FOREST:

Sir.—Some of the Cranberry bogs of New Jersey are infested with a disease which is known as the Gall Fungus, or by some called "red rust." In appearance to the naked eye it consists of a small, deep red, gall-like structure extending from the surface of the infested plant. The galls may appear upon any young-growing part, and in a badly attacked branch they are in large numbers upon the stem, leaves, flowers and finally the fruit. In extreme cases the whole surface of the diseased bog is reddened and the plants are stunted or killed and the crop is a failure. This fungus, when considered microscopically, is quite different from the rusts of the grain-fields, the smut of Corn, Oats and the like, the mildew of the Lettuce and the various moulds which attack many kinds of plants. For the present purpose, however, it may be only said that it belongs in the great group of fungi which contains thousands of strange and minute forms of plants, ranging in size from the puff-balls and toad-stools down to those so minute that a high magnifier is needed to make them appear of the real size of such fungi as bread mould and Grape mildew. The gall fungus of the Cranberry is one of the simplest forms of those peculiar parasitic plants.

In the inspection of the infested bogs it has been found that

at least five other kinds of plants are attacked by the same fungus. These plants are closely related to the Cranberry—belonging to the same family of plants and associated with the affected Cranberry plants. Some of these plants grow only upon the borders of the bog, and it was evident that the disease was confined to these plants located close to the bog. For example, the narrow-leaved *Kalmia* (here called Calf-kill) was badly attacked only when close by the bog. The same was true of *Azalias*, of *Cassandra* and certain species of *Huckleberries*. It seems quite probable that the infection in the form of spores reached these border plants during the time of high water.

There are many important points to be determined concerning the life history of this destructive pest, including the time and method of the dissemination of the spores. It will be necessary to learn, if possible, the present exact limits of the trouble and all the species of plants that are susceptible to the disease. It is hoped that all readers of GARDEN AND FOREST who are Cranberry growers will inspect their bogs and report if they find the disease present. If there still remains any doubt, the best way will be to send some suspected specimens to a competent mycologist. As soon as the disease is circumscribed, means may be taken for the eradication of the pest.

N. J. Exp. Station, July 17th, 1889.

Byron D. Halsted.

Notes.

Mr. W. F. Massey has been appointed professor of horticulture, arboriculture and botany in the college of agriculture and the mechanic arts recently organized at Raleigh, North Carolina.

Professor Hartig suggests that the superior durability of wood, cut in the winter, may be largely due to the fact that it has time to dry on the outside before the atmospheric influences are favorable to the development of fungi. The spores of these are always about and in the summer at once attack freshly-cut wood, while in the winter they are dormant.

The grain plant-louse, *Aphis avenæ*, has seriously damaged the wheat crop from Ohio westward through Indiana, and as far north as Grand Rapids, Michigan. An invasion so serious has not happened for some years. There is little danger of a renewal of the attack next year, for the parasitic enemies of this pest multiply as rapidly as the Aphides themselves, and keep them in check.

Some exquisitely naturalistic reproductions of various Orchids are displayed by the Messrs. Tiffany & Co. at the Paris Exposition, wherein the most delicate tints and textures are imitated in gold, enamel and precious stones. *Odontoglossum Harryanum*, *O. zygotetrum*, *Cattleya bicolor*, *Vanda Sanderiana* and *Phalanopsis Schilleriana* are among the flowers most successfully used as models.

From a private letter we learn that the Black Rot and Mildew are so prevalent in Vineland and other parts of southern New Jersey that the Grape crop will be nearly ruined except where the vines have been treated with the Bordeaux Mixture. But it is hard to use this precaution and keep the leaves and berries fortified against the fungus when it rains seven days and nights in succession. Colonel Pearson writes that so far the Iron-clad Grape has escaped, while even weeds and forest-trees all about it are rotting and mildewing.

It is the practice in many English gardens to grow the Rose-Acacia (*Robinia hispida*) as a wall-tree. It is treated in this way because when grafted on a standard, as is usual, it is easily injured by high winds. But the additional warmth of the wall helps to ripen the wood and make strong buds, so that the racemes seem longer and the color more rich. A correspondent writes of a tree grown this way for several years, nailed to a sunny wall, and the result is that it blooms for a full month, and is then one of the most striking features of a famous garden.

The Hollyhock fungus (*Puccinia Malvacearum*) seems to have spread rapidly this year, for reports of it come to us from widely separated localities. This fungus was carried from Chili to France in 1872 and soon spread all over Europe. Three years ago it was introduced into the United States from Europe at Beverly, Massachusetts. Next year it appeared in the Boston Public Garden, and although the plants were pulled up and destroyed at the suggestion of Professor Farlow its progress was not arrested by these precautions, and it will probably spread all over the country.

The production of raisins in California has grown steadily year by year until it reached the amount of 1,250,000 boxes last year. Careful and systematic experiments have been made

in cultivating, curing and packing the fruit, and several growers have visited Spain to investigate the methods practiced there. The result of this energy and study was seen in last year's pack which proved superior to that of any previous year in quality and attractiveness of appearance. California raisins are sweeter than those of Spain and they will keep more than twelve months, while the Spanish raisins will not last longer than six months without extra sugaring. There is likely to be some European demand for this year's crop of California raisins while Australia and other countries on the Pacific Ocean offer a hopeful market. At all events there is at present little danger that the industry will be overworked, for last year's enormous pack went at once into consumption at good prices and the market is already bare and hungry.

To several inquiries about the best nozzle for spraying plants where insecticides and fungicides are to be applied in this way, it may be answered that the Cyclone nozzle, perfected and recommended by Professor C. V. Riley, throws a spray as fine as a thin mist, but does not throw it far. For shrubs or small trees, the tops of which can be reached with a light bamboo pole, nothing can be better. It will completely and evenly wet the foliage without applying so much as to cause a drip. The finely-divided spray adheres easily, and the poison is economically and effectively applied. Another apparatus is called the Nixon nozzle. It is patented and is made and sold at Dayton, Ohio. Various sizes are made, the smallest throwing a spray as fine as the Cyclone's, and throwing it with much greater force. These nozzles can also be adjusted to throw a solid stream to a considerable height, the size and force of the stream varying with the size of the nozzle. Any good force-pump can be used with the nozzle. The nozzle company make machines adapted to all kinds of spraying.

The *Libraire Paul Klincksieck*, 15 Rue de Sèvres, Paris, is to publish in two volumes, accompanied with an atlas of 300 lithograph plates, an account of the plants of Yun-nan, based upon the collection of the Abbé Delavay, by M. A. Franchet, of the Paris Museum. Yun-nan is a vast province in the south-eastern part of the Chinese Empire, surrounded by Eastern Tibet, the Himalayas, Assam, Burmah and Tonquin. The plants of this vast region are now first known through the labors of a priest of the foreign missions of France, M. Delavay, who has been stationed during the last four years at Tapin-tze, near Lake Tali, and whose plants have been studied by M. Franchet. In the territory explored by Delavay he has gathered 3,200 species of plants, 1,200 of these being new to science. Plants of real ornamental value abound in Yun-nan. Among M. Delavay's discoveries are some forty species of Primrose, and as many new Rhododendrons; Evergreen Oaks, *Leguminosæ*, *Rosaceæ* and Orchids are numerous, and probably there is no part of the world from which so many valuable additions to garden plants can now be expected. The *Planta Delavayana* will be published in twenty parts (four or five a year). The price of subscription is 200 francs.

It is well known that plants of *Dictamnus Fraxinella* at the close of a dry, sunny day are surrounded by a gas which is inflammable and will ignite with a sudden flash of flame when a lighted match is applied to it. M. H. Correvon gives in *The Garden* the results of some investigations lately made with regard to this phenomenon. Certain plants, and very notably the *Rutaceæ* and *Labiata*, secrete various products, such as essential oils, resins, gums, balsams, etc. Secretory organs which are buried in the substance of the parenchyma elaborate these products, while hairs of various forms and textures conduct them to the surface and there excrete them. The secretory organs are termed internal glands, and the excretory hairs are known as external glands. These latter glands are surrounded at the base by a part of the epidermis, which the hair has pushed up in issuing forth to make its appearance on the surface of the stem, and in the *Fraxinella* this raised part of the epidermis covers a gland which is very richly provided with resin and essential oil. When this gland was examined with a microscope on a hot day it was empty, its contents having been drawn out by the heat through the cells of the epidermis or through the hair that terminates the gland. It must be understood that the surrounding air has to be pretty strongly impregnated with the gas of the volatilized resin in order to take fire when a lighted match is applied to it. This experiment has also been carried out in France by placing a pot-plant of *Fraxinella* in bloom under a bell-glass and leaving it there for some time, when the air in the bell-glass was found to be so highly charged with the resinous gas that it ignited the moment a lighted match was applied to it, and it may be added, without doing the slightest injury to the plant.

Country Foot-Paths.

WRITERS on health have long lamented that Americans, and especially American women, take little exercise on foot. As compared with the English and the Germans, our distaste for pedestrian exercise is very marked, and it is a familiar fact that even men and women who walk a great deal in town, content themselves in summer with sitting out-of-doors, boating and driving; or, if young and active, turn to tennis or some other sport, but walk comparatively little. Yet we are not a lazy, apathetic race, but a nervous, energetic, even restless race; and we are not, like the French, so wholly devoted to social pleasures that we are comparatively indifferent to the charms of Nature. Nor does our climate afford a sufficient explanation of our distaste for walking. It is true that we have many summer days when the sun is very hot and the temperature very high. But we have many others, even in the middle of summer, and long successions of them in spring and autumn, when Nature seems to have done her very best to tempt men out-of-doors—when, under the right conditions, walking would be pure pleasure.

The real trouble is, perhaps, that we cannot always walk in the country under the right conditions, and the fact that we cannot is doubly unfortunate. It would be better for our health as a people if the love of exercise were more general; and it would be better for our intellectual and spiritual development if the love of Nature were more general. We do not associate these two statements in a casual or careless way. The love of walking and the love of Nature are more intimately connected than most persons realize. Only he who goes abroad on foot can really learn to know the beauties of Nature, because only he lives, for the time being, with those beauties, passing among them, not beside them, and seeing the smaller ones as well as the greater, the more intimate and secret as well as those which are freely displayed. To contemplate a beautiful prospect from a veranda or to traverse a charming country in a carriage means much to him who has eyes to see; but to spend an hour in the woods or to follow on foot the course of a winding river means vastly more. And while a beautiful outlook from one's home or

the chance to drive and ride at will are luxuries of the rich, the foot-path is free to the poorest.

But just here is the trouble—just here we find the reason why we cannot walk under the right conditions. Broadly speaking, there are no rural foot-paths in America. There is the high-road which takes us where it wills, not where we will, and never, of course, into the heart of Nature's loveliness, and, which, moreover, is too often hot and dusty. There are the fields and meadows that walls and fences encircle even when the crops are gone and upon these we must not tread. And there are the woods with a few paths, perhaps, but often trackless, briery and tangled; and, even when they offer easy passage, often secluded from approach by cultivated fields, brooks or marshes. Of course the born lover of Nature, blessed with sturdy thews and sinews, makes light of such impediments to his pleasure, and might possibly say that he preferred the wildwood flavor of an American country walk to the tamer enjoyment offered by an English lane or a German forest-path. But such vigorous enthusiasts form but a small minority among the multitudes who live all the year round in country neighborhoods, or go forth summer after summer in search of health and recreation; and among these multitudes are thousands who might grow to be lovers of Nature too, if only the path were made a little smoother for them. It is not, in the majority of cases, a matter of mere taste or convenience. Even a strong woman is seriously hampered by her clothing in a cross-country walk, and to a delicate woman the effort involved would be impossible. To climb fences or take down heavy rails, to ford brooks, to clamber up rough hill-sides and over rugged fields and under matted forest branches, and, if it has rained of late, to get soaking wet in the process, is a prospect uninviting to the average city-bred man, even, and necessarily deterrent to the average city-bred woman. Both are thrown back perforce on the high-road with its very limited offers of pleasure; and the days are indeed many in an American summer when the high-road is as forbidding, in its own way, as is the trackless forest.

In England, on the other hand, one may walk through a county without troubling the high-road. The winding by-road with its bowery sides is everywhere at our service, and everywhere, too, we find the foot-path, crossing private grounds, perhaps, as sanctioned by some ancient right-of-way; edging the little river and passing it by the bridge which is always to be found where needed; bordering the farmer's fields, leading from one hospitable gate or turn-stile to another, and finding its way to every attractive point of view. Of course the physical conditions of the two countries are very unlike—England has been cultivated for so many centuries that scarce an acre appears which the hand of man has not put to some sort of service, while even in the most thickly-settled parts of our older States there are many tracts which are still almost in their primitive condition. Horses, too, are cheap with us and dear in England, so the English rustic is obliged to walk where his American cousin may ride if he will. But to explain why we have not so many foot-paths as the English is not to confess ourselves satisfied with the want of them. Nor is there any reason why we should not have them in far greater numbers. It costs a good deal to make a road but very little to make a foot-path, for, of course, we need merely a narrow path which a well-shod and sensibly-dressed person can traverse with a moderate degree of comfort—not a gravel-walk fit for slippers and muslin gowns. Often a couple of planks across a brook, a few loads of earth dumped in a marshy spot, two or three stones set, as steps, against a wall or fence, and a little cutting away of tree-branches and undergrowth, would open up a delightful tract of country which now is almost impossible of approach. Nor do we think that the farmer's or landed proprietor's interests would suffer by such trifling civilities paid to possible pedestrians. More persons would cross his property, but those who did

cross would do it less damage. The path might keep even boys' feet from straying into less desirable directions, while those for whose especial benefit it was formed would, of course, be limited by its bounds. If even the rudest, simplest paths were thus generally formed in our rural neighborhoods their influence would at once be felt in the village itself as well as in the summer colony. Ask any farmer's daughter why she does not walk more and she will answer, like the city woman, "Where shall I walk? The road is unattractive, the meadows and woods are always more or less difficult to cross and often impassable." More paths and simple bridges and stiles are what we need, alike in the interests of healthful physical development and of healthful growth in the sentiment for Nature.

How to Mask the Foundations of a Country House.—II.

IT was stated last week that, no matter how good a chance Nature may give the architect to unite his house-foundations well with the soil, the aid of the planter is always needed to make the union perfect. Nature's help is greatest when the site is broken and rocky and the foundations can be built of rough-faced local stone. Then, as we tried to explain, vines alone may often suffice to blend her work agreeably with man's, but one kind is not so effective for the purpose as a mingling of several harmonious yet contrasting kinds.

Wistaria, Virginia Creeper and the so-called Japanese Ivy are most commonly used in this part of the country for planting against houses. They are very beautiful, each in its own way. The Wistaria needs some support other than that which a flat wall supplies, and though it may be trained on wires, it is most effective when covering a balcony or trellis, forming irregular masses that are scarcely more charming in profuse flower in spring than later when the foliage is fully developed. The Virginia Creeper adapts itself in the most versatile way to such support as it may find, now twining around a fence or lattice and throwing out long free garlands, and now spreading a flat yet gracefully flowing mantle over wide level surfaces. It stands midway in habit between the Japanese Ivy and the Wistaria, less massive than the latter, less close and uniform than the former. A judicious union of these three vines on a country house is far more beautiful than either alone could be, that spot being chosen for each where, from its manner of growth, it will look particularly well. But the list need not be so short as this. There are a multitude of other hardy creepers which ought to be commonly employed—Climbing Roses, for instance, Honeysuckles, Clematis, and above all the Trumpet Creeper. Quite apart from the splendid clusters of orange-colored flowers which this produces in mid-summer, the beautiful form of its leaves, the charming masses they make when it is rightly cared for, and especially its dark-green hue, render it a most valuable plant to contrast with others. The Japanese Ivy, it may be added, looks best when clinging to stone or brick. It is never lovelier than in winter with its delicate tracery of leafless branches, as though etched by some skillful decorator's hand; and this tracery does not show nearly so well on wood as on other materials.

Of annuals we do not speak in this connection. Their variety is endless, and the beauty of some of them is very great. But when the object is to give the walls of the house a garment which will unite it with the ground from which it springs, plants of a more lasting kind should be chosen. Otherwise the work will never be thoroughly well accomplished, and what is done will have to be done over year after year. Annual creepers may be planted among those that are permanently established, but should not be relied upon for the main adornment of the house. Moreover, if vines alone are used about the foundations of a house, some should be of evergreen varieties. We want the walls to look united with the site in winter as well as summer, though when all Nature is stripped half bare the harmonizing garment need not be so extensive as when she is fully clothed.

But in the majority of cases vines alone should not be depended upon for the purpose we are discussing. Unless very irregular rocks form the foundation upon which the walls are set, they will need more massive and spreading foliage at their base. The fact is generally acknowledged to-day by the owners of country and suburban homes—for we seldom see one where plantations have not been made close to the walls, at least along some part of their course. Unfortunately these plantations are usually flower-beds filled with annuals or tender

ornamental plants. Their effect is, perhaps, better than utter nakedness, although when the choice is a particularly tasteless one even as much as this cannot be granted. In the first place, what has been said of annual creepers applies equally to tender plants of other sorts—the work is done, the effect is produced, for the season merely. When winter comes, nakedness returns in a worse shape than if no flowers had been planted—the house stands not on grass even but on a line of empty earth which makes its want of harmony with its surroundings most painfully apparent. And then in the spring the labor of clothing its base must be begun again. In the second place flower-beds are too monotonous. We need variety in the clothing green; we need to diversify it by massing, by carrying it up in certain places higher than in others, and by spreading it out here and there to connect or group with other plantations in the vicinity. What we want to mitigate is that rigid formality of architectural features which does not blend with the undulating variety of growing things; and a flower-bed is almost as artificial, as rigid in effect, as foundation-courses of masonry. Of course, if the whole garden is formally disposed, then the base-plantations may correspond; but such cases are rare in this country, and a natural arrangement of the grounds demands a thoroughly natural looking garment for the lower walls. Hardy shrubs are the things required. How they should be chosen, and, in a general way, how they should be planted, we shall try to point out in a future chapter.

Recent Botanical Discoveries in China.—V.

Lilium.—Considering the number of magnificent species previously known to inhabit eastern Asia it was hardly to be expected that further discoveries would surpass them in beauty or brilliancy, yet Dr. Henry has added one very handsome new species (*L. Henryi*, Baker); and he has also sent specimens of *L. giganteum* and *L. cordifolium*, which were previously unknown, from China. In general habit, Mr. Baker states, *L. Henryi* most resembles *L. tigrinum*, but the fully-developed leaves rather recall those of *L. auratum*, and the narrow perianth segments those of *L. polyphyllum*. The flowers are borne in loose corymbs, sometimes a foot across, and consisting from four to eight yellow, red-spotted flowers from three to three inches and a half long. *L. Duchartrei* and *L. Davidi* are new species of the affinity of *L. speciosum*, discovered by the Abbé David in Eastern Thibet. They all await introduction.

Euonymus.—A score of species, at least, inhabit China, but among the novelties there is nothing to equal the familiar and favorite *E. japonicus* in its numerous varieties. *E. gracillimus* is an evergreen, exceedingly slender-branched species, founded upon a specimen collected by Mr. J. Reeves, who resided at Canton between 1820 and 1830, and introduced many Chinese plants into English gardens, and after whom Lindley named the Chinese genus *Reevesia*. *E. carnosus* is an evergreen species from Formosa, allied to and very similar to *E. japonicus*, but probably not so hardy. It is remarkable for the large fleshy calyx and disk. Among the unnamed specimens of *Euonymus* received at Kew since the publication of the second part of the "Index" is one with lanceolate evergreen leaves, three to five inches long. It is from the neighborhood of Ichang, and may be worth the attention of a horticultural collector.

Celastrus.—Two new species of this genus are described in the "Index"—namely, *C. latifolius* and *C. variabilis*. The former is said to be a dwarf shrub, though it has oblong or orbicular leaves six inches across, and the flowers are in long, narrow, terminal panicles, suggesting a plant of larger stature. It hardly comes within the category of ornamental shrubs, but is of interest in another respect. According to Dr. Henry it bears a name equivalent to "turnip-fly-killer," and the leaves and shoots are dried in the sun and pounded to a powder that is reputed to be very efficacious in killing insects that infest Cabbage, Turnips and allied plants. *C. variabilis* is a trailing, often spiny shrub, of interest only to those who form botanical collections.

Hydrangea.—Although the number of species enumerated as Chinese does not exceed seven, the forms are very numerous and many of them highly ornamental, and they probably originated under cultivation. Thus of the protean *H. Hortensia* I have seen no specimens of undoubted wild origin; possibly, however, those collected by Wright in the Luchu Archipelago may have been obtained from wild plants.

Among the novelties sent by Dr. Henry are several forms which I have doubtfully referred to *H. scabra*, which, so far as I am aware, is not in cultivation. One which I have named *H. scabra*, var. (?) *macrophylla*, has elegant leaves nearly a foot long and corymbs of flower six inches across. Another, var.

(?) *augustifolia*, has very narrow leaves, and between these there are various intermediate forms. The flowers present as much variation as the leaves, alike in the size, shape and color of the outer barren ones. In one of the intermediate varieties the barren flowers, which are apparently white, are nearly two inches in diameter, very strongly veined, and of such consistence that they persist long into the winter. In another they are of a reddish color, and there are specimens wholly destitute of these enlarged sterile flowers. *H. longipes* is an elegant new species, resembling the Japanese *H. scandens* (syn. *H. petiolaris*) in the shape of the leaves and in the very long petioles, but otherwise quite different. It has slender branches and papery, cordate, ovate, densely serrulate leaves on slender petioles, two to four inches long, or as long as the blade, and terminal small corymbs of minute flowers, with a few outer sterile ones, about an inch in diameter, on long, slender pedicels. It is of erect habit, and two or three feet high. There is a variety *lanceolata*, differing only in the shape of the leaves. The type is from Nanto and the mountains northward, and the variety from Patung. Both are worth looking after.

Spiraea.—A shrubby species named *S. Henryi*, and several forms treated as varieties of *S. Blumei*, are the best novelties in this genus. *S. Henryi* is a densely-branched shrub, six or seven feet high, with small leaves coarsely-toothed in the upper part, and small white flowers in very dense compound corymbs, differing in the last-named characters from those species to which it is most closely allied. The leaves are one of the many substitutes for tea in China. *Spiraea Blumei*, var. (?) *latipetala*, is remarkable for its large flowers, and may possibly be a distinct species. *S. Blumei*, var. *rotundifolia*, and var. *hirsuta*, differ respectively from the type in the manner indicated by their names. There are several less-marked varieties, and the species as a whole is a very attractive one.

Liquidamber.—The materials of this genus are sufficient to prove that *L. acerifolia* of Maximowicz (*L. Maximowiczii* Miquel) cannot be maintained as distinct from *L. Formosana*, but there are imperfect specimens of probably two other species. *L. Formosana* is an important tree, furnishing much of the timber used for making tea-chests, and it is probably a handsome tree, though too tender to succeed even in the south of England.

Acanthopanax.—A new species of this genus, *A. diversifolium*, has the appearance, from dried specimens, that suggests a striking object. It is a shrub about ten feet high, with stout, straight branches and very leathery, prickly-toothed leaves of two kinds, simple and trifoliate, intermixed on the flowery branches. Of course there is nothing particularly ornamental in the flowers of these Araliaceæ, but they afford variety when variety of this kind is cared for.

In concluding this my first series of notes on Chinese plants, I may mention that I have not yet examined the materials of many of the natural orders at all, but when I have, if it should be considered of sufficient interest to the readers of this journal, I may contribute another series. W. B. Hemsley.

Magnolia glauca in its Most Northern Home.

NEXT to the Mayflower (*Epigæa repens*), or "Trailing Arbutus," as it is too often called, there is perhaps no local plant whose flowers are more prized by lovers of native flowers about Boston than the *Magnolia glauca* of botanists, or "the Magnolia," as it is everywhere known in this vicinity. Although Emerson (Trees and Shrubs of Massachusetts, p. 603) says, in a note: "It is said to have been found in the County of York, Maine," I do not know that the fact has been proved. With this possible exception, the only place in New England where this Magnolia is known to grow is in the swamps of Essex County, about twenty-five miles north of Boston, and near the latitude of 42° 40'. Here it has been known for over a hundred years, having been first brought to notice by the Rev. Manasseh Cutler, who was famous as a botanist, a theologian and a statesman, and for many years (from 1771) minister of Hamlet Parish, then a part of the town of Ipswich.

The chief and original locality for this Magnolia here is in what is known as the Magnolia Swamp, not far from the famous old fishing-town of Gloucester, and within a short distance of the sea-coast, now occupied, as is nearly the entire stretch of the New England shore, as a summer resort.

So eagerly have the flowers been sought for by collectors, and especially by those who wished to make money out of the sale of both plants and flowers, that there has been some apprehension that the day would soon come when the Magnolia could only be classed in New England floras as one of the indigenous plants of the past. The hope is now entertained, however, that the owners of the woods where it oc-

curs, appreciating its rarity and interest, will take care that its existence, in a wild state, may be perpetuated.

Turning off from the main road into the Magnolia Swamp there is little to remind one of the vicinity of civilization. No attempt has been made to improve upon Nature, and rest and peace meet the eye everywhere. Few birds seem to make a home within the swamp, and the full, rich note of the wood-thrush is the most striking sound heard. If the explorer would find the swamp Magnolia in its best flowering condition, he must make his excursion about the first week in July, and be prepared for a rough tramp. Bogs, springs, rocks, thickets and fallen branches and trees may beset the way, but every plant is interesting, and bears testimony to the fact that Essex County contains, within its small area, one of the richest floras in New England. (Mr. John Robinson, in "The Flora of Essex County, Massachusetts," 1880, enumerates about twelve hundred species of flowering plants.)

The ground in the lower wet places is thickly covered with Cranberries (*Vaccinium macrocarpum*) in full flower, and growing out of the sphagnum, over which the Cranberry loves to spread, we find Habenarias, *Calopogon pulchellus*, the sweet-scented Pogonia and two species of Sundew (Drosera). On the hillocks or knolls are thick carpets of the Checkerberry or Partridge-berry (*Gaultheria procumbens*) in bloom, while the leaves and flower-stalks of *Cypripedium acaule* and other early-flowering plants stand above this low-creeping shrub. The Black Alder and *Andromeda ligustrina* are the most common of the larger shrubs in flower in the thickets. Several species of Blueberries and Huckleberries are common with ripening fruit, and *Clethra alnifolia*, which will not bloom until after Magnolia blossoms are mostly gone, is abundant everywhere. Indeed, plants of the Heath family seem to predominate in the shrubby vegetation of this region.

Several species of Cornus may be found, and *Viburnum acerifolium*, *V. lantanoides*, *V. cassinoides* and one or two other species are in fruit. The Common Elder (*Sambucus Canadensis*) is in full bloom, and it must be counted as one of the handsomest native shrubs flowering at this season. The other native species, the early-flowered Elder (*S. racemosa*), is much less common and has ripened its fruit, which has all been eaten by birds. The Wild Roses at this time cannot be surpassed for beauty and fragrance, and they grow wherever there is the least encouragement by soil and sunlight.

Among the most conspicuous trees is the White Pine (*P. Strobus*), which is found almost everywhere, while *Pinus rigida* and the Hemlock (*Tsuga Canadensis*) accompany it in many situations. The Red Maple is, perhaps, the most abundant of the deciduous trees in the swamp, and the Sugar-Maple, the Yellow Birch (*Betula lutea*), and the favorite aromatic Black Birch (*B. lenta*) grow wherever the ground is elevated enough to be moderately dry. Witch-hazels, Alders, Poison Dogwood (*Rhus venenata*), etc., may be found growing in the immediate vicinity of the plant sought for.

The Magnolia here grows as a shrub from five to ten or fifteen feet high. A great many of the plants have become badly broken by the recklessness and vandalism of collectors, so that well-grown, uninjured specimens are now rarely found.

Many have been transplanted from the woods to gardens in the surrounding country, and some fine bushy specimens are preserved in this way. Although naturally growing in swampy situations, the plant thrives very well on high and comparatively dry land, especially if a little shaded from the sun. In cultivation it grows much faster, and will produce finer specimen plants if grafted upon stock of the Cucumber-tree (*Magnolia acuminata*), the only other species of Magnolia in America which reaches as high a latitude as *M. glauca*. In western New York it extends about a degree further north to the southern shores of Lake Ontario. The Umbrella Tree (*M. tripetala*) is more generally used for stock, as it is more easily grown and transplanted. It is, however, more liable to sucker than the other species.

According to Dr. Charles Pickering ("Chronological History of Plants," p. 908), the first reference to *Magnolia glauca* was made in a report of some navigators, in 1584, who, proceeding to Roanoke Island (North Carolina), found "the tree that beareth rind of the Black Synamon, of which like Captain Winter brought from the Straights of Magellaun." It is found from New York and New Jersey through the Atlantic States, generally near the coast, to Florida, and through the Gulf States into Texas. In the southern States it sometimes becomes a large tree sixty or seventy feet high, with a trunk three or four feet in diameter, and is an evergreen.

It has been suggested by some enthusiasts that this should be chosen as the "national flower," if we must have one. But, although the exquisite beauty and fragrance of the flower

make it popular and desirable wherever known, it is recognized and prized by a comparatively small number of the people, and there may be other reasons why it would not be suitable. In the same swamp with it grows *Kalmia latifolia*, which cannot be surpassed in beauty, which has a much more extended geographical range, and whose merits for distinction as the national floral emblem are so well set forth by Mrs. Van Rensselaer in a recent number of GARDEN AND FOREST.

Jamaica Plain, Mass.

Notes Upon Some North American Trees.—III.

RHAMNUS.—*Rhamnus crocea*, Nutt., must find a place among North American trees. It is a widely-distributed Pacific-coast species from the valley of the upper Sacramento to Arizona. It most frequently occurs and has been described as a low spreading bush, five to ten feet high, but Mrs. T. S. Brandegee, the botanical curator of the California Academy of Science, calls my attention to the fact that this species is sometimes truly arborescent in the neighborhood of Antioch, where it grows with a stout trunk ten inches in diameter. This is the form named *R. ilicifolius* by Kellogg (*Proc. Cal. Acad.*, ii., 37), a name which can hardly be retained even for a variety, as in his locality (Lake County) this species passes from a low, nearly prostrate shrub, with matted branches and minute, nearly acute leaves, into the arborescent specimens, with the large, nearly round, Holly-like leaves of Dr. Kellogg's plant.

Rhamnus insularis, Greene (*Bull. Cal. Acad.*, ii., 392), (not *R. insulus* of Kellogg, *Proc. Cal. Acad.*, ii., 20, which, according to Mrs. Brandegee, in litt., is one of the Mexican species, with black bilocular fruit, related to *R. terniflora*) inhabits the Santa Barbara group of Islands and Cedros Island off the California coast, and is not rare, apparently, on the mainland (Santa Cruz Mountains, Brandegee). This, although a much larger plant in every way, and quite distinct in the form and serratures of the leaves, I cannot separate specifically from *R. crocea*, and should therefore propose to call it *Rhamnus crocea*, var. *insularis*.*

It is a tree attaining a height of twenty or twenty-five feet, with a straight, naked trunk, five or six inches in diameter, covered with smooth, light-gray bark. The leaves are about three inches long and nearly two inches wide, but not distinguishable in texture and in the peculiar yellow color of the lower surface from those of *R. crocea*. The fruit of the insular form is much larger, but not otherwise distinct, and according to Mr. Brandegee, the variety flowers about the 1st of May, while *R. crocea* in the same regions flowers in March. The variety ascends to rather higher elevations in the Santa Cruz Mountains, although the two are found together on the foot-hills and in the gulches, nearly to the sea-level.

More information than now exists based upon field observation upon the different California species of *Rhamnus* is very desirable. Proper limitations of the different species and varieties are still doubtful, and really nothing is known of the life histories of these plants.

CEANOTHUS VELUTINUS, Dougl. Mrs. Brandegee reports that this widely-distributed shrubby species sometimes occurs as a tree in Lake County, California; and I should propose to consider as a variety† of the same species Mr. Greene's *C. arboreus* (*Bull. Cal. Acad.*, ii. 144), which I cannot distinguish from it except by its arborescent habit, its rather stouter and softly pubescent young shoots, the more constant pubescence covering the under surface of the leaves, and by the pale blue (not white) color of the flowers.

This interesting and very handsome plant is common on the northern slopes of the Island of Santa Cruz, the largest

of the Santa Barbara group, where it forms at the highest elevations a small round-headed tree twenty to twenty-five feet high, with a clean, straight trunk six to ten inches in diameter (Greene); it is less common and of much smaller size on Santa Rosa (Brandegee). It is the largest and most truly arborescent of all the *Ceanothus*. It was first detected by Nuttall, whose specimen is preserved in the herbarium of the Philadelphia Academy, and who noted its large size and arborescent habit (Trelease in *Trans. St. Louis. Acad.*, v., 365).

51. **ÆSCULUS FLAVA**, Aiton.—The oldest name for this species would seem to be *Æ. octandra*, of Marshall (*Arbustum Americanum*, published in 1785). *Æ. lutea*, Wangerheim, in "Schrift Gesell. Natuf. Fr. z. Berl.," viii., 133 (1788), is also older than that of Aiton published in 1789. The *Æsculus octandra* of Miller's Dictionary is the *Æ. Pavia* of Linnæus.

65. **ACER DASYCARPUM**, Ehrhart.—This is really the *Acer saccharinum* of Linnæus (Species, 1st ed., 1055), but although this has long been known, the change of names was never made, that the confusion which would naturally arise if the name *Acer saccharinum* was used to designate another tree than the true Sugar Maple might be avoided. The Linnæan name, according to the strict rules of botanical nomenclature, should be adopted; and, after all, it is not a very bad one, as sugar has always been made in small quantities from the Silver Maple. If the name *saccharinum* is transferred, another name must be found for the real Sugar Maple. The oldest for this tree is that of Marshall (1785), antedating by two years that of Wangerheim, who first (*Amer.* 36, t. 11, f. 26) called it *A. saccharinum*, confounding the real Sugar Maple with the plant described by Linnæus as *A. saccharinum*, and starting all this confusion. But Marshall's name is *A. saccharum*, and if the Silver Maple is to be called *A. saccharinum*, a name so nearly identical with it as *A. saccharum* for another species could only lead to hopeless confusion, and Michaux's *A. barbatum* (*Fl. Bor. Am.*, ii., 253) would have to be taken up. An older name for the Silver Maple than Ehrhart's (1789) is that of Marshall (1785), *A. glaucum*, which should be used if the Linnæan name is discarded.

68. **NEGUNDO CALIFORNICUM**, Torrey and Gray.—I cannot distinguish specifically this plant from the common eastern *N. aceroides*. The characters relied upon to separate the two species—the number and cutting of the leaflets, the pubescence on their lower surface, and on the shoots and fruit—cannot always be depended on, and the eastern species in the dry Texano-Mexican region approaches too closely to the California plant which I should propose to consider a variety and call *N. aceroides*, var. *Californicum*.

C. S. Sargent.

New or Little Known Plants.

Vaccinium hirsutum.

THE men who are now the editors of this journal made a horseback journey through the mountains of western North Carolina in the autumn of 1886. Starting from Cæsar's Head, an outlying spur of the Blue Ridge, in South Carolina, early in September, they explored the wild and picturesque region where the Horsepasture and the Toxaway unite their precipitous torrents and form the Keowee, the great eastern fork of the Savannah River, being rewarded here by the rediscovery of Shortia,* probably on the very spot where Michaux discovered it ninety-eight years before. They then crossed the Blue Ridge, and afterwards the Little Tennessee River at Franklin, and continued westward into Graham County, their object being to rediscover, if possible, a peculiar Blueberry found in "the mountains of Cherokee County" half a century before by Mr. B. S. Buckley, but not seen again. Their only way of conveying to the few inhabitants of this remote region, with whom they fell in as they rode along, an idea of the plant

* *Rhamnus crocea*, var. *insularis*, arbor. foliis petiolatis, oblongis-ovatis basi obtusis, apice mucronatis, minute glanduloso-serratis.

† *CEANOTHUS VELUTINUS*, Dougl., var. *ARBOREUS*, arbor, ramulis hornotinis villosis; foliis ovatis, acutis, serratis vel plus minus crenulatis, subtus discoloribus dense pubescentibus; floribus cæruleis.

C. arboreus, Greene, l. c.—Trelease in *Proc. Cal. Acad.*, 2 ser., i.—Brandegee, *Flora of the Santa Barbara Islands* in *Proc. Cal. Acad.*, 2 ser., i. 208.—Parry in *Proc. Davenport Acad.*, v. 169.

C. sordidatus, Lyon in *Botanical Gazette*, xx. 204, 333 (not of Hook & Arn.).

* See GARDEN AND FOREST, i, p. 506.

they were in search of was by describing it as "a hairy Huckleberry;" and at Robbinsville, the county-seat of Graham County, a man was met with who had "heard tell" of such a thing. A promised reward of five dollars for specimens of the plant set all the boys in the county astir, for five dollars is a great sum of money in Graham County, North Carolina; and during the following summer I received a box of *Vaccinium* fruit covered with short white hairs, from Mr. W. F. Manney, of Robbinsville, who had marked some of the plants from which this fruit was gathered, and later sent a supply of grafts and seedling plants to the Arboretum. Some of these flowered in the spring of last year, and Mr. Faxon was enabled to make the drawing which is reproduced upon this page.

*Vaccinium hirsutum** is, according to Mr. Buckley's description, a low shrub one or two feet high. The stems are green, grooved, obscurely four-angled; those of the year, covered with stout, spreading white hairs, which cover also the lower surface of the leaves, the calyx, corolla, and dark blue, globose fruit. The leaves are ovate, entire, tipped with a minute mucro, and an inch and a half long. The ovoid campanulate corollas, minutely five-lobed, are nearly half an inch long and pure white; they are borne on one to two bracted-pedicles in terminal or axillary racemes.

The hairy flower and fruit of this species will serve to readily distinguish this plant, of which nothing is known, practically, with regard to its geographical distribution or the situations in which it grows—information which botanical travelers in the extreme western corner of North Carolina will soon, it is to be hoped, be able to furnish, for it is hardly probable that another half century will pass before this little shrub is found again.

The plants sent to the Arboretum have flourished, and were covered in June this year with their handsome flowers.

C. S. S.

Foreign Correspondence.

London Letter.

ENGLISH gardens have this year been deprived of a great deal of their accustomed June brightness by the scarcity of *Rhododendron* bloom. This is attributable, no doubt, to the excessive rain last summer, which was conducive rather to the formation of leaf than of flower-buds. We hope, however,

that we shall reap the benefit of this strong leaf-growth next season, when, if this summer is warm and dry, the flower-crop will be of unusual splendor. The failure of such a popular garden-plant in setting flower-buds is a serious matter to the large growers of *Rhododendrons*, as there is an enormous trade in spring with *Rhododendron*-plants which give good promise of bloom. Many customers, too, go to the nurseries and select the sorts they most admire when in bloom. The failure has been general throughout the country, although it has not visibly affected the exhibitions of the flower that are annually made at Hyde Park and various other places in London. You notice it most in the nurseries where the *Rhododendron* is a specialty, and in no place more than in the extensive nurseries at Knap Hill, in Surrey, where no fewer than sixty acres are devoted solely to *Rhododendrons* and other

so-called American plants. Usually these sixty acres are ablaze with color from the middle of May till the end of June, furnishing a spectacle probably unequalled in any part of the world. But though the flower-crop was not abundant, the nursery, as I saw it the other day, was delightful, and you seemed to enjoy occasional glints of color amid the greenery much more than if the place was all bright with bloom. One could readily discern that there are some sorts of *Rhododendron* that produce a crop of bloom no matter what the previous season has been. I made note of a few of the favorite sorts that carried abundant flowers, and among them are Mrs. H. Ingersoll, John Walter, J. Marshall Brooks, C. S. Sargent, Lady Armstrong, Pink Everestianum, A. B. Mifford, Mrs. Arthur Hunnewell, Mrs. J. Clutton (one of the finest whites), Roseum Elegans, Album Elegans, and the ever popular Lady Eleanor Cathcart. These were some of the most conspicuous which had carried their flower-buds through a most trying winter and spring, which is valuable testimony to their hardiness. But some very beautiful sorts cannot so withstand the elements, and it is painful to see how

splendid sorts, such as Kate Waterer, for example, have their flower-buds killed by the frosts of early spring. The secret of raising thoroughly hardy *Rhododendrons* lies in the breeding from the robust and hardy *R. Catawbiense* strain, and this is what is done exclusively by Mr. Anthony Waterer. The new seedlings which I went to see specially were not up to the mark this year though last year among the virgin seedlings there were some startling novelties in color, in size, shape and truss, and these would have been finer still this year after another season's growth. One would have thought that the climax of perfection in *Rhododendrons* had been reached long ago, but one can see great improvements in the new sorts in color especially. Some have white flowers, with the petals margined more or less widely with bright colors, others again are spotted heavily like show *Pelargonium*-flowers.

Though the *Rhododendrons* were only moderate this year, their relatives, the Azaleas, were superlatively fine, and a wet

Fig. 119.—*Vaccinium hirsutum*.—See page 364.

* *Vaccinium hirsutum*, Buckley in *Am. Jour. Sci.*, xiv., 175.—Gray, *Syn. Flora N. America*, ii., 1, 23.

season is evidently most enjoyable to them. We look upon the Knap Hill nursery as the birthplace of this magnificent race of hardy shrubs, for here it was that the original species, brought here from North America, were worked upon by the Waterers of by-gone days. In Loudon's time, during the first quarter of this century, Knap Hill was the headquarters for Azalea-raising, and it has been going on ever since, for the present proprietor is as keen upon rearing new kinds as ever his predecessors were, the result being that the Azalea has been worked up to such a high state of perfection that one is inclined to wonder how it can be further improved. But Mr. Waterer will not be satisfied until he gets flowers as large and as fine in form as the best of his Rhododendrons, and he is certainly leading them up to that. One would think that nothing could surpass in richness and brilliancy the color of such old sorts as *Coccinea*, *Cuprea splendens*, *Fulgens* and the like, but they even are dull when compared side by side with the new race of seedlings raised within the last few years at this nursery. There are among them fiery scarlets and crimsons, the purest whites and yellows, and in not a few there is a striking combination of tints, such as scarlet and orange or white and orange. Parallel with the improvement of flower in size, color and form has been the improvement in the habit of growth, the aim being to get a race that will not grow into those straggling (though to some picturesque) specimens which are commonly met with in old gardens. But the greatest improvement, I think, is that of inducing a leafiness at the time of flowering. The old sorts, especially the light sorts bred from *A. nudiflora*, have a naked appearance when in bloom which detracts from their flower beauty. It has been Mr. Waterer's aim to get a race that produces flowers and leaves together, and is therefor far more effective than the majority of the old sorts. You see at Knap Hill acre after acre of nothing but Azalea-seedlings, among which exceptionally fine sorts are continually cropping up at flowering-time, and the process of selection and comparison goes on daily for weeks. But only a comparatively few from these great seedling-beds are selected as worthy of naming, so that one may be sure that those that are honored with names are of superlative merit. There was one new sort named Mrs. Walter Druce that struck me much. It has a pure white flower, with a bright yellow spot on the upper petal. The early-flowering Chinese *A. mollis* is now an established favorite in all parts of this country, both as an open-air shrub and for pot-culture for early forcing. There are a good many so-called varieties with distinctive names (chiefly Belgian), but the range of color is very limited. There are, in fact, very few shades of tint between yellow and the bright flame-colored sort, which, I believe, was that originally introduced. But time and industry will doubtless accomplish much in the improvement of this race, especially if it can be made to intercross with the American race. The double-flowered sorts, of which that named *Narcissiflora*, with yellow flowers like a double Jonquil, may be taken as the type, is decidedly popular, as the flowers last longer in perfection than the single ones. Bouquet-florists have already taken them in hand, as the flowers are just the size required for small floral devices. There is a fair range of color, too, among them—yellows of various shades, pure white and pale pinks, while all have a delicate fragrance. The thorough hardiness of all these Azaleas is a great point in their favor, and I imagine that they could be grown in America, even where the Rhododendron, on account of its evergreen foliage, would fail.

London, June 27th.

W. Goldring.

Cultural Department.

The Small Fruit Garden.

THE yield of Raspberries for the season of 1889 has been abundant with such varieties as passed the winter and spring unharmed. The excessive and frequent rains have favored the development of the fruit to its maximum size, and, at the same time, has ruined a large per cent. of the crop, making it so soft that a few hours of hot sunshine caused rapid decay. This was particularly the case with blackcaps, fully half of the crop being wasted. They, however, furnished fine feed for bees, and this, to some extent, kept them from the red varieties. The birds also have feasted on them in preference to the red kinds. The first crop of blackcaps is always the best; the second, though heavier, generally runs smaller, and after this I prefer to root them out and commence anew. The red varieties will give satisfactory returns for a number of years if well cared for. Our leading varieties are Caroline (yellow), Marlboro', Montclair and Cuthbert, ripening in the order named. The former we esteem very highly

for table use, but it is too delicate to keep long or carry any great distance. It is perfectly hardy here and very productive, and a general favorite with those who know it. Of the others the Cuthbert is the most productive, but Marlboro' and Montclair are firmer, "stand up" better and are a little superior in flavor; but to untrained palates there is little difference among the red varieties. All are highly esteemed for canning, with or without currants, and no house-wife's stores are complete without them. Shaffer's Colossal, a reddish-purple berry of the cap habit, is especially valuable for canning; a berry of the largest size, an enormous grower and very productive. The canes are sometimes injured during winter.

The crop having been gathered the old canes should be cut out, removed, and burned as a sanitary measure. The ashes are of more value and less unsightly than the canes. Some people advocate deferring this work till winter or spring, on the plea that the old canes protect the young ones, but I see no reason for the delay. As their duty in fruit-producing is ended, it only remains for them to die a natural death, and the process of ripening and maturing previous to this make an unnecessary draught on the roots and soil which the young canes need and which they can better utilize. Besides, the freer admission of sunlight and air will aid them to develop and mature, and better fit them for duty another season. For these reasons I practice the immediate removal of old canes and also thinning out the young canes to the needs of next year, unless the surplus plants are needed for planting elsewhere. Two or three good stout canes left in a hill is ample, and much better than a greater number. Weeds should be pulled out to prevent seeding, and they are useful as a mulching. On the approach of winter a dressing of stable manure will be found beneficial; the fertilizing properties will find their way to the roots and be all ready for the plants to appropriate it in the spring. People who desire the finer foreign or tender sorts must take the trouble to lay down and cover the canes during the winter. For small quantities this is not much trouble, but for large growers this is impracticable.

The same course may be pursued with the Currant-bushes. The fact that their fruit has been gathered is no excuse for general neglect, and especially for permitting weeds to grow and ripen their seeds among them to make extra work another season. The crop of this fruit has been abundant, but the four days' rain which ushered in the month of July just as the Currants were ripening caused them to burst to an extent I have never witnessed before. Quite one-half of the fruit remaining on my plants at that time split open and spoiled. Fay's Prolific maintains its reputation for size and productiveness. I do not think I ever made a better investment in the fruit line for its size than when I paid \$10 for a dozen plants of this Currant. It is not difficult to remember many poorer ones. A friend recently stated that he was surprised, in a recent day's drive through the country, to notice the numerous gardens where the Currant-bushes still held their fruit while entirely denuded of their leaves by the Currant-worm. Such fruit never can ripen and develop to perfection, and it is unaccountable that so many people, either from carelessness or a mistaken fear of being poisoned, will permit such an exhibition on their grounds when hellebore is so cheap and effective a remedy and is so easily applied. People whose Currant-bushes are allowed to become breeding-places for this pest do great injury to their neighbors.

The light Grass crop, generally, is favorable to a rank growth of the vines. If summer pruning has been attended to so far in the season the pruning now will be the final one. If the main canes and laterals are now stopped after-growth will not be excessive, and the remaining canes will have an opportunity to properly develop and ripen their wood. The season has been very favorable for wood growth, which, if allowed to go on unchecked, will result in feeble buds on the wood nearest the vine, and these are the ones needed for next season's fruiting. All the fruit a vine should carry can be produced within six feet of its trunk as well as twenty or fifty feet away. Bearing canes, if stopped three leaves beyond the last cluster of fruit, will have all the foliage necessary to perfectly ripen the fruit provided the foliage remains in healthy condition. Clean and healthy foliage elsewhere on the vine will not compensate for the loss of the leaves near the fruit. Mildewed and rotting berries should be picked off and buried or burned to destroy the germs of the fungus infesting them. The lightness of the crop ought not to prevent proper attention to the health of the vines on which next season's crop depends, but it will naturally tend to neglect in this direction.

Montclair, N. J.

E. Williams.

Rose Notes.

FROM the differences of opinion expressed by different Rose-growers in regard to their experience during the past season it is somewhat difficult to make positive statements as to the relative value of varieties. For instance, one large grower asserts that, after repeated trials, he has decided to discard American Beauty for forcing, because it has proved unprofitable. While another grower a few miles away from the first mentioned declares that American Beauty netted more money per square foot of space occupied than any other variety he grew last season, and a third man states that he cut thirty thousand blooms (good, bad and indifferent, but a majority of them saleable) from a house 135 feet long and twenty-five feet wide. The evidence seems rather contradictory, yet the balance is decidedly in favor of this Rose, and this judgment is confirmed by the large numbers of this variety planted this summer. In the newer Teas, Madame Hoste (Guillot fils, 1888) has been highly recommended by some growers and may prove of much value, its large buds of light yellow shaded with buff having encouraged the hope from some Rosarians that it may prove a worthy successor to the old standard variety Perle des Jardins. We should not forget, however, that alleged rivals of the Perle have been offered each season for several years past, and so far the old variety has been able to hold its own as a profitable sort. Madame Hoste has not yet been before the public long enough or in sufficient quantity for a thorough test, and it will, therefore, be better to withhold a positive opinion until some future time. Madame Cusin, though not of very recent introduction, having been in the market for the past eight years, has only become prominent as a forcing Rose during the last two or three seasons, its peculiar color and lasting qualities when cut having gained it much popularity, and it has doubtless proved profitable when well-grown. Madame de Watteville, another introduction by the same firm, has also attracted much attention, and though not specially notable in form, is very pretty, and is being planted in large quantities by some commercial growers. Miss Ethel Brownlow (Dickson, 1887), a much-prized variety in Europe, has not yet aroused much enthusiasm among American growers, though possibly a valuable Rose. But among so many good pink Roses already in general use, the test of a new variety of that color is apt to be somewhat exacting.

Mrs. John Laing retains its place among popular Hybrid Perpetuals, though not always entirely satisfactory for very early forcing, but as it may be depended on for a crop of flowers by the 1st of February, and is really a beautiful Rose, it is justly considered a decided acquisition either for forcing or for out-door planting, as in the latter case it is of vigorous growth and very free. I am reminded by this allusion to early forcing of another new Hybrid Perpetual, supposed to be of American origin, which is now in preparation for the market. It is somewhat in the style of Magna Charta, but is said to force easily in time for Christmas. Another new Hybrid Perpetual of value as a bedding Rose is Dinsmore, introduced by Peter Henderson & Co. in 1887, its bright-colored flowers being of fair size and freely produced during a considerable portion of the season. Earl of Dufferin (Dickson, 1887) has not as yet been extensively grown on this side of the Atlantic, possibly on account of the limited sale for extremely dark Roses as cut flowers.

As a winter-blooming variety the Tea Rose, The Gem (to which reference has been made in a former article), has not been highly commended by those who tested it during the past season, but as a bedding Rose it is useful, though the blossoms become much tinted with pink on the outer petals when grown in the open air, and consequently it cannot be compared with Marie Guillot for purity of color.

Possibly a valuable race of out-door Roses may be brought forth as the new type of hybrids of *R. rugosa* is further developed, the first variety of this class in commerce being Madame Georges Bruant (Bruant, 1888), the result of a cross between *R. rugosa* and the Tea, Sombreuil, and is said to be very vigorous in growth, pure white in color, and very fragrant. The blooms are produced in clusters. Another hybrid already alluded to in GARDEN IN FOREST is that peculiar one originated by Mr. E. S. Carman by crossing *R. rugosa* with Harrison's Yellow, the product bearing a flower somewhat like Jacqueminot in color.

Interest has again been aroused in some localities in the question frequently discussed before as to the value of worked Roses in comparison with those on their own roots, when used for forcing, and after comparative trials it has again been decided by some of the growers that plants on their own roots

are fully equal, and in some cases superior, to those depending on the roots of another variety for sustenance. From this it will be seen that the opinion expressed by Mr. John N. May and a few other noted growers, several years ago, to the effect that "a Rose that would not grow on its own roots was not worth growing at all," was based on the sure foundation of personal experience.

Holmesburg, Pa.

Orchid Notes.

Progress in Hybridizing.—There was quite a flutter among the Orchidists, at a recent meeting of the Royal Horticultural Society in London, when the new hybrid between *Lalia Digbyana* and *Cattleya Mossia* was exhibited. Nothing so remarkable had been seen since that charming little plant, *Sophrocattleya Batemanniana*, \times first appeared, and it was universally admitted that the plant was a great acquisition, and added yet another to the many triumphs of the great pioneers in Orchid hybridization—Messrs. James Veitch & Sons, of Chelsea. It may almost be called a *Cattleya Mossia*, with fringed flowers, though the influence of the pollen-parent is seen in several other of its characters—the long-beaked ovary, the tube-like base of the lip, and the white sheaths of the pseudo-bulbs, for example. "May possibly be the forerunner of a race with fringed flowers," said a writer in the *Gardeners' Chronicle*, when describing it.

And what possibilities for the future does such a success indicate? *Lalia Digbyana*, in spite of its gloriously fringed lip, does not appear to be a very popular garden-plant; possibly on account of that unmistakable tint of green in its flowers, but once the possibility of transferring the beautiful fimbriation to some of the more popular *Cattleyas* and *Lælias* is demonstrated, further experiments are sure to be made; though we must wait a few years for the result, as the present plant was seven years old before it flowered, and *Lalia caloglossa*, raised in the same establishment, did not flower until it was nineteen years old—certainly an inordinately long time to wait, even for the choicest of hybrids.

In spite of this, however, hybrid Orchids are now becoming a very numerous class, and include in their ranks some of the choicest ornaments of our gardens. *Lalia Exoniensis* \times is one of the showiest of autumn-bloomers; *L. flammea* \times a plant of unusual brilliancy, whose distinguishing characteristic is well indicated by its name; *L. Amesiana* \times , *L. bella* \times , and *L. callistoglossa* \times , are all magnificent flowers, and among the most brilliant of those raised by the Chelsea firm. "We grow our own new Orchids, instead of importing them," said Mr. Harry Veitch, during a recent visit.

Another good point about these hybrids is that in the majority of cases they possess good constitutions. Some of them are plants of remarkable vigor, as the showy *Cypripedium Sedeni* \times for example, and there are instances where two species difficult to cultivate have given rise to a hybrid of good constitution. *Cattleya porphyrophlebia* \times has been cited as a case in point, as of better constitution than either *C. intermedia* or *C. superba*, its two parents. Again, *Cypripedium Fairieanum* is reputed to be one of the most difficult species to cultivate successfully, while *C. vexillarium* \times , and *C. Arthurianum* \times , of which it is the pollen-parent, are among the easiest.

Cypripediums seem to be in the ascendent just now. The remarkable hybrids raised by Dominy & Seden have attracted others into the same field, and as *Cypripedium* is the genus which, of all others, is most easily managed, and as the seedlings reach the flowering-stage in a comparatively short period, it is not difficult to see why it should have been thus taken in hand. "So generally is muling among Cypripedes practiced," remark Messrs. Veitch in their recently-issued Manual, "not only in Great Britain, but also on the Continent of Europe and in the United States of America, that there is scarcely an Orchid collection of note in which a batch of seedlings may not be found." A considerable increase of novelties may therefore shortly be expected.

Already they are more numerous than the species, and a very various lot they are. Some of them are among the showiest grown, while others are of rather a weedy character, and suggest an early application of the principle of the "survival of the fittest." In some cases the characters of the parents seem to neutralize each other, with the result that the hybrid offspring is inferior to either parent, though more often, perhaps, the reverse is the case. The well-known *C. Sedeni* \times was a pleasing surprise, for so good a thing was not expected from a combination between such species as *C. longifolium* and *C. Schlimii*. The variety *C. candidulum* is still better, and the number of allied forms which have since appeared show what

a decided hit Mr. Seden made. Probably the ultimate fate of these hybrid *Cypripediums* is to become florists' flowers, for any amount of improvement in them seems possible.

London.

Calypto.

Cypripedium Rothschildianum.—It is now nearly two years since this handsome Lady's Slipper was first introduced to cultivation by Messrs. F. Sander & Co., and it is certainly one of the most interesting and remarkable novelties among Orchids

the months of February and March last several plants were in flower here, and remained in good condition over six weeks. Now here are several more blooming, and, if anything, an improvement on those produced earlier in the year. *C. Rothschildianum* has sub-erect, leathery leaves, of a uniform deep green color, and are from nine to eighteen inches or more long and two to three inches broad, with a sharp prominent keel on the under surface. The strong scape, which is over a foot long, is of a dull purple, covered with a downy pubescence,

Fig. 120.—A Specimen plant of *Trachelospermum Thunbergii*.—See page 369.

which has been seen of late years. Although this species has been imported in large quantities from various places in the eastern Archipelago, it has not been long enough in cultivation yet for many to know it; but there can be no doubt that, in the course of a few years, a specimen of it will be found in every collection worthy of the name, for it is a species which not only produces remarkably large and handsome flowers, but possesses the additional recommendation of producing them very freely at two or three different times of the year. During

and generally bearing two or three flowers, the pedicels of which are clasped at the base by large showy bracts of a greenish-yellow color, handsomely and regularly striped on both the inner and outer surfaces, with dark purple. The ovate, elliptic-acute upper sepal is about two and a half inches long and a little over two inches broad in the widest portion, and fringed on the margins with short purplish hairs. The ground color is more or less of an agreeable pale yellow, longitudinally marked with broad blackish-purple stripes of unequal

length, which show through on the back, where they are more or less confluent in the centre. The lower sepal is slightly smaller, but otherwise similar. The tapering petals, at first, are spread out horizontally, but, as they become older, they get more or less depressed and much longer, eventually attaining a length of as much as six or seven inches. They are wavy on the margins at the base, pale yellow, marked with longitudinal lines and blotches of dark purple, which vanish towards the dull purple hairy-tips. The large projecting lip very much resembles that of *C. Stonei* in shape; it is reddish-brown in front, washed and veined with dull purple, and usually having a pale yellow stain just under the edge of the mouth, while the under concave surface, as well as the infolded lobes at the base, are of a pure creamy-white which presents a very striking contrast to the adjoining color. The peculiar staminode is one of the chief characteristics of this species; it is swollen at the base and densely covered with purplish hairs tipped with a whitish glands; the anterior portion is bent at a sharp angle to the basal portion, is cleft slightly at the tip, and fringed only on the sides with similar glandular hairs.

Judging from the plants growing here, it is safe to say that *C. Rothschildianum* may be grown with the greatest ease, provided that it has a warm and moist atmosphere. Rough, fibrous peat, with a little sphagnum and charcoal mixed, suit them admirably; abundance of water must be given at all seasons except during the winter, and even then the plants require a moderate supply. Shading is also necessary during hot days, otherwise the leaves are apt to become spotted and burnt, thus giving the plants a very unhealthy look.

St. Albans, England.

John Weathers.

Notes on Wild Flowers.

Asclepias tuberosa (Butterfly-Weed or Pleurisy-Root), now in flower, is one of the finest of this genus. Under cultivation the plant grows about two feet high, bearing one or more good-sized umbels of showy, orange-red flowers, which remain a long time. The plant is leafy throughout, and the dark-green foliage makes a pretty contrast with the bright flowers. It is one of the easiest plants to grow, and is largely cultivated in Europe. Another pretty plant of this genus is *A. quadrifolia* (Four-leaved Milkweed). This species grows about eighteen inches high, bearing an umbel of pale pink flowers which are quite pretty. This plant seems to prefer dry, half-shaded locations.

Astragalus Canadensis is a plant of the Pea family, which grows from one to four feet high, bearing its flowers in dense spikes, about two inches in length by three-fourths of an inch in diameter. There are often several stalks from one plant, and three or more of these flower-spikes on each stalk. The flowers are of a greenish-white color, slightly tinged with purple, not showy; but the plant is an interesting one, with handsome, dark-green foliage, and takes readily to cultivation.

Allium cernuum.—One of the wild Onions, now in flower, is a hardy species bearing a nodding umbel of pale pink flowers. The plant grows about a foot high from a bulbous root. It seems to thrive in almost any ordinary location, and may be planted at any season except in winter.

Calochortus flavus and *C. madrensis* (Butterfly Tulips), two species from Mexico, are in flower. The latter, in cultivation, grows from six to twelve inches high, bearing, in succession, several—sometimes eight—bright yellow flowers, an inch or more in diameter. Sometimes two are open at once, but often only one is in bloom, but the flower remains in good condition several days. *C. flavus* often grows fifteen inches high, bearing six to eight purple and yellow, nodding, bell-shaped flowers, three-fourths of an inch in diameter, and hairy inside. The flowers are not only very pretty, but they are durable and are produced in succession, so that the flowering season of the plant is greatly prolonged. The bulbs are easily kept in dry sawdust during the winter, and should not be planted in the open ground before the 20th of May or 1st of June. Early setting does not seem to hurry them at all. Both of these species produce their flowers on long stems, which makes them valuable for cutting. A warm, dry, gravelly loam seems to suit them best.

Another new and interesting plant just in flower is *Nemotylis Pringlei*, first found in northern Mexico by Mr. C. G. Pringle. The stems come from a small bulb, grow about eight inches high, bearing a light, bluish-purple flower, which this season is fully two inches wide. The leaves are long and narrow, and the plant is quite inconspicuous except when in flower. The flowers are as short-lived as those of the *Tigridias*, lasting only a few hours.

Oxalis decaphylla, also from Mexico, is a very interesting

little plant under cultivation. The leaves are divided into six or eight long, narrow sections, often two inches in length, deeply notched at the ends. The flowers are borne in umbels, on separate stems from the root, six to eight inches high. The numerous flowers are three-fourths of an inch in diameter, of a delicate pinkish-purple, with a green centre. They open in the early part of sunny days, closing in the afternoon, and last several days. The plant seems to have several periods of flowering during each season.

Charlotte, Vt., July 22d.

F. H. Horsford.

Plant Notes.

Trachelospermum Thunbergii.

THIS plant, known generally in gardens, where it has long been a favorite, under the name of *Rhyncospermum jasminoides*, is a native of southern China and of Japan. It is one of the best garden-plants of its class, and can be grown where the severity of the winter is too great for it, as our illustration upon page 368 shows, into a fine specimen pot-plant, suitable for exhibition or for the decoration of the conservatory or the veranda.

This plant is now a conspicuous feature in the gardens of some of the cities of the Southern States. It may be seen in New Orleans climbing to the third stories and completely draping some of the largest houses with its brilliant, lustrous evergreen leaves; the delicious perfume of the pure white abundant flowers pervading, during the month of April, the whole atmosphere of the neighborhood.

At the north it is not hardy, but it may be kept during the winter in a cold green-house, or much better in a cellar or pit, from which the frost can be excluded. It can then be brought into bloom any time after February in four or five weeks after the plant is removed from its winter quarters with the aid of a little artificial heat; or if it is allowed to bloom naturally—that is, without artificial heat—it will come into bloom in this climate about the 1st of June, and will remain covered with flowers during nearly a month. It thrives, as a pot-plant, in rich, rather heavy, well-drained soil, and it is found that the plants are improved and flower more freely if they are taken out of the pots and planted in the open ground as soon as they have finished flowering. They should, if treated this way, be planted in rich soil, copiously watered during periods of drought, and lifted in the early autumn and re-potted.

The plant which our illustration represents has been grown in the neighborhood of Boston, and is, probably, about twenty-five years old. It is eight feet high above the tub, and the frame over which it is trained is four feet through at the widest point.

Correspondence.

Thinning Forests.

To the Editor of GARDEN AND FOREST:

Sir.—I have read with interest the editorial on "Thinning Forests," in your issue of May 15th, and agree with you in the main proposition, namely, that it is necessary to show definitely whether the thinning of a White Pine growth for cultural purposes alone would at the present stage of our development pay in the end. I may be allowed to add, however, that the results of European experiments, as far as these furnish figures capable of mathematical handling—not simply general experiences and opinions—seem to me quite sufficient to teach us the general lesson of what results may follow certain operations.

These experiments, to be sure, have reference to species different from our own, and cannot therefore answer absolutely for our own conditions; yet if we compare results obtained with species of similar behavior, we may feel some confidence of approximating similar results. From my own observations I would claim that in the eastern United States forest-growth is more luxuriant than in Germany, for instance, and that since in general our soils are not overdrained like those of the Old World, thinning would produce even more favorable effects in quantitative production than there, and the result of European experiments in thinning would be rather under-statements of what we may expect here.

From these experiments we can show not only that "trees will grow more rapidly if they are judiciously thinned," but we can also show how much more rapidly they will grow. If our present ideas of value and quality of timber prevail, upon which you have made your calculations, we must admit that with White Pine or any other coniferous wood, rapidity of development—which is the object of thinning—does not go

hand-in-hand with appreciation of value and quality, as it would with broad-leaved trees. But our methods of utilizing wood material seem destined to undergo a rapid change by the introduction of processes which allow the utilization of inferior products (paper-pulp, indurated fibre, etc.) and the use of substitutes for the better qualities of timber (iron, stone, etc.). Thus, it may become a question whether it is not more profitable to produce the greatest possible quantity of wood per acre in the shortest time than with slower development to secure better quality. Let us now suppose that we are working our Pine growth simply for box-boards, where quantity and not quality, within reasonable limits, is to be sought for, and what may be the financial result of this thinning?

I have cited in the Report of the Forestry Division for 1887 a number of experiments on thinning, with their results, which will show the quantitative appreciation of the thinned growth. In making inferences from these results upon possible results with the White Pine, it may be expected with confidence that in regard to the effects of thinning, the White Pine compares more nearly with the Norway Spruce than with the Scotch Pine, that is to say, the effect of thinning would be at a greater ratio on the White Pine than on the Scotch. To these notes, from which it will appear that the rate of accretion can be accelerated by thinning three to four times, allow me to add the following as bearing upon the question:

Since thinning means reduction of the number of plants per acre, those experiments are here applicable which show us the result which a difference in the number of original plants per acre makes in amount of wood production. In 1862 there were eight fields sown and planted with Scotch Pine for experimental purposes in Saxony. The planting was done in the fall, the sowing in the spring; the field planted in squares at 4.7 feet distance showed the maximum production. In 1886, after twenty-five years, the results obtained from the field which was planted at three and a half feet distance each way compared with those obtained from a sowing in drills three and a half feet apart, after both had been moderately thinned of inferior material, showed the following:

	No. of trees per acre.	Aggregate cross-sections of stems, sq. ft.	Average Height, feet.	Amount of wood, cu. ft.
Planting.....	1,447	137.0	36.3	3,117
Sowing.....	1,464	102.6	31.0	2,073

The planting, or less crowded position, then had produced $3\frac{1}{2} \times 129.8$ cubic feet yearly average; the sowing, or dense position, only $2\frac{1}{2} \times 82.9$ cubic feet. There were 1,044 cubic feet difference in favor of the former, or an advantage of over 32 per cent. in material, and besides, with almost the same number of plants, better proportions.

Allow—for the sake of a comparison, which is not unfair—these conditions to hold to a New England White Pine-forest, and let us assume this growth to be cut for box-boards. The Scotch Pine, to be sure, would not yet have reached suitable dimensions, but I believe the White Pine does reach workable dimensions for box-boards at the age of twenty-five years; otherwise it would be reasonable to assume that the differential advantage between the two growths gained at this age would be at least maintained for the next five or ten years, where the trees may have attained such dimensions. We may allow sixty per cent. of the material useful for the purpose of box-boards in both cases, although, in fact, the planted growths would show less waste.

The more openly-grown part would have produced, if box-boards bring the present price of \$12.00 per 1,000 feet B. M., \$90.19 more than the denser growth. If, then, it should have cost \$5.00 to thin out the natural growth when six years old, and another \$10.00 when fifteen years old, this expenditure, with four per cent. interest at the age of twenty-five years, would have been equal to about \$25.00, and the balance in favor, \$67.19 per acre. And even if we had to wait ten years longer before utilizing the crop and paying interest on the expenditure for thinning, the balance in favor of thinning would be \$52.00. In this case the sowed part started under more favorable conditions than most of our natural growths, in which the dense position increases the struggle for existence unduly.

When we admit that the "finest Pines grew without any assistance from man," we must also admit that time was no object to Nature, and that if we apply strict financial calculation—figuring interest on the value of land—these giants of Nature's forest would be immensely dearer than the price we now pay for the lumber furnished by them.

I do not mean by this to underestimate the value of forestry

experiments to be undertaken in this country—which I have strongly urged in my report—but I do believe that the knowledge of such experiences as those cited above can only encourage and induce an early beginning of similar experiments here, and that nothing is gained by disregarding and discrediting, in a general way, the experiences of Europeans in the art of forestry.

Washington, D. C.

B. E. Fernow.

Rosa humilis, Marsh., var. plena.

To the Editor of GARDEN AND FOREST:

Sir.—Humphrey Marshall, in the "Arbustum Americanum," 1785, enumerates and, in part, describes four species of Roses as being indigenous to Pennsylvania, among which is *Rosa Pennsylvanica plena*, differing from his *Rosa humilis* in no important respects save in its having double flowers. Ehrhart, in *Beitrag zur Naturkunde*, 1789, describes, from bushes taken from this country and cultivated in the gardens at Hanover, *Rosa parviflora*. This Rose, likewise, had double flowers, which, however, were attributed to the stimulus of cultivation. Marshall's Rose could not be thus accounted for.

These three Roses are regarded by botanists as being one and the same, in name, *Rosa humilis* having priority. It would seem strange that a flower so markedly disposed to become doubled under cultivation should not now and then exhibit the same tendency in its wild state, yet, so far as I know, there is no recorded instance of the kind from Marshall's time to the present. *Rosa Pennsylvanica plena* has been a standing puzzle among rhodologists. Dr. Watson, in speaking of *Rosa humilis* says: "It is not easy to account for the double-flowered form of this," and Dr. Porter, who has collected extensively in almost every part of Pennsylvania, says he never saw it. It is, therefore, evident that the Rose in question is rare, or rarely observed—perhaps the latter.

On the 12th of June, about three miles from Rosemont, New Jersey, growing by the road-side, I found a large patch, fifty bushes or more, of the double-flowered form of *Rosa humilis*. On either side, the ordinary single-flowered form grew in profusion, but not a bush of that kind among these; all were doubled, having from fifteen to thirty petals, much smaller, however, than usual. This, in all probability, accounts for Ehrhart's name, *Rosa parviflora*, small-flowered Rose, a name very inappropriate when it is remembered that this Rose is two or three inches in diameter in full bloom.

The historical associations make this a very interesting find. The influences of cultivation, I think, can be eliminated without a doubt; I never saw it cultivated. While I do not think it possesses characters sufficiently distinct to separate it from *Rosa humilis*, yet it has a *cachet* that marks it as different from the ordinary forms of this variable species. I suggest that it be known as *Rosa humilis*, Marshall, var. *plena*, n. v.

Rosemont, N. J.

G. N. Best.

Flower-beds in Chicago Parks.

To the Editor of GARDEN AND FOREST:

Sir.—Allow me to express my satisfaction at Herr Jaeger's denouncement of the "lunacy" of the flower-bed decorations of the South Park of Chicago.

I speak feelingly on the subject, not only because I have been held responsible for them, but what is still more aggravating, because I have been complimented upon them—and that by educated people—oftener than for any portion of what really constituted my design for the park. Only last summer a gentleman from New England, and a graduate of Harvard, to whom I chanced to be introduced, asked if the South Park was not my work, and immediately launched into an enthusiastic description of a life-size floral representation of three men rowing a boat!

My hope has been that men of sufficiently cultivated taste to appreciate justly the floral eccentricities that have distinguished that city for years (camels, elephants, baseball players, etc.), would equally appreciate the anomalous position of a landscape-gardener in the mind of the average Park Commissioner, and not hold him responsible for outrages he is powerless to prevent. But the number who have spoken to me of this form of monstrosity in terms of admiration is so large in comparison with those who have treated it as it deserves, that at times I have felt disheartened and ready to despair of ever finding a more elevated standard of public taste.

H. W. S. Cleveland.

The Bermuda Lily.

To the Editor of GARDEN AND FOREST:

Sir.—A note in GARDEN AND FOREST recently spoke of imported flowers of this Lily as inferior to home-grown flowers

of the same kind. There may be a difference in the quality of the Lily-flowers grown at Bermuda, but it would be impossible to find anything more lovely than some groups of this Lily now in flower at Kew. These are all from bulbs imported from Bermuda last year. They are from five feet to six feet high, well-leaved down to the base, and each stem bears from five to eight large flowers of the purest white. Nothing to equal them has been seen in England (so it is said). Certainly I never before saw this Lily so strikingly beautiful as it now is here. The bulbs are cheap enough, and they are as easily managed as Hyacinths. Unfortunately this extraordinary vigor and floriferousness is not permanent in the Bermuda Lily, as when grown a second year in England the plants are simply *L. longiflorum*. But the Bermuda Lilies the first year after importing are grand beyond all question.

Kew.

W. Watson.

The Albemarle Pippin.

To the Editor of GARDEN AND FOREST:

Sir.—Allow me to inform Mr. E. J. Wickson, in reference to his note on page 346 of the GARDEN AND FOREST, that in the later editions of the "American Fruit Culturist" (see page 530) I gave Albemarle Pippin as a synonym of the Yellow Newtown Pippin, although in my statement to which he refers (in a private letter not intended for publication, as stated by the editor) I did not go into any distinction between the two sub-varieties of this Apple, which I did fully on page 250 of that work.

Recent Publications.

All About Pasadena and its Vicinity, by C. F. Holder. Boston: Lee & Shepard, 1889.

This unpretentious little handbook to one of the tourist-haunted districts of California gives some interesting facts with regard to local fruits and flowers, wild and cultivated. To show the perennial richness of the climate of Pasadena in edible fruits, the following catalogue is given: "Oranges, lemons and limes are found in the market every month in the year, and may be kept a year or more on the tree. These fruits naturally ripen in February, March or April; cherries from June to August; blackberries and apricots from June to September. From June to January you have raspberries and peaches; from June to November plums and prunes; nectarines, July to September; grapes from July to January; pomegranates and quinces, August and December; Japanese persimmons, November and December; loquats, April to July; guavas, all the year; currants, May to July; apples, May to February; alfalfa, five to seven crops a year; potatoes, two crops a year, and on good land two crops of grain have been taken. By the use of a system of cold storage now introduced here, nearly all fruits can be had at any time during the year. Vegetables are raised all the year round. The Orange groves, taken in masses, constitute the chief beauty of the country. . . The Orange was probably introduced into this country from Spain, and the oldest trees, of seventy years or more, are to be found down at San Gabriel. Hardly a portion of Pasadena but boasts a grove; in fact, the city is laid out as a vast Orange-grove. Orange Grove Avenue, the finest resident street, is cut through one. . . Trees will bear when three or four years old, and begin to pay when five or six. The third year one may count on a few Oranges for home consumption; the fourth year upon fifty oranges to a tree and the fifth year upon 200. The trees attain their full development at fifteen years, and may then be twenty-three or twenty-four feet high, with a trunk three feet in circumference. Such a tree may bear 4,000 Oranges a season, the retail value of which at the East would be \$200. The Orange, Lemon and Lime-trees are the ones which need irrigation, being watered well three or four times during the season. This is done by scooping up basins about the trees and connecting them by canals, so that the basins are all filled." The fruit is gathered by Indian, Mexican and American gangs of peripatetic pickers, then washed, wiped and sorted, according to size and color, and shipped to the East. "On many ranches . . . are fine groves of the English Walnut. The trees are extremely beautiful, and those of some orchards realize \$200 per acre in a season. The tree comes into bearing when about ten years old. . . The vast vineyards that cover miles of country here attract attention in winter by their grotesque appearance, resembling roots set on end with some regularity. This is due to the fact that every fall the vines are cut back." In 1885 southern California sent out over half a million boxes of raisins. "At Linda Vista the visitor will find an experimental station where forest trees are

to be planted. . . In almost every place in the city are found Fig-trees bearing a large crop. . . There are up to date about a thousand acres in California planted with Olives. The tourist will notice in the Pasadena landscape square blocks of forest trees rising plume-like to a height of from 60 to 100 feet. These are the Eucalyptus forests, or groves, planted for fire-wood by ranchers who have land to spare. Taking an actual case, a rancher planted sixty acres with 26,000 Eucalyptus plants which cost \$10 a thousand. Planting, mowing and cultivating cost, including the trees, nearly \$1,000, which was the expense for the first year. The second year it cost \$480, after which there was no expense. The trees grow rapidly, and at five years are large enough to cut."

Mr. Holder speaks appreciatively of the wealth of herbaceous plants, Ferns and shrubs which clothes the plain and the mountains during the various seasons of the year; and the frontispiece to his little volume gives an instance of luxuriant development that it would be hard to overmatch. It shows the gable end of a house which cannot have been standing many years. It is apparently about twenty-five feet wide and thirty feet to the top of the gable; yet it is entirely covered, so that small trace of the windows appears, with the prolifically flowering branches of a single climbing Rose.

North American Birds, by H. Nehrling; with colored plates after water-color paintings by Ridgway, Goering and Muetzel, Milwaukee. Published by George Brumder, Part I, 1889. This is the beginning of a new popular history of North American Birds, upon which the author has spared neither labor nor expense. The text is not burdened with dry scientific details, but is filled with pleasant reading about the habits of the different species considered; with much information upon the forests and fields which they frequent at the different seasons of the year, and many pleasant allusions to trees and herbs. These extracts, taken at random, will give an idea of the writer's style and of the sort of information which may be gathered from his thoroughly interesting and always readable pages.

"Among wild fruits the Robin is particularly fond of Elder and Poke-berries. In winter these birds are unusually common in the beautiful Hammock-woods of Florida, where the mealy Sparkle-berry and the Holly with its shining vermilion berries grow in abundance. The plumage of the bird's breast is often stained with the violet juice of the Poke-berry.

"From early in the morning to late in the afternoon these birds are busy almost without interruption. It is only during the hot part of the day that they are somewhat less active. Their flight is smooth, rapid and skillful, and does not lack grace and beauty. To one who has seen, during migration, flocks of several hundred individuals rapidly flying high over the forest trees it seems easy to understand how they can traverse such an immense expanse of country in so short a time. They move about nimbly among the boughs and are perfectly at home on the ground." And of the Mocking Bird—the finest songster of them all—we read: "Most of the males commence singing between three and four o'clock in the morning. First a single individual begins its lay from a Magnolia draped with gray Spanish Moss, or from its hiding place in a Banksian Rose, or even from the top of a chimney. Another male sleeping in the neighborhood, probably in a tree overgrown with a large Wistaria, or Trumpet-Creeper, excited to rivalry, also begins to sing. The song, first softly uttered, gradually grows louder, intenser, more inspired and modulated. More singers join in the chorus, till one can often hear five or six different voices at the same time. Thus they excite one another to greater efforts. These are incomparable bird concerts, which produce a deep and lasting impression on the listener in the quiet nights when all nature lies in deep slumber. When the gray dawn appears in the far east, and soon afterwards the sky reddens, all the Mocking Birds sing diligently, and the Cardinal Red-birds, the Nonpareils and others join in the chorus of jubilation to greet the day-star as he rises above the horizon. Very rarely a Mocking Bird is heard during the hot hours of the day; the greatest number are silent, and only towards the late afternoon does the chorus commence again."

But it is not necessary to continue these extracts in order to show that their author is a keen lover of nature; and that much information can be gathered from his pages.

The illustrations are carefully and accurately drawn by accomplished naturalists, but the coloring of the chromo-lithographic reproduction is not very successful; and the grouping of the individual birds is not always fortunate. The thin red margin-line which surrounds the pages of text detracts from their otherwise good typographical appearance.

Notes.

The *Horticultural Times* notes with approval an increasing use of Ivy-leaved Geraniums in window-gardens.

In the latter half of August a Botanical Congress will be held in Paris, when an exhibition of maps, photographs, books and other articles relating to botanical geography will be opened.

Our readers will be glad to hear that Belmont, near Boston, the old estate described in GARDEN AND FOREST, for July 10, has been purchased for the use of a new boys' school, to be called Belmont School. A finer setting for such an institution can hardly be imagined.

The Kansas Board of Agriculture reports that chinch-bugs are dying by the million of some contagious disease. Experiments are now in progress to ascertain whether the disease can be introduced artificially among healthy bugs, so that the ravages of this most dreaded enemy of the western farmer can be held in check.

Major O. P. Rooks, in a recent address at Fruitland, Florida, spoke of some admirable seedlings from both the Peen-to and Honey Peaches. The fruit of the Peen-to seedlings was so large that a peach would rest on the top rim of an ordinary tea-cup, and peaches borne by the Honey hybrids were eight inches in circumference. The fruit was also of excellent quality and beautiful color.

Colonel J. A. Price argues strenuously for the selection of Indian Corn as the national flower on account of its essential beauty and the adaptability of all its parts—stalk, leaf, plume, silk, husk, ear—to purposes of art and architecture. Its cheerful colors, too—the green of summer, the gold of autumn and the tinted red and yellow of the ears—all contribute to the infinite variety in which it can be used for ornament. In the *Decorator and Furnisher* for the current month Colonel Price offers a prize of \$100 for the best adaptation of Maize to the industrial and architectural arts.

In a careful review of the spring plant trade *The American Florist* observes that there has been a decrease in the total sales from those of last season. Among causes assigned for this are: (1) The mild winter, which permitted many plants to be carried over; (2) the general curtailment of trade among the people who are the largest buyers of ornamental plants; (3) the unfavorable weather, which discouraged planters during the selling season. A smaller demand for Coleus and similar plants was generally reported, and for this a partial explanation is found in the prevailing cold weather, which would naturally check the sale of such tender plants. It is probable, however, that the popularity of this class of plants is beginning to wane.

Professor Forbes gives an account in *Insect Life* of some experiments with the Plum curculio, from which it was learned that they would eat the petals of Roses and the blossoms of bush Honeysuckles and Snowballs, so that it seems not improbable that the beetle gets only a small part of its subsistence from fruit-trees. It is therefore worth while to make the attempt to attract the adult insect to other plants than the Peach or Plum for the purpose of poisoning it there. This is especially worth trying late in the season, when the use of arsenites upon fruit might be dangerous. There is no longer any doubt that very weak solutions of London purple or Paris green will be fatal to the beetle. It is true also that the leaves of the Peach are liable to be scorched by a mixture of London Purple, even when applied at a rate of one pound to 200 gallons of water.

Mr. W. T. Thiselton Dyer, in writing of the principles of Orchid nomenclature, argues that all the botanist can do is to refer any Orchid submitted to him to some well-defined species which has already been described in intelligible terms, or to describe it as new if this has not already been done. For horticultural purposes it is evident, however, that something more than this is wanted. Within the limits of a species it is known to every one that there are variations of size, color and texture which practically elude botanical terminology, and yet are of paramount interest and value to the cultivator. The difference between a fine form and a poor one of the same species can often with difficulty be seized, even in ordinary language, and yet it is recognizable at a glance by every experienced Orchid-grower. It is a great mistake to suppose that a botanist can deal with such forms in any useful way. Their distinctness and merit is a matter for the judgment of experts, just as in the case of any other cultivated plant. Nothing, then, is gained by giving such forms Latin names, which imply that they are well-marked varieties. The proper course is to

give them arbitrary names in English or some other language, and these should not be accepted as authoritative till they have received the approval of the Floral Committee of the Royal Horticultural Society.

An investigation at the Delaware Experiment Station shows that the farm and garden seed found in the markets of that state has a germinating power up to the average standard. The purity of the seed, too, was found to be above the average, and yet the report makes it very plain where most of the farmer's weeds come from. He sows their seeds, and he sows them on well-prepared land, where they are sure to thrive. For example, a moderately pure Clover seed, with but a trifle more than one per cent. of impurity by weight, was found to contain the seeds of Plantain, Rag-weed, Smart-weed and Foxtail Grass in sufficient numbers to put one seed every foot in drills fifteen inches apart if the Clover seed were sown eight pounds to the acre. In another instance, a very clean sample of Alfalfa seed, with less than one-half of one per cent. of impurity, and that mainly dirt, showed the presence of the minute seed of the Clover Dodder (*Cuscuta Trifolii*) at the rate of 720 to the pound. If the Alfalfa were sown at the rate of fifteen pounds to the acre, this would place one seed of Cuscuta every two feet in drills two feet apart. The sowing of so much of this seed would be a dangerous proceeding, for when this Dodder once winds its wiry stem about a Clover plant and begins to suck its juices, the doom of that plant is sealed, and the Dodder is soon reaching out its arms for a new victim. These seed-tests were made by Professor F. D. Chester, and the bulletin containing his report furnishes some instructive reading for the farmers and gardeners of Delaware.

A writer in the *Gardeners' Chronicle* speaks with enthusiasm of the natural beauty in the extensive gardens and pleasure-grounds of Baron Ferdinand de Rothschild's noble estate, Waddesdon Manor, a beauty which has been developed to the very highest by the arts of the landscape-gardener at every point. From the elevated plateau on which the mansion stands some of the most beautiful views in the country are commanded, and the devious and carefully-arranged walks in the grounds reveal different gardens, each distinct, but all in harmony, a result which the clever planting of the whole of the grounds in clumps and groups of the same kind does much to secure. By planting in this manner, each thing, whether flowering Weigelas, Rhododendrons, Escallonias, Philadelphus, double and scarlet Thorns, or whatever it may be, appears to make its individuality distinct, which is not the case where single plants, instead of groups of each kind, are used. The effect of planting in groups brings out some fine effects in the Waddesdon gardens—notably in the case of the silvery-leaved Sea Buckthorn, the mingled white variegated Maples and Copper Beech, and the noble clumps of Pampas-grass. There is plenty of bloom in every part of the gardens. The view from the terrace over the main flower-garden being especially brilliant with the rich scarlet of Pelargonium, Henry Jacoby, the pink of Pelargonium, Mrs. Lever, and other effective flowers worked in with variegated foliage, among which the Pelargonium, Flower of Spring, employed amounts to over 8,000 plants.

The edible Banana, it is said, is known to seed only in one small spot on earth, the Andaman Islands. However this may be, it is universally grown from suckers. Its cultivation in the West Indies has vastly increased during the past fifteen years, owing to the demands of the United States for its cheap, wholesome and luscious fruit. About 400 or 500 trees are planted to the acre, and the plantations are called "Banana-walks." In former days any available spot was chosen, usually an abandoned cane-field, where the ground was most easily prepared for the new crop. But experience and competition have brought about more careful methods of planting, and the best place for a Banana-walk is now considered a valley or hill-side with a western prospect. The tree fruits the first year, and the expense of cultivation is so small that a bunch of Bananas, delivered at the sea-coast, need have cost its owner no more than four or five cents, while it may be sold in the winter months for from twelve to eighteen cents, and in the spring months for four times as much. There are risks attending Banana cultivation, however, for the thievish negroes often seriously decrease the value of a crop, and it may be entirely swept away in a single hour by a hurricane. As soon as the Bananas begin to cast a shade, young Cocoa plants are set out between them, as this tree needs protection from the sun in its youth; and when the Bananas cease to be profitable—which is at the end of three or four years—Almond-trees or other fruit-trees are often set in their places while a new "walk" is laid out elsewhere.

A Worthy Example.

A CORRESPONDENT describes in another column the means adopted by a few public-spirited people living in a rural neighborhood for preserving a piece of natural scenery, which, without such intervention on their part, was doomed to speedy destruction. In many other places objects of great natural beauty have been sacrificed because no organized effort has been put forth to save them, and this little body of men and women—neighbors and friends—deserve the thanks of all intelligent and patriotic people, because they have acted on the principle that the destruction of an attractive bit of scenery, like the fringe of forest on a lake border, or a glen through which a mountain stream foams and tumbles, is a public loss. They believed that natural beauty is something to be cherished because it has a genuine value, and that we have no more right to waste it than we have to squander any other inheritance. The community for whom the scenery of the Chittenango has been preserved will be richer for all time because this possession has been secured to them and to their children, and many another community would have reason to rejoice if this example of establishing a trusteeship to hold against invasion and defacement some characteristic piece of wild nature were often imitated. The illustration of a portion of this amphitheatre, on page 379, from a photograph kindly furnished by Mr. L. W. Ledyard, will give some suggestion of the beauty which was threatened and rescued.

A special act of the Legislature was needed before a body corporate, with the power of succession, could be formed to hold and guard these falls and their surroundings, and keep them free forever for public use. But a general act for the incorporation of societies for providing parks and children's play-grounds was passed by the Legislature of this state, and approved by the Governor on May 15th, 1888. This act not only authorizes the acquirement of land by an association of citizens for use as public pleasure-grounds and play-grounds, but it gives them the right of employing officers, who shall, for the purpose of enforcing order and compliance with their rules, have all the powers and authority of public officers or patrolmen

in the city, town or village where these parks or play-grounds may be situated. It enables any fifteen or more citizens to do, under certain restrictions, what the public-spirited people of Cazenovia have done. It permits them to secure lands for park purposes and for play-grounds when the municipal authorities of such communities are not inclined to do this as representatives of the people. Corporators, under this act, can acquire property by gift, purchase or bequest to the amount of half a million dollars, "and such additional amount as may be authorized by the Mayor and Common Council of any city, or supervisor of any town, or trustees of any village in which it is proposed to establish such parks."

It seems probable that, in many towns, parks and reservations can be established under this act, when it would be impossible to acquire them in the ordinary way. Distrust of the local government often restrains the generosity of those who would otherwise be inclined to give or bequeath land or money for such purpose. If the donor could name the men whom he desires to administer the trust, instead of turning over the property to officials subject to the mutations of politics, and to the influences that control professional politicians, donations of this sort would be more common. At all events, associations of citizens have now another way of securing reservations for parks and play-grounds besides the tedious and uncertain one of laboring for them through the municipal authorities, and any community which is willing to pay for a reservation can command the assistance of the local government to enforce their regulations for its control.

We observe that an association, under this act, has been formed in the city of Brooklyn for the purpose of establishing small parks and play-grounds about the city. It is to be hoped that other cities and towns will follow this lead, and that the act, which seems to us a wise one, will be fruitful of good results throughout the state.

The series of letters by Mr. J. B. Harrison, Corresponding Secretary of the American Forestry Congress, now in course of publication in GARDEN AND FOREST, deserves the attention of all who are interested in forestry in this country. Few American writers have studied the subject so long or so thoroughly, or have seen so much of the treatment of forests and woodlands throughout our country. His clear perception of the value and functions of forests, and his thorough comprehension of their importance to the national welfare, give to his discussions, in an unusual degree, the quality of directness and reality. We owe to him a vital development of the idea of the relation of forests to civilization, and his treatment of this subject is remarkably practical as well as philosophical.

After many years of familiarity with the Adirondack forest-region Mr. Harrison has recently engaged in a new examination of it, and our readers will find in this series of letters more complete information regarding actual conditions and tendencies there than they can obtain in any other way.

A joint resolution for the appointment of a Commission to ascertain the feasibility of purchasing and preserving the forests of New Hampshire has been introduced in the Legislature of that state, and referred to the Judiciary Committee. It is a model of clearness and brevity.

Whereas, The preservation of the forests of New Hampshire is essentially necessary, not only for the prosperity of our vast manufacturing interests, but also to preserve and increase that natural beauty of scenery which is so attractive to our visitors; and

Whereas, The hills and mountains in this state are being rapidly denuded of timber, and rendered unsightly by the acts of private parties owning the same; therefore

Resolved, That the Governor, with the advice of the Council, is hereby authorized and empowered to appoint a Commission, consisting of three able and discreet men, who shall examine and ascertain the feasibility of the purchase by the state of the whole or any portion of the timber-lands upon the hills

and mountains in the state, near summer resorts, or bordering upon the principal sources of the water-supplies needed for manufacturing purposes, with the view of preserving the same as public lands and parks, and report their finding to the next session of the Legislature.

Another joint resolution provides for the appointment of a Commission to inquire into the subject of preserving a portion of the unoccupied or other lands within the state as a public state park. The preservation of the mountain forests of New Hampshire is a subject of great importance to the manufactures of that state, to the owners of hotel property at the summer resorts, to land-owners, lumbermen, and, indeed, to the entire population. It is encouraging to see that the representatives of the people are disposed to action in the matter.

Some Popular English Plant Names.

IN English books, both old and new, the American reader often comes upon the names of flowers and plants, names which seem to be commonly used in England, but are not quite clear to him.

How often, for example, have we read of the Guelder Rose, naturally fancying it must be a Rose of some sort. But it is simply *Viburnum Opulus*, the familiar Snowball of our gardens. Michaelmas Daisies, again, are very well known to us, though we never use this name for them. It denotes various species and varieties of our wild Asters, which are largely cultivated in English gardens and much prized because they bloom so late in the year. For the same reason the so-called Christmas Rose is prized—another "Rose," which is not a Rose at all, although the Germans likewise call it the *Christ-rose*. It is the Black Hellebore (*Helleborus niger*), a perennial herb of the Ranunculus family, which has large palmate leaves, and on leafless scapes bears from one to four flowers, some three inches in diameter, white, five-petaled, with a tuft of yellow stamens, and, altogether, not unlike single Roses in appearance. In the warmer parts of England the Black Hellebore blooms as late as December; in the few American gardens where it is cultivated its flowers appear in winter or in earliest spring.

The Rowan-tree of Scotch literature is the Mountain Ash. The tree commonly called the Scotch Fir is not a Fir, but *Pinus sylvestris*, properly the Scotch Pine. The Weymouth Pine, of English books and nursery catalogues, is simply our common White Pine (*Pinus Strobus*), which was introduced into England by Lord Weymouth in the last century, and is now very largely grown there. The Sycamore of English writers is always the Sycamore Maple (*Acer Pseudo-platanus*), never the Buttonwood (*Platanus occidentalis*), as with us. Sallow is a common name in England for several species of Willow, but especially for *Salix Caprea*. The Wayfaring tree is *Viburnum lantana*, which we often grow as a garden shrub. A Lime-tree means a Linden, as every reader probably knows, although the name is rarely, if ever, used in this country. The true Lime is, of course, a relative of the Orange and the Lemon—*Citrus Limetta*. The Service tree is *Pyrus domestica*, but the name is also often given in England to some other species of *Pyrus*, as to *P. terminalis*, which is properly the wild Service tree.

Every one says "as black as a sloe," but many Americans would be puzzled to identify this fruit. It is the fruit of the so-called Black-thorn, which is not a Thorn, but a species of Plum (*Prunus spinosa*) that is a native of Europe, and possibly the remote ancestor of the cultivated varieties of to-day. It may be found in many old-fashioned New England gardens, and seems to have naturalized itself to some degree in their neighborhood. Witch Hazel is the name we give to *Hamelis virginica*, and this signification is accepted even in English horticultural dictionaries; but when we meet with the term in transatlantic literature it denotes the true Hazel, for the *Hamelis* does not grow spontaneously in Europe. The two plants belong to quite different orders, but the shape of their leaves is similar. The American tree, doubtless, got its name from this resemblance, while the Hazel had been often called Witch Hazel in England because of the use of its twigs for divining-rods.

The Laurel of Europe is, of course, not our Mountain Laurel (*Kalmia latifolia*). The true Laurel (*Laurus*) is a genus of two species of evergreen shrubs, one of them a native of the Mediterranean regions and the other of the Canary Islands. The Daphne, of the Greeks, is another name for the Laurel; and so is the Bay. Again, the Hemlock of the Greeks and of

modern Europe is not our familiar forest-tree, which is properly the Hemlock-spruce, but a genus of biennial poisonous herbs, belonging to the *Umbelliferae*. The generic name is *Conium*, and the common Hemlock is *C. maculatum*. And Myrtle is another name that we misuse, often applying it to *Vinca minor*, which is properly the Periwinkle, and is always so called in England. The true Myrtle is *Myrtus communis*, a sweet-scented shrub with white blossoms, which is a native of southern Europe and hardy in the warmer parts of England. It was dedicated to Venus in classic times, and is still the accepted flower for bridal wreaths in many parts of Europe.

Traveler's Joy is *Clematis Vitalba*, and all native species of *Clematis* are called in England Virgin's Bower. The Woodbine is a species of Honeysuckle (*Lonicera Periclymenum*). In this country the name is often applied to the Virginia Creeper, but the practice should be avoided, in spite of the fact that it is recognized in certain English horticultural dictionaries. When a plant has so pretty a popular name of its own as the Virginia Creeper, it is foolish to forget it and increase the confusion which, do what we will, can never be wholly obliterated from vernacular terminology.

"Trailing Arbutus" is plainly a misnomer for our May-flower (*Epigaea repens*); but the genus properly called *Arbutus* belongs to the same great Heath family. It includes trees and shrubs with evergreen, laurel-like leaves. The Strawberry-tree is *Arbutus Unedo*, and Pliny is said to have given it the name *Unedo* because the fruit was so bitter that no one would eat it twice. Yet, Ovid writes of "The *Arbutus* heavy with its warm, ruby fruit," and says that in the Golden Age it afforded acceptable food. Perhaps no fruit was bitter in the Golden Age!

Whin, Furze and Gorse are all the same thing—*Ulex Europæus*, a plant of the Pea family, with small yellow flowers. Broom (*Cytisus scoparius*) belongs to the same family, and has likewise yellow flowers. Another allied genus is *Genista*, which includes the Woad-waxen that has naturalized itself in certain districts near Boston. A popular name for the Broom was once *Planta genista*, as all readers of English history know.

There has been much uncertainty even in England in the use of the pretty word Eglantine. Many old writers undoubtedly intend by it the common English Sweet-Brier (*Rosa rubiginosa*), as Shakespeare, when he writes:

"Quite over-canopied with luscious woodbine,
With sweet moss-roses and eglantine."

But the Woodbine (which has already been identified as *Lonicera Periclymenum*) now goes by the name of Eglantine in certain parts of England, and this is probably what Milton means when he speaks of the "twisted Eglantine." Gilliflower, or Gillyflower, is another name which has borne various significations. It was borrowed of the French *Giroflée*, which signified some species of Pink, usually a Carnation. With the older English writers—Chaucer, Spenser and Shakespeare—it likewise meant the Carnation (*Dianthus Caryophyllus*). Now, however, it is commonly given in England to one species or another of the *Cruciferae*, as to the Wall-flower or the Stock; and if used in this country it is apt to denote the Stock. Stockgillies is a name not infrequently heard.

With the Shamrock we have a third case of confusion. In Ireland to-day a Shamrock is often a White Clover (*Trifolium repens*), but as often the Nonesuch (*Medicago lupulina*), which belongs to another genus of the same great Pulse family. In England the name is commonly given to the Wood Sorrel (*Oxalis Acetosella*), and antiquaries are puzzled to decide which plant should be deemed the original Shamrock of St. Patrick. They have even discovered that among early authors the Water-cress was called the Shamrock, and meet the objection that it has not a three-fold leaf by saying that the now accepted interpretation of the Shamrock's significance is of comparatively modern origin.

The tall Shrubby Althæa (*Hibiscus Syriacus*) is usually called the Rose of Sharon in this country, and in view of the specific botanical name of the plant that seems an appropriate term. But in England to-day the Rose of Sharon is *Hypericum calycinum*—a dwarf under-shrub, with yellow flowers, belonging to the same family as the St. John's wort.

The true Daisy—the Daisy of Chaucer, of Burns and of all English poets—is, of course, not the White Weed to which we give the name, but *Bellis perennis*, the low-growing little double flower which we know only in the garden. The White Weed is commonly called in England the Ox-eye Daisy, a term which we apply sometimes to the Cone Flower (*Rudbeckia*). But the White Weed and not the true Daisy is the *Marguerite* of the French. All these Daisies belong to the vast composite

family, but the White Weed is not closely related to Bellis, being *Leucanthemum vulgare*, or *Chrysanthemum Leucanthemum*, the genus that includes all our cultivated Chrysanthemums.

When we use Bitter Sweet we write it as two words, and apply it to *Celastrus scandens*, which we also call Wax-work. When an Englishman uses it he writes it as one word—Bittersweet—and means a species of Nightshade (*Solanum Dulcamara*). This is a trailing perennial, with small, red berries, which is not native to America, although naturalized now in some places. Another species of the same genus (*S. Sodomum*) is supposed to be the Apple of Sodom, described by Tacitus and Josephus.

London Pride is a Saxifrage (*Saxifraga umbrosa*), of southern Europe, which is very commonly cultivated in England, but rarely in this country.

The common Primrose of England is *Primula vulgaris*, and bears pale-yellow flowers. *Primula officinalis*, of a brighter yellow, is the Cowslip—a name we often give, unfortunately, to that very different plant, the Marsh Marigold. The Oxlip is still a third species, pale yellow and taller, *P. elatior*. The Pimpernel, known to all readers of Tennyson, belongs to the great Primrose family, but to another genus. It is *Anagallis arvensis*, also called Poor Man's Weather-glass—a little, low herb, with tiny white, red or blue flowers that close at the approach of rain. It is grown in gardens in this country, and in some regions has run wild in waste, sandy spots. When Longfellow wrote "Blue are her eyes as the Fairy-flax," he doubtless meant *Linum perenne*; but the name is more commonly given in England to the common Flax (*L. usitatissimum*).

Ophelia's Rue, which might be called "herb-grace o' Sundays," was, of course, not the Meadow Rue which is the only American plant we call by the name, but *Ruta graveolens*, which we sometimes see cultivated in gardens—an evergreen, somewhat shrubby plant. The Fennel which she mentions should not be conceived as the Fennel-flower, also called Love-in-a-Mist (*Nigella Damascena*), but as the herb of the vegetable garden (*Foeniculum vulgare*), which was regarded as a plant of ill-omen in former days. An old proverb says "Sowing Fennel is sowing sorrow." Rosemary we also sometimes find in our gardens—*Rosmarinus officinalis*, an evergreen shrub. The Basil of the poets is an East Indian plant, *Ocimum Basilicum*; but the wild Basil of northern countries is *Calamintha Clinopodium*, a plant of the Mint family.

Amaranth is a word often used by the poets to denote some unfading flower. One species of Amaranth is called, to-day, Love-lies-bleeding, and another Prince's Feather; but it is doubtful whether in poetical speech any particular flower has always been intended. It would be difficult to decide just what Milton had in mind when he wrote:

"Amaranth, a flower which once
In Paradise, fast by the tree of life
Began to bloom."

The Gardenia, so often mentioned in English novels, is the flower we more often call the Cape Jessamine, although Gardenia, which is both the botanical and the proper vernacular name, is gradually coming into use with us. The plant is not a Jessamine, and it is not a native of the Cape. It belongs to the *Rubiaceæ*, and was introduced from China.

The Cuckoo-flower is the same as the Lady's Smock, a Cruciferous plant—*Cardamine pratensis*. The name Cuckoo-flower is also sometimes applied in England to one of the Pinks—*Lychnis Flos-cuculi*. Good King Henry is the Mercury Goosefoot (*Chenopodium Bonus-Henricus*), a common pot-herb in the northern parts of England. And the Love Apple of England, like the equally high-sounding *Paradisappfel* of Germany, is nothing but the Tomato.

Notes Upon Some North American Trees.—IV.

RHUS INTEGRIFOLIA, Brewer and Watson.—This species must find a place among the arborescent species of this continent. In southern California, where it abounds near the coast, covering the hills over great areas with an impenetrable mass of dense foliage, it rarely rises to a height of more than a few feet; on the Santa Barbara Islands it is sometimes a stout tree with a short, much-branched stem; and south of our boundary in Lower California it becomes a tree with a trunk sometimes nearly three feet in diameter.

No. 74. PISTACIA MEXICANA, HBK.—This plant, so far as is known, has been seen within the limits of the United States only near the mouth of the Pecos River, where Dr.

Bigelow, the botanist of one of the Pacific Railroad-route expeditions, found a single plant forty years ago, which, in his notes, he described as "a small tree." It is widely distributed in northern Mexico, and very abundant on the mountains near Monterey. It is not a tree there, however, and it may be safely dropped from the North American Silva.

82. CLADRASTIS TINCTORIA, Raf.—The proper naming of this plant involves a question of nomenclature, which just now much interests botanists, who are pretty equally divided in their opinion with regard to it. The tree was discovered by the elder Michaux, whose son bestowed upon it the name of *Virgilia lutea*. Much later, Rafinesque, discovering that the plant was not a Virgilia, created the new genus Cladrastis for it, and ignoring Michaux's specific name called the tree *Cladrastis tinctoria*. One school of botanists affirms that a specific name being once given to a plant referred to its proper genus it cannot be changed unless an older name under the same genus is found. This school would, in changing a plant from one genus into another, retain for it the specific name under which it was first published, but in the case of a plant changed by some earlier author who had not retained the first specific name (either intentionally or accidentally), as in the case of our Virgilia, they would not correct his mistake. The other school takes the ground that the specific designation is the most important part of the name, and that it being once given to a plant it should be retained for it; and that if an author in changing a plant from one genus into another has neglected this rule, his mistake should be corrected under all circumstances, except, of course, where the specific name is already occupied by another plant in the same genus. M. A. De Candolle, the author of the "Rules of Botanical Nomenclature," whose particular studies and peculiarly critical mind give the highest value to his judgment in all such questions, supports, in a letter addressed last year to the *Journal of Botany* (xxvi., 287), the views of those authors who would retain the first specific name for a plant, even when another had come into long-established use. Mr. Bentham, the most experienced and judicious systematic botanist, held the other view; and so did Professor Gray, although he did not always strictly follow his rule in his works of descriptive botany. A rule which is not absolute, and which can be changed to meet special cases or to suit the personal inclinations of different authors, is likely to be often disregarded, and so to increase rather than diminish confusion of names. Changes in the names of plants are greatly to be regretted; and the creation of synonyms is an abomination, which nothing but the hope of reaching stability in nomenclature by this means can justify. For the changing of long-used specific names must cause confusion and inconvenience; but the tendency of the times points to the strict adherence to fixed rules in natural-history nomenclature, and the sooner changes are made, which sooner or later are destined to occur, the more easily will the new names be adopted and the smaller will be the inevitable confusion which such changes occasion. A rule which provides for the adoption of the earliest specific name and allows of no exception, if strictly carried out, must eventually bring stability. I shall follow, therefore, in the Silva the custom partially adopted in the "Prodromus" of De Candolle, in Koch's "Dendrologie," and more recently in the writings of several American botanists, notably in the "Preliminary Catalogue of Anthophyta and Pteridophyta reported as growing spontaneously within one hundred miles of New York City," and restore, as far as possible, the specific names first applied to our trees. *Cladrastis tinctoria*, Rafinesque, will, therefore, become *C. lutea*, Koch, who first (*Dendrologie*, i., 6) united the specific name of Michaux with Cladrastis.

85. GYMNOCLADUS CANADENSIS, Lamarck.—This tree was named by Linnaeus *Guilandina dioica*, and I follow Koch in calling it *Gymnocladus dioica*.

87. GLEDITSCHIA MONOSPERMA, Walter.—Carl Koch (Dendrologie, i., 9) called attention to the fact that the oldest name for this plant is *G. inermis*, of Miller (1768), and that Walter's *G. monosperma* (1788) is later also than Marshall's *G. aquatica* (1785) and than Lamarck's *G. Carolinensis* (1786). The change from *G. monosperma* to *G. inermis* is certainly to be regretted, for the Water Locust is horribly armed, while the name *inermis* was used by Pursh (in 1814) to designate a thornless variety of *G. triacanthos*. If, however, the rule of priority is to be followed, the change seems necessary, as it is certainly contrary both to the spirit and to the laws of nomenclature to change a name simply because it happens to be inappropriate. C. S. Sargent.

New or Little Known Plants.

Rosa Engelmanni.*

MR. FAXON has here given a very good representation of a Rose that is widely distributed through our western region, but which has not hitherto been recognized as distinct. It has now been in cultivation at the Arnold Arboretum for several years, having been raised from seed collected by Dr. Engelmann near Empire City, Colorado, in 1881. It is the only species in temperate America that is characterized by an oblong fruit, and it is in this respect the representative of the Old World species, *R. acicularis* and *R. alpina*, to which it is otherwise also nearly allied. It is, indeed, in part the *R. acicularis*, var. *Bourgeauiana* of M. Crepin, the distinguished rhodologist of Brussels. But the only specimen of this species in the Gray Herbarium that was collected by Bourgeau (at "Fort bas Garry" in 1857) is ticketed by M. Crepin as *R. blanda*, var. *setigera*, while most of his variety *Bourgeauiana* (including Bourgeau's own specimen, ticketed "Mt. Roches à la base, 8 Aout, 1858"), belongs to the somewhat similar, but still quite distinct species, *R. Sayi*. In my revision of our species, published in 1885, the fruiting specimens that I had seen were referred to as belonging to a possible new species of the *R. Fendleri* group, though most of the flowering specimens were disposed of under *R. Sayi*.

R. Engelmanni is distinguished from *R. acicularis* most prominently by the frequent occurrence of a pair of slender spines below the stipules, by the resinous puberulence often found upon the leaves, with the accompanying glandular serrulation of the teeth, by the naked peduncles, and in growing specimens (so far as *R. acicularis* is represented in our gardens) by a difference in appearance of the foliage and in habit, which it is not easy to describe. The stems in both species are usually covered with slender prickles, and the rather large flowers are almost always solitary.

R. acicularis is rather more northern in its range, extending through northern Russia and Siberia to Japan and across Behring Sea into northern Alaska. *R. Engelmanni* appears to be frequent on the shores of Lake Superior and at some points on Lake Huron, and thence ranges westward by the Lake of the Woods, Pembina, and the upper Missouri to the Rocky Mountains. Here it is found from central Colorado to north of the boundary in British America, and westward to Idaho, and the upper Columbia in Washington Territory, where I collected it in 1880 near Fort Colville. It is a showy species in cultivation, both from its large flowers and its conspicuous bright red fruit.

Foreign Correspondence.

London Letter.

IT is nearly midsummer, and the Rose still monopolizes the talk and the work of the floral world; it is teeming in every garden, in every drawing-room, in every flower-shop, and even the street-hawkers' barrows are laden with Roses in

early morning. The Rose exhibitor never was so busy, for he well knows that, if this hot and dry weather continues, the Rose season, like that of the Strawberries and Peas, will be very brief. One week we have a Rose Conference, and the next the Royal Botanic Society initiates a "Floral Parade and Feast of Roses," with an accompaniment of harmless absurdities. At the Alexandra Palace the populace is treated to "a celebration of the beautiful festival, 'The Crowning of the Rose Queen,' with full procession, choir, band and organ," while the great show of the National Rose Society, at the Crystal Palace, is patronized by the Persian monarch and the Prince and Princess of Wales. As to the Rose Conference, held by the Royal Horticultural Society, I hardly know whether to call it a success or a failure. It was a failure as regards the patronage it received, for it leaves the Society none the richer. It was a success both as regards the exhibition and the high character of the discussions. The majority of the visitors were those who took a real interest in Roses, and all seemed delighted at the abundant gathering of all sorts and conditions of Roses that could not possibly be seen at an ordinary Rose show or in the most richly-stocked Rose-garden. Besides an ample display of the modern Hybrid Perpetual race, the Teas and Noisettes, there were to be seen hundreds of old-fashioned Roses, which for real beauty, fragrance and interest do not yield much to their fashionable successors. Under the same tent were displayed the Roses loved by the gardeners of the last century, such as the Provence, the Monthly and the Damask, with the latest productions of modern growers, and though the difference between the old and the new is striking, the true rosarian loves them all.

It was an excellent opportunity for such noted growers as the Pauls, of Waltham Cross and Cheshunt, to exhibit the hundreds of the old flowers that blossom in comparative obscurity in their historic rosaries; and Mr. William Paul not only showed a marvelous array of old sorts, but a first-rate collection of new Roses that he has raised or put in commerce so that he might fairly lay claim to having shown the Rose as it was a century ago and as it is to-day. What delighted and interested visitors most were the collections of old garden Roses, especially the rambling sorts still found in some of the oldest English gardens, where change of fashion is unheeded. Of late years there has been a demand for these old climbing Roses, but the supply in many cases cannot be met. The fact is, the modern race had almost entirely supplanted the old sorts, and it did not pay nurserymen to keep them in stock. The date of the conference was a week too late for the full flower-tide of the climbing varieties, but, as it was, there were to be seen huge clusters of such favorites as the Ayrshire, the semi-double white Dundee Rambler, the pink Virginian Rambler, the old white Bennett's Seedling, called also Thoresbyana, which is one of the best of pillar plants. Then came the Evergreen Roses (*R. sempervirens*), such as the beautiful Felicité Perpetue, Flora, Myrianthiflora and others, all of which are matchless for festoons and pillars. The other climbers and ramblers were of the Polyantha, Multiflora and Hybrid races, and among them was the exquisite little Laure Davoust, a Multiflora with clusters of small pink rosettes; the Garland Rose, with its fawn-colored buds; Madame d'Arblay, a hybrid Musk Rose, with pink flowers; the nankeen yellow, Claire Jacquier and numerous other double ones. The typical *Rosa polyantha*, with clusters of small white single blooms, is very lovely if you catch it at its best, but it does not last so long as the double ones. As to the other old-fashioned Roses, the French, Gallica, Boursault, Provence and Damask, I imagine that almost every variety was to be found in the Waltham and Cheshunt collections, and amongst them were such much-prized climbers as Blairii No. 2, one of the best of all pillar Roses, Madame Plantier, Paul Perras, a pink climber, and the old Charles Lawson, still among the best kinds for growing in or near a shrubbery, where it will hold its own and ramble over the shrubs in a beautiful way. The variegated or striped sorts, such as the York and Lancaster, Rosa Mundi, Perle de Panachées, represent a distinct and beautiful class, to which has been lately added the Pride of Pergate, which is a striped petaled sport from Countess of Oxford.

The more modern garden Roses include, of course, the charming American W. A. Richardson, which grows more and more popular; Perle d'Or, a neat little variety of the Polyantha race with flowers paler, but of a similar tint to W. A. Richardson. It is, I am told, greatly in demand for coat bouquets. Quite a new addition is a sort called L'Ideal, also a climber, with smallish flowers of a sort of salmon-buff tint. It is quite different from any other in color, and is sure to become popular. Of the Pacquerette Roses, which is the

* *R. ENGELMANNI*, Watson.—Stems three to four feet high or less, usually more or less densely covered with scattered prickles, the infrastipular spines, when present, straight and slender, often wanting; leaflets five to seven, often somewhat resinous, puberulent beneath, and the teeth glandular-serrulate; stipules narrow; rachis unarmed; flowers usually solitary, the peduncle and receptacle naked; sepals entire, naked or somewhat hispid; fruit oblong-obovate, six to twelve lines long.

general name for the double Polyantha sorts, the best were Annie Marie de Montravel, producing an abundance of white rosettes; Cecile Brunner, a bright pink, and much better than Mignonette Gloire des Polyantha. Golden Fairy and Little Dot would be my choice among the rest. I must not omit the much cherished Moss Roses, which in every garden are indispensable. Here one could see all the sorts of the *R. centifolia muscosa* arrayed before him. Among the whites the best

huge flowers of lovely color, and of fine form and substance. Its defects are the flatness of the blooms when fully open, and the absence of strong perfume. But it is a noble Rose, and a triumph for the English raiser. It is *par excellence* an exhibition Rose, and no collection is complete without it. Other Roses of Mr. Bennett's raising were also uncommonly fine, especially such first-rate sorts as Grace Darling, Princess Beatrice, Lady Mary Fitzwilliam, all of which are to be found

Fig. 121.—*Rosa Engelmanni*.—See page 376.

were Blanche Moreau, Perpetual White, Mousseline, Reine Blanche and White Bath, and of the colored varieties there were few that were so worthy of admiration as the old Common Moss which everybody knows.

Among the hundreds of varieties of Hybrid Perpetuals, Teas and Noisettes familiar to your readers, there was no Rose throughout the show so much in evidence as Bennett's new Her Majesty, which, I hear, bears such a high character in America. Here it was on every stand in superb condition,

in every Rose collection now. Mr. William Paul celebrated the occasion by a special exhibit of his new Roses. These included Duchess of Albany, a dark sport from La France, which is sure to make a way for itself; Marchioness of Lorne, an extremely fine Rose; Queen of Queens, shown splendidly in several collections; Pink Rover, which, as I have before remarked, is a really valuable addition to large-flowered climbing Roses; Sappho, a Tea-scented variety of a distinct rosy-fawn color, excellent in form and size. In Messrs.

Keyne's collection were specimens of the new Climbing Niphetos, which seems to differ from the well-known favorite only in its climbing habit of growth, and which will prove a valuable quality, especially in house culture. The novelties at this exhibition, it will be seen, were comparatively few, and it was remarkable, not so much for new things as for old. The conference was held on two days, but, as none of the papers will appear in print before the journal of the society is issued, we shall have to wait an indefinite time for them. What to me seemed the most important outcome of the conference was the introduction to the notice of rosarians of a grand new rose, *Rosa gigantea*, a native of India. Dried specimens were exhibited, which showed what a large size the flower attains. It measures five inches across, and is pure white. It is satisfactory to know that seedlings have already been raised at Kew, but so far no one seems to know whether it will be hardy enough for open-air culture. Even if not, it will make a beautiful green-house plant.

London.

Entomological.

The White Pine Weevil.

(*Pissodes Strobi*, Peck.)

THIS insect causes considerable damage in gardens and on grounds where evergreens are grown for ornamental purposes; not only White Pines are attacked, but other species of Pine and Spruce suffer equally. A letter recently received from Warren County, New Jersey, describes the injury so well that I reproduce parts of it. "Many of my evergreens—Spruces especially—are much infested by a borer which seems to deposit its eggs at the base of the new shoots and leaders, and spreads downward, killing all of the tree that is above it. . . . In this section every White Pine has lost its leader. I don't think I have seen a single exception. Is this done by the same insect that attacks the Spruces, or is it a different one? It is most provoking to see one's best and most promising trees cut down in this way."

The letter was accompanied by specimens of infested Spruce twigs, which showed the characteristic work of the White Pine weevil, *Pissodes strobi*. The insect is a well-known one, and its history was first made out many years ago by Dr. Harris, who thought it required more than a year to come to maturity. Dr. Fitch afterward gave a very full account of the species, giving it a period of one year to undergo its transformations. Other writers have mentioned the insect at intervals, until most recently Dr. Packard has written on the subject and has recorded the species from April to September, his dates leaving little margin for intervals. Dr. Packard gives one brood for the species, the generalized account being that the imago appears in spring or early summer and oviposits soon after. From my collecting and observations, I believe there are in the latitude of New York two broods annually. The first of these issues as imago early in spring, say the latter part of April, or early in May, ovipositing in May, the larvæ of the second brood coming to maturity the latter part of July, the imago issuing during early August and ovipositing during that month.

The larva is a white grub, about one-third of an inch long,

with a horny, yellow head, slightly curled as it lies in its cell. When full grown it forms an oval cell either just under the bark or in the pith, and changes to a white pupa, and very soon afterward to an imago. The imago is an oblong-oval and rather narrow weevil, about a quarter of an inch long, of a dull, dark chestnut color, with two dots on the thorax, the scutellum and a short irregular band back of the middle of the wing-covers white, the wing covers also variegated with a few patches of tawny yellow. The eggs have not as yet been described. They are deposited in the leaders and other small twigs and branches—sometimes also on the trunks of old trees—at very short intervals. The larvæ eat very little more than twice their own length into the wood or under the bark, and a single, comparatively small shoot will harbor thirty to forty of them. Of course the smaller twigs thus interrupted in growth, and damaged, die, and the shape of young trees is spoiled, unless the owner believes—as some do—in small, bushy trees, in which case they are no serious drawback, since they seem never to kill larger branches or trees.

No satisfactory remedies for borers have yet been discovered. Their mode of life is such that they are at no time in position to be attacked by insecticides. This weevil has its parasites that keep it in check somewhat, and some of our smaller birds seek out the larvæ and pupæ under the bark, and feed upon them. The only way of checking their ravages when they appear in parks is to trim out and burn all the infested branches and twigs very early in spring, and again about the middle of July. In this way the larvæ will be prevented from coming to maturity, and there will be no imagos. So long as there are other unpruned trees about, this remedy is palliative merely; but still, so many will be destroyed that a much larger proportion of leaders will escape, and the injury will be considerably reduced.

Rutgers College, July 25th, 1889.

Cultural Department.

Shrubs with Conspicuous Fruit in July.

IN the early part of July there is usually no lack of shrubs in flower, many of which begin to bloom in the latter part of June. In the first week or two of July some of the Spiræas continue to give a more or less abundant show of flowers. *Spiræa sorbifolia* and the Steeplebush (*Spiræa tomentosa*) come into their best condition then, and they are accompanied by the fragrant Swamp Rose (*Rosa Carolina*) and by the odorless but very showy Prairie Rose (*Rosa setigera*).

The Common Elder (*Sambucus Canadensis*) is the most conspicuous native white-flowered shrub, and it is followed by the rarely seen *Stuartia pentagyna*, by the St. John's Worts (*Hypericums*), and by the Pepper bush (*Clethra alnifolia*), which joins the procession just in time to be counted a July bloomer, but will continue to open its fragrant blossoms throughout August. These are among the most conspicuous of the shrubs which flower about Boston in July, but as flowers become scarce, ripening fruits, or those that assume rich colors, come daily more and more into notice. The list of shrubs with showy or highly colored fruit in this month is short. There are many fruits which ripen, but most of them are insignificant in quantity, or inconspicuous, or, in some cases, so concealed by dense foliage that they are rarely observed.

The Early Elder (*Sambucus racemosa*) is one of the earliest to fruit of the tall, growing shrubs. Two groups of these plants growing side by side in the Arboretum present distinct variations in time of ripening and in color of fruit. The plants of one lot, originally collected in the western part of this state, had begun to ripen fruit by June 12th, and at the end of two weeks the berries had all been eaten by birds. This fruit was of the ordinary type, bright red, in somewhat loose cymes. The other group of plants, obtained from a New York nursery, did not ripen its berries until several days after the birds had eaten the last one of the first lot. These berries were very handsome, bright coral red, in close compact bunches, and they remained on the bush until about the middle of July, when the robins ate them.

Although these berries attracted the attention of all who saw them, there is probably no fruit so much remarked upon, at this season, as that of a form or species of bush Honeysuckle at present known as *Lonicera Ruprechtiana*. In many respects this species greatly resembles the common Tartarian Honeysuckle, but the flowers differ in size and shape, while the fruit of some individuals at least is incomparably superior. This fruit begins to ripen about the end of June, and up to the end of July the plants are beautiful objects. The shining dark-red berries, hanging in pairs on each stalk, almost literally cover the branches, which droop nearly to the ground under the weight.

Another Asiatic species, *Lonicera Morrowii*, also bears an abundance of handsome fruit on a background of lighter colored leaves than the last. The fruit of this species is said to be poisonous, but toward the end of July, when it has become very ripe, robins and catbirds eat it as freely as they do the fruit of *L. Ruprechtiana*. Some forms of the common Tartarian Honeysuckle also have claims to attention for their beautiful fruit, which is found to vary from dark red to orange on different plants when grown from the same lot of seed. When a plant of any of these Honeysuckles bears exceptionally beautiful fruit, it should be propagated by cuttings or layers, or in some other way than by seeds, if its special characteristics are to be preserved. Some varieties of the well-known *Lonicera Xylosteum* are exceedingly handsome, with shining, dark cherry-red fruit, which remains on the bushes throughout the month and often through August. Occasionally plants are found which are unusually prolific,

The Falls of the Chittenango.—See page 373.

and their berries are often half an inch or more in diameter. This species does not grow as large or tall as the Tartarian Honeysuckles, and the flowers are not as attractive, but it is a neat compact shrub.

Some of the fruit-eating birds are very partial to the white or bluish-white fruit of *Cornus alba*, a shrub usually sold by nurserymen under the names of *Cornus sanguinea* or *Cornus Sibirica*, with additional names for varieties. The red or scarlet bark of this species is its chief attraction, but the fruit is pretty and reaches its ripest state about the middle of July or even earlier. About ten days later it is followed by *Cornus alternifolia*, the berries of which begin to ripen and become blue-black. *Elæagnus longipes* (figured in GARDEN AND FOREST, vol. i., p. 499) does not appear to be one of those plants which

produce a full crop of fruit only every second year, but annually bears an abundance of its rich, red, plum-like fruit, which, on long peduncles, hangs thickly along the under side of the branches for several weeks. When fully ripe this fruit is much liked by many persons, and it might be improved in flavor and size by cultivation and selection. Birds have found out that it is palatable, and this season, for the first time at the Arboretum, it was all carried away by them.

It is a pity that such a charming native shrub as the Cranberry Tree (*Viburnum Opulus*) is not more frequently seen in gardens. The showy flowers of the sterile form, known as the Snow-ball, and so commonly cultivated, are not as graceful or pretty as those of the wild plant. The sterile plants are very apt to look diseased and to be infested with Aphides, and, of course, they bear no fruit. The Cranberry Tree does not ripen its broad flat panicles of fruit until much later in the season, but in the latter part of July the berries, which are then quite large, assume a striking greenish-yellow tinged with bright red on the side toward the sun. The fruit of the Wayfaring Tree (*Viburnum Lantana*) is still green, but it, too, is bright red on the exposed side.

The Staghorn Sumach, with its large cone-shaped heads of scarlet fruit, which it retains during the rest of the summer and autumn, makes a most pleasing effect when grown in groups, and is always certain to attract attention in its native haunts.

The well-known Smoke Tree (*Rhus Cotinus*) hardly needs a notice. Its "smoke" is in its best condition during June and July, and in the latter month the few very small fruits it bears usually disappear, leaving only the pedicels with their feathery hairs and branchlets, which give the loose panicles the appearance from which the plant takes its popular name.

The different species of Amelanchier, Service-berries or June-berries, ripen their dark-blue, purple, or black fruits in the latter part of June and during July, but, as soon as ripe, they are eaten by birds. The native American species generally seems to ripen earlier than those from Europe and Asia. Two species of low-growing Cotoneaster in the Arboretum have ripe fruit in the last two weeks of the month, and it remains on the plants for a long time. The color of one is purple, and the other bright scarlet.

Daphne Mezereum, though a small shrub, and generally not very attractive, has two periods in the year when it does not fail to attract attention: (1), when its purple blossoms appear, before the leaves, in early spring; and (2), when the bright-red berries are seen among the foliage at the end of June. There is no plant more deserving of a place in small gardens or in larger shrubberies than *Rosa rugosa*. It continues to bear some of its large, single, purple or white flowers until frosts check all growth, and its fruit, which begins to ripen in the latter part of July, is at first bright scarlet, and later changes to a dark red. It is often an inch and a half in diameter, and remains on the plants until winter.

Arnold Arboretum.

J. G. Jack.

Transplanting Conifers in August.

IN the year 1870 I proposed to overflow a tract of land for the purpose of ice-cutting. In order to do this it became necessary to remove about 40,000 trees of my nursery-stock, consisting of Spruce, Pine, Hemlock, Arbor Vitæ, etc., of various sizes, ranging from two to seven feet in height. The

transplanting was done during an unusually dry August, and the distance of removal was about half a mile. The fall months continued to be so exceptionally dry that many trees in the forests perished in consequence, yet the new plantation proved to be remarkably successful. This was due to the fine, yet compact, condition of the soil enabling the young roots to form rapidly, and the trees were well established before winter set in. Perhaps this was the first extensive experiment in the August planting of conifers in this country. But it was so conspicuously successful that confidence in the practice was soon established. The common name, Evergreen, indicates the persistence of the foliage, and these trees must be in full leaf at whatever season they are planted. The essential point to secure is quick root-action, to sustain the tree as speedily as possible. It is well known that the roots of evergreens are in active growth long after the upper growth is formed and while it is hardening. Hence it seems reasonable to conclude that when the soil is warm in the last half of August and early September and the air is growing cooler the equilibrium of a transplanted tree will speedily be restored. In the month of May, when by far the largest number of trees are planted, active growth soon follows, evaporation is excessive during the hot June days, and it is the common experience that the strain, upon trees of any size, is severe.

Let me cite two cases during the past year by way of comparison. On the 25th of August, 1888, I transplanted from the nursery into groups on an avenue eleven White Spruce trees, averaging five and a half feet high. They had ordinary care and have made healthy growth, none of the terminal shoots being less than twelve inches in length. Indeed, they compare favorably with their companions, which remain in the nursery. On the 14th of May last Mr. Bowditch, the well-known landscape-gardener, ordered 200 Spruce trees of the same size, and, as is his custom, sent his men to dig and replant; but, finding that he had dug forty trees more than were wanted, he requested permission to replant these in my grounds. Now, since his men are as careful planters as mine, a good opportunity offers to compare the results of planting in August or in May. Mr. Bowditch's trees lived, of course, but they look as May-planted trees usually do—that is, as if they had passed through a fit of sickness from which they were slowly recovering. In no case is the annual growth more than seven inches, and the average is less than six inches. In my judgment the different times of planting will account for all the difference in growth, and this is so obvious that I am sure Mr. Bowditch will excuse me for citing the case.

Newton Highlands, Mass.

Wm. C. Strong.

Two Lessons in Strawberry Culture.

DURING a recent visit to the extensive small fruit and vegetable gardens of Mr. J. M. Smith, of Green Bay, Wisconsin, my attention was called to two striking facts in Strawberry culture. Mr. Smith is a large grower of Strawberries, and still adheres to the old Wilson as the most profitable variety, all things considered. Although this time-honored sort has generally failed of late years to maintain its former excellence, on his grounds it continues to yield immense crops, and has not as yet been surpassed in productiveness by any of the more recent introductions.

Mr. Smith ascribes his success with the Wilson chiefly to his method of propagating the plants. About ten years ago he noticed the fact that a bed set with plants that had grown from a setting made the preceding spring, and which had, consequently, never yielded a crop of fruit, made a better growth and bore more Strawberries than another bed of plants formed on a setting that had already yielded a crop. This raised the question in his mind whether the vital force required to mature a large crop of Strawberries in a productive variety like the Wilson may not so far impair the vigor of the plants that their progeny will become weakened. Since that time Mr. Smith has been careful, in setting new beds, to use only plants propagated from those that have never borne a crop, and as the result his Wilsons have fully maintained their original vigor and productiveness. In favorable seasons they still yield as high as 400 bushels per acre. The rust, which has been the ruin of this variety in most localities, does not appear in his newly-planted beds. After a bed has yielded a large crop of fruit, however, the plants are severely attacked by the rust; but as Mr. Smith does not usually take more than one crop from a setting, the rust has no opportunity to work harm.

Now for the two lessons. Mr. Smith generally, after plowing up a bed of Strawberries, devotes the ground to other crops for a year or more before re-setting it again with Strawberries. In the spring of 1888, however, he found it conve-

nient to vary the rule, and to re-plant a portion of some beds that had produced Strawberries the preceding year. Although this ground had been kept in a high state of fertility, the result was most marked. The stand of plants on the ground that had produced a crop the year before was noticeably thinner and less vigorous, and the yield was smaller by half.

In one part of this ground, that was occupied the second time in succession, another experiment was tried. Mr. Smith departed from his custom here in another particular, and used young plants that had been propagated from a bed which had already borne a crop. He expected little from this portion of his field, but he received literally nothing, for the plants, which suffered a double abuse—first, in having been raised from weakened stock, and again, in having been planted in old Strawberry-ground, unrefreshed by rest and rotation—were so far enfeebled that they were abandoned as worthless and plowed under.

Mr. Smith's experience has proved it unwise to grow Strawberries after Strawberries on his ground, even with high manuring. There is nothing particularly novel in this, however; but very full of suggestion is the fact that a variety like the Wilson, which has been considered "run out" in many places, has not only maintained its vigor when propagated from vigorous young stock, but has also escaped damage from rust. Here is another field for experiment, not only with Strawberries, but with other fruits, upon which our experiment-stations should be prompt to enter.

Madison, Wis.

E. S. Goff.

[Professor Goff sent with this article a photograph of the field described, and it enforces in a striking way the lessons of the text.—Ed.]

Orchid Notes.

Odontoglossum Harryanum.—Although only in cultivation for the short space of three years this species has acquired great popularity, and is universally acknowledged to be one of the best *Odontoglossums* yet introduced, presenting, as it does, a type of beauty different from that of any other species of the genus. It is not generally known that *O. Harryanum* is a native of Colombia, where it was discovered by a traveler named Rodriguez Pantoja, who, in 1886, sent plants of it to Messrs. Horsman & Company, of Colchester, England, from whom the stock, at that time, was obtained by Messrs. Veitch, to the head of whose establishment it was dedicated by the late Professor Reichenbach. Since then quantities have been imported by Messrs. Sander & Company, so that there is not much doubt of it being soon found in most collections.

The much compressed oval-oblong pseudo-bulbs, which become more or less wrinkled and furrowed when old, have on their summits two strap-shaped, pale-green leaves, from nine to twelve inches long. Cultivated plants generally produce racemes about a foot or eighteen inches long, bearing from four to twelve flowers, each over three inches in diameter; but in imported plants, racemes over a yard long, and having from twelve to twenty flowers, have been seen. Perhaps they will produce as many some day under cultivation! The elliptic oblong sepals are slightly recurved at the tips, more or less undulate on the margins, and of a deep chestnut-brown with yellowish, transverse, hieroglyphic markings, chiefly on the basal portion, while all round the margins is a conspicuous, narrow, yellow border. The petals have usually the appearance of being only partly expanded, a fact which many consider to be the only defect in the flower; occasionally, however, flowers may be seen which have the petals well spread out. They are oblong-acute in shape, reflexed at the tips, and much narrower than the sepals; the basal portion is pure white, blotched and spotted with mauve-purple; the upper portion is deep chestnut-brown, passing into a golden-yellow blotch at the tip, from which it extends into a narrow border on each side to the base. The subcordate-pandurate, acuminate lip is remarkable for the great beauty of its colors which present a striking contrast to each other. The basal portion is bright yellow, with a few brown spots, and from seven to nine serrulated crests, on each side of which are oblique stripes of rich violet-purple on a white ground; the anterior portion of the lip is infolded or convolute at the apex, and pure white in color, which, however, changes to bright yellow in old flowers, and in dried ones also.

O. Harryanum seems to be a continuous bloomer, as plants were in flower here last Christmas, and since then there has always been some in flower. July, however, seems to be the proper flowering season, there being several plants with fully expanded blooms, and many others in bud. During the summer months a cool and somewhat moist atmosphere

—such as *Miltonia vexillaria* likes—suits this species well, and a moderate supply of water, which, however, must be reduced in quantity while the plants are in flower, and for sometime afterwards, also. When the new growths appear, the plants, if necessary, should be repotted or top-dressed, and the compost should consist of rough fibrous peat, with a little sphagnum and charcoal mixed.

St. Albans, England.

John Weathers.

Erises Lobbi.—This is a handsome and useful Orchid, flowering profusely at a season when flowers in variety are scarce. It may be grown with little trouble in a warm, moist house, suspended in a basket filled with moss and charcoal. The lorate, leathery, deep-green leaves are about a foot long, and from the axils of these are produced densely-flowered racemes, from one to two feet long, and often branched. The flowers are white and rose, prettily dotted with amethyst. When placed in a cool, dry atmosphere, these flowers will last in perfection quite a long time. There are several varieties in cultivation, though none are particularly distinct. The type was introduced from Moulmein in 1868.

Another Orchid profusely in bloom just now is *Rhyncostylis retusa*, popularly known as *Saccolabium guttatum*. This is an old plant introduced from Java nearly seventy years ago. The short, stout stems are clothed with distichous, leathery, deeply-channeled leaves, about a foot long, and dark green. The cylindrical racemes are drooping, closely set with small white flowers, spotted and blotched with rosy-purple. There are a great many varieties of this fine Orchid. One of the rarest and best is *Holfordianum*, now in flower with us, a much stronger plant than the type, with longer and broader leaves, larger inflorescence, and a lip of rich crimson. *Giganteum* is not much inferior to this. These plants thrive in the warmest house, with abundance of water, if placed in pots, baskets or cylinders in a compost of peat, moss and chopped leaves. Without abundant sunlight good spikes need not be expected, but care should be taken that the leaves do not get burned.

Oncidium luridum.—This is not a very showy Orchid, but, if it lacks in quality, it certainly does not in quantity, for its flowers are produced by the hundred even on quite small plants. They last a long time in perfection, and are welcome at this season. It is an old plant, having been introduced in the early part of this century from Mexico, but some choice varieties have since been found in the West Indies. It is a bulbless Orchid, with large, very thick, carinate leaves, more than a foot long, dull green or nearly reddish-brown, and much spotted. The panicle is produced from the base of these matured leaves, and is from six to nine feet long. The flowers, nearly an inch across, are olive-green, blotched and spotted with brown. In the variety *Dodgsonii* the ground color is yellow; in *Morrenii* it is rose, spotted with crimson and tipped with yellow; *Roseum* is mottled with white and bordered with yellow. This Orchid is very easily grown in small pots and little soil, which should be rich and open. After growth is finished the plants should be put in a dry, airy house, with a good exposure to sunlight, and should be kept pretty dry through the winter, but while growing they require the maximum of heat and moisture.

Dendrobium crystallinum.—This is a fine summer-blooming Orchid, which we have had in flower for several weeks. It is a Burmese species, with long, slender, upright stems, from the sides of which the flowers are freely produced. These are white, tipped with magenta, the lip being orange at the base. They last a long time in bloom. This is an easy plant to grow, with the ordinary *Dendrobium* treatment.

F. Goldring.

Some Native Plants.

ONE of the Gentian family (*Frasera Carolinensis*) is now worthy of notice. A remarkably fine plant, seven feet high, was found here in full bloom early in July. The stem about two inches through is a dark-purple color, with the oblong pointed leaves growing in whorls; these are light-green, smooth and glossy. The compound panicles of flowers follow the same arrangement as the leaves; in color greenish-white marked with dark spots, and with a fringed gland on each petal. The stately bearing and subdued color of this plant render it a pleasing object among gayer flowers and darker foliage. Moisture favors its growth, though it will live in dry situations. For brilliancy of color the *Asclepias tuberosa*, already spoken of in GARDEN AND FOREST, is now the most conspicuous of our wild flowers. It is not unusual to see upon one plant a mass of bloom two yards or more in circumference. All shades of orange are represented on different plants. Several of the Milkweed family have more attractive foliage than this,

but none with us equal it in brightness and profusion of flowers. Among others, the slender *A. verticillata* is found here, and its threadlike leaves and tiny flowers are in strong contrast with its coarse relatives.

A pretty vine is *Dioscorea villosa*, on which the inconspicuous flowers are giving place to racemes of three-winged seed vessels of great beauty. Notwithstanding the angularity of these pods, the slender stems by which they hang admit of a very graceful arrangement, and their pale-green color and glossy surface add to their beauty. Of these clusters, containing from five to nine pods each, I have counted twelve on two feet of vine. The twining habit of this vine leads it into higher places than it could reach by the support of shrubs. In the instance noted it is so closely wound about a *Smilax* as to be scarcely distinguishable from it at a casual glance, the leaves of the two plants somewhat resembling each other in shape, color, and veining. The *Smilax*, with its profusion of tendrils, has climbed a rail-fence and grasped an overhanging apple bough, carrying with it the weaker neighbor. Both these vines would be valuable in the wild garden, though, perhaps, their mission is better fulfilled in this tangle by the roadside, where, shaded by a thicket of Hazels, they help to form one of Nature's charming masses of verdure.

Parnassia Caroliniana is an interesting little plant just coming into bloom upon the low wet ground. The flowers, which last well into autumn, are of a creamy-white color marked with delicate lines of green. The symmetrical arrangement of the stamens surmounted by little spheres is most noticeable, being in rows of three opposite each petal. It makes an admirable addition to the bog-garden or water-border.

Klinger Lake, Mich.

Dorcas E. Collins.

The Pyramidal Saxifrage.—During the last few years the great value of this alpine plant for culture has been fully recognized by the London market florists, who were the first to bring it out of the obscurity of botanical collections. Its scientific name is *Saxifraga Cotyledon pyramidalis*, but is well known now as the Pyramidal Saxifrage. It belongs to that large section of the genus having fleshy-incrusted leaves, arranged in symmetrical rosettes. The rosette of a full and well-grown plant of this variety measures quite nine inches across, and from its centre springs the tall flower-spike, which rises from sixteen inches to twenty-four inches high and about half as much in diameter. It is minutely branched and bears thousands of white flowers about half an inch across, and these remain in perfection for several weeks if the plant is kept out of doors or in an airy green-house. The exquisite beauty of this Saxifrage makes it a great favorite with window-plant gardeners, and I have seen plants of it in window-boxes that came into bloom a month ago still in perfection and with more flower-buds to expand. Though it is a perfectly hardy plant and grows and flowers well on an open rockery, it is only by careful pot culture it can be flowered to perfection. The plants require to be grown in good, rich, loamy soil, and every runner picked from the main rosette as soon as it appears, otherwise the plant exhausts itself in feeding the runners instead of gathering strength for the production of a fine flower spike. Unheated frame culture is the best treatment for it, and a runner, if strong, taken off and rooted this year will flower the next; but, as a rule, three-year plants flower best. If this plant is not already known with your market florists, they should get it, as it would always repay culture. It sells as well as anything we have in Covent Garden at the present time.

Kew.

Turnips.—Many persons, in their fear of an early freezing, sow seed of the Flat Dutch and Purple-Top Strap-Leaf Turnips too early. These Turnips can be grown very quickly, and are only good when so grown, like a Radish. If sown early they grow too large for table use, and are worthless for any purposes but stock feeding, and only a little short of worthless for that. Flat Turnips, grown rapidly in the cool autumn weather, to about the size of an ordinary biscuit, are good enough for any one. When grown on a large scale, I have never found it profitable to sow in drills or rows. For sowing broadcast, I plow the ground and give it a heavy coat of manure on top, then harrow so as to slightly mix the manure with the surface soil, sow the seed and roll. The most difficult thing is to sow the seed uniformly without getting it too thick. This is best accomplished by roasting a lot of old and worthless seeds of Kale, Cabbage or Turnip in an oven until certainly dead. One part of good seed is then mixed, and mixed thoroughly, with about ten parts of the dead seed. This seed is then sown as uniformly as possible all over the ground at the rate of about ten (10) pounds of the mixture to

the acre, and this scatters the good seed thickly enough. The sowing may be done at any time in August, the latter half being better than the first, and, in the latitude of Virginia, September is early enough. Still, unless plenty of manure or fertilizer is used, the crop will not be of the first quality for table use—a quick growth being essential. For late use in winter and towards spring these flat Turnips are not desirable, and if none of the Long White French Turnips were sown early in July, a crop of Robertson's Golden Ball sown the first week in August, in drills, well enriched and carefully thinned and cultivated, will make a good crop of a very superior quality for winter keeping.

Fall Peas.—It will always pay those who are fond of Green Peas to use a spot otherwise vacant for sowing a crop of Premium Gem Peas about the middle of August, with a succession some ten days later. Select, if possible, a piece of land naturally moist, and plow a deep furrow by running the plow twice in a furrow. Scatter the Peas along the bottom of this deep furrow and cover lightly. This will leave the rows in a depression, which will be gradually filled in cultivation, and the plants will be able to stand an autumn drought better than if sown nearer the surface. The chief trouble will be from mildew, and if they escape that, the crop is reasonably sure. It will be worth while to experiment with some of the copper mixtures now used for fungus on Grape-vines, for preventing the mildew on Peas.

Correspondence.

Forests and Civilization. IV.—The North Woods.

To the Editor of GARDEN AND FOREST:

Sir.—The boundaries of the original Adirondack forest-region are not very distinctly marked by Nature, and estimates of the extent of its area differ as the lines may be drawn so as to include more or less of the foot-hills, or slopes, connecting the more elevated central region with the plain below. It is, however, probably safe to say that we had here a tract of at least five millions of acres, or nearly eight thousand square miles, all of which was much better adapted to permanent forest growth than to agriculture, and upon which, therefore, forest conditions should have been permanently maintained. It would have yielded a steady revenue forever, as the trees matured and were cut off; the rivers would have been sustained by unfailing springs, and the uncontaminated air of this mountain forest-region would have made it the most valuable sanitarium in the world. It would have become a resort for health-seekers from all lands, and the addition to the wealth of the State from this latter use would have been far greater than the value of all the lumber it would have produced.

The State should never have sold the land or any part of it, but should have trained and equipped some of its young men for the care and management of this inestimable possession. This policy of State ownership and intelligent administration of this forest-region would have aided greatly the development of all the interests and resources of the State of New York, and would have made it far richer and more highly civilized than it is to-day. But we are obliged to accept the past, because it is out of our reach and beyond the possibility of change. We can deal only with existing facts and conditions. After a careful examination of nearly every part of the entire region I conclude that more than three-fourths of the original forest has been cut off, and that not more, probably, than about a million acres of virgin forest remains.

Most of this is in Hamilton County. St. Lawrence County has considerable, Herkimer has less, and Franklin County still less. Clinton County has been nearly all cut over. Essex County has but a small extent of virgin forest. Warren County has very little, and Saratoga none. Lewis and Oneida Counties have none, or next to none. Fulton County is nearly all cut out. The annual cutting increases every year, much more ground having been cut over, or more timber taken out, during the last season than in any one year before. Twenty years ago the Glens Falls lumber people thought that they had cut about as far up into the woods as they could go, and had nearly exhausted the region which was then accessible to them—that is, that they had cut nearly all the timber that could be floated down the streams to the mills. (The hard woods will not float.) But soon after that time they began "improving" the smaller streams, straightening and deepening them here and there, building dams, etc., and now they run logs down little threads of streams where a few years ago they never dreamed that they could float timber out profitably.

A tract of three hundred and eighty thousand acres in Her-

kimer, Lewis and Hamilton Counties, which formerly belonged to the Durant estate, has recently been purchased by a company of capitalists and lumbermen. Two of them are now in the St. Regis Lumber Company, and they will go on at once to begin cutting off the timber of the new purchase. Of this seventy-five thousand or a hundred thousand acres have been partly denuded of timber; the rest is all virgin forest. Most of it is Spruce, then Hemlock and White Pine. They will cut the hard-wood timber where they can get it out, and when it is wanted there will be means for getting it out everywhere. But the first thing thought of is the Spruce, of which between the Lowville region and Lake Ontario there are tens of millions of feet. The Popple is about all cleared out. This is the greatest body of Spruce now remaining in the country, and the plan is to make a Spruce trust. It is expected that the price of Spruce to be used in paper-making will go up, perhaps fifty per cent.

The Saranac water-shed was cut over long ago, and there is very little first growth now remaining. Upper, Middle and Lower Saranac, and their tributaries, drain a large region, but the cutting here has been light of late years, mostly second growth. The lumbermen have cut down to eight inches or below. It is absurd to cut so small timber, taking out young saplings which would be so much more valuable in a very few years, but in all that region there is very little thought about the future.

The Morgan Lumber Company bought the Oxbow tract in Hamilton County some time ago, and are cutting it off, and here they have met the cutting from the west.

There have been very heavy cuttings in the Grass River country, in St. Lawrence County, during the last year.

As has already been noted in your journal, the various railroads which penetrate the wilderness are being extended, and the destruction of the forest will, in consequence, proceed much more rapidly than heretofore. There has been a great deal of very indefinite writing and talk about the Adirondack forests, some of it misleading, because not based on any considerable knowledge of the facts of the actual condition and course of things in the woods. From three-fourths to four-fifths of the original forest has already been cut off, and hundreds of square miles—hundreds of thousands of acres—have been utterly denuded and ruined by the burning and washing away of the soil, so that centuries must pass before these vast tracts of bare and sun-scorched rocks can again produce valuable trees. Any rational or fruitful way of thinking of the matter must embrace a recognition of these facts. Whatever we may desire, whatever "might have been" if things had been entirely different, no amount of rhetoric or sentiment will avail to make the facts other than they are.

Cor. Sec. American Forestry Congress.

Mountain Meadows.

To the Editor of GARDEN AND FOREST:

Sir.—Your article on "A Mountain Meadow" on page 314 reminded me of what are without doubt the most striking mountain meadows in the eastern United States.

The highest mountains east of the Rockies are on the borders of Tennessee and North Carolina, the loftiest point being Mount Mitchell, 6,717 feet high. The traveler among these mountains will notice as a strange feature, the absence of crags and precipices. As a general rule, from the foothills to the summits of the highest mountains, we find moss and verdure. In May I climbed to the summit of Clingman's Dome, an altitude of 6,660 feet, and all the way to the summit, excepting in case of two or three short passes, our way led over nothing but rich loamy soil or turf. Just before ascending the Big Balsam mountain, from the west, one traverses the "Silas Meadows," fully 6,000 feet in altitude, a beautiful stretch of as true meadow as can be found in the lowest valleys. Here were ranging about 150 horses and cattle, alone on the summit with no cabin within miles. From this mountain meadow one can look over a grand wilderness, covering hundreds of square miles, where the axe of the wood-chopper has scarcely been heard, a truly virgin wood with magnificent forests of Balsams, Beeches, Birches and Tulip-trees extending in all directions.

On the summit of Thunderhead, made famous in Craddock's dialect stories of the Tennessee mountains, at a height of over 6,000 feet, in May, were grazing on a meadow of hundreds of acres, 500 cattle, 200 swine, and a large herd of horses and mules. The turf is fine and compact, and consists of Poas, Panicums, and other grasses. This meadow is not a little cleared patch of a few acres, but is of large area, bare of growing trees. In places on the summit may be found groves of

Beeches and Red Birches, stunted, gnarled and twisted, but they grow in a moist soil comparatively free from stones, and attain a height of 20 or 25 feet. On Defeat Knob, a part of Thunderhead, at the very top, is clustered a clump of Rhododendrons covering several acres, compactly growing together. And about this group is an abundance of moist sphagnum, which is fully three inches deep.

From this meadow, with an entirely unobstructed view, I counted nine distinct mountain ridges lying in various directions. And here on this top, where in May the snow had been "shoe mouth deep," were grazing on fine pasturage hundreds of domestic animals. Truly this was a strange sight!

Early in March the Trailing Arbutus had been on sale in Knoxville market, and the trees were leafing out, while in early May vegetation was well advanced, the trees being in full leaf. Yet on the tops of these mountains in May, when the trees were just expanding the bud, I gathered in their prime, Spring Beauties—Anemones, Trailing Arbutus—all the earliest flowers of spring. It was a striking fact that the clusters of Arbutus, which were much larger than any I had ever gathered among the hills of New England, were almost entirely devoid of odor. Yet they were exceedingly beautiful.

I cannot draw this communication to a close without referring to the enormous fields of Rhododendrons, or Laurels, as the mountaineers term them. They grow in such dense masses that it is absolutely impossible to pass through them, excepting over a bear trail which has been enlarged. For four miles a companion and myself struggled over the trail, passing down Miry Ridge, between thickets of Rhododendrons through which the only course was in the beaten path, just wide enough for cattle to pass on their way to the summits of the Smokies. This ridge, at least 5,000 feet high, comes to a sharp edge, and up the sides to the narrow top crowd these evergreens. And strangest of all, at times the trail is so mucky and wet that it is almost impassable. Frequently our horses, on a top not over forty feet wide, where one would have thought all moisture would rapidly drain off, sank into the muck above the knees, and nearly stuck fast.

In almost any direction, from these summits, one can see the dense green, level tops of Rhododendron thickets passing up and down the mountain slopes, and, as my companion remarked to me, "patches of fifty acres make a mighty small showing." Certain it is, northern people who have never been in these mountains can have no conception of the remarkable abundance of the Rhododendron.

Knoxville, Tenn.

C. S. Plumb.

The Preservation of Chittenango Falls.

To the Editor of GARDEN AND FOREST:

Sir.—Permit me to report an instance of the preservation of a beautiful natural object by a rural community, a case that is probably quite unique. Two streams flow from the hills of Central New York; one, the Chenango, an Indian name meaning waters flowing south; the other, the Chittenango, the waters flowing north. The Chenango winds through broad, fertile valleys until, lost in the Susquehanna, it finds the sea in the gleaming Chesapeake; the Chittenango plunges eight hundred feet within a few miles, over crag and boulder, to the lowlands, and on through Oneida and Ontario to the wild St. Lawrence.

Midway between Cazenovia and the village named for the stream, the Chittenango plunges over ledges of the limestone that upholds the hills of many midland counties, and falls one hundred and forty feet into as beautiful an amphitheatre of fern-clad rock as fancy ever painted. (See page 379.)

Cedars, Hemlocks and kindred trees cling to the ragged cliffs, where, dripping with spray, they shelter rare forms of *Scolopendrium vulgare* and other dainty Ferns and flowers. Since Jan Van Lincklaen, an officer of the Dutch navy, won by the beautiful surroundings of Cazenovia Lake (Owahagina), settled the place nearly a century ago, the falls of the Chittenango have been dear to all who loved undisturbed nature, and when plans for turning their power to mechanical use were proposed, the idea gave a shock to many of the old residents of the hill-top village, whose solicitude was so aroused that it assumed a protective purpose two years ago. Then a generous "trust" was formed; and money was raised with which the property was purchased; and an especial Act of the Legislature was procured, forming a perpetual trusteeship to hold and guard the falls free and forever. A little prudent work has opened a drive, enabling persons who cannot scramble to view the falls; but no art will be allowed to mark or mar the exquisite work that centuries have wrought with water, frost and glacier crush—the free-hand tools that have

rough-hewn the crags which dainty nature decorates anew with the frailest and fairest plants, watered with the spray that drifts from forming rainbows in the sunlight to pearl drops in the shade.

The general Government has the Yosemite and the Yellowstone; New York and Canada have rescued Niagara; and the small rural community of Cazenovia has found the temptation to preserve the Chittenango Falls strong enough to win several thousand dollars for this unusual and, perhaps, all considered, unique purpose.

The late Horatio Seymour often said that "good works were catching." Perchance many other picturesque places may yet be saved from the axe, the forest-fire and the heavy tread of material purpose.

Cazenovia, N. Y.

The Floods in Pennsylvania.

To the Editor of GARDEN AND FOREST:

Sir.—The accounts of the late damages by flood in Pennsylvania and New York are accompanied, in nearly every instance, by statements of large losses of timber and lumber, washed away by the high waters. At Milford, Pennsylvania, it is said that \$200,000 worth of unidentified lumber was deposited upon one single farm by the receding waters. The presumption, therefore, is that the water-sheds from which these floods originated have been recently and largely denuded. It would be well worth the while of friends of forestry, accessibly situated as to these devastated districts, to look thoroughly into the conditions of these water-sheds, and to publish the scientific results of their investigations. The statements in the newspapers indirectly confirm what foresters would expect to find as one cause of such unusual floods as have occurred this summer; that is to say, forest-destruction upon the water-sheds of the streams—and the amount of this destruction is shown by the immense losses of lumber—has presumably helped to swell these floods. Each new flood is headed in the newspapers by "Waterspout," or "Cloud-burst." It is hardly reasonable to suppose that so many of these rare phenomena of Nature have occurred within so limited an area, and within so short a time. It is much nearer the results of experience to say that these terrible floods were caused by heavy, but not unprecedented, rainfall upon surfaces denuded of forest-growth by the axe, or fire, or both, and consequently unable to detain or absorb the rainfall, as they had formerly done. I trust that competent persons will be led to investigate the true facts as to the floods referred to.

My Handkerchief Garden. By Charles Barnard. E. H. Libby, New York, 1889.

Mr. Barnard is popularly said to write on more subjects than any one else, not excepting Mr. Gladstone, and to write equally well upon them all. Certainly nothing could be better of its kind than this little volume, into the sixty-nine pages of which is crammed much useful information, conveyed in a delightfully easy way. His "Handkerchief Garden" was a house-plot in a suburban town, measuring twenty-five by sixty feet. In one year it yielded him "a garden, fresh vegetables, exercise, health and \$20.49," and the why and the how are so clearly explained that any one who reads and remembers need not despair of doing likewise. How the beginning was made, what work was done, and at what times and seasons; how preparatory plans were laid and plants started in the house, are successively set forth. A couple of chapters on special products follow, and then two—perhaps the most interesting of all—called "What to Do With a City Yard" and "A City Fruit Garden." For those unfortunates who are compelled to pass the whole summer season in large towns, there is a wealth of happy suggestiveness in these pages, where we find no vague bits of general advice, but exact directions, what is best to plant, and how to plant it, and sketch-plans illustrating the text. We should have liked to see more attention paid to flowers, the culture of vegetables being that which Mr. Barnard most insistently recommends. Nevertheless, it is certainly true, as he says, that while vegetables can be cheaply bought in the city, it is hard to get any of them fresh, and many kinds cannot be considered perfectly fresh except when gathered just before they are eaten. No extracts from the little volume would be valuable—its merit is in its continuity and careful regard for details. Nor would it in any case be necessary to cull for our readers' benefit any information from a work which can be purchased for so small a sum as twenty-five cents.

Notes.

A Redwood-tree, twenty-eight and a half feet in diameter, was recently cut in Tulare County, California.

Mr. Henry Shaw, the founder of the celebrated botanical gardens in St. Louis, has just celebrated his eighty-ninth birthday.

During the wet, warm weather Tomato-plants have been making extraordinary growth, while setting very little fruit. Good gardeners often run a sharp spade down beside the plants to prune their roots and induce the formation of fruit.

The Asparagus beetle this year seems proof against air-slacked lime. London purple and Paris green are out of the question while the plants are being cut for table use, but an occasional sprinkling with the arsenites even now will materially lessen next season's labors to hold the pest in check.

In California the fruit of *Prunus Simoni* develops into a handsome oblate, deep purple Plum much larger than it appears in the engravings of the fruit grown elsewhere. It ripens very early, and is very durable in shipment, so that it promises to take a high rank there among early-market Plums. The *Pacific Rural Press* observes that nurserymen are propagating it extensively.

The Longfellow Memorial Association in Cambridge, Massachusetts, is now preparing the land which lies between the old mansion and Charles River. The plan includes a terrace, commanding a wide view over the broad green river-marshes, a loggia upon this terrace, the walls of which will bear reliefs and inscriptions, and a garden lying below the terrace and overlooked from it. The object is to unite to appropriate monumental memorials the open prospect which Mr. Longfellow so much enjoyed. Charles Eliot, landscape architect, and C. Howard Walker, architect, are in charge of the work.

A bulletin just issued by Professor Cook of the Agricultural College of Michigan, illustrates the important services of parasitic and predaceous insects in overcoming our insect foes. About July 1st the wheat heads throughout a large region in the western states were crowded with aphides, five or six often attacking a single kernel and sucking out its vitality. It seemed as if the grain crop was doomed, but in a week the rapidly increasing enemies of the lice were in the ascendent, and in ten days the crop was safe. The bulletin gives illustrations of these parasites, together with the predaceous flies and the Lady-bird beetles and of their mode of attack. Tiny as these insects are, they have saved millions of dollars to the farmers of the West this year.

In a recent work by Professor Hartig it is stated that a count of the annual rings of a tree when cut three or four feet from the ground may not give the accurate age of the tree. Where trees are crowded in a forest and have developed feeble crowns, the greatest annual increment is just below the crown, and it diminishes regularly downwards. When the leaf-area is not sufficient to afford food-material to provide for a sheet of cambium all over the tree, the growth stops before reaching the bottom, and the ring which is found twenty feet up the trunk may fail altogether before it reaches the ground. In such trees there may be rings lacking at three feet high for certain years, and the total number of rings would be less than the number of years in the tree's life.

A bill has been introduced into the English House of Commons, the object of which is to provide instruction in agricultural and horticultural subjects in public elementary schools, and to afford practical illustration in such teaching. The Industrial Agricultural Education Bill, as it is called, would not only secure for children in rural districts practical instruction on such subjects as fruit, flowers, and vegetable growing, the proper method of keeping cattle, rotation of crops, packing fruit for market, and other matters of equal importance; it proposes, further, that the instruction in these branches shall be carried on after the children leave school. To effect this, it is proposed to establish schools at which lessons would be given in the evenings and on Saturday afternoons. To induce parents to keep their children at school for a longer period, or to send them to the new schools, the promoters of the measure advocate the provision of a small number of scholarships of the value of thirty shillings per annum, and tenable for two years, for children who have passed the fourth standard.

The free Gladiolus show, which Peter Henderson & Co. have established as a regular feature of the floral year in this city, was visited by several thousand people last week, and the flowers, in spite of the drenching and pelting they had received from unusually violent rain-storms, were notably good. A new Gandavensis seedling, nearly pure white, was greatly admired, as was a fine group of hybrids

containing the blood of *G. purpureo-auratus*. Mr. Sturtevant sent, from Bordentown, a tank full of Nelumbiums and other aquatics. Mr. Henderson showed some remarkable flowers of a variety of *Lilium auratum*, known as Rubro Vittatum, in which the golden band through the petals is replaced by one almost crimson. A superb display of flowers of tuberous-rooted Begonias was contributed by Mr. T. Griffin, gardener to Alfred Sully, Esq., of Hackettstown, New Jersey. Many of the single flowers were nearly five inches in diameter, and the double ones were nearly as large as Hollyhocks, while the colors could hardly be excelled in richness, delicacy or variety. The plants were seedlings, and had grown in the open air and exposed to full sunshine. The exhibition remained open three days.

Constant and growing demand on a constantly diminishing timber supply in all the civilized countries is beginning to have a visible effect. In a careful article the *Lumber World* states that despite the systematic efforts of the various European countries to maintain by forestry regulations an adequate supply, the whole wooded area of Europe has dwindled to 500,000,000 acres, or less than one-fifth of the area of the continent, while the demand goes on increasing as the population increases in density and consequent poverty, forcing them to use timber, as a cheaper material than brick and stone, to build houses. Norway and Sweden have parted with nearly all their available forests. Northern Russia has been stripped so bare that at present the single city of St. Petersburg demands more than that country can spare. The fostered German forests yield an ever decreasing supply, which constantly deteriorates in quality. Bohemia, Galicia, Transylvania and some adjacent sections still possess considerable areas of forest, but they are in inaccessible mountain regions, with neither railroads nor navigable streams to make the timber available. The forests on the shores of the Adriatic have disappeared. France and Spain, Portugal and Italy, Turkey and southern Russia have little or no timber that is available. Great Britain long ago ceased to depend to any extent upon her own small woodland areas for timber. In the United States the consumption of timber goes on at an amazing rate, each year seeing hundreds of thousands of acres stripped of forests. Canada has large wooded areas yet, but the demand upon them makes it only a question of time when they shall be stripped. Asiatic, African and South American forests are still important, but at present they are unavailable because of their remoteness from the centres of consumption. The civilized world will soon awake to the fact that its timber supply is exhausted to a serious degree, but as yet there seems to be but little appreciation of the true state of affairs.

According to the New York *Lumber Trade Journal* Birch twigs are worth a good deal, besides their reputed value as accelerators of the sluggish school-boy. Even the leaves and young shoots secrete a resinous substance, which, under long names, is sold as a medicinal preparation for as high as sixteen dollars a fluid ounce. The inner bark secretes a bitterish alkaloid, not unlike cinchona in its nature, and is used largely as an adulterant for quinine in many parts of Europe. The so-called "Cinchona Mixture" has been found by analysts to consist, in many instances, of the alkaloid found in the inner bark of the humble Birch tree. The outer bark, subjected to dry distillation, yields an empyreumatic oil, having the peculiar odor of Russia leather; and the secret of preparing skins—and that too of the very poorest quality of skins, being taken from cattle that have perished on those barren, desolate plains—is the only obstacle, thus far, to prevent American artisans from competing with Russia and Austria in fine leather goods. The oil of Wintergreen, so useful, fragrant and expensive, is nearly always adulterated with Birch oil—much of it even is Birch oil, pure and simple, but is sold as Wintergreen oil, and is Wintergreen oil to all intents and purposes, having, when properly prepared and refined, the same properties. The Birch limbs, twigs, bark, and even the leaves, if a more commercial oil is to be made, are gathered and placed in a large tub containing a coil for steam heating, and as fast as the mass accumulates it is kept covered with water. After becoming nearly full, steam is turned on, and the batch kept about blood-warm for twenty-four hours. This will dissolve nearly all the oil and resinous matters, which, being precipitated, causes the mass to assume a very sticky consistency. By means of a wooden connection with a small barrel or keg, the tank is made tight and brought to a boil. The steam, having previously dissolved the oils, etc., will now vaporize them, and will condense in the last named keg. After a few hours the job is done, the keg is bunged or corked up, and is ready for shipment as commercial Wintergreen oil, though made from Birch refuse.

GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, AUGUST 14, 1889.

A Literature Worth Indexing.

WITHIN the past three weeks we have received as many reports of state horticultural societies, each one a stout volume, and each containing papers of genuine and permanent value. In most cases the states print these books as public documents and distribute them free within their respective limits. Add to these reports the bulletins from the experiment stations, the official reports of state entomologists and botanists, the proceedings of such bodies as the pomological and viticultural societies, and the associations of seedsmen, nurserymen and florists, and we begin to realize how rapidly the volume of this literature is increasing. In fact, if one were in the way of securing all these books, he would soon find the shelves of his library filled with works on horticulture and agriculture.

We do not speak of this to question the wisdom of this distribution. As a matter of fact, these reports are year by year growing better, as increasing popular knowledge on the subjects discussed makes a demand for the more thorough treatment of them by men of special training. But it is none the less plain that they could be made much better without serious difficulty, and the information they contain could be made much more accessible, and therefore more widely useful. These books should be more carefully edited, and much that is of ephemeral or local interest, like the average "address of welcome," for example, should not be allowed to cumber their pages and add to their expense. The only way to secure careful editing is to pay for it, and, as the secretaries of these societies do not now receive adequate salaries for the duties demanded of them, an increase of their salaries is the obvious suggestion. If the money expended for printing and publishing and mailing thousands of pages of useless matter were paid to judicious men for editing out of these documents all that is not worth preserving, this important literature would at once take a higher rank.

But perhaps the most serious defect of these books is their lack of proper indexing. A hasty examination of each of the three reports alluded to at the beginning of this article disclosed many things to which we might often have occasion to refer, but it would be necessary to search

through the books, page by page, before the desired passage could be re-discovered. More than a year ago it was suggested in these columns that the work of making a full topical index of these reports was one not unworthy of the Department of Agriculture. Since then an officer has been appointed by the Secretary, whose duty it is to collate and classify the bulletins of the experiment stations as they appear, to make a condensed statement of progress in the various lines of investigation, and to publish this periodically, with notes for unscientific readers. Beyond question, this new office is capable of wide usefulness. The indexing of state and society reports would not naturally, however, come within its scope, and yet we cannot but hope that the Department of Agriculture will find some way to accomplish this work. This is the only agency through which it is likely to be undertaken.

In the June number of *Harper's Magazine*, Professor George H. Darwin writes of an important discovery relating to the constitution of Saturn's rings. This discovery was made forty years ago by M. Edouard Roche, but it has taken all these years for the scientific world to discover the discoverer and his works. M. Roche patriotically gave his memoirs to the Academy of Sciences of Montpellier, where he was professor, and there they were published—practically buried, that is; for so many learned but local societies are publishing papers that none but the largest libraries can collect them all, and no one can hope to read them all. Unless, therefore, scientific memoirs are issued at such centers as London or Paris, years may pass before their merits are recognized. Accident directed Professor Darwin to the work of this man of genius, and he could not find a single English mathematician who had read M. Roche's papers. We can hardly imagine any great horticultural discovery buried in a state report, but suggestions of great practical moment might easily be lost in this wilderness, which is now trackless and rapidly growing more dense and more extensive. It would be worth while, we repeat, for the Department of Agriculture to explore and make it accessible.

The inhabitants of dry regions like central and southern California, where Grass will not grow in the summer without irrigation, would welcome with grateful appreciation any plant which would keep green under these arid conditions, and furnish them with something like a lawn or stretch of greensward. In the issue of GARDEN AND FOREST for March 13th, 1889, M. Charles H. Naudin, director of the gardens of the Villa Thuret, who has an unrivaled knowledge of dry-country vegetation, suggested the names of two or three plants which he thought might answer this purpose. In a personal letter to the editor of this journal, M. Naudin again alludes to the subject, and we quote his interesting statements in regard to two other plants which may be used to furnish lawns for California. Our readers are aware that it is a species of *Pyrethrum* which is successfully used as an insecticide under various names, so that the effect upon mosquitoes of *P. Tchihatchewii* is not altogether surprising.

"I think *Pyrethrum Tchihatchewii* would succeed in California. It has done remarkably well here, and makes a beautiful sward, without watering, wherever the soil is not of too poor a quality. Perhaps it will do as well in California, especially where the soil has been tolerably well tilled. Besides its ornamental uses, this plant, which is a native of Asia Minor, serves here as a destroyer of mosquitoes. It asphyxiates them, so that they are harmless for several hours at a time. We dry the heads when the plant is in flower, and in the evening burn them on a red-hot iron plate, or otherwise. The essential thing is to produce a smoke which can circulate through the apartments. The pests fall insensible, and it becomes possible to sleep in peace.

"Another plant, which might succeed even better for grass-plots, and which is very suitable to dry soil, is *Lippia canescens*, or *L. repens*, a little plant which roots as it creeps in every direction along the ground, and multiplies very rapidly. It is a native of the dry regions of Peru, which explains its ability to resist drought."

A WELL-WRITTEN letter from Walnut Grove, Arizona, in the *Evening Post* of July 24th, describes the great dam recently built for a storage reservoir at that place. It took more than a year to construct it, the work going on day and night. It is of solid masonry, and is 110 feet high. It is thirty miles southeast of Prescott, on the Hassayampa river. Above it is a wide valley, shut in on all sides by high mountains, the only outlet a narrow cañon, through which the river runs. The dam blocks up the mouth of the cañon where it leaves the valley, and the valley is changed to a lake basin. There was a heavy snow on the mountains, and at last a great rain.

"Every crack in the rock fed a hollow, the hollows fed the streams that grew quickly into torrents that tore their way down the sandy washes into the lake. The lake rose three feet in an hour as the result of the local rain, but the warm rain and snow on the mountains were yet to be heard from. The catchment area of the reservoir, extending over 300 square miles, has its outer circle of mountains at least thirty miles away. It might take all night for the snow to melt and come down. But at midnight a cowboy rode in on horseback to tell us there was a wave anywhere from 50 to 100 feet high coming down the 'Hassayamp.' We took our *ponchas* and lanterns, and started for the boom. We could hear the roar of the water three miles away, but it was an hour before the wave rolled in upon us, like a great tidal swell, fifteen feet high and fifty feet across, boiling and bubbling with foam, and carrying huge rocks and trees along with it. Above the roar of the storm we could hear the boom of the other streams that one after another came on, great rivers, where an hour before there had been nothing but creek-beds.

"We went home to find the water half-way up the camp-hill, and everybody awake and rustling. The croakers who had built on the edge of the flat, in defiance of the dam level, were scurrying about in the dark, scooping their belongings into gunny-sacks, and hurrying up the hill to establish new and rival claims above the 110-foot line."

When the letter was written the water was within five feet of the top of the dam. If the mountains above were clothed with forests, the water would not be likely to come down in such enormous waves, carrying huge rocks and trees along with it. Such masses of *débris* will, of course, fill up the reservoir rapidly, but that is not so serious a matter as the probable effect upon the dam of the pressure of an unusually heavy flood. Let us hope that the dwellers along the stream below who cannot keep their claims and belongings "above the 110-foot line" may never learn from experience the destructive force of so great a volume of water when once it is set free.

How to Mask the Foundations of a Country House.—III.

HARDY shrubs, it was said in an earlier chapter, are the best things to plant close to the foundations of a house to give it the look of being integrally united with the soil beneath it, and to bring it into harmony with the natural features around it. Whether creepers are profusely used or not, whether or not trees stand near by, shrubs can hardly be dispensed with if the house is to seem to belong exactly where it stands, and nowhere else. Flower-beds can never rightly take their place, for they are at once too formal, too monotonous and too ephemeral. What is wanted is a garment that can be high in some places, low in others; here dense and massive; there light and graceful; that can now cling closely to the walls, and now spread away a little to unite them with neighboring plantations. Shrubs give us everything that is thus required, and in endless variety.

Just in this profusion of species among which he can choose lies, however, danger for the planter. When so many beautiful shrubs are offered, and so many striking novelties, he may easily forget the exact purpose in question and think too much of the claims of individual plants, and thus produce a confused medley of inappropriate plants instead of an harmonious and appropriate variety. If "specimen plants" are wanted, their place should not be here. Here the effect of the house is the first consideration. If a tall shrub is planted, it should be because a tall one is needed, not because a particularly handsome tall one has been seen in a nursery or in some neighbor's grounds. The question should not be whether one likes Lilacs especially, but whether Lilac-bushes

can be well used in the general scheme. With a little care a good spot can be found for any special favorite; or, if not, something that will win itself as high a place in its owner's affections can be found to use instead.

Of course an over-use of shrubs should be avoided. We do not want a house to look as though it grew in a thicket, or as though the cultivation of shrubs were its owner's chief concern. Mass shrubs in the angles of stoops or bay-windows, carry them along in lower groups, then break them, and for a little space let the foundations be seen resting on the grass, in order that their stability may be clearly manifest, and then in another angle place another more important group. Take the outline of the house and the character of its features as your guide, and accent these while uniting the building, as a whole, with its site. Do not conceal beautiful features, but sedulously plant out those which, like out-houses and drying-yards, should not be seen.

Plant closely at first, and then as the individuals develop thin out those which are no longer needed, for crowded, ill-grown shrubs are as ineffective as a garment for the walls as painful to the eye of the true lover of plants. Each shrub should be well developed and have room to display its peculiar habit, and the masses, as a whole, should have that play of light and shade and that freedom of movement which overcrowding ruins. Above all, never shear off the tops of these shrubs to a horizontal line; nor clip them into stiff or formal shapes; nor trim away their lower branches and cut back their heads to make them look like dwarfed trees. If the proper selection has been made, all pruning and training should be with a view to bring out the distinctive character of each shrub, and not to force any of them into alien and unnatural forms. Shrubs which stand in front of a plantation should sweep the ground with their branches. Behind these may stand others of a different habit, but to place individuals which naturally grow well above the soil in the foreground, or to clip others till they present a similar, but, of course, less pleasing appearance, is to give a shrubbery a bald, ill-grown and ungraceful look. Nor is there any place where this look is so unfortunate as in shrubs, the very purpose of which is to unite the base of a house with the ground upon which it stands. If a shrub thus placed grows too large, take it out and let its neighbors gradually fill the space, or plant a smaller one in its stead. Severe cutting will only spoil it, and in spoiling it you will injure the effect of the whole group to which it belongs.

Color should be especially regarded in choosing shrubs and creepers. One monotonous tint of green is to be avoided, and, still more, an excessive use of bright-hued plants. Green is Nature's color. The bright-hued plants which, in this climate, she spontaneously produces are few, and the vast majority of those which the nursery-gardener offers us are those sports and freaks of Nature which she herself, perhaps, would regard as lamentable mistakes. Curiosities have, however, a great attraction for the average man, especially at the moment when they rank as novelties also, and far too many places are disfigured by an accumulation of abnormally colored plants, with striped or blotched or speckled foliage, and especially with foliage of those sickly yellow hues which go in nursery catalogues by the attractive name of "golden." A single plant of this sort may often produce a pretty effect, if grouped among others of a normal tint—as a slender Golden Honeysuckle climbing amid others of ordinary kinds, or a single red Japanese Maple, associated with a mass of dark-green shrubs. But to plant too many of them, and to mingle reds and yellows, streaks and spots, in the reckless manner that we often see, is to destroy all peacefulness and unity as well as all naturalness of effect.

But, even when shrubs of a normal hue are adhered to, there is still need for selection. The different shades of green should be well distributed. Each should form a mass of sufficient size to prevent any look of spottiness and restlessness in the general effect, each should harmonize with its neighbor, and each should be in right relationship to the house itself. A dark-blue green should not stand next to a light and rather yellowish green—there should be a medium tint to make a transition between them. Nor does a pale grayish-green harmonize well with a yellowish tint, although, against a dark blue-green, it may look well. Again, a rather yellowish shrub, which might have an excellent effect against a shingled or a painted wooden house, may look too crude against a red brick wall, while each different color in stone will make a different demand upon the exhaustless resources of the intelligent planter. In general, if dark-colored foliage is used in the background and lighter colored in the foreground, and if there is more variety of hue near the eye than further back, the shrubbery will gain in depth and richness of effect.

Florence Nightingale's Home.

MISS Nightingale was born in Florence and named after that beautiful city, but her early years were passed in England, where her father owned two estates, Embley Park, in Hampshire, and Lea Hurst, in Derbyshire. Lea Hurst was the favorite residence of the family during the summer months, and it is this house which our picture on page 391 represents. It is a stone house, not very large, which stands among woods in a place containing about 5,000 acres, and commands wonderful views of the Peak country. It is about two miles from Cromford station, and not far from Matlock, in a delightful district watered by the river Derwent, and rich in picturesque dales and dingles, moss-grown masses of limestone rock, and wide stretches of moorland. In the vicinity of Lea Hurst stands Willesley Hall, formerly the home of Arkwright, with the mill where the spinning-jenny was first used; and likewise Wingfield Manor, where Mary Queen of Scots was imprisoned for nine years.

The house at Lea Hurst is in the Elizabethan style of architecture, but we can find no evidence that it is a genuine relic of Elizabethan times, and, at all events, the bay-window in the foreground of our picture, with its balustraded roof, is a piece of modern construction. The interest of the building lies, first, in its associations with a very famous and admirable woman, and then in its typical charm as an example of an English country-house of a modest kind, tastefully surrounded by luxuriant plantations. The point to which we especially desire to call attention—as illustrating the counsels we give on another page—is the intimate union into which these plantations have brought the house and its site. The clinging robe of vines, clothing yet not wholly concealing the walls, and the masses of shrubbery, highest opposite the high gables of the front, and sloping irregularly downward toward the entrance steps, form a delightfully soft, graceful, and natural-looking transition between the house itself and the landscape which we imagine further away; and the rugged irregular Cedars of Lebanon on either side of the steps give a desirable accent of force and picturesqueness. If we fancy this house deprived of its shrubberies and standing naked on a stretch of lawn, or encircled by flat, formal, gaudy flower-beds, we realize the advantages of the more rich yet natural arrangement that we see.

The Art of Gardening—An Historical Sketch.

VIII.—The Love of Nature.

THE Greeks and Romans, we are often told, cared much for art, little for nature; a genuine appreciation of the charms of the inanimate world is a product of modern civilization, and only within the past two centuries, with the general growth of "romantic" habits of mind, has it reached its full development. Of course a comparison of classic with modern literature has been the basis for this belief; and it certainly seems justified if we study both classes of writings from the same point of view and confine ourselves strictly to the one subject under discussion.

Nevertheless, while it cannot be denied that there is a distinct and important difference between the classic world and ours as regards the love of Nature, its degree has been much exaggerated, and the true reason for it is not generally understood. The first approach to a right conception of the matter was made, I think, by Humboldt in the second volume of his "Cosmos," but even yet his views do not seem to have greatly influenced current thought. As he points out, the witness of Greek literature to a want of poetic sentiment in the presence of Nature is negative, not positive; it consists in the almost total absence of such descriptive passages—analytical, rhapsodical, sentimental—as occur in profusion in all the verse and prose of our day. But, he explains, this negative evidence does not prove a "deficiency in sensibility" so much as a lack of strong desire to express it in words. The Greek was chiefly interested in active life and in the spontaneous movements of the human soul; his poetry therefore took a dramatic, lyric or epic form; in neither of these is there much place for descriptive writing, and his love for Nature was commonly expressed in the personification of all its elements, not in panegyrics upon its actual aspect. If Greek writings are studied with these fundamental and illuminative facts in mind, they unquestionably prove that a stronger feeling for natural beauty existed than we have been taught to believe. It revealed itself in a way quite unlike our way, yet was vital and widespread. Do what a modern writer will, man is always the central figure in his pictures, as in the pictures of the ancients. But to-day it is contemplative, receptive man, as affected by the emotions

which Nature excites; and her aspect is therefore portrayed with infinite detail and extended explanatory comment. In the classic world, on the other hand, active man—doing, thinking, originating man—was always the central figure; his feeling for Nature expressed itself by reading into her beauty his own spontaneous emotions; by vivifying, personifying her elements; by giving her, so to say, a multitude of human hearts and souls.

But, it may be objected, this is a mere begging of the question. If the Greek had really loved Nature as we do, his mood would often have been like ours—subjective, contemplative, receptive; and he would have created a form of literature proper for its expression. Humboldt's position, as he explains it, is indeed open to this charge; but he might have greatly strengthened it by showing that the Greek's lack of impulse toward descriptive expression was not confined to the emotions which Nature excited. It will hardly be disputed that the Greek, above all other men, had a true, passionate, acute and widespread appreciation for art of every kind. Yet how much does his literature contain in the way of an analysis of the emotions that works of art excited in his mind, or even in the way of detailed description? Almost endless catalogues of buildings, statues and paintings exist from the pen of travelers and historians; but if a phrase of description or criticism occurs, it is so brief and superficial that we might fancy it written by some barbarian stranger rather than by a man akin to those who had created such marvels of beauty and skill. How little we know about the perished paintings of Greece—how much we should know had a single essay of the modern kind been written about them—a single tourist's record, a single chapter of criticism! No Greek writer helps the modern antiquary in his disputes over the manner in which the temples were adorned with color; and even of such celebrated works as the Olympian Jove and the Cnidian Venus we know less than a newspaper reporter of to-day would have told us in a passing paragraph. Works which have excited modern men to a hundred volumes of rhapsodical description and hair-splitting analysis are passed over by the old writers with a word; they were eager enough to tell what fine things could be seen in this place or in that, but it rarely occurred to them to say just how they looked, never to explain how they affected their own sensibilities. If we take up such a book as Jefferies' "Field and Hedgerow," we may think that it reveals more love for Nature than the whole literature of Greece, but all this literature contains less evidence of a delicate feeling for the qualities of a work of art than the single essay in this same volume on the "Crouching Venus" of the Louvre. And if we do not draw the conclusion that modern Englishmen feel art more keenly than ancient Greeks, we should be careful not to be too hasty in our generalizations with regard to a love for Nature.

I do not mean by all this to assert that the Greek loved natural beauty just as we love it to-day. Perhaps he felt it as intensely in some of its manifestations, but he seems to have been comparatively blind to others. Or, to speak more exactly, while he loved all that he thought beautiful in Nature, the term was not so wide a one for him as for us. All his works of art unite in proving that beauty to a Greek meant simplicity, sobriety, clarity, grace, balance and repose. The stern majesty of Egyptian architecture was as foreign to his spirit as the elaborate variety of Gothic; the fantastic rhapsodies of an Indian epic could no more have sprung from his brain than the awesome, terrible imaginings of a Dante. He had no love in art for the complex, the irregular, the mysterious, the grotesque, or the gloomy; and I think almost the same can be said of his love for Nature. In classic thought, moreover, a far greater place than we give to-day was given to the claims of the physical as distinguished from the spiritual man, and this fact naturally limited the Greek and Roman in their appreciation of such scenes as are palpably unfit for man's comfortable habitation. The love we now feel for the awful, the terrible, the savage and grandiose in Nature, was certainly not shared by the men of classic times; but this truth—illustrated by many hackneyed anecdotes—has too often been misread to prove that they did not really care for Nature in any shape.

Another point which Humboldt makes has regard to the reason for this difference in sensibility. As I have said, it is usually cited to mark an unlikeness between ancient and modern times, but it is rightly explained, not by facts of time, but by facts of race. That kind of love for art and Nature which the Greek displayed is "classic" in the narrower sense referring to Greece and Rome, not in the wider popular sense which includes all the races and peoples of the ancient world. The Greek differed from the modern German in his love for Nature, not because he was earlier born, but because

his blood was different, and with it his whole mental and spiritual attitude. As were the Greeks and Romans, so, broadly speaking, are their descendants of to-day in the south of Europe; as are to-day the peoples of the north of Europe, so, broadly speaking, must have been their ancestors in central Asia. The Teutonic influence has now largely permeated the south, and the classic influence has spread everywhere at the north; but fundamental, racial characteristics have nowhere been obliterated, and whenever a genuine, spontaneous impulse speaks through art, then they are still clearly voiced. As, after centuries of effort and practice, classic architecture has never become thoroughly at home in England, so the true subjective Teutonic sensibility to all forms of Nature, and its marked preference for awe-inspiring, irregular or picturesque types of landscape, has never become part and parcel of the Italian temperament.

I have had to make a place for these general explanations in order to show later on why the art of gardening developed as it did in different countries. Of course the attitude of a community towards the beauty of natural scenes was not the only cause which affected the development of this art; but it was one of the causes, and it should not be left out of sight if we wish to understand how gardening, like all its sister arts, illustrates the fundamental characteristics of each nation that has practiced it.

New York.

M. G. Van Rensselaer.

Notes Upon Some North American Trees.—V.

PARKINSONIA.—Mr. Watson finds (*Proc. Am. Acad.*, xi, 135) that "the characters which have been relied upon to separate *Cercidium* of Tulasne from *Parkinsonia* do not hold good in regard to our western species," and he therefore unites, so far as concerns our North American plants, these two genera. A re-examination of all the available material in our eastern herbaria shows, however, that the valvate imbrication of the calyx-lobes is constant in *Cercidium* and that the thickened glandular claw of its upper petal does not appear in our species of *Parkinsonia*. But the real distinction between the genera lies in the fruit which in *Parkinsonia* is linear, rounded and torose, while in *Cercidium* it is linear-oblong compressed, and in one species slightly contracted between the seeds. This difference in the fruit seems sufficient to keep the two genera apart, and I should therefore propose to replace *Parkinsonia Torreyana*, Watson (*l. c.*), and of the Census Catalogue, by *Cercidium Torreyanum*; and to include in the *Silva* the original North American species *C. floridum*, Benth., which, it is now known, becomes a tree of considerable size in the valley of the lower Rio Grande, especially south of the river, where I have seen it in great numbers along the road between Monterey and Seralvo, growing to a large size. The eastern and western species are very closely related, and the two trees are hardly to be distinguished as they are seen growing. Mr. Watson's characters (*l. c.*) for the fruit of the western species—"pod with a double groove along the broad, ventral suture, usually two inches long or more, two to eight-seeded, straight or somewhat contracted between the seeds; seeds very thick"—serve, however, to distinguish it from the lower Rio Grande-valley plant, which has much smaller and thinner pods, with a narrow acute margin on the ventral side, and smaller and thinner seeds; but the flowers of the Arizona species are certainly axillary, and only accidentally terminal, as described, an error due, perhaps, to the fact that the original flowering specimen which served for the figure published in the Pacific Railroad Reports (v., t. 3), and preserved in the herbarium of Columbia College, is an unusually vigorous shoot from a broken branch, with larger leaves than are usually produced, and terminated by a short raceme of flowers. From this single shoot the branch which appears in the figure, with numerous terminal racemes, must have been made up. The racemes in all the other specimens which I have been able to examine are axillary, as they are in *Cercidium floridum*. Mr. C. G. Pringle, who has enjoyed excellent opportunities for observing these trees where they grow, sends me the following note, which serves to confirm Mr. Watson's opinion that they are specifically distinct: "I have given considerable attention to *Parkinsonia Texana*

(the *Cercidium floridum* of Benth.), but did not arrive at a clear opinion as to its relation to *P. Torreyana*, of Arizona. The Rio Grande tree has a bright-green bark, even to the trunk, while the other has a rough-barked trunk in adult specimens, and the bark of the limbs is olive-green or yellowish-green, a difference which may be caused by differences of climate. The Texan, even on fertile plains, appeared to be a much smaller tree, which seemed surprising to me if both belong to one species. The Arizona tree flowers profusely in April, and few leaves put forth until after the mid-summer rains come. I do not know the habit of the Texan tree; last year it must have flowered, though but scantily, throughout July and August, and it must be in full leaf from April till October." I found it early in April, 1887, in full flower on both banks of the Rio Grande.

96. *LEUCENA PULVERULENTA*, Benth.—This, "the *Mimosa*" of the American inhabitants of the lower Rio Grande Valley, is a much larger and more beautiful tree than the notes of early travelers in the region implied. I have seen specimens growing wild on the banks of the Rio Grande, ten or twelve miles below Brownsville, which were fifty or sixty feet high, with straight trunks, covered with cinnamon-brown bark, at least twenty inches in diameter; and there were specimens in some of the gardens of Matamoras which were nearly as large. This tree is exceedingly ornamental in habit, in foliage, and in flower; it grows with great rapidity, and it might be introduced advantageously into all the Mediterranean countries and into California as an ornamental tree. The wood which it produces is valuable, too, being very hard, heavy and close-grained, of a rich, dark-brown color; the color of the sap-wood being bright, clear yellow. The large specimens, however, in its native country, are generally hollow or defective, so that it is esteemed as an ornamental tree only. The illustration upon page 389, which is made from a photograph taken last summer by Mr. Pringle, represents a moderate-sized specimen, and shows the graceful habit of the trees of this species. C. S. Sargent.

New or Little Known Plants.

The Chinese Quince.

M. ANDRÉ joins some interesting notes to a beautiful colored plate of *Cydonia Sinensis*, published recently in the *Revue Horticole*. This plant, which must not be confounded with the Japanese Quince met with so generally in gardens, is not often seen in cultivation, although it may be expected to thrive in the middle and southern states.

Cydonia Sinensis is a small tree, with numerous upright, slender branches, oblong or obovate glandular-toothed stipules, and oval, serrate leaves, pointed at the two extremities, the lower surface at first pubescent, but becoming quite glabrous at maturity. The calyx-lobes are acuminate-reflexed, and the petals are small, not more than half an inch long, oval, pale pink, streaked with red. The fruit is shaped like a barrel, five or six inches long. The diameter of each of the two ends is somewhat greater than that of the middle, and it is prominently depressed at the top and bottom. The flesh is hard, granular and dry, creamy-white or yellow. The skin, at first green, ripens to a beautiful dark yellow, dotted with brown or nearly black spots. The odor is peculiar, and intermediate between that of the fruit of the common Quince and of *Cydonia Japonica*. M. André notes that the figure in the *Revue Horticole* is the first that has been published of this beautiful fruit, and that the climate of Paris is not hot enough to thoroughly ripen it without the aid of espalier cultivation. The Chinese Quince flourishes, however, in the south of France, and its fruits, sent from the neighborhood of Toulouse, are seen sometimes in the markets of Paris, where, although not very well known, they are esteemed for preserves.

Cydonia Sinensis is widely distributed through western

Fig. 122.—*Leucaena pulverulenta*.—See page 388.

Asia, and, could seed be procured from near the northern range of its distribution, plants could be raised which might prove hardy in the northern states.

It would be interesting to know if this handsome plant is cultivated anywhere successfully in the United States.

Foreign Correspondence.

London Letter.

THE great Rose tournament in honor of the Shah of Persia at the Crystal Palace was simply an ordinary Rose show magnified several times, and therefore needs no description. Your readers will be more interested in the new Roses, which, as a rule, are shown in full force, as the National Rose Society's gold medal for the best new Rose not in commerce is a much-coveted prize—is, in fact, the blue ribbon among rosarians. Mr. Bennett, the raiser of *Her Majesty* and other fine Roses, has done much to elevate the standard of excellence in new Roses, so that now a gold-medal Rose must be of superlative

merit. This year the fortunate medalist is Mr. Prince, of Oxford, who is undisputedly a prince of Tea-rose growers, and the sort that gained the honor is the *Souvenir de S. A. Prince*, a pure white sport from the old favorite, *Souvenir d'un Ami*. The flowers are large and full, of fine form, and deliciously fragrant. If it can be always grown as Mr. Prince shows, it will prove one of the best of white Teas. He grows it, as, indeed, he does all his Teas, on the seedling Brier, and few hereabouts can equal his blooms. I was much pleased to see how very prominent the lovely American Rose, *The Bride*, was at this show. It was in all the best collections, a proof that it has established itself in the good graces of critical rosarians. Of the new Roses already in commerce there was a goodly show, and the first prize for twelve trusses was taken by *Lady Alice*, a pale sport from *Lady Mary Fitzwilliam*, whose good qualities it possesses, but it was not so much admired as *The Bride*, which was second, while a good crimson hybrid perpetual, named by Paul, of Cheshunt, *Queen of Autumn*, was third. The collections of a dozen new Roses were fairly good, and among the winning twelve were *Grand Mogul*, *Her Majesty*, *The Bride*, *Primrose Dame*, *Silver Queen*, *Viscountess Folkestone*, *Miss Ethel Burnside*, *Duchess of Leeds*, *Earl of Dufferin*, and *M. Mat Baron*, all first-rate sorts. The prizes (silver medals) for the finest blooms in the whole show of hybrid perpetuals and Teas or Noisettes were won by Ulrich Brunner and *Comtesse de Nadaillac* among nurserymen, and among amateurs, *Marie Baumann* and *Comtesse de Nadaillac*, which says a great deal for the Tea-scented variety, which has been grandly shown this season everywhere. The classes for specified varieties are generally well represented, as the sorts are usually those most popular and grown on a large scale. Thus there were classes for a dozen blooms of *Lady Mary Fitzwilliam*, *Marie Baumann*, *Her Majesty*, *A. K. Williams*, *Marechal Niel*, and *Niphetos*, which are, probably, the most extensively grown sorts now. The classes for Roses of particular colors were interesting. *Prince Camille de Rohan* was the finest dark crimson, *Alfred Colomb* the best crimson, *Merveille de Lyon* the best white, and *Madame Caroline Kuster* the best yellow.

The last fortnightly meeting of the Royal Horticultural brought a few novelties to light, and some of sterling merit. Among the Orchids there was a lovely variety of *Cattleya Mendelii*, from the Blenheim collection, and named *Duchess of*

Marlborough. It was called a white variety, though it is not quite pure; but the delicate suffusion of mauve, which overlies the whole flower, renders it very charming, and the large size and fine form of the flower add to its beauty. It won a first-class certificate, as did also a wonderfully fine variety of *Oncidium crispum* called *Grandiflorum*. Its flowers are nearly twice the ordinary size and richly colored, while the spikes were a yard long and widely branched; in fact, it was, in this respect, more like the branching-spiked *O. Marshallianum* than the ordinary *O. crispum*. Other noteworthy Orchids were *Phajus Humboldtii*, one of the rare terrestrial Orchids from Madagascar, which one seldom sees in flower or even in good health; but it is not a remarkable beauty—not comparable with its companion, *P. tuberosus*. The magnificent *Laelia callistoglossa*, one of the hybrids from *L. purpurata*, was grandly shown. It resembles its parent in growth and in flower somewhat, but the labellum, the finest part of the flower, is larger and of a very rich amethystine purple. The beautiful, small, late-flowering variety of *Odontoglossum vexillarium*, named *Superbum*, was shown in fine flower. It is smaller than the ordinary form, and its blossoms are paler, but enriched with a large crimson

blotch in the centre. The new *O. Harryanum* seems to be common now, and has proved not difficult to manage, and one of the best forms of it was shown, which is far more beautiful than those one usually sees of it. Those interested in Orchids of botanical merit were pleased with the little *Phytosiphon Loddigesii*, which has leaves like a *Masdevallia*, and tiny nankeen-yellow flowers on slender spikes. A botanical certificate was unanimously voted to it.

The General Floral Committee awarded four first-class certificates. One was to a golden-hued conifer, *Retinospora filifera aurea*, shown by Messrs. Veitch, and which is considered a "good thing," but, as the ordinary green form of this conifer is not a first-rate hardy tree, the golden form of it can scarcely be expected to be so, except in a few localities. An enormous variety of *Iris Kämpferi*, named White Banner, received a unanimous award. The flowers measured no less than ten inches across, with petals four inches wide, and the whole almost pure white. In fact, it carried but a faint suggestion of a lilac tint. It is the finest *Iris* yet seen. A first-rate plant is *Rhodanthe maculata flore pleno*, which Messrs. Veitch showed. The flowers are very double, and perfectly globular, like an incurved *Chrysanthemum* in miniature. There were two forms, one with pure white flowers, the other a rich rosy-pink. It is said to come here from seed, and lasts much longer in perfection than ordinary single flowers. Mr. Ware won a certificate for his new variety of Panther Lily (*Lilium pardalinum luteum*), the flowers of which are a rich orange-yellow, copiously spotted with black. It differs from the variety Warei (also new), which, besides the absence of crimson in the flower, is spotless. Some awards of merit were voted to a pure white *Carnation*, a border variety, with large, smooth-petaled flowers, an improvement on *Gloire de Nancy*; to some exceptionally fine flowers of the Hose-in-hose *Canterbury Bells* (*Campanula Medium calycanthema*), with tints ranging from pure white through pinks to purples; to a neat little *Capsicum*, named Coral Red, with an abundance of small, bright-red fruits, and to a collection of *Auricula*-flowered Sweet Williams, a beautiful class of plants that of late years seem to have suffered neglect.

Among other noteworthy exhibits were some flowering shrubs from Messrs. Veitch, including the pretty *Notospartium Carmichaelæ*, a leguminous shrub from New Zealand; a variety of *Cupressus Nutkaensis*, with silvery-touched foliage; and *C. Goveniana*, a Californian species recalling the common *C. macrocarpa* in general aspect.

The Fruit Committee had a few good novelties to deal with, and they certificated a new Raspberry, named Hornet, from Messrs. Rivers; a new Pea, Consummate; a large-podded Marron Melon, Countess, white, very juicy and richly-flavored; and Lettuce la Grosse Paresseuse, a late Cabbage variety, of French origin, but shown by Messrs. Veitch. *W. Goldring.*

Cultural Department.

Planting Strawberries.

THE fall-planting of Strawberries is generally attended with the best results the more nearly it approaches summer-planting. July is as much better than August for this work as August is better than September. Those who claim that planting can be done as late as October and November, with success, probably mean that these plants will pass the winter safely; but the results of such late work will not compare with that following work done a month or two earlier. Even then all conditions should be favorable, and the plants should be merely moved from one portion of the grounds to another, and with as little disturbance of the roots as possible. In case of plants received from a distance, such late work, as a rule, is not very satisfactory, and is not to be commended. A partial crop of fruit is all the advocates of fall-planting can expect.

Plants set now, and well cared for, should give a full crop next season, a gain of a year over next spring's setting; but to insure this the plants should be handled with care, and have the benefit of good soil and generous treatment. The ground from which early Peas, Potatoes or Sweet Corn has been taken is a good place for the new Strawberry-bed. If the ground is not rich, it should be made so by well-decomposed stable-manure or commercial fertilizer, well worked in, and the plants carefully lifted, with sufficient soil attached to keep the roots intact and cause as little check as possible. Rows twenty inches apart, and plants set twelve to fifteen inches in the row, are very good distances. Care should be taken to get the crown of the plant even with, but never below, the surface of the ground. A deviation from this rule, simple as it is, often proves fatal to the plant. The advice to set trees a little deeper

than they stood in the nursery is good in some instances, but it should in no case be extended to Strawberries.

This excessively moist weather is extremely favorable for the successful establishment of new beds, and when the elements favor, is our opportunity. Plants that have been rooted in pots while still attached to the parent plant, have of late years become quite an important item in the trade, and for transporting long distances, if properly managed, they help to insure against losses, because when turned out of the pots, and the ball of earth, with every root entire, is wrapped in paper and well packed, they carry with perfect safety. But where one has plants of his own growing, or when he gets his stock near by, potted plants possess no advantage. If they have been potted so long as to become pot-bound, they are really inferior. With such plants it is best to break up the ball of earth and roots when planting, to give new roots a better chance to start. If plants are dry or wilted on arrival, they should be watered when set, and shaded from the sun a few days till they recover. The removal of one or two of the first leaves is also beneficial in either case, as there is less surface for evaporation. Where one can dig his plants with a lump of earth attached and the roots in their natural position, one has no occasion to use potted ones.

For the amateur there is no better way than to renew his beds every year, as above indicated. The ground can be kept in constant use, and Strawberries invariably produce the finest and best fruit at the first crop. It is often more expensive and troublesome to clean out an old bed than to plant and care for a new one. These new beds should be frequently hoed, to induce the greatest growth possible, and on the approach or advent of freezing weather, the entire bed should be lightly covered with leaves, salt hay, straw, or coarse manure. It is frequent freezing and thawing that injures Strawberry-plants by lifting and breaking the roots. Mulching is of more value in keeping the frost in than keeping it out, and should not be so thick as to smother the plants. In spring the crowns of the plants can be uncovered when danger of late frosts is over.

Among the newer sorts that seem to have made a record the past season over a wide extent of country, of sufficient promise to justify a general trial in a limited way, we may mention Pearl, Jessie, Bubach, Warfield and Haverland.

Montclair, N. J.

E. Williams.

Transplanting Herbaceous Perennials.

A GOOD portion of the hardy herbaceous perennials, if properly cared for, can be transplanted with better results in the latter part, or even the middle, of summer than late in autumn. Early-flowering plants, which start into growth as soon as the snow is off in spring, make their preparation for this the previous autumn. If we will examine closely our beds of such early plants as the Trilliums, Claytonias, Early Anemones, etc., just before winter, we will find the flower-buds for the coming year well formed, ready to start into growth the moment spring arrives. The middle or last of August is not too early to set such plants. It is much better to set them early, so that they can make their autumnal growth where they will remain through the winter, than to transplant them just before winter. There is always more or less loss of fibrous roots in lifting such plants, and, when the transplanting is done early, the plant can recover before winter. Such plants as the Trilliums, Erythroniums, early-flowering Anemones, Thalictrums, Violets, etc., will do better the next season if transplanted early. Indeed, this list, so far as hardy herbaceous plants are concerned, could be almost indefinitely extended. We have transplanted during their flowering season, with the best possible results, such kinds as the Lady Slippers, Golden Rods, Asters, *Senecio aureus*, *Pentstemon pubescens*, the Cone-Flowers, etc. Such varieties should be cut back almost, if not quite, to the roots.

It frequently happens that the driest part of the year comes at this time, and, if such is the case, sufficient moisture, which is very necessary, should be artificially supplied until the plants become well established.

Most of our bulbs for fall planting do better when set early. A new growth of fibrous roots is formed, which enables the plant to start sooner and stronger in the spring. We have had better success with Lilies which were planted early. In fact, we prefer wintering them in a cool cellar to late setting. Many plants, especially Lilies, are greatly reduced by seed-bearing. Plants of *L. Canadense*, taken up while in flower and the bulbs then replanted, will give better blooms the following year than if left to seed in their original location. The same may be said of others. As soon as the seed-vessels begin to form there is a great demand upon the bulb. Those who do not allow their

Lilies to go to seed will get more and better flowers the next season. The California Lilies are among the first to bloom here. We believe *L. Washingtonianum* and *L. Columbianum* are the earliest of these. *L. Humboldtii* is also an early species. These plants seem to require a good deal of time to establish themselves. We find that unless the bulbs are set very early they seldom flower before the second year. Last fall, just before winter, we planted some of the largest and finest bulbs of *L. Washingtonianum* we ever saw. Not one of them has flowered, and only a small fraction of them have come up at all.

Charlotte, Vt.

F. H. Horsford.

Root Cuttings.

THIS easy method of propagation may be used to advantage with a number of plants, and in many cases will be found superior to the usual system of cuttings of the top growth in producing more shapely plants, resembling seedlings in habit of growth. It will also be found that a larger number of

growers on the ground that the plants so produced prove more floriferous than those from cuttings of the roots. In the case of the double varieties, there is also some risk of reverting to the original form from which they have been derived when propagated from the roots. From an æsthetic point of view this would not be a misfortune, as the single-flowered form of either variety is undoubtedly far more beautiful than the double.

The preparation and planting of root-cuttings of the few species mentioned above are very simple operations, and but little experience is necessary to make them successful. In the first place strong roots should be selected and detached from the parent plant without being bruised or crushed, after which they should be cut into pieces about one and a half to two inches in length, and dibbled into the pots or pans prepared for them. These pots should be well supplied with drainage, about one-third the depth of the vessel being a good proportion, and on this a layer of light soil should be placed, and the filling concluded with a layer of clean sharp sand, in which the cuttings are to be placed at such a depth as to entirely

The House of Florence Nightingale at Lea Hurst.—See page 387.

young plants may be raised in a given time by means of root-cuttings than of top-cuttings among certain species, as, for instance, several varieties of *Aralia*, top-cuttings of which require a considerable time to root, and frequently refuse to start into growth for some time after rooting. Probably the most satisfactory varieties of *Aralia* for the amateur grower to experiment with in the matter of root-cuttings are *A. papyrifera* and *A. Sieboldii*, both of which are readily increased in this manner. Many of the *Clerodendrons* can also be propagated in quantity by the same plan, and, these plants being naturally vigorous in root, a supply of root-cuttings is very easy to procure, and seldom fails to give a crop of young plants. As to varieties, it may be added that *Clerodendron Thompsonii*, *C. splendens* and *C. speciosum* are easy to multiply in this way.

Some of the *Allamandas*, for example, *A. Hendersonii* and *A. Schottii*, may also be propagated in this way, and, being of rapid and easy growth, the young plants soon become large enough to flower. It is hardly necessary to call attention to the fact that many of the *Bouvardias* (*B. jasminoides* is not of that class) may be propagated in this manner, though the old method of soft-wood cuttings has been again adopted by many

cover them. The pots or pans should then be put in a house where they can receive some bottom heat (about 75° to 80° being sufficient), and watered enough to keep them damp. If these conditions are maintained, the young plants will most likely be pushing through the surface in from three to four weeks, and will soon be ready to pot off in the same manner as other cuttings.

This operation may be performed at any time of the year, but is usually most successful during the summer months, most of the plants mentioned above being in full growth at that season, and therefore the cuttings start away sooner, and give a greater percentage of plants than when put in during the winter. In the latter season, too, the cuttings are much more likely to damp off.

Holmesburg, Pa.

W. H. Taplin.

Diplarrhena Moræa, offered this year as a novelty by Mr. W. Bull, the English nurseryman, is not likely to be very popular, because its flowers are not of long duration (lasting only a day at most), and they are not numerous enough to satisfy the very large number of persons who want their plants to

bear a blaze of blossoms all the year round. Nevertheless, the plant is not without merit from a gardening point of view, for it is both beautiful and interesting. The three divisions of the flower which correspond to the "falls" of an Iris are broad except at the base, and bear an orange or yellow spot on a pure white ground. These divisions are nearly flat, but are bent slightly downward where the broad part begins. The three divisions which alternate with the falls are spoon-shaped, snow-white, and incline somewhat upward. The stigmas, shaped like those of an Iris, are light purple.

These flowers are about two inches in diameter, and are produced at intervals of a few days nearly all the year; the same stalk bearing them at the tip and increasing constantly in length though not in thickness, and, after flowering for years, producing a new plant at its extremity. A specimen in my possession, which has stood on a high shelf for six years, has sent a flower-stem down to, and along, the ground to a length of about ten feet, but of no greater thickness than an Oat-straw.

Some of the theorists of the present day believe that every prominent spot of color on the petals of a flower is placed there as an "indicator" to guide the bees, so that in getting the honey they may fertilize the blossom. The orange blotch on a snow-white ground would seem to be admirably adapted to this purpose, but, alas for theory, this plant, so conspicuously marked, is perfectly self-fertilizing. Theory often breaks down when put to the test.

Diplarrhena is one of the fibrous-rooted, evergreen genera of iridaceous plants, and contains only two species, natives of Tasmania. Seed of *D. Moraea* is sometimes offered under the name of *Vieusesxia alata*.

Canton, Mass.

W. E. Endicott.

Vanda Hookeriana.—This remarkably pretty species was first described in 1856 by Professor Reichenbach in Seemann's *Bonplandia* from a specimen seen in the herbarium of Sir William Jackson Hooker, who, at that time, was director of the Royal Gardens, Kew, and to whom this plant was then dedicated. Famous accounts of it were heard from travelers who had seen it growing in Borneo on the trunks of trees along the banks of rivers, and fully exposed both to the burning sun and heavy rains. For many years numerous attempts had been made to introduce it alive to England, but, though the plant grew so freely and strongly in its native home, it could not stand a long voyage, and, consequently, when the plants reached Europe they were either all dead or beyond recovery. In this way many hundreds of plants perished, until towards the close of the year 1873 several plants at last reached London alive, and were consigned to the collection of Lord Rothschild, of Tring Park. Here they remained until September, 1882—or about nine years—before one of them flowered. Before this event took place the plants excited little interest, as many believed them to be only slender forms of *Vanda teres*. But when the flowers appeared, great was the surprise and admiration of every one who saw them. Unfortunately, this species seems to be a shy bloomer. Mr. Hill, the gardener at Tring Park, first succeeded in flowering it, and still continues to do so every year. At the present time he has several fine specimens in flower, which present a magnificent sight.

When not in flower, this *Vanda* may be described as having the general appearance of *V. teres*, but may be readily distinguished from that species by its more slender, quill-shaped stems and leaves, the latter being sharper and glaucous green. The short peduncles, which are produced from the upper portion of the stem, usually bear two or three flowers. The upper sepal is erect, obovate, and undulate, pure white, faintly tinged with rose in the centre, and the elliptic-oblong, wavy, lateral sepals are similarly colored. The sub-rhomboidal petals, which are also white, but more heavily washed with rose than the sepals, make a half-twist forward at the base, thus bringing their back surface uppermost, and in a horizontal position. The projecting trilobed lip is quite two and a half inches across, pure white, washed with crimson at the base, and heavily blotched and spotted all over, but especially at the base, with deep crimson-purple. Two or three deep-purple lines run down the centre from two pinkish calli, below which are two obliquely triangular crests, with a very large ovate-falcate auricle on each side, of a very deep purple, becoming paler at the edges, and obscurely spotted. The short projecting column is slightly pubescent, deep crimson behind, and pinky white in front. The surface of the entire flower has a peculiar crystalline appearance, the minute particles, as it were, flashing in the sunlight.

In Borneo, *V. Hookeriana* is subject to great heat—the mean annual temperature there being about 82° Fahr.—and abundance of moisture. It, therefore, requires to be grown in a

warm and damp atmosphere, and may be fixed on rafts or blocks of wood, which should be placed in pots or pans, filled with corks and charcoal, covered with a layer of fresh sphagnum moss. During the summer months a liberal supply of water and frequent syringings must be given, and also a moderate amount of air, so as to ripen the growths and induce the flowers to appear. The plants require a lightsome position as possible, and much less water, for a month or more, after the flowers have been produced.

St. Albans, July 3d, 1889.

John Weathers.

Named Hollyhocks.—For two years past we have been growing and flowering all the named Hollyhocks it has been possible to obtain of the famous Chater strain, numbering, in all, some twenty-five sorts, all of which are distinct, and some for perfect form and rich color well deserving the epithet beautiful. For the guidance of those who wish to grow these fine, old-fashioned garden-flowers, I would recommend among white varieties *Virginalis* as the best, it being pure white and of good form. *Royal White* has a tinge of yellow in the centre; *Enchantress* is a pretty, delicate blush; *Lady Paxton* is pink, with a large flower and very wide guard-petals; *Constance* is pink, large, and very double; *Fairest of the Fair* is a bright rose, large, and very pure in color; *Fanny Chater* is a dark rose; *Reverend Dix* is crimson, and a first-rate kind; *George Eyles* is dark crimson; *Theresa* is crimson and pink, prettily fringed; *Warrior* is salmon-red; *Royal Scarlet* is orange-red; *Imperator* is dark-red; *Plurimus Dulcis*, a beautiful buff; *Joshua Clarke*, sulphur-yellow; *Gem of the Yellows*, an intensely bright yellow; *Royal Purple*, a dark purple, and a fine flower. Every one of those named is distinct and worthy of cultivation. If seeds are sown as soon as gathered, and the plants carefully potted off and protected during winter, most of them will flower during the following summer. Our plants were raised from seed sown early in spring and planted out in the open, where they flowered the following year. This is the best way to get strong, large, flowering stems; many of ours were eight feet high and flowered five feet of their length. We find it necessary here in New Jersey to protect the plants in winter when left in the open ground, and place a covering of leaves or salt hay around them just after the ground freezes and before snow. It would be better still to pot them and place in a cool house, or frame and plant out again early in spring. We do not anticipate any such evil results in this climate from the Hollyhock disease as have occurred in England, where the culture of this flower has been almost given up. Here, in wet seasons, we have had plants slightly affected, but they have invariably grown out of it and been none the worse. Hollyhocks may always be relied upon to come true from seed. Of the thousands we raised, not one showed signs of variation from the description given of them.

Viola pedata.—The pretty Bird's-foot Violet, when planted in quantity, is one of the finest of its genus for the decoration of the garden, not only on account of its unique form, both of flowers and foliage, but on account of its free flowering qualities. The varieties of this plant, *V. p. alba* and *V. p. bicolor* (the Pansy Violet), are prettier than the type. This Violet seems to vary considerably in size of flower and shape of leaves; the best that have ever come under my notice are a quantity received last spring from Tennessee. These were planted in a bed and have become thoroughly established, having flowered for some time, and, in spite of recent heavy rains, remain as bright as ever. Many of the blooms measure one and three-fourths inches in diameter, eclipsing any we have ever seen that were collected in the eastern states. Many are under the impression that this plant is difficult to cultivate, and our own experience was not satisfactory until we tried planting in sandy soil well enriched with decayed vegetable-mould, when the results proved all that could be desired. All the varieties of *V. pedata* come from true seed, but seed is very liable to be scattered by the plant itself, owing to the propelling power of the divisions of the capsule when ripening, so that these must be picked as soon as ever they show signs of maturity and the seed sown at once and allowed to freeze during winter; germination will then take place the following spring. *Viola pedata* should be taken up every third year, the crowns separated and replanted; and this is best done early in the fall, so that the spring crop of flowers may not be diminished, as would be the case if this operation were deferred until spring.

Passaic, N. J.

E. O. Orpet.

Insects and Manure.—Many kinds of insects breed in decaying organic matter, and the soil of land heavily enriched with animal excrement becomes the home for increasing myriads of these. It is not necessary to suppose that all of them prey

directly upon or are indirectly injurious to cultivated plants, but it is certain that few of them do good, and they are all by their burrowings likely to cause more or less harm to crops in their early stages of growth. Many of them are directly injurious, and the presence of such is one of the serious drawbacks to horticultural operations. The gardeners of the past all held it to be essential that manure for the garden should be "old and well rotted," and that it should be used in moderation. This practice has been much departed from, especially in market-gardening, and the result is often seen in the coarse character of the products of such gardens. One very important result of composting is to lessen the attraction of manure for insects when depositing their eggs, especially when the other rule of moderate applications has been observed. Chemical fertilizers do not directly have any attraction for insects, and insects increase in land manured entirely with them only as the organic matter, in the form of the unremoved roots and other portions of the crops, accumulates in the soil. These do not much attract flying insects, but earth-worms increase almost as rapidly in soil dressed with chemicals as in that enriched with barn-yard manure. When possible, it is best not to use land continuously, over long periods of time, for gardens. It is better, when the soil becomes foul with insect life, to throw it into grass for a number of years. But in gardens attached to buildings, and intended to be permanent, some other plan is needed, and none is better than that of the old gardeners, which may be supplemented by the judicious addition of chemical plant-foods. Every gardener of experience knows the incidental value of this method in the avoidance of the foul seeds introduced in crude organic manures. In common practice I have found the increase of soil-insects materially arrested by a moderate annual application of air-slaked lime and unleached wood ashes. A substratum of coal ashes, several inches in thickness, placed below spade depth, has also been found very beneficial. It helps the drainage, is repugnant to earth-worms, and is not in any way prejudicial to the plants.

T. H. Hoskins.

Lettuce.—In spite of all that has been said about hot-weather Lettuces, I never found any fit to eat during our hot summers, and few people care for them at that time. But as autumn comes on, and Lettuce can be grown without so much development of the bitter principle, how to get it at its best becomes of interest. For Lettuce, to be headed in frames, so as to be protected from the early cold, and had in use up to Christmas, make a sowing of Boston Market Lettuce about the middle of August, and another the last of the month, in case the first sowing should get too far advanced early in the season. In the latitude of Virginia the first week in September is early enough. Late in September set the plants in a well-prepared cold frame, and cover with sashes when the nights become frosty, but keep open in day-time. The warmth with sashes closed will be enough for this early crop, which should all be headed before severe freezing weather, leaving the frames empty for the regular winter crops. No sowing of Lettuce for the winter and spring crops should be made, even at the North, before September.

The Forest.

The Forest Vegetation of the Lower Rio Grande Valley.

THE Rio Grande of our southwestern boundary—the Rio Bravo del Norte of our Mexican neighbors—born of the snows and the thunder-clouds of the high mountains of Colorado and New Mexico, for eight hundred miles of its course, from the vicinity of Espinola down to Rio Grande City, flows through an arid and treeless region. Its turbid waters glide thin over yellow sands which fill its bed. Bluffs, which are the verge of high, brown plains, or of black, volcanic *mesas*, and rugged desert mountains—now purple-hued, now gray—crowd upon its narrow valley. Only by the river-side, on flood-washed belts of gravel or strips of alkaline meadows, is an arborescent vegetation possible. Here we see an almost uninterrupted line of Cotton-woods, standing irregular and scattered, and with them a few Black Willows. The roots of these trees drink of the river, and the trees attain to ample, if not lofty, proportions, and maintain, throughout the long, summer droughts, a luxuriant foliage. But in the thin and dry soil of the *mesas* and mountain-sides one can detect scarcely more than shrubs—Sage-brush, Grease-wood, Mimosas, etc.

For more than four hundred miles of its course through

this region our river receives scarcely an affluent to make good its loss of water by evaporation under burning skies and by absorption by a thirsty soil; but below Presidio the Conchos comes in from the North Mexican Cordilleras, the Pecos from the mountains of eastern New Mexico, and the Sabinas and San Juan from the Sierra Madre of Coahuila and Nuevo Leon; and then, with a strong and deep current, it flows out a few miles below Rio Grande City upon the lowland plain bordering the Gulf of Mexico.

From Rio Grande City to the river's mouth is about one hundred and twenty-five miles; but the meanderings of the river over the plain make the distance by water fully three times as great. On its way through this low country the river shifts its channel in some part or other with every annual inundation; hence, on either hand and at greater or less distance, we meet with numerous lagoons, narrow and tortuous, abandoned channels of the river, disused some of the more remote must be since early cycles of the land's history. The connection of these lagoons with the current of the river and with each other has been more or less completely broken by that process by which a lowland river builds up its banks above the level of the adjacent lands, the precipitation of its silt in the first still water of its overflow. Each great rise of the river, however, fills the lagoons, and they remain throughout the rest of the year shallow and slender lakes, winding through silent swamps or woodlands, richly stocked with aquatic plants, and the undisturbed haunts of numerous species of water-fowl.

This low country, with its deep and well-watered soil and with a large amount of humidity in its atmosphere, insured by its proximity to the sea, presents the conditions favorable to the growth of a forest; and to the numerous trees indigenous to the region it offers a choice of three diverse situations:—The raised, sandy banks of its present and former river-channels; the muddy soil of swamps lying without those banks and of filled-up lagoons; and the levels lying above the overflow. The character of the forest, covering nearly all of this region, seemed unique to one more familiar with upland and mountain growths. The larger growing species, excepting such as occupy, by preference, the banks of the river and lagoons, stand scattered, and form low heads which are borne on crooked, irregularly-branching trunks, and the intervening spaces are filled up with smaller species, and with thickets of interlacing shrubs, bound together by widely clambering vines.

It is along the rich banks already described that the tallest and densest forest growths are to be found. Here *Leucana pulverulenta* attains its fullest development, making a tall tree hardly overtopped by *Ulmus crassifolia*, associated with it. It grows with a straight and sound trunk clear of low branches. The largest specimen measured had a circumference of fifty-six inches at three feet from the ground. The species appears to be mainly confined to banks and not to be abundant; but it is esteemed the most valuable tree of the region for sawing.

Here, too, and only here, as far as observed, *Cordia Boissieri* (on higher ground a stiff shrub branching from the base) becomes a tree, large with respect to trunk-diameter at least, but crooked, ill-shapen and low-branching. The circumference of one specimen measured was forty-seven inches; but no trunk approaching such size, and sound and straight for five feet, could be found for the Jesup collection.

Condalia obovata showed its largest specimens on these banks, but its trunks illustrated the extreme of wretchedness of condition, being little better than lacerated shells of living and dead wood alternated. The trunk divides, moreover, from the base upwards into numerous erect stems. Its wood is chosen for fuel because it makes a fire of intensest heat.

Even in these situations *Pithecolobium brevifolium* makes but a slender, straggling tree, and a specimen exceeding five or six inches in diameter was scarcely seen. On higher land it grows in clumps as a mere shrub.

Coming, now, to the wetter, more open situations—most frequently the lagoons or ends of lagoons, which are nearly filled up with mud—we find these to be the favorite habitat of *Parkinsonia aculeata*, a pretty little tree with clean, green-barked stems, seldom more than six inches thick, branching at five or six feet, and bearing heads of fine, drooping foliage and abundant yellow bloom.

Associated with this as an undershrub, half its length submerged during much of the year, perhaps, is *Mimosa Berlandieri*, with conspicuous racemes of rose-colored flowers.

Leaning over the edges of these sloughs stand the ungainly forms of *Acacia Farnesiana*, with crooked, low-branched trunks, and broad, drooping heads.

On the plains, lying above the reach of high water, the tree most conspicuous by reason of its close and symmetrical heads of dark green foliage, and the one most valued, is *Acacia flexicaulis*, the Ebony of Texas. The height of the tree varies from twenty to thirty feet, and the diameter of its trunk from twenty to thirty inches. Its wood is much used for fuel; and, but for the fact that adult trees are invariably hollow at the heart, its reddish-black heart-wood, exceedingly hard and heavy, and capable of taking a fine polish, would make it of great value for cabinet work, etc.

Acacia Greggii, the Cat's-claw Mesquite, in this region and on these lands reaches its best dimensions—a diameter of ten to twelve inches. Its trunk is seldom erect, and its head is low and spreading.

Prosopis juliflora, the Mesquite, occurs here as a tree of somewhat larger size than the last, but of similar form. It contributes largely to the ties used by the railroad on the Mexican side of the river; but so crooked is its timber it requires much pains in hewing and laying to get the ties in line for the rails.

Parkinsonia Texana, the Texan Palo Verde, or Green tree—green as to its entire bark—is at home here as a small tree, with short, crooked stem, sinuous branches, inconspicuous leaves, and showy yellow flowers. Its wood is light, and little used, even for fuel.

Ehretica elliptica, with a trunk diameter of twelve to twenty inches, and a height of some twenty-five feet, is widely scattered throughout the valley, as are, also, in various situations, *Bumelia lanuginosa* and *Celtis occidentalis*, the Palo Blanco of the Mexicans, the *Bumelia* having a diameter of six to eight inches, and the last of one or two feet.

Diospyrus Texana, the Texan Persimmon, is a small tree, seldom a foot in diameter. Its fruits are fairly edible in a region where wild fruits are few. They are globular, one-half to three-fourths of an inch in diameter, black when ripe, and covered with a pubescent, leathery skin.

Kæberlinia spinosa here branches from its crown, but its divergent stems rise to a height of ten or fifteen feet, and may be found six inches or more thick.

The undescribed Palmetto, discovered by Berlandier below Brownsville and Matamoras more than fifty years ago, extends up the valley for a dozen miles or more above Brownsville. Aside from its uses in sub-tropical ornamentation, it is a most valuable plant. Its stems, twelve to eighteen inches thick, and as many feet in length, are used for posts and piles, because practicably indestructible by wet; and its leaves to make a clean and durable thatch.

A list of the shrubs of the region would include, principally, *Leucophyllum Texanum*, most striking of all, and surpassingly lovely, with profuse purplish bloom surmounting velvety white foliage; *Mimosa malacophylla*, a horribly hook-spined climber, which spreads over surrounding shrubs a sheet of white flowers; *Salvia ballotifolia*, a blue-flowered sage, five or six feet tall; *Lantana Camara*, of so extensive range, with orange-red flowers; *Forestiera angustifolia*, *Porlieria angustifolia*, *Celtis pallida*; *Karwinskia Humboldtiana*, with *Clematis Drummondii* and two species of *Vitis*, probably varieties of *V. cordifolia* and *V. æstivalis*, to bind together the stiff and spiny thickets formed by several of the last-mentioned, and masses of the white-flowered *Baccharis glutinosa*, and the pretty yellow-flowered *Nesaea salicifolia* by the water's edge.

Palms from Seed.

To the Editor of GARDEN AND FOREST:

Sir.—The excellent article on Seedling Palms in GARDEN AND FOREST of July 3d, omits mention of one method which can be adopted successfully with some species which require a long time—often several years—for germination. This is to “stratify” the seeds in pots in a mixture of chopped sphagnum moss and pounded charcoal, which keeps the seeds sweet and fresh and allows many more to be housed in the same space, provided they are examined occasionally and the sprouted seeds removed and potted off. This economy of space is important where, as with all the species of *Acrocomia*, the seeds rarely germinate in less than four years under the most favorable circumstances, and often require six and eight years.

During the past five or six years I have endeavored to get a small quantity of the seeds of each Palm offered by European seedsmen in each year, excepting only the tenderest equatorial species. Usually I preserved a specimen seed of

each packet, and a review of the collection thus formed shows that it is rather the exception than the rule that the same species should be sent out twice under the same name by any dealer.

This, of course, does not apply to sorts like the so-called *Latania Borbonica* and a few others which are sold in vast quantities, but it does apply to nine-tenths of the species catalogued, and I often wonder whether the growing Palms offered by nurserymen at home and abroad must not be similarly mixed and untrue to name.

An illustration or two may not be out of place. I am just potting off the fourth species of *Phoenix* received as *P. Siamensis* from the same dealer within three years—one sort imported from Siam, the others said to be grown in southern Europe. Some of these lots of *P. Siamensis* seeds are more distinct from each other than are the seeds of any of the twenty-six other alleged distinct species of *Phoenix* that I have grown. I have had five species sent as *Cocos Bonneti*, and one of the most extensive and trustworthy dealers in Germany habitually sends out as *Borassus flabelliformis*, seeds which have but one-thousandth part of the bulk of the genuine, and probably belong to a species which never grew naturally nearer than six or eight thousand miles of the habitat of *Borassus*. Of course, the dealers not being experts in the determination of Palms, necessarily give the names as furnished them by collectors all over the world, but in discussing the hardness or other characters of any Palm which has been raised from such seed, it is well to bear in mind the great probability that the name by which the Palm goes is not the one which belongs to it.

Oviedo, Fla.

Theodore L. Mead.

Dig the Potatoes Early.

To the Editor of GARDEN AND FOREST:

Sir.—The Potatoes are rotting badly. An inspection of several large Potato-farms shows that the vines are prematurely dead, and the crop will not only be short, but of poor quality. This rotting is due to a well-known fungus, *Phytophthora infestans*, which usually makes its appearance upon the upper leaves, and afterward extends to the stems, finally reaching the tubers. One of the most favorable conditions for the growth of this mildew is a moist atmosphere. If to this is added a medium summer temperature, the Potato-field is quite apt to be “struck by the rot.” The succulence, dense shade, and nearness to the ground of the Potato “tops” in July all favor the rapid development of this mildew, which is a first cousin of the one that preys upon the Grape, and this is also abundant this season.

July has been a very wet month, as the disastrous floods in many valley-towns and cities do not permit us to quickly forget. In fact, the past four weeks have been of that peculiar character known as “close” or “muggy,” when moulds thrive in every possible place. With the Potato crop, since the advent of the rot fungus in 1840, the wet summers have been the seasons of decay of the tubers.

The question now is how to best save what crop there is. If moisture and medium temperature favor the rot, it is evident that it is wise to get the tubers out of the soil as soon as possible. The moist soil, warmed by the excessive sun since the rains, furnishes the best conditions for decay, and the longer the crop is left unharvested the poorer it will be. As a precaution against contaminating the exposed tubers, the vines should be raked into heaps and burned. This is an inexpensive task, and serves to destroy millions of spores of the rot fungus. After leaving the Potatoes upon the ground until the surface is thoroughly dried, they should be stored in a dry, cool, airy place. This may be in a barn or loft until cold weather comes, using shallow bins, or even shelves or the floor. Avoid large heaps, and frequently inspect the crop and discard any decayed tubers before they spread the rot to their neighbors. Air-slaked lime may be sprinkled, a handful to a bushel, upon the Potatoes as they are stored.

N. J. Exp. Station, Aug. 7th, 1889.

Byron D. Halstead.

Ribbon Grass.

To the Editor of GARDEN AND FOREST:

Sir.—At Nonquit, Buzzard's Bay, the Ribbon Grass (*Phalaris arundinacea*, var. *picta*) is found growing abundantly in a low plain adjoining the salt marsh, but in 1888 did not flower. Is this inaptitude to flower a characteristic of the variety? This form is spoken of by authors of the earlier period as occurring wild and as cultivated for ornament. It is figured

by Perra and Lobel in their "Adversaria," 1570, under the name of *Gramen sulcatum vel. striatum album*, as also by Dalechamps in 1587; by Lobel in 1591 and Tabernaemontanus, 1590; Gerarde, 1597 and 1636, and by J. Bauhin in 1650. It is described by Camerarius in 1588; Bauhin, 1596, 1623 and 1658; Parkinson, 1629; Ray, 1688; Morison, 1699; Tournefort, 1700; Scheuchzer, 1719; Boerhaave, 1727, in two varieties, and by Linnæus in 1737, in his "Hortus Cliffortianus." In 1742 Weinmann gives a colored figure. All these figures represent the grass in bloom, and nearly all our references speak of the plant as variegated with white, and some say white, greenish-white or of a purplish cast. Not one refers to the golden variegation which characterizes the Nonquit plant. The vernacular names given by Bauhin in 1658 are: German, Spanischgrass, Welschgrass, Strimechtiggrass; Belgian, Widthgheestreept Gras; English, Ladie Lace Grasse, or Painted Grasse; French, Aguilletes d'armes. Bauhin also says it is grown for ornament in Germany, England and Belgium; the seed first brought from Spain, although also wild in Savoy and neighboring France. Linnæus, in his "Species Plantarum," says it grows in Europe in moistish places along river-banks.

This grass is the *Arundo colorata*, Ait., *Digraphia arundinacea*, Trin. var., Striped Grass, or Ribbon Grass, Benth and Hooker. In my library I find no record of the golden variegation, nor of the name Ribbon Grass until quite recent times. Gray, in his "Manual," says, *Phalaris arundinacea*, L. var. *picta*, the leaves striped with white. The authors of *Flore Naturelle et Economique*, Paris, 1803, say "il y en a une variete a feuilles panachees, qu'on nomme chiendentruban."

Is this golden variegation common, or have I been mistaken in identifying the species not seen in bloom? This latter supposition does not seem probable, yet I think it is the fact. It has been suggested by some authors that this variegated form readily reverts or changes to the common form, and it is even said that it thus changes when removed from dry to humid soil. How far is this idea correct? One thing is indeed noteworthy—that the variety, both wild and cultivated, in its white form, has remained constant despite diverse climates, from 1520 to the present time. It would be interesting, also, if it were determined whether the many distributions have been from a common origin, or whether this diversity has appeared spontaneously in diverse regions. Who can throw light on this point? Gray notes the species as indigenous to this country, and the variety as introduced. Has any one noted the variety in sparsely settled regions, or in what may be called a wilderness? Does it occur along with the common form? I trust some observant reader of GARDEN AND FOREST can answer some of these queries.

South Framingham, Mass.

E. Lewis Sturtevant.

Insensibility to Odors.

To the Editor of GARDEN AND FOREST:

Sir.—The instances given by your correspondent "T. B. F." regarding insensibility to certain odors were quite interesting. I can add but one touching the sense of smell. Violets, whose fragrance is said to be delightful to most persons, and which to Perdita were "sweeter than the lids of Juno's eyes, or Cytharea's breath," have, to the writer, no other odor than that which the sister of "J. B. F." finds in the *Datura*, namely: "A certain earth-like smell proper to growing things in general."

With regard to the sense of taste, however, I recall the case of a prominent Chicago physician, who declared that he could detect no difference between the taste of Castor-oil and of Olive-oil. To test the question, his wife dressed a salad with *Ol. Ricin.*, which he partook of with great gusto, but not without enjoying afterward all the remedial benefits of the drug.

Santa Barbara, Cal.

Frank M. Gallaher.

[Perhaps the last instance cited is only another example of inability to detect certain odors. The peculiar "flavor" of castor-oil is conveyed through the olfactory nerves. Children are directed not to breathe through the nose while taking this medicine, and in this way they escape its disagreeable "taste." The subject has interested many readers. One writes: "it seems like an affectation to say that Mignonette has any odor. It has no more to me than a clean china plate." Another writes that the members of his family frequently praise the delightful fragrance of the flowers of a large vine of *Clematis crispa*, now in full bloom, while he has never yet been able to detect the slightest odor in these flowers.—Ed.]

Recent Publications.

The Garden's Story; or, Pleasures and Trials of an Amateur Gardener, by George H. Ellwanger. New York: D. Appleton & Co., pp. 345.

Under this somewhat fanciful title Mr. Ellwanger has written a little book in which are agreeably mingled the practice and poetry of hardy-flower gardening. Beyond all question a natural arrangement of hardy herbaceous plants and shrubs and climbers is the most effective and satisfactory way of adorning home grounds. Without doing any violence to its essential character, such a garden can be adjusted to the requirements of a village lot, the enclosure about a country farmhouse or the more pretentious surroundings of a suburban villa. It will unfold new charms every day, from the hour when the first Snow-drop shows its "vestal white and vernal green," until the last Monk's-hood is faded and frozen. Even the winter does not destroy such a garden, as it does one in which bedding-plants and ribbon-lines are the principal features, but simply enables it to rest for an awakening into fuller life. Next spring the Daffodils and *Spiræas* will be more abundant and beautiful than they were last spring; the vines will clothe rock and trunk and trellis with richer drapery; the shrub-border will show a nobler sky-line and deeper shadows with bolder headlands and more spacious bays, about and into which the greensward flows, and the whole design will have made a visible advance toward a more perfect expression of the thought of its creator. A garden of such universal adaptability, of such constant and varied beauty, and with a continuity of life which enables its owner to plan hopefully for coming years, can well be made an object of affectionate interest and wholesome recreation, and is by no means an unworthy subject for a writer like Mr. Ellwanger, whose taste is refined without being fastidious, whose love of nature is unaffected and catholic, and who can speak on matters of practice out of the stores of abundant experimental knowledge.

Mr. Ellwanger wisely refrains from laying down any specific garden-plans, for no two gardens worthy of the name were ever fashioned after the same pattern. He attempts no elaborate description even of his own garden. But, in a pleasing and instructive way, he writes from different points of view of the various elements and features of the garden and their changing phases as the seasons hasten on. The novice need not expect to find a garden already prepared for him on paper, with maps and specifications, but he will find, when he lays down the book, that his mind is furnished with a hundred delightful pictures, like that of tall red Lilies rising from a bed of Sensitive Fern, which will guide and restrain him when he comes to make a garden of his own as no mere formulas or precepts could. And those who already know what it is to enjoy gardens of their own will follow with sympathy this chronicle of a garden year in which their own trials and triumphs are so pleasantly revived. The book is not a formal treatise on garden art, nor a text-book of hardy plants, nor a manual of cultural instruction, and yet it contains a careful selection of herbaceous perennials, shrubs and vines, with admirable suggestions for arranging them, and practical counsel as to what is needed to make them take hold of the ground and grow. A chapter on the rock garden, as distinguished from the chaotic stone-heap, popularly known as "the rockery," and descriptions of the wild garden and wood garden, reveal a deeper feeling for those aspects of nature that are dainty and shy, or wild and wayward, than is usually expected of one who celebrates the trim graces of a more civilized garden. This appreciative love of nature will not permit Mr. Ellwanger to think of his garden as fenced in and complete in itself, but, as it makes its history with the revolving year, a chronicle of the wild flowers as they blossom runs beside it. The birds and butterflies, too, are named and welcomed in their order, and to this story of the interwoven lives of plant, and bird, and insect, are added many extracts from, and allusions to, the literature of flowers and seasons.

In matters of detail we should feel constrained occasionally to dissent from Mr. Ellwanger's judgment, as, for example, when he pronounces a well-grown *Lilium auratum*, with a stalk five or six feet high, supporting a dozen or more deliciously-scented blooms, as the "grandest of all hardy flowers." Such a specimen, if properly placed, might be made most effective in the garden, but we should hardly rank it the "grandest," even if the word is used in a restricted sense to mean the "stateliest," of flowers. The list of desirable plants is not meant to be exhaustive, and yet, when so much praise is given to the large-flowered garden forms of the *Clematis*, one can hardly understand the omission of such fine native species as *C. coccinea*, with its coral-colored flowers, *C.*

crispa, with its fragrant, bright purple flowers, and *C. Pitcheri*, rather coarser than the others, but, like them, blooming all summer long. Our common Virgin's Bower (*C. Virginiana*) would grace the more elaborately dressed portions of a lawn-border as becomingly as it would mingle with the untamed intricacies of the wild garden, and so would *C. Vitalba*, the Traveler's Joy, of Europe. And how could one be satisfied with his garden if he missed in it the beauty and fragrance of *C. flammula* in August? We should want *C. graveolens*, *C. integrifolia*, and several more—indeed, we could dispense with most of the Jackman class of hybrids with less sorrow than the loss of one or two of these species would bring. But these are questions of detail, and certainly no suspicion of narrowness or illiberality in selection will lie against a book in which the prim, old-fashioned flowers of the farm-garden, the tangle of Green-brier and Bitter-sweet in the wild garden, the Gold-thread and Prince's Pine and Beech-ferns of the shaded wood-garden, and the cool mosses and minute Alpine flora of the rock-garden, are all welcomed with sympathy and appreciation.

It is to be hoped that this dainty little volume will have many readers, for it can hardly fail to accomplish the worthy purpose of its author "to stimulate a love for amateur gardening that may be carried out by all who are willing to bestow upon it that meed of attention it so bountifully repays."

Notes.

The young city of Victoria, in British Columbia, has just voted \$15,000 to improve its public park.

Near Bethlehem, in Montgomery County, Tennessee, stands a Tulip-tree which is six feet and one inch in diameter, five feet from the ground, and apparently of the same size up to the first limb, which is seventy-five feet from the ground. The next limb is a hundred feet from the ground. The *Southern Lumberman* reports this tree as probably sound, and estimates that it contains more than fifteen thousand feet of lumber.

The agents of the California State Board of Horticulture are now raising the Australian ladybird in such numbers that colonies are furnished to all applicants whose trees are infested with the cottony cushion scale. These imported insects have proved effective destroyers of the scale, and there seems to be a reasonable ground for hope that this most serious enemy of the Orange, the Lemon, and other trees of that family can now be held in check.

Vaccinium hirsutum, of which an account was given in GARDEN AND FOREST for July 31st, has ripened fruit at the Arnold Arboretum. It is fully as large as the fruit of the common Huckleberry (*Gaylussacia resinosa*), and is of a shining black color, and has quite an agreeable flavor. As it appears in cultivation, the berry is not so densely hairy as it is represented in the figure, which was drawn from wild specimens sent from the native habitat of the plant.

Mr. F. L. Temple, of Shady Hill Nurseries, writes from London in regard to English Gooseberries, which he had been led to believe were far superior to any thing grown in America. But upon testing some of the sorts most highly praised he found them coarse or watery, or of low quality in some particular, and altogether disappointing except in size and appearance. No patriotic American will admit that the best of them are as finely flavored as our native varieties.

A year ago we published a note from M. Naudin (GARDEN AND FOREST, I, 289), who was trying for the third time to naturalize in Provence the Japan Clover (*Lespedeza striata*), which has proved so useful as a forage plant in our southern states. He was not very sanguine of success in that dry climate, but had sent seed to Brittany and other places with some hope. He now writes that the Clover will certainly not thrive in Europe. It has been moderately successful in Algeria, but even there the amount of forage yielded is insignificant.

Mr. William Falconer reports, in the *Rural New Yorker*, that he planted, in May, some Lima Beans, pushing them into the ground, eye down, and every seed grew. Seeds of a second lot were laid flat and covered loosely, and those of a third lot were laid the same way, but the soil was tamped firmly on top of the beans. All the last lot sprouted and grew as well as those planted with the eye down, but the loosely-covered ones nearly all rotted. Mr. Falconer has not found that pinching back the vines has hastened the maturing of the beans a day, and thinks that allowing the vines to climb on poles at will is the best and least troublesome practice.

Inasmuch as there is usually some basis of truth for any widespread popular belief, the inquiry was made in these columns

not long ago, whether there was any foundation in fact for the prevalent opinion that the Beech-tree is never struck by lightning. In a late number of *Science*, Dr. D. L. Phares gives an account of a remarkable flash out of an almost clear sky which struck a Beech-tree, killed one ox, and stunned all the others of a team of six which happened to be drawing a wagon under its branches. Two men in the wagon were stunned. Dr. Phares adds that this is not the only instance which has come under his observation where a Beech-tree has been struck.

Mr. A. H. Fewkes, of Newton Highlands, Massachusetts, who makes a point of testing all the new varieties of Sweet Peas, reports that the only one of this year's introduction which came up and showed enough flowers for comparison was *Blanche Ferry*, and this is apparently an improved *Painted Lady*. The two are much alike, but when seen together the new one seems to be brighter in color and to have a purer white keel. In habit it is very free. *Boreatton* and *Splendor* of last season are proving fully as good as they promised, and, with *Invincible Carmine*, *Princess Beatrice*, *Bronze Prince*, *Orange Prince* and *Adonis*, show a very decided improvement on the older varieties.

Professor Bailey has been making some experiments with seeds with a view to determine the influence of certain conditions upon germination. The most interesting of several conclusions reached was that drawn from tests with different quantities of water. Sprouting was proved to be decidedly more rapid and general where the seeds received less than the usual amounts of water given in green-houses. Seeds of Tomato, Cucumber, Pepper, Lima Bean, Carrot, Celery, Lettuce and *Cobaea scandens* were all tried, and almost without exception, of those planted in soil kept simply moist, a larger percentage sprouted, and sprouted more rapidly than of those in soil more profusely watered. Professor Bailey explains what the latter phrase means by the statement that the seed-pans were shallow and had more than ordinary drainage, so that no stagnant water could remain, and the water was rarely applied in such quantities as to cause any drip from the pans; that is, the so-called profusely-watered plants received no more water than is given in many houses.

The garden at Glen Eyre, Southampton, is one of the most interesting in England, owing to the experiments in growing exotic plants out of doors, which were made there some years ago by the late Mrs. Eyre Crabbe. "The house," says a recent description in the *Gardeners' Chronicle*, "looks east and stands right at the head of a deep, narrow valley or gorge. . . . A series of steep terraces, profusely planted and richly decorated with flowers . . . filling the beds, vases and baskets, gives to the garden a resemblance to some scene in Italy rather than in England. Away on the steep slopes on the sides of the valley there are numbers of very noble conifers . . . truly marvels of production considering that the slope" is in many places so steep that "it is difficult to stand erect upon it. Beyond and about these conifers are huge masses of Rhododendrons, Azaleas, Kalmias, etc., all exhibiting wonderful growth. Especially on the north side of the valley with its southern aspect there is a perfect forest of Rhododendrons, the huge heads standing up like miniature mountains and ablaze with tufts of flowers in vast quantities." But the most remarkable feature of Glen Eyre is its masses of Camellias which Mrs. Eyre, full of faith in the hardiness of the plant, set out by hundreds and which have justified her confidence by the most luxuriant growth. The gardener's house stands upon the north slope of the valley and between it and the mansion are a large number of fine Camellias growing with other plants in a border, many of them being ten feet in diameter. On the wall of the stableyard is trained a dark red Camellia ten feet in height and fifteen feet broad, and another twelve feet in height and eight feet in depth from the front to the wall, with companions of almost equal size. Everywhere else on the grounds Camellias are plentiful in many varieties, sometimes massed, sometimes standing singly. "The finest specimen, the lion of the collection, is a grand plant of the old double-striped which stands on the upper terrace, or house-level, in a very exposed windy spot, but looking south. This splendid fellow is some ten feet in height and forms almost a perfect square of thirteen feet each way, and blooms profusely every year." The success of the gardens at Glen Eyre is all the more remarkable because it is not very many years since they were started and the soil was "originally very poor, producing nothing but coarse Heather with some Scotch Fir. The skill and perseverance of the gardener have, however, transformed the unkind-looking wilderness into an earthly paradise."

Design in the Surroundings of Houses.

A FEW months ago Mr. Charles Eliot, the well-known landscape-gardener, read before the Massachusetts Horticultural Society a most instructive paper with the above title. Assuming that every one desires to have his house and grounds beautiful as well as convenient, Mr. Eliot insisted (1) that the real beauty of what he aptly termed the "house-scene" is never derived from added decoration, but must spring directly from the scene itself; and (2) that this beauty can be attained only when the house and its surroundings are thought out together as one design and composition. These truths are fundamental, and yet the ordinary practice is to build houses without much reference to the land about them, and often with no thought of so essential a matter as the way of approach. After the building is complete some attention may be given to making the scene a pleasant one to look upon; and this is usually done by inserting flower-beds or specimen plants here and there, without reference to the nature of the ground.

Illustrations of the truth of both these propositions can be found in town and country, but it is our purpose now to present a portion of Mr. Eliot's paper which relates to the suburb—a district where roads and houses dominate the landscape. Generally the ground here is level, the boundaries straight, and the lots comparatively small. In such neighborhoods the architect's share in making the scene is predominant, and an error in the style of the house is fatal to the effect of the house-scene. A many-angled and many-gabled building on a smooth site, in a straight-bounded enclosure, is out of keeping, and so is a tangle of bushes and boulders, or a sharply-curved approach-road. This does not imply that the curve must be forbidden and the path made straight when the streets are curved or when the house-door is reached most easily by a curved line, but it does mean that purposeless curvature, such as prevails in many suburbs, should be shunned.

But we leave Mr. Eliot to speak in his own language:

"Awkward and breadth-destroying lines of approach are the rule in the suburbs, and the architect is often responsible for them, for he frequently places the house door in such a position that the path or road leading to it must necessarily cut

the ground before the house into lamentably small pieces; and he does this, too, when a little thought might perhaps have brought about that happiest of all arrangements in which a stretch of grass as long or longer than the building is brought without a break up to the house-wall itself. No subsequent planting can obliterate mistakes in these controlling elements of the suburban house-scene, the house and the approach; and no planting can accomplish what it otherwise might, if, by reason of unmindfulness of the effect of the house-scene as a whole, the framework of the scene is wrongly put together.

"It is seldom that a suburban lot, after the house and approaches are built, retains much of its former vegetation. A few large trees may survive the necessary gradings, but the natural ground covering is generally killed out. On the completion of the grading, grass is sown, and from the resulting sheet of green, the house-walls and the boundary walls or fences rise abruptly. It is surprising to see, as one may everywhere, well-designed houses, adorned within with much rich ornament, and probably inhabited by people who appreciate art and nature, standing thus naked in naked enclosures. The contrast between a handsome building and bare surroundings is sufficiently obvious in summer, but in winter in this New England climate it becomes positively startling, so that it is difficult to understand how educated people can fail to be impressed by it, and how they can longer refuse to comprehend that the house and the house-ground should be treated in the same spirit.

"From another point of view this nakedness is equally surprising. Here in the suburbs is an opportunity for adding to all the usual advantages and ornaments of city life the new and delightful pleasantness of verdure, fragrance, and bloom. As a matter of fact, it is an appreciation of this opportunity that causes the first plantings in most suburban grounds. Trees and shrubs, selected for their profuse flowering or their striking habit, are set out here and there, and brilliant beds of flowers are perhaps added. Desire for ornament of this sort grows by what it feeds on, and causes the pressing demand upon the nurseryman for plants of marked appearance. The effect upon house-grounds resulting from planting undertaken in this spirit is generally unfortunate. Specimens of many sorts planted promiscuously on a lawn compose an interesting, though ill-arranged museum, but not an appropriate setting for a house. They wholly destroy all that breadth of effect which is so difficult but so important to preserve in small grounds; if they grow large they interfere with the prospect and the aspect of the home, and, whatever their size, they give the scene the appearance of having been adorned to make a show, and remind one of the saying of the Greek sculptor, who charged his pupil with having richly ornamented a statue because he knew not how to make it beautiful.

"An ambition to possess a collection of handsome, curious and rare plants, like the similar passions for shells or minerals or precious stones, is entirely praiseworthy and honorable, and may well be indulged *ad libitum*, provided a place can be set apart and fittingly arranged for the purpose, as cabinets are prepared indoors for collections of curios of all sorts. Out of doors a flower-garden is such a cabinet, and there is no reason that tree and shrub gardens should not be similarly arranged by those who desire to grow many striking sorts. In formal and highly decorated pleasure-grounds, specimen trees are already used in this way, and with good effect. Before stately buildings and in connection with terraces and formal avenues, appropriate specimens are always in keeping; but in New England house-scenes not especially arranged to receive them, they destroy the last hope of good general effect.

"With what object, then, should the planting of the suburban house-ground be planned?

"I answer, with the object of helping the building, and the other controlling parts of the scene, to form an appropriate and pleasing whole. In the very smallest front yards one thing which should seldom or never be omitted can be accomplished just as well as it can be in grounds of larger area, that is, the connecting of the house-walls with the ground by means of some sort of massing of verdure. Shrubs planted near the base of the house-wall remove at once all appearance of isolation and nakedness, and nothing can help a building more than this. Here, if nowhere else, some evergreens should be used, and it is fortunate that in a climate in which hardy evergreens are few, the stiff sorts, like the box and arborvitæ and the junipers, are all entirely appropriate in close connection with a building. The more irregular the structure, the more varied in detail may be these wall-plantings, but if the house is of formal design, a hedge-like row of bushes may be best. The older houses in many New England villages often have bushes set out thus along their walls; and at the Longfellow

Place in Cambridge the same purpose is accomplished by a low-terrace balustrade, half covered by creepers.

"In grounds a little larger than the smallest, the securing of some breadth of effect by means of grass should be attended to next after the wall-plantings. If there is space enough to get this openness and, at the same time, have some bushes near the street line as well as next the house, so much the better. Plant nothing which will grow to a size disproportionate to the scene. Large trees on small lots are not only inappropriate, but they shade the ground excessively and make it difficult to grow the indispensable ground-covering of shrubs. Maintaining sufficient openness, plant shrubs also against the naked fences, or grow climbers on them if space does not permit of anything more. In large grounds give the house a setting or background of appropriate trees. Where, as in New England, climate keeps deciduous plants leafless half the year, plant for effect in winter as carefully as for the summer; use all possible broad-leaved evergreens and all the cheerful fruit-bearing and colored-stemmed shrubs, and for summer add various sorts of foliage and bloom, but keep the whole scene to its own appropriate style, admitting brilliant decoration only in detail, and conspicuous single objects only rarely if at all. If many flowers are desired, they should be grown in a garden or in formal beds close beside the formal building. The permanent scene can be helped only in its details by the temporary beauty of bulbs and herbs.

"To appreciate that a house-scene depends for real effectiveness upon its general design and not upon decoration, one need only look upon some such ground as that of the Longfellow Place, before mentioned, where the planting consists of two Elms supporting the sides of the house, creepers covering the balustrade at its base, and lilacs flanking the balustrade and forming a hedge along the street-wall. The open space of grass is well proportioned, and the whole scene is one which, in its formal symmetrical style, is not surpassed for effectiveness in all New England. Suitable general design is just as effective in any other conceivable style."

Among Oaks, Madrones and Redwoods.

I HAVE just returned to San Francisco after a visit to that portion of the Coast Range that lies between Austin Creek and Russian River, in Sonoma County. From Cazadero, on Austin Creek, eighty-nine miles north of San Francisco, I drove about twelve miles east, over a mountain road of wonderfully varied beauty, to Guerneville, on Russian River, and the Redwood forests there; thence southwest along the Russian to the mouth of Austin Creek, and up that stream to Cazadero again, a total round of about thirty miles, and, all in all, one of the most characteristic drives to be had anywhere in the California mountains.

The Azaleas were still in bloom in very large masses on Austin Creek, near Cazadero. The Bohemian Club of San Francisco have their summer camp here, in a grove of fine Redwoods, on a "flat" between the stream and the mountain. The twenty acres of timber are valued at \$20,000, and are a part of the Montgomery estate of over 1,200 acres, on which no Redwoods are to be cut for many years. Outside of this property the waste and the ravages of fires are frightful. In almost every side-gulch are the remains of old lumber-camps. A few men are working up the stumps for fuel for the railroad company. In places the forest fires have destroyed the soil and leaf-mould, leaving only the rocks, and even the hardy Redwood sprouts have not survived.

Ascending the mountain ridges east of the beautiful Redwood forests of Cazadero, the most striking features on the summits are the groups of Oaks, both White and Black, and of superb size and proportion. The way in which Oaks cluster on the vast rock-masses that rise out of the mountain-tops like ancient hill-forts is almost worth a separate paper. They seem to crown old castle ruins or fallen Cyclopean walls, and the form of the stratified rock-ledges adds to the illusion.

The Madrone is one of the great features of this mountain region. Hanging over a wild cañon was one whose trunk girthed nearly twenty feet, and in spread of boughs it was as large as a Valley Oak. Sometimes, for miles of travel through the woods here, the scarlet Madrone stems, gleaming under their broad green leaves, illuminate slope after slope, and height after height. Stems of from half an inch up to five or six inches in diameter stand in thickets with young Douglas Spruce and Tan-bark Oaks in blossom. The color of the Madrone, though a real scarlet at its brightest, begins in browns, greens and yellows, and has more chameleon shades in sun and shadow than any painter could hope to imitate. About the base there are dark browns, streaked with yellows and

dull scarlets when the thin husk of the outer bark falls apart in veins or breaks off in flakes, till one can gather a handful at the base of the tree. Below the beautiful crowns of leaves, as large and almost as dark as the leaves of *Magnolia grandiflora*, the new wood is light, clear-hued green, yellowing downward for several feet. Then comes the reign of a scarlet, so delicate, so rich and firm and healthy, that one half believes the remark of an old pioneer who was once lost at night on these mountains. He said he "had to see his way by the Mathrona stems; they kep' the light an hour longer'n anything else."

No one knows the beauty of the Broad-leaved Maples who has not seen them in the mountain woods. In the lowlands they are plain Maples, very fair and large, with brown trunks and large green leaves. On the mountains they have lovely white and gray stems, and grow tall and graceful in clumps of from ten to a hundred, at the heads of well-watered gulches. Indeed, the bark become at times so resplendent for color that I am tempted to say that these trees rival the New England White Birches, and to call them the California Birch-Maples of the Coast Range. The Buckeye shows much of the same gray-white mottling of the bark, but the Maple is far the finest in general effect.

There are one or two farms on the very top of the mountain, and hay-fields, orchards, and vineyards extend across the heads of the ravines, but there will never be any more tillage here than now. The mountains are too steep and rocky. It is chiefly deciduous growth on the heights, chiefly conifers in the gulches, and it is a natural forest-land for miles on miles. The more intelligent men in this region see and acknowledge the necessity for strict forest-laws before it is too late, and I am told that in the best forest-belts there is comparatively little pasturage, and few cattle or sheep are kept here. The mountains are too steep. If two hundred and fifty square miles of this region, extending north and south, could be put under a forestry commission, or some safe supervision, it would secure the permanence of all the streams that head here, and water a territory half as large as the State of Connecticut.

Guerneville is an old lumber camp, but it is situated on a broad, deep and beautiful river, one of the largest in the state, next to the San Joaquin and Sacramento, and it has an immense tributary country of valleys, lesser foothills, and "land for the fruit-grower." All about it are giant stumps of fire-swept Redwoods, with orchards and pastures among them. The original forest that stood here along the Russian River was a magnificent one, but there is hardly a tree left, nor any young growth. Men are beginning to saw the great stumps off close to the ground, and work up the wood for fuel and ornamental veneers, even down to the larger roots. I am told that the blackened stumps in this district are estimated to contain two million feet of valuable and marketable Redwood. They are dead beyond peradventure, and this is the best thing to do, of course. But it makes a man heart-sick to see how clean the sweep has been. Fifty of the largest trees left scattered over the valley would have glorified Guerneville for ages to come. In the very streets stand stumps of trees that were thirty and forty feet in girth and three hundred feet in height.

The Guerneville "basin" extends east. At the head of the little valley Col. J. B. Armstrong, a prominent Ohioan, who settled here after the war, owns 800 acres of as fine Redwood as exists in the state. The best 400 acres of this he will leave uncut, and dedicate it to public use in some educational and permanent way that will preserve it forever. I spent long enough in the heart of this primeval Redwood forest to feel its almost unique value. It has not been smitten by an axe, nor is it pastured. The forest shows every type of Redwood growth: single trees, clumps of twos, threes, fours, and so on, up to circles of ten or twelve, about the roots of some giant of an earlier generation; seemingly solid walls of green banked against a ravine; open lawns, where tall Laurels and Oaks grow, slender as the Redwoods themselves. The very side-sprouts that grow up beside the Redwoods are as large as the pines of many other countries. The largest tree I measured was forty-seven feet in girth, and three hundred and twenty-five feet high. If Col. Armstrong's plans are carried out, and this superb forest is preserved, it seems to me that it will prove in the future one of the most valuable of gifts that the people of any American state have received from a citizen. What form the gift will take, or how its permanent value will be maintained, I have not asked. Col. Armstrong loves his forest with a great and abiding love, and he can be depended upon to secure its perpetuity for future students, botanists, and lovers of trees.

Niles, Cal.

Charles H. Shinn.

The so-called "Grit" in Apple-twigs.

IF two Apple-twigs of equal size be cut with a budding-knife one may exhibit more of that quality which is known as "grit" than the other. Pear-twigs are more "gritty" than Apple-branches of the same size, while Cherry-twigs have less of this quality. With many horticulturists this grit, which is a resistance to the knife not easily defined, has been employed as a test for hardness, and, therefore, is a quality of much interest to the fruit-grower and nurseryman.

In determining what the substance in question is, we may note that a growing twig is not gritty, this quality being associated with maturity of the stem. Thus, if we cut the tip of a "water-sprout," and compare the resistance there met by the knife, with that experience when a mature twig is cut, the difference is very evident: Again, if a mature twig is cut through its well-formed terminal bud the knife meets with none of the grit, but when the twig is severed a short distance below the bud the grittiness is strikingly prominent. A better way to determine the location of the grit is to pass the knife down lengthwise through the tip of the twig. In this way the knife runs easily down for, perhaps, a half-inch or more, when it strikes the point where the resistance begins. If another twig of the same sort has the terminal bud stripped from it, along with the bark and the thin zone of wood, there will be left behind a cone of brittle pith. Instead of breaking this stiff cone apply the knife, and shave the pith when the peculiar sensation of cutting the grit will be felt. This cone of pith consists of small cells, which are about as long as broad, having their walls unusually thickened and the cavities closely packed with starch. As the lower end of the twig is approached, the central portion of the pith is found to be thin-walled, without starch, while the wood-zone is thicker and serves to support the twig. In other words, near the tip the wood-layer is so thin that the pith within it must take a very prominent part in holding the bud, and, from the nature of the cells, brittleness, instead of flexibility, must characterize the upper two or more inches of well-matured Apple or Pear twigs.

It still remains to consider the nature of the grit of older parts of the twigs as, for example, at those portions which are used for cions—that is, several inches below the extremity of a branch. As the bark of all Apple or Pear twigs is nearly the same and offers none of that peculiar resistance to the knife, it may be discarded in the present consideration. The grit is, therefore, either in the wood-zone or the pith, or both. It has been already stated that the pith diminishes in grittiness as the distance from the grit-cone near the terminal bud increases, and, therefore, if there is a considerable grit in an old twig it probably resides in the thick ring or zone of wood. The outer portion of the pith may have undergone the process of lignification, and the thick wall of the cells thus resulting possesses the grittiness; but there is in such twigs a system of radiating plates of pith-like cells known as the medullary rays or "silver grain," composed of cells in the thick walls, and in that respect agreeing with the cells of the outer portion of the pith. These rays are very numerous in the twigs of the Apple or Pear, and during the winter are repositories for starch. Besides these plates of cells stretching from the pith to the cambium, or growing layer just under the bark, there are other thick-walled, square-ended cells running at right angles to the "silver grain"; these, also, bear starch, while the wood fibres, between them and the ducts and vessels, are without this wood substance. The wood itself offers more or less resistance to the knife, but it is not of that kind caused by "grit." It is easy to see that making a section lengthwise of the grain is principally a splitting process after the knife is once set between the fibres, which are long and slender. In cutting through the pith, in whatever direction, owing to the nearly cubical shape of the cells, there can be no splitting, but, instead, the knife must pass through one hard lignified cell-wall only to encounter another just beyond—a condition of things that produces the sensation of grittiness.

The statement that the grit encountered in cutting twigs of our common fruit-trees is due to the presence of a deposit of sand in the wood is not borne out by microscopic examinations. The nature of the tissue composing a whole or part of the pith and of the "silver grain," which is only the pith pressed into plates by the growing wood, does not call for any such theory.

This lignification of the pith and medullary rays and their storage with starch is one of the best indications of the maturity of the twig, and that is as far as one dares to go in his deductions from these conditions. That it may be an indirect index of hardness is to be presumed, for it is undoubtedly

true that immature twigs are not hardy, and it has been shown that such do not present the quality of grittiness.

It is also an observed fact that the lignified pith cells are the only ones containing starch, and in freshly-gathered twigs in midwinter these thick-walled cells invariably contain starch. The grittiness, therefore, becomes a fair index of the amount of starch stored as a reserve-food material in the twig, and the presence of such a substance, other things remaining the same, becomes a possible criterion by which to judge of the adaptability of the plant to the conditions which surround it. In other words, of two varieties of apples the one having the greater grittiness would be the one which had stored up the larger amount of reserve-food substance in the form of starch, and from that fact it might be inferred that it was the healthier, had better prepared itself for the winter, and, therefore, for growth the succeeding spring. That it would live longer and bear more fruit than its less provident neighbor must be determined by orchard test, and not by microscopic investigation. The variety which matures its wood most thoroughly and stores the most starch may start into vigorous growth too early in the spring and be injured, perhaps, seriously thereby. Grittiness is, therefore, a good sign, but it does not become a perfect test for hardness.

Rutgers College, New Brunswick, N. J.

Entomological.

The Asparagus Beetle.

THIS summer, Asparagus growers in eastern Massachusetts have been making complaints of injuries to their plants caused by the Asparagus beetle (*Crioceris asparagi*), generally indefinitely spoken of as a "fly," "slug," or "bug" by those making its acquaintance for the first time. In some gardens the plants have been completely defoliated, leaving only the bare, dry stalks and branches, much to the injury of the vitality of the roots and of the value of the next season's crop.

Remedies do not seem to have been generally known or used, and in some cases it is to be feared that more injury has been done to the plants in efforts to exterminate the pest than if they had been left undisturbed.

Late in July, upon finding the Asparagus badly eaten by the insects, some gardeners have cut down every living shoot that was above ground, and kept all cut back for some time in the hope of "starving out" the insect. By cutting away the tops so late in the season much injury is done to the roots, and, as many of the larvæ will have reached full growth, they are not starved but merely enter the ground or find some other suitable place to pupate or prepare a new lot of beetles to deposit eggs on fresh shoots when they appear. The first lot of beetles begin to deposit their eggs in the spring, at a time when the Asparagus is cut daily for market and table use, and if growers were careful to keep down all seedling or stray shoots, and destroy all those that have become wild, during this period, it would help to starve out the first brood at least, because the beetles would be forced to deposit their eggs on the shoots that were to be cut for use, and they would thus be destroyed before hatching out. If this practice is followed by all the growers in any district it will have the effect of materially lessening the numbers of the pests, so that later in the season they will not be so troublesome.

As soon as the young larvæ appear, after the marketing season is over and the Asparagus is allowed to grow naturally, the use of insecticides should be resorted to, and repeated during the summer whenever the insects recur in any number.

Fresh slacked lime dusted on the plants is found by many to be very effective, and one of the cheapest and most easily applied of remedies. It is efficient only against the larvæ, the beetles being unaffected by it. Arsenical poisons, such as Paris green or London purple, used in the same manner and proportions as for the potato beetle, are as effective against the Asparagus insect as they are in preserving the potatoes.

The Asparagus beetle is an importation from Europe, and its first appearance in this country was on Long Island, New York, thirty years ago. It soon became very destructive to the large plantations on the island, and a few years later it was doing much damage in New Jersey. Since then it has slowly spread over a large territory, estimated by some to be less than at the rate of twenty miles a year. The beetle averages about one-fourth of an inch long, and has the head, antennæ, legs and under side of the body black. The thorax is red with two long black spots on the top. The wing-covers are black with three large lemon-colored spots on each. The middle and the anterior spots are often joined, and appear as one irregularly-shaped long spot, and then the black has very much the

shape of a cross with a broad shaft. There is an orange band around the margin of the wing-covers. The dark brown eggs, which are deposited by the beetles on the stems, branches or leaves are set on end, and are a little over one-twentieth of an inch long. These eggs hatch in about a week or a little more, and produce larvæ which grow rapidly and attain full size in ten or twelve days. They are then about three-tenths of an inch long, fleshy and slug-like, with the body much larger towards the hinder part than towards the head. The color of the body is a dull ashy-gray, and the head and legs are black and shining.

The time necessary for the insect to go through all its stages, from the egg to the imago, or perfect beetle, is about thirty days.

To-day (August 5th) the beetles and eggs are very abundant in many gardens about Boston, and fully-grown larvæ are also quite plentiful.

Another species of Asparagus-beetle, known as *Crioceris 12-punctata*, also an importation from Europe, made its appearance near Baltimore some years ago, and is said to be very injurious if neglected. As yet, however, it is not reported as having come very far north.

Jamaica Plain.

J. G. Jack.

Notes Upon Some North American Trees.—VI.

ACACIA FARNESIANA, Willd.—This plant is now so widely distributed through the tropical and sub-tropical regions of the world, having been long cultivated for the fragrance of its flowers, that its native country is not easily determined. Mr. Bentham (*Trans. Linn. Soc.*, London, xxx., 502) was of the opinion that it was indigenous to western America from northern Chili to Texas, as well as to northern and north-eastern Australia, and perhaps to south tropical Africa. It is one of the most commonly cultivated trees in all the towns on both sides of our Mexican boundary, and I have found it growing spontaneously on the Texas desert between San Antonio and the Rio Grande, in situations where it does not seem possible that it could have been introduced. It seems desirable, therefore, for these reasons, to include this beautiful species among the trees of our territory.

ACACIA FLEXICAULIS, Benth.—This species must be included also among the Texas trees. It is the largest and, after *A. Farnesiana*, the most beautiful of the Acacias, growing naturally within the limits of the United States. It is found abundantly on the dry plains, which rise from either bank of the lower Rio Grande, forming a round-headed evergreen tree attaining a height of twenty-five or thirty feet, with a short, stout trunk, sometimes twelve to fifteen inches in diameter. It is known locally as "Mexican Ebony," from its very hard, compact and beautiful, dark wood, which is greatly prized by cabinet-makers, and for posts (as it is almost indestructible when placed in contact with the ground) and for fuel. The pale-yellow flowers are delicately fragrant. The large seeds of this species are sometimes boiled by the Mexicans while they are green and are said to be palatable and nutritious; or, when fully ripe, they are toasted and used as a substitute for coffee. The illustration upon page 401 of this issue, from a photograph made by Mr. Pringle last year on the lower Rio Grande, shows the habit and the general appearance of this tree, but does not display, of course, the beauty of its bright and lustrous foliage.

99. **ACACIA BERLANDIERI**, Benth.—This plant, so far as I have been able to see it in Texas and in Mexico, or to learn about it from others, is never more than a shrub, and it may be dropped, therefore, from the list of our trees.

PITHECOLOBIUM BREVIFOLIUM, Benth.—I have found this species growing as a slender tree, twenty-five to thirty feet high, on both banks of the lower Rio Grande, although more common and of larger size south of the river. It should properly find a place, therefore, in the North American Silva.

109. **PRUNUS CAPULI**, Cav.—This name for the widely-distributed Cherry-tree of Mexico and the Pacific coast of Central and South America, appears to have been published first by Sprengel in his "Systema Vegetabilium," ii., 477 (1825); and Mr. Watson has pointed out

(*Proc. Am. Acad.*, new ser., xxii., 411) that an earlier published name is *P. salicifolia*, HBK., "Nov. Gen. et Sp.," vi., 241, t. 563 (1823), although, as Mr. Watson suggests, the name *Capuli*, always credited to Cavanilles, may have been published by him before it was taken up by Sprengel (*l. c.*).

113. **PRUNUS ILICIFOLIA**.—An interesting variety of this tree, with nearly entire adult leaves, was first noticed by Mr. W. S. Lyon on Santa Catalina Island, off the California coast. He referred it (*Botanical Gazette*, xi., 202, 396) to *Prunus occidentalis* of Nuttall—a name which Nuttall seems never to have used for any western American plant, and which had already been appropriated long ago by Swartz for a West Indian tree. Mr. Edward L. Greene found this plant upon Santa Cruz Island, and notes (*Bull. California Acad.*, ii., 7, 385) the resemblance to the mainland *P. ilicifolia*, and the fact that the smaller spinose-toothed leaves of this last are identical with those on young seedlings found on the island. Mr. Brandegee examined the trees on Santa Cruz and Santa Rosa Islands last summer, and in his "Flora of the Santa Barbara Islands" (*Proc. California Acad.*, 2 ser., i., 2, 209) it appears as *Prunus ilicifolia* var. *occidentalis*, and this name should, therefore, be retained by those authors who consider the insular tree as a more robust, entire-leaved variety merely of *Prunus ilicifolia*, although the name, in view of the West Indian species, is not a fortunate one. The island tree, according to Mr. Greene (*l. c.*), rises to a height of twenty-five feet, with a stout trunk covered with rough dark bark, and a compact, well-rounded head. The leaves are evergreen, ovate-acute, three to four inches long, entire, or sometimes remotely denticulate, or rarely spinose-serrate. The fruit is larger, but not otherwise different from that of the mainland tree. According to Mr. Greene (*l. c.*), "the thin pulp is sweet, with also a bitter-almond flavor, but no acidity or astringency." On Santa Rosa Mr. Brandegee found "it confined to the bottoms of the cañons—much larger and more tree-like than in Santa Cruz." He notes that in the Santa Inez mountains, near Santa Barbara, the leaves of *P. ilicifolia* sometimes have entire margins.

114. **VAUQUELINIA TORREYI**, Watson.—This Arizona tree was first described by Dr. Torrey (Emory's Rep., 140) as *Spiræa Californica*. Mr. Watson, in referring it to its right genus (*Proc. Am. Acad.*, xi., 147), dropped the specific name under which it was first described (for the reason, no doubt, that this tree has not been found within the actual limits of the State of California), and substituted for it the name of the first describer. Instances are not wanting in the annals of American botany of geographical specific names having been improperly applied; and unless all such names are to be corrected, it would be better to retain the earliest specific name for this plant, which would thus become *Vauquelinia Californica*.

122. **CRATÆGUS RIVULARIS**, Nutt.—This species, founded on specimens collected "in the interior of Oregon" by Douglas, I am unable to distinguish specifically from *C. Douglasii*. The leaves on the original specimen are narrowly lanceolate and simply serrate, as are those of the common form found in the Wasatch Mountains of Utah, where this plant is not rare. But this narrow-leaved form passes gradually in northern Montana, where the black-fruited Thorn abounds along the margins of mountain meadows and streams, into that with broad, doubly serrate, and often incisely cut and lobed leaves. The two forms mingle in the coast region of Oregon and Washington even, and vigorous shoots of the Utah plant are apt to display the cut leaves which have been largely depended on to separate the two species. The stipules (always an unreliable character in *Cratægus*) and the calyx-lobes, which are described as "usually glandular," cannot be depended on to distinguish these two forms. The spines, which are rather more abundant on the coast plant than on that of the interior, are the same, as are the fruit and its stones. The flowers of the latter are somewhat smaller. I should propose, therefore, to call the narrow-leaved black-fruited

Thorn of the dry interior region west of the Rocky Mountains, which is a stout branching shrub rather than a tree. *Crategeus Douglasii*, var. *rivularis*.* C. S. Sargent.

New or Little Known Plants.

Uniola Palmeri.†

IN 1885 Dr. Edward Palmer collected, near the mouth of the Colorado River, some specimens of a grass from which he said the Cocopa Indians obtained the seeds in large quantities and used them as food. At the time he was there the grass was out of flower; he found only a few disconnected spikelets, and the botanical characters could not well be determined. In April of the present year Dr. Palmer, being employed by the Department of Agriculture to make botanical investigations,

that genus. Its general appearance and habit is that of *Distichlis*, from which it differs in having four of the lower glumes (instead of two only) in each spikelet empty, *i. e.*, without palea or flower, and in the disarticulation of the rachis between the spikelets of both sexes—that is, the spikelets break apart between the several flowers when mature. This disarticulation occurs also to some extent in the fertile spikes of *Distichlis*, but not in the male or infertile ones. On the other hand it differs from *Uniola* in its dioecious character, and here agrees with *Distichlis*. It seems, in fact, to connect these two genera, but so long as the two are kept distinct it must stand as *Uniola*. Specifically it is new, and I have given it the name of *U. Palmeri*.

The following notes I collect from Dr. Palmer's letter:

The specimens were collected at the Horseshoe Bend of

Fig. 123.—*Acacia flexicaulis*.—See page 400.

made another visit to the locality and obtained in that region specimens in good condition, enabling me to locate the plant botanically. As the genus *Uniola* is defined by Benthams & Hooker, our grass must be considered as of

**CRATEGEUS DOUGLASHII*, var. *RIVULARIS*, frutex glaber, 10–15 pedalis, foliis ovatis, lanceolatis, obtusis vel acutis, argute serratis, inciso-serratisve, stipulis acutis inciso-glandulosis.

†*UNIOLA PALMERI*, Vasey.—Culms wiry and rigid, sometimes cane-like, two to four feet high, from subterranean root-stocks, often much branched, and many culms from one root, leafy to the top. Leaves distichous (sometimes less than an inch apart, sometimes two to four inches apart), smooth, rigid, erect, involute, with long, pungent apex, the lower two to four inches, the upper four to eight inches long and exceeding the panicle. Ligule nearly obsolete, with a light woolly tuft at the angles. Raceme of the staminate plants six to nine inches long, narrow, the branches mostly in twos and threes, the lower ones one to three inches long, erect, compound below; spikelets eight to ten lines long and about two lines wide, 7–9 flowered. Racemes of the fertile plant shorter, thicker and more condensed, being four to six inches long, and the branches sessile or short-stalked; spikelets usually one to one and a half inches long, 7–9 flowered, the two lower pairs of glumes empty; outer pair of empty glumes five to six lines long, the flowering glumes six to seven lines long, lanceolate and acuminate, with a stiff, pungent point, smooth, obscurely many- (about 20-) nerved; palea one-fourth shorter than its glume, with about three nerves on each side of the strong, deep keel; grain linear-oblong, three lines long, not including the thickened, more or less united style.

the Colorado River, thirty-five miles south of Lerdo by the river, and twelve to fifteen miles from its mouth. This is the most extensive locality of the grass, thence extending down to the mouth of the river. It covers a space of from one to twenty miles wide, and occurs on both sides of the river. It is estimated that there are from forty to fifty thousand acres covered with this grass. It grows from two to four feet high, from strong, deep root-stocks, frequently many culms from the same root. The stems are covered to the top with the sharp, stiff leaves. The sterile plant grows more or less mixed with the other, but at times in masses entirely by itself. Dr. Palmer noticed several forms. One of these is more slender, with the leaves shorter, more numerous and more finely pointed. This, he says, grows on land that has but little overflow. Where, by changes in the river, any patches are left above tide-water, they soon die.

The Indians come together here at the proper season,

in April, and gather this, to them, important article of food. As its quantity depends on the overflow of the tides, and the tides are sure to occur, they have an assured crop without any other labor than gathering and caring for the grain. The gatherers enter the fields as soon as the tides have entirely run off, where the soil is an adhesive clay so soft that the Indians often sink nearly to their knees in gathering the grass, and as soon as the tide begins to flow they return with the result of their labor to their camps. It is quite difficult to pull up the plant by the roots, as these are often two to four feet long, but the stems are brittle and easily break off above the root. The Indians, in harvesting, use any old knife, or, if they have none, they take a flat piece of wood and form an edge on each side, and with this they sever the stems, the left hand grasping the tops, which are then thrown into a basket. The rigid, spiny-pointed leaves make the process a painful one. The grain has to be cut when a little green, because of the easy separation of the spikelets. In order to dry the heads as quickly as possible, large fires are made, and the heads are piled around so that the flames penetrate between them. When they have been sufficiently exposed to the fire a stick is used to thrash the heads, which breaks up the spikelets, but does not separate the chaff or glumes from the grain. The dried and dissevered spikelets are then taken to a piece of ground prepared for the purpose, and the Indians tread upon and rub the grain between their feet until the seeds are shelled out.

This process is more easily accomplished after the grain has been exposed a while to the sun, but in any case it is pretty trying to the feet because of the sharp, stiff points of the chaff. The action of the tide knocks off and carries away considerable of the grain, but this is left in rows at the edge of the contiguous dry land, and the Indians gather much of it and rub it out. They have to be expeditious in their harvest, as wind storms are liable to arise and destroy or injure the product of their labors.

Dr. Palmer was accompanied on his trip by two gentlemen connected with the United States Fish Commission, who took photographs of the grain-field, and of the thrashing and treading out of the seed from the chaff.

It is not yet ascertained how far up the river this grass extends, but probably to the limit of tide-water, and in this case it will yet be found within our boundaries. The related *Distichlis maritima* grows not only on the sea-coast, but in nearly all saline and alkaline grounds in the interior of the country, but we cannot infer from that fact that this species might be cultivated outside of the reach of the tides.

George Vasey.

Foreign Correspondence.

London Letter.

THIS being the jubilee year of the Royal Botanic Society, it was thought desirable to celebrate the event by a floral carnival in Rose time. It has been a commendable attempt to introduce the pretty, if frivolous, customs of the flowery Riviera, so familiar to the sojourners at Nice in early spring, when the hills and valleys teem with blossom. The custom may migrate northward and take root, now that "society" has set its seal of approval upon it, but, to our sober minds, some of the items in the schedule seemed to be absurdly extravagant. The flower-bedecked horses and carriages were, however, not so absurd as the "triumphal canopies," "May-poles," "bridesmaids' arches," and "wreaths on poles," which only served to illustrate how insipid flowers become when maltreated in a way that cannot by courtesy be termed artistic or tasteful. The most tastefully decorated Victoria carriage and pair of horses was quite a flower-garden. The whole body of the carriage, from the wheels to the pole-end, was glowing with flowers, prettily arranged in harmonious colors; while the horses were caparisoned with emerald-green harness and trappings and roses. I heard that this was the work of a professional floral decorator from Nice, and that no less than £20 worth of ribbon was used on the horses. It won the highest gold medal besides a prize from the Princess of Wales, who was present to distribute the prizes. Some of the pony cars were extremely pretty, especially the first-prize one, which was

smothered with roses, paneled in different colors, the predominant variety being the pink La France. One pony was wreathed with the long, slender flower-stems of *Tropæolum speciosum*, with scarlet flowers; in another, the trappings were all of roses. The decorated riding-horses were not remarkable, but the children's carriages and sedan-chairs, loaded with live babies almost hidden by flowers, were, perhaps, as popular as any part of the show. The arches, May-poles and canopies were not worthy of favorable comment, neither were the decorated boats on the lake, which were absurdly wreathed with tender tropical flowers, and the sterns crammed with pot-plants such as Crotons, Ferns, and Palms, which seemed quite out of place. Simplicity should have been the aim of the decorator, and it would have been an easy matter to have adorned the boats with bright, hardy flowers, which would not have withered so quickly. Besides, flower-bedecked boats seem quite out of character in our climate under leaden skies and drenching rains.

The display of Roses, or "Feast of Roses," in the exhibition tent was a much-admired feature, for some of the leading Rose-nurserymen contributed large and full collections, the most extensive being that from the great house of W. Paul & Son, of Waltham Cross, who worthily won the chief gold medal with their display. This firm made a commendable attempt to break through the orthodox style of exhibiting cut Roses, by arranging their blooms in masses of distinct and contrasting or harmonizing colors, marked out by geometrical yet graceful lines, and relieving the flatness by groups of pot Roses, Ivies, and other shrubs. The flowers lose nothing, but gain much, in being set out in this way, and the flower-loving public evidently appreciate the innovation, judging by the admiration it bestowed upon this Waltham Cross gathering. The "feast" was not exclusively of Roses, many other classes of plants being shown by the leading houses in the trade, and, perhaps, none were so remarkable as the magnificent group of Begonias, from the celebrated raisers and growers of these popular flowers, the Messrs. Laing. In their large and representative group one could see all types of Begonia and the various styles of growing them, from the prim staked-up "specimen" plant to the graceful drooping plants in suspended baskets. It is very evident that this modern race of Begonias has taken quite a hold upon the public. Even ladies of the most refined taste in colors admire the great flowers of the most fiery scarlets and reds, perhaps because these colors glow in flowers of exquisite form and substance. This season's crop of new varieties is unusually large, but as most of them are still under trial and nameless I must reserve comment upon them for the present. They are obviously all improvements on the older sorts, and, taken altogether, they serve to illustrate more forcibly than ever the praiseworthy efforts of this firm (which has identified itself with Begonias) to bring this valuable race of green-house flowers every successive year to a still higher state of perfection. Begonias, as open-air flowers, have not made much headway with us, though now and then one sees examples of exceptional success in this direction; and on the Continent, where they enjoy more sun and heat than here, they seem to be supplanting the Pelargonium. I shall not soon forget the spectacle I saw last August in one of the parks at Zurich, in Switzerland, where there was a large mass of Begonias thriving and flowering in great luxuriance. The varieties were of the small-flowered class, not many removes from the typical *B. Boliviana*, and they seemed much more suited to "bedding out" than the large-flowered sorts, which are more liable to be damaged by rains and winds.

Although this is the "off season" for Orchid bloom, there was quite a fine show of them at the "feast," and especially that from Messrs. Low, who had in their large collection some very choice kinds. Most interesting to me, because it was the first time I had seen it, was the new *Cypripedium Rothschildianum*, introduced a year or two ago by Messrs. Sander. I was somewhat disappointed with it, perhaps because I had heard so much laudation of it. But it is not one of those plants that "take your breath away" at first sight. It looks to be a near ally of *C. laevigatum* (now called *C. Philippinense*), the flowers being about the same size. The slipper is like that of *C. Stonei* in shape and color, the dorsal or upper sepal is shaped and striped like that of *C. laevigatum*, but the long lateral sepals which stretch out at right angles are pointed and copiously spotted, and unlike those in any other species. A much prettier and probably a more really valuable Lady-slipper is *C. bellatulum*, with which Messrs. Low seem to be plentifully stocked, as they showed the flowers of it on trays like Pansies. Everybody admires the wax-like flowers so quaintly blotched with black-crimson, and on the plant they

Fig. 124.—*Uniola Palmeri*.—Two-thirds of natural size.—See page 401.

1. A male plant; 2. A female plant; 3. A male plant with small, close leaves; A. A spikelet of the male plant; B. Empty glumes of same; C. Flowering glumes of same; D. Palet of same; a. Female spikelet; b. A pair of empty glumes of same; c. A flowering glume of same; d. Palet of same; d'. A transverse section of the palet; e. Young fruit with the styles united; f. Older, ripe fruit, with the styles separate. The dissections are magnified three diameters, excepting "f," which is magnified four diameters.

are set prettily amidst the handsomely marked foliage, and last for weeks in perfection. Though the present is the lowest ebb of the Orchid-flower season, there is much activity among Orchidists on account of the numerous novelties, genuine and otherwise, that appear at the auction-rooms. *Cypripedium* seems to produce most novelties, and this week there are to be sold the "new and beautiful *C. Savageanum*,"

the new *C. Seegerianum*, *C. Pageanum*, *C. Buchanianum*, *C. Godseffianum*, *C. Winnianum*, *C. regale*, *C. pavoninum* and *C. Javanico-superbiens*. Here is a list for the specialists in *Cypripedia*, who probably are the only people who will be able to define and appreciate the subtle differences between them and well-known species. As to the names of these so-called new Orchids, it seems as if we are getting from bad to worse. Every one assumes that he has a right to christen Orchids, now that they cannot be sent to Reichenbach, and the result is that they are making confusion worse confounded. Instead of one competent man describing new Orchids, we have two or three, and their descriptions of the same plant do not agree, and, in some instances, old species have been described and named as new. The work could be done very well at Kew if the cultivators and importers would only be loyal to the recognized headquarters of botany in this country. Let us hope that no other large family of plants will suffer from such excessive popularity as Orchids. Among the list of the newest novelties I see a pure white variety of our old favorite, *Dendrobium nobile*, and if this does really come up to description we shall have indeed a valuable addition to winter flowers. How many have sighed for it, and how often have collectors been instructed to be on the look-out for it at home and abroad. It will be interesting to see what figure such a rarity will be sold for. It must be white and nothing but white to be of value, but this has to be proved. A pure, colorless variety of *D. nobile* is what florists want for winter work, but it will be many years probably before they will get it. When I was in India I was continually on the look-out for it, but no one had seen or even heard of it.

Cultural Department.

A Few Summer Pears.

I AM asked to name a list of Pears for family use by one who is fitting up his garden in a newly-acquired home, and having but little room, and getting well on toward the meridian of life, he wants trees that will be likely to yield fruit as quickly as possible, and of quality fit for table use. As a rule, the actual popular knowledge of Pears is limited to the Bartlett and Seckel, and, perhaps, a few old-timers, which, in the childhood of people, like our enquirer, were voted excellent. People of this class have usually given some study to the books and the catalogues of some eminent nurserymen. They have probably made a list after much thought, only to have some acquaintance or tree agent advise an entirely different one. Such persons should be told at the outset that all Pears do not succeed equally well in all localities. Besides this, individual tastes differ widely. One will prefer a sweet Pear to an acid one, and another the reverse, so that if these, and other characteristics, are fairly stated, they can make the most satisfactory selection themselves.

Pears do best generally on a stiff, heavy, rich, well-drained soil, such as a clay loam. The earliest Pear I have ever grown is the Summer Doyenne. It usually ripens here from the 15th to the 20th of July, and lasts about a week. It is small, about the size of a Seckel, good specimens measuring about one and a half inches in diameter, nearly round, sweet, with a handsome red cheek. Altogether it is a very agreeable and welcome fruit so early in the season. The tree is healthy, a good grower, and an early bearer. It is sometimes called a summer Seckel.

The Madeleine comes in at the same time, is nearly, or quite

twice the size of the preceding, and of an entirely different character, light-green, juicy, and slightly acid, and more refreshing in character on this account, but its season is very short. It decays at the core so quickly that it is gone before one is aware of it. The tree is a good grower and an early bearer.

The Bloodgood is another of the small summer Pears, and is better in quality than either of the foregoing, but my tree has never done well. The fruit is yellow, sweet, and of excellent flavor. Were I to plant again simply for family use, I would group these three, if not more, on one tree, by grafting. This at ten or fifteen years old would yield enough to answer the purpose of an early desert fruit and at the same time give a variety.

Following these comes Giffard, a larger, better Pear, of short duration. The tree is a slender grower, and succeeds best when top-grafted on a more vigorous variety. The next to ripen with me is Clapp's Favorite, a handsome Pear, fully as large as the Bartlett, and in its prime now (August 12th); not a rich or high-flavored Pear, but juicy and agreeable. The tree is a strong grower and an abundant bearer. It is in season about a week, and like all Pears must be gathered while hard, and house-ripened to get at its real merits, and when fit to eat it must be eaten. When Pears reach maturity no days of grace are added. After ripeness comes sudden "heart-failure." No one ever enjoys a perfect Pear who waits for it to ripen on the tree.

My next Pear is the Tyson, a sweet, rich, juicy Pear, about half as large as the Giffard, but better in quality and in keeping. The tree is a good grower, and is generally tardy in coming into bearing, but when it commences business it attends to it, yielding abundantly in alternate seasons, and seldom missing a fair crop on the off year. A city friend asked my advice about grafting over a tree of this variety a few years ago. He said it never bore anything, and he was tired of waiting. I suggested that it might reward him in time, and advised him to confine his grafts to a few limbs. This might tend to induce earlier fruitfulness in the tree, and then he could judge better as to the probable advantage of further changes. Last year the tree commenced declaring dividends, and this season it is loaded, and so well is the owner pleased with it that he has decided to spare it, and if any limbs are cut it will be the grafted ones.

Ott comes next, a seedling of the Seckel, a very sweet, good Pear of about the same size. The tree is healthy, a good bearer, and very much like the Seckel in growth.

I mention the Rostiezer because nearly all authorities do, but it is not a favorite of mine, and it does not deserve, in my opinion, the commendations often bestowed on it. The tree is a healthy, sprawling grower, and bears well. The fruit is small, hardly averaging as large as Madeleine, with a coarse, gritty flesh, covered with a dark thick skin, often with a ruddy cheek, sweet, and in good specimens tolerably high-flavored. These, however, are the exception; they usually rot before presenting any appearance of ripeness. With me they seldom present such an appearance, and are altogether unattractive.

I might mention also the Rousselet Stuttgart, a very good Pear, with a peculiar spicy flavor, and generally much admired. It is of far better quality than the Rostiezer, but it has the same fault of most of our summer Pears—soon ripe, soon rotten. The tree, however, is healthy and productive.

Next comes Boussock, a large, handsome yellow Pear of good quality, with flesh a little coarse, but juicy. The tree bears abundantly of fruit that is generally fair.

Now comes the Bartlett, the universal favorite, so well known that a description is unnecessary. Some seasons it develops a musky flavor, not agreeable in a dessert fruit to many palates; but it is the universal favorite for canning, and so firmly has its name and reputation become fixed in the minds of the people that they will call for it out of season, and unscrupulous venders will not hesitate to palm off on those who know no better not only other Pears, but other trees, too, when opportunity offers. It is really an autumn fruit here, ripening in September.

Then there is the Souvenir du Congrès, an early, handsome Pear, and larger than any I have named, but quite inferior for dessert purposes. It answers for cooking, and I occasionally sell Pears of this variety, hoping, however, that purchasers will not try to eat them.

And what about the Comet-Lawson? Well, it is said to be early, and as pretty as a Pink. But my grafts have all died; and there are Pears in the above list that will answer every purpose better.

Manning's Elizabeth is a Pear which, according to a recent authority, is the best early Pear. I have failed, however, to find

any merit in it that would justify me in keeping a tree of it, and have grafted over the only one I have. It is not as early as the above-named, and about as poor an apology for a Pear on my ground as can be conceived. Perhaps it would do better on light soils. I might add notes on Washington, Catherine Sterling, Miller's Early, and many more, not omitting the Summer Bell (Windsor), an excellent old-time favorite for cooking, and still as good as ever for that purpose; but the list is sufficiently long for the summer kinds. Pears for autumn will be spoken of in another paper.

Montclair, N. J.

E. Williams.

Memoranda from a Northern Garden.

THE cool, wet season, especially at the north, while unfriendly to the Potato-crop, has been very favorable to the true root-crops. In no recent year have Beets, Turnips, Carrots and Parsnips made a finer growth.

The lessons of this season are many, and those who have lost by their crops may, in some degree, make it up by the teachings of experience. Rust and blight of the Potato are fungoid diseases; but the fungi are destructive in proportion as a favorable nidus, as well as a favorable season, attends them. Early-planted Potatoes of early kinds, well fed with fertilizers, on light land, sloping enough to prevent water from standing, are yielding excellent and well-ripened crops, where, just in proportion as these conditions fail, the crop fails, too.

Long-rooted Parsnips, Carrots and Beets are getting yearly more out of favor, apparently quite as much with buyers as with growers. Still, they make a good appearance at vegetable-shows; and there is some sale for them, in spite of their inconveniences. To get the finest specimens, the soil should be evenly and deeply dug, and enriched with fine manure or fertilizer. I have found the best specimens where the rows crossed the spots at which roots had been pitted the winter before. They went to the bottom of the excavation—large, straight and with a perfect taper.

The advent and increase of many foreign insects, as well as some hitherto localized native species, like the Potato-beetle, have added greatly to the burden of garden-work. Where any advantage is seen, it has been for the benefit of commercial growers, at the expense of private gardeners, a large number of whom have given up the culture of fruits and vegetables so attacked. In small village gardens, Currants and Gooseberries, Onions, Cabbages, Turnips, Radishes and Potatoes have been in many cases abandoned; and the interest in this sort of gardening is greatly cooled by the troubles incident to insect-fighting.

Amateur gardeners, engaged in a contest with insects, commonly fail in not applying the remedies promptly at their first appearance. The Currant and Gooseberry worm must be met with the hellebore douche at the first hatching of the eggs, which is contemporary with the first bloom. As for the various root-worms of the anthomyia race that attack all the cruciferous and alliaceous vegetables, no practical methods suited to small gardens seem to answer, though lime-water, freely applied, or weak lye of wood-ashes, can sometimes be made to succeed.

Undoubtedly a rapid growth, secured by ample and deep fertilization, and aided by irrigation, enables the market-grower to get pretty good crops of Cabbages, Turnips, etc.; but even these are glad, when they can, to get hold of spots of fresh ground, or a new "burn," where they can take a few crops before the enemy has found them out. It seems a pity that crops once so easily and cheaply grown, should now have become costly, far beyond their intrinsic value to the buyer, on account of these difficulties.

The worst of these insects are imported, and most of them did not reach our shores until after the advent of the trans-Atlantic steam service. They were brought over in the steward's stores, the waste from which was thrown out at landing. In this way we got the Currant-worm and the Cabbage-worm, by the way of Quebec. Both of these have reached northern New England, and spread southward within the last twenty years, while, unfortunately, the parasites that keep them down in their old home did not come with them.

We have heard a good deal about importing these parasites, and it does seem as if it might be successfully done at no great expense, considering the ravages now made in our gardens by the unchecked enemies. English readers of this journal, or European entomologists, at least, should be able to give some practical information on this subject, which, so far, seems to have been inefficiently and unintelligently met on this continent.

Newport, Vt.

T. H. Hoskins.

Aquatics in Small Gardens.

HAVING made an experiment in the culture of water plants in my small garden (part of a city lot), with very satisfactory results, I should like to call the attention of other amateurs, especially growers of hardy plants, to some of the possibilities of the water-garden and its surroundings—and especially of the surroundings—for this feature has been somewhat neglected by the numerous writers on the subject. Owners of the smallest gardens, if sunny, will find a water-garden an attractive and useful feature and a very slight trouble; if there are any difficulties in cultivation I have yet to find them. The catalogues of dealers in these plants give full particulars as to construction of tanks, etc., but, in a primitive way, barrels or casks cut in two answer very well, though rather cramped quarters laterally for vigorous plants. There is an æsthetic objection to them, too, since their rims break up the water surface and reduce its apparent "breadth." It is well to sink the tubs several inches below the ground-level and slope the ground towards them.

A tank may be cheaply constructed of Portland cement alone in heavy soil, or with cement and bricks in a light porous one. Four to six inches of good fibrous loam with one-third well-rotted manure should be firmed in the tubs and covered with an inch of clean sand, to prevent the manure from rising; in this compost the plants are to be fixed carefully and firmly and tubs are then filled with water, after which water is only added as may be made necessary by evaporation, for the temperature should not be reduced unnecessarily. A pair of goldfish in each cask and a frog or two will keep the water sweet and clear, add life to the picture and interest the young members of the family.

Rare varieties of Water Lilies, etc., are held at high prices, but a visit to the nearest pond and swamp will furnish abundance of interesting material and enable one to study closely some of our attractive native plants. Our native Pond Lily may, of course, be had in many sections for the gathering. But it is in the surroundings of such a garden that I have been specially interested, as such a station is the place for many things, large and small, which are more or less unhappy in an ordinary dry border and flourish in moist earth and, perhaps, a somewhat humid atmosphere. Every grower of alpine will appreciate such a locality in his garden. It will be well to vary the height of the surrounding ground so that stations more or less dry may be had for various plants according to their requirements.

In the background may be grown bold groups of Cannas, Eucalyptus, some of the Irises, Spiræas, Caladiums, Bamboos, and the large grasses. The low and intermediate places will be havens for some of the Saxifrages, Primulas (*P. obconica* is a treasure there), Ferns, Lobelias and a host of little things. Peat-beds should be made near the borders in which to grow terrestrial Orchids and various peat-loving plants, which are so interesting and so difficult to care for in the borders. The clumps of peat will be sure to send up some interesting wildings. Of course, in planting out, it will be necessary to arrange that shade shall be provided over some of the shade-loving plants. If tubs are used their margins may be hidden by some of the vigorous creepers. My "lake" consists of four half-casks, three in a row, with rims touching, and the fourth in the angle between the second and third, to give some irregularity of outline. Three varieties of *Nymphæa* are blooming here with Water Poppies, *Pontederias*, and many more. Just now, under the shadow of some *Caladium* leaves, *Shortia* and *Galax* are both thriving in the peat and among the Ferns. Any amateur who is fond of other than routine work will be sure to find the water-garden and its borders, arranged as hinted above, a decided and, perhaps, novel pleasure, and he will be surprised, too, at the number and variety of beautiful plants that can be successfully grown and effectively grouped in the water and about its borders.

Elizabeth, N. J.

J. N. Gerard.

Crotons as Bedding Plants.

AFTER a period of comparative neglect, this very handsome class of variegated-leaved plants seems to be gradually regaining a place in popular favor, though on a very different ground from that which they once occupied. Formerly they were only known and treated as stove-plants. And while splendid specimens have been produced for exhibition in this way, the plants so grown were, nevertheless, of little value for any other purpose, and in some cases the foliage was so soft from high cultivation that an exposure to the atmosphere of an exhibition-hall for three or four days was enough to ruin them for the remainder of the season.

We must admit the beauty of specimens four to six feet in height and almost as much in diameter, for such have frequently been shown in the past, but the knowledge of the method by which they were grown has, no doubt, caused a feeling of distrust in the minds of amateur cultivators in regard to the value of Crotons for their use, and the popularity of these noble plants has, therefore, seemed to diminish until recent years, when it has been abundantly proved that another field for usefulness and distinction lay open for them. That is, it has been shown that they possess great decorative capabilities when used as bedding plants out-doors. A notable instance of this was seen in the large Croton beds near Horticultural Hall, Fairmount Park, Philadelphia, where their beauty excited much favorable comment from visitors last season.

But when Crotons are used in this way it should be remembered that strong, healthy plants only should be chosen. Disappointment almost certainly awaits the planter who puts out small, weak plants in the hope that they may be improved thereby. And, again, the plants should be prepared for the change by removing them from the stove in which they may have been grown, and placing them in a light, airy house for some weeks before planting, for it is hardly reasonable to suppose that a plant grown in the close, moist atmosphere of a tropical house will be able to withstand the very variable conditions of a summer in this latitude without a hardening process in preparation for the change.

The plants should be well established in four-inch to six-inch pots, or even in larger ones, since they can be so arranged in the bed that the sizes will not interfere, and they should also be planted moderately close together, so as to give an immediate effect. The beds should be thoroughly prepared, and, if the ground is low, should be well drained and filled with a light, rich loam, or suitable mixture. As regards location, they should have plenty of sunlight, as this tends to bring out the rich colorings of the foliage and encourages stronger growth, and it may be added that if the season be dry it may be found necessary to give the bed a thorough watering at intervals.

As is quite natural from the native habitat of these plants (the South Sea Islands), they are quite susceptible to cold, and consequently should not be planted out too early in the season—from the 10th to the 15th of June being quite early enough in an ordinary season—and, since it usually is desirable to preserve them for use another year, it will be found best to lift them at the first sign of frost, so that they will need no nursing to restore them to their previous vigor.

When lifted in the fall they should be cut back quite hard, potted into as small pots as possible, placed in a warm, moist house, where they should have frequent light syringings to induce them to break into new growth, after which they may be potted on, as it becomes necessary, and treated as usual. Among the multitude of fine varieties of Crotons now in cultivation it is somewhat difficult to pick out a short list of sorts to be used for bedding-out, and the taste of the individual grower must be consulted in the selection of varieties, bearing in mind that the better plan is to select those of strong growth, distinct form and rich coloring. Almost any variety possessing these marked characteristics is likely to give satisfaction.

The following list may serve as a basis to work from—all the varieties are easily procured, distinct and reliable: *Croton Evansianum*, *C. majesticum*, *C. Mortii*, *C. Veitchii*, *C. Youngii*, *C. interruptum*, *C. longifolium*, *C. Challenger*, *C. princeps* and *C. pictum*—these giving enough variety to experiment with. Additions may easily be made to this list as required.

Holmesburg, Pa.

W. H. Taplin.

Filling In About Trees.—It became necessary to raise the level of the ground two or three feet in a small garden, last spring, where a dozen young Pear-trees stood. It was not deemed worth while to transplant the trees, which were some fifteen feet high, and just commencing to bear, and therefore it was decided to fill in about their trunks and let them take their chances. The precaution was taken, however, of placing around them broken stones for a space of about three feet in diameter, a little earth only being spread over the top. The thought was that the stones might allow the air to reach the roots, and that the trees would thrive. When fall came all the trees were growing as well as ever, with one exception, a Bartlett, which showed a perceptible yellow color of foliage. Surrounding this tree, apart from the stones near its trunk, the soil was largely clay, while the others stood in loam, and this was thought to cause the difference. This season all the trees flowered profusely and bore immense crops of fruit. Ten per cent. of all that set was cut out, leaving still a large crop. The trees are doing well. The foliage is healthy, and,

with one exception, I see no difference in their usual behavior. This difference is that all the varieties seem to be perfecting their fruit earlier than usual. Clapp's Favorite, for instance, I have been accustomed to gather about August 10th, ripening them about the 15th. This year there was not an un-ripened fruit by the 5th of the month. Brandywine behaved in the same way. The Bartletts on the tree spoken of are changing color perceptibly, and Howells, an October Pear here, is in much more forward condition than usual, while Sheldon, Beurre Superfin, Lawrence and Kieffer are all ripening in their fruit with similar speed. Of course this early ripening shows the trees to be less healthy than they should be, but no other symptom of any lack of vigor is manifest. Fruit and foliage are perfect, so that I hardly fear any serious or permanent evil to the trees from the earth about their base.

Planting Deciduous Trees in September.—I read with interest Mr. W. C. Strong's article on transplanting evergreens in August. It is undoubtedly one of the best months in the year for the purpose, and, let me add, that deciduous trees can be planted to advantage much earlier than they usually are in autumn. There is no need of waiting for the fall of the leaf. If transplanted in September such trees would not only do well, but, in very many cases, they would do better than if removed later. A transplanted tree bears some analogy to a cutting. The propagator, in a green-house, knows, when he puts in a cutting, that the sand in which he inserts it should be warmer than the air, and so he gives bottom heat. When a deciduous tree is transplanted in September, the earth and air are in much the same relative condition as is desired for the green-house cuttings. The warm ground forces out fibres at once, and when cold weather sets in the tree is well established, having an abundance of roots to help it through the winter. This is not a matter of conjecture, but something that I have tested many times. If any reader, for experiment's sake, will transplant a small tree in early September, and dig it up again in October, the number of new fibres which have been formed will probably surprise him. If trees are planted before the leaves have fallen, these should be pulled or cut off.

Germantown, Pa.

Joseph Meehan.

Fruits and Vegetables for Forcing.—Peach-trees in pots or boxes, intended for early forcing, should now be in a good sunny position out-of-doors, and where the growth is completed and the fruit-buds have plumped up, water should be gradually withheld, but not so long at a time as to allow the leaves to wilt so that the wood will shrivel. If the growth is weakly and not matured, give a few applications of liquid manure for a week or ten days. The best varieties for very early forcing are Alexander, Amsden, Hale's Early, and John Haas, the last a very finely-colored, good-flavored, new Peach. Tomatoes for winter-fruited will now need strict attention. They should be in five-inch pots, and each plant must stand free and have room to strengthen. As to varieties, the Lorillard, Livingston's Perfection and Volunteer are all good. I had great success last year with cuttings taken from Volunteer as late as the first week in September. These cuttings were from plants that had set fruit very freely in the open ground. They were fully six inches long, and were put separately in thumb-pots placed in a shady green-house. They were rooted in a few days, and were then shifted into five-inch pots and treated the same as those raised from seed.

Preparing for Flowers.—Good Primulas, Cyclamens, Cinerarias and Calceolarias are very satisfactory, but when inferior, this is a group of plants which one does not care to see. It is at this season when all these plants must have attention. Seedling Primulas and Cinerarias should now be nicely established in two-and-a-half-inch pots, and kept in a frame shaded from the hot sun during the day, with the sashes removed entirely at night when the weather is fine. A syringing twice a week with weak tobacco-water prevents the white thrip from destroying or crippling the young growths. Calceolarias should be pricked out as soon as large enough in pots or pans half an inch apart, in soil that is shallow, sandy and friable, and when large enough they must be potted singly. All these plants should be grown quickly and never checked, and then they will prove among the most beautiful of our winter and spring flowers.

Pearl River, N. Y.

John Thorpe.

Kale is one of two or three vegetables I always sow broadcast. I prepare the ground first as for sowing Flat Turnips, by putting a heavy coat of manure on a freshly-plowed surface and harrowing it in lightly. The seed is then sown much more thickly than Turnip-seed, using about six pounds of good seed per acre. The green curled Scotch is the best in

quality and comes in use earlier in spring, but it becomes worthless much sooner than the Siberian, and a sowing of both should be made soon.

Crozet, Va.

Correspondence.

Forests and Civilization. V.—The North Woods.

To the Editor of GARDEN AND FOREST:

Sir.—The Adirondack region, as a place of resort for summer rest and recreation for those who love the wildness and freedom of the woods, is coming to an end. Not many persons see this now. Many never perceive that anything is coming till a good while after it has come. I know a man who is still lecturing against slavery, and especially against the sin of the churches in upholding the peculiar institution. He complained to me a few months ago that the great mass of our people are still indifferent in regard to this gigantic wrong. He has not learned that slavery is dead. If he had been a soldier on either side in the Civil War he might have found it out. The time is coming when the people who live in, by, and from the North Woods will awaken and find that their occupation is gone. Not many will believe this now. Some are even glad of the changes that put great tracts of the forest here into the hands of rich men, clubs, syndicates, and corporations, glad that, "if the state will do nothing, the woods will still be saved by private owners."

But a few of the great hotel men of the Wilderness begin to have a sense of something in the air which bodes no good to them. The effect of maintaining forest conditions over large tracts will, of course, be equally salutary in the retention and distribution of the water which falls upon them, whether the land is owned by the state, by individual citizens, or by clubs and corporations. This function of mountain forests, as natural storage reservoirs for water, is, perhaps, the most important of all their uses. But the Adirondack forest is valuable to the people of the state and of the country in several different ways. It should have been forever the source of inestimable benefits as a mountain summer resort, a region of infinite sylvan variety, beauty, and peace.

Let us use a little analysis here. In the early times of our country's history, when we had but a sparse population, which nearly all lived on farms or in small towns, summer vacations and excursions for rest, recreation, and the restoration of wasted energies were not needed as they are now. But, as our country has filled up, and millions of our people have crowded into cities to live, there has arisen an absolute necessity for a change of conditions and methods of life in the hot season of the year for a great proportion of our whole population. People must get out of doors. They must lay aside business and put off the burden of daily care. It is a most practical matter, a matter of the wisest and most necessary economy—of the economy of life itself and of its highest forces.

Without such a pause in work, such a period of contact with nature and the out-of-door world, as a means for the restoration of exhausted vitality, neither physical nor mental health can long be maintained. Life will not continue to be sane and efficient without an occasional visit to the sources of healing and strength in Nature's great sanitarium—the open air. It is true that there are multitudes of persons, especially of women, in our country who never have such a vacation, for whom there never arrives "a lull in the hot race," to use Mr. Arnold's expressive phrase, but they need it all the same, and it is a calamity, not only to them but to all who are near them, that the hard conditions of their lives forbid their ever yielding to the imperative need for out-of-door rest and enjoyment.

Now, the people who have been coming year after year to this great interior country of woods and lakes and shaded, winding waterways, may as well take down their maps and mark this region of their unrestrained wandering and delight all over with big black letters, "No trespassing here." This woodland heritage of the people is passing from them. No matter who has owned these forest lands hitherto, everybody has been free to wander over them. A man could go where he pleased, and this freedom to go where he pleases is one of the chief sources of enjoyment in the woods for a man with a healthy nature. It is the wandering, the exploring, the going on to "fresh woods and pastures new" which inspires the "vital feelings of delight" in a true lover of the woods. Wordsworth's wonderful expression describes perfectly the experience of many thousands of weary men and women in these abodes of beauty and freedom and peace in former days.

"No trespassing here." Everywhere, as I pass through the country, I am told that the land is passing into the hands of capitalists, clubs, and companies. They have a perfect right

to buy all the land they can pay for, and to fence it in and put a sign across every woodland path and mountain brook with the inscriptions "Keep out," "No hunting or fishing here," "Trespassing forbidden under penalty of the law," but their acquisition of whole townships of mountain woods and lakes and streams will not make the region more attractive to tourists or lovers of the wilds. The people of the woods tell me everywhere that "the clubs are getting lots of land," and I could give the names of rich men and companies who are each acquiring territory enough for a principedom. One estate owns a township not far from Racquet Lake, in Hamilton County. A well-known capitalist and his friends "have the option" on 53,000 acres. That is more than eighty square miles. They can have the tract if they want it. A club of New York city men holds about 35,000 acres. These three blocks run up together, and stretch across the map for nearly thirty miles. The club has three-fourths of a mile of coast on Racquet Lake, a large part of Big Forked Lake, and all of Little Forked Lake. Brandreth Lake, with its tributaries, belongs to one family. The 53,000-acre block includes part of the shores of Tupper Lake and nearly all the coast-line of Smith Lake, which is one of the finest lakes in the North Woods. The state owns just a little of the outlet of Smith Lake.

This is to be the character of the next great period in the history of the Adirondack region: the gathering of many small holdings into a few large ones; the utilization, protection and enjoyment of these vast tracts by their owners; and the consequent and necessary exclusion of the people from the woods. The multitudes of visitors will go elsewhere; the state will lose the revenue which they have hitherto brought into it; the great hotels will be lonely places, and the innumerable summer camps will be broken up. If the state owned the land, its people could enjoy the freedom and peace of the wilds forever.

Now, a note relating to another feature of the general situation, and to arrangements for a Forestry exhibit at the International Exposition in New York City in 1892. I think we should arrange to set up a papier-mâché model of the Adirondack region, showing the extent and location of the devastations which have already been made, the tracts of denuded rock-surfaces, and those of burned-out, blasted land. Perhaps the Chamber of Commerce of New York City may feel an interest in this suggestion.

Star Lake, N. Y.

J. B. Harrison,
Cor. Sec. American Forestry Congress.

Orchids in Flower in Brooklyn.

To the Editor of GARDEN AND FOREST:

Sir.—Even at seasons when Orchid bloom is scarce, a visitor to the collection of Mr. Frederick Scholes will invariably find a rich display among the contents of five large span-roofed structures devoted to these plants. Each house has narrow side-stages and broad centre-stages, the former containing Cypripediums, Lycastes and *Odontoglossum grande* by the hundred, the latter being well filled with Eucharis, Palms, Ferns, and *Phajus grandifolius* in great numbers standing in a bed of Selaginella, Panicum, and Tradescantia, and forming a perfect mass of green. On a recent visit I found the roof of each house entirely hidden by the hundreds of wire baskets and wooden boxes containing Cattleyas, Lælias, Aerides, Vandas, Oncidiums, Phalænopsis, and many others whose long aerial roots enjoy the humidity rising from the dense bed of foliage below. Among the Cattleyas several specimens of *C. Dowiana* were showing enormous blossoms with unusually broad labellums, finely fringed, the rich golden veins running through the dark-purple ground in pleasing contrast, and the yellow in the sepals and petals unusually bright. Next to these the beautiful *C. maxima*, a pale but very pretty variety, bore fine flowers of a light-rose color, with conspicuous purple lines on the lip. *C. Harrisonia*, always admired for its soft color, was represented by at least a dozen specimens, well bloomed, among which were one or two highly-colored varieties. On a block, and suspended near the glass, was a splendid variety of *C. Schilleriana* bearing on a stem three well-developed, finely-colored blossoms, the sepals and petals a very deep rose, and the color of the lip unusually vivid. Here, also, in perfect health, were two plants of *C. Acklandia* in full bloom, and both in more vigorous condition than this species usually shows. It occupies a place here with such varieties as *C. guttata*, *C. intermedia*, *C. Harrisonia*, and produces its large green and dark-purple flowers annually. A plant of the pretty scarlet-flowered *Broughtonia sanguinea* was attached to a block near the glass. *Batemannia Burtii* was also yielding its odd reddish-brown and yellow flowers from

a strong plant grown on the stage where ample moisture surrounded it during active growth.

Oncidiums are grown extensively in this collection, and among the most notable in bloom were several plants of *O. leucochilum*, yielding stout, many-branched spikes, bearing the white and brown spotted flowers in great abundance. One remarkable specimen carried no less than 180 flowers on two stems. Some fifty plants of *O. Jonesianum* hanging in a sunny position were also promising flower, some with two and three spikes, and several already in bloom. The flowers of this variety are exceedingly pretty; the lip is broad and white, more or less spotted with rich purple, the sepals and petals being spotted with dark brown on a greenish-yellow ground. The Bee Orchid, *O. dasytyle*, was also in full bloom having three strong spikes of cream-yellow flowers, each with a blackish-purple centre, greatly resembling a Bee in shape. Stanhopeas could be counted by the score in great variety, many having four, five and six spikes each, and a fine group of *Odontoglossum Schleiperianum* were well flowered and very rich in color. The Phalænopsis, although not very numerous here, are probably the largest in the country. The individual plants are wonderful examples of cultivation. They are grown in wire baskets, and suspended about two and a half feet from the glass in a temperature much cooler than we usually find them. During the past winter this group, consisting of *P. Schilleriana*, *P. amabilis*, *P. Stuartiana*, *P. grandiflora* and *P. Sanderiana*, produced a magnificent display of bloom; no less than a thousand flowers were fully expanded at one time, easily the first among them being a remarkable specimen, *P. Schilleriana*, which carried 131 blossoms. At the time of my visit this plant had three growths, and eighteen sound leaves, many of which measured fifteen inches in length, and appeared well prepared for another display next season. *P. Esmeralda* was represented by a specimen with twelve spikes just showing for flower. It has six growths, and like all the other species mentioned is in vigorous condition, with stout, thick foliage and strong roots. All lovers of this beautiful genus will find the owner of this remarkable group of plants, or his skilful grower, Mr. F. Gardiner, ever ready to explain how such marvelous results have been achieved with one of the most beautiful Orchids ever introduced.

Summit, N. J.

A. Dimmock.

Diseases of Ampelopsis.

To the Editor of GARDEN AND FOREST:

Sir.—Will you please examine the leaves of Virginia Creeper enclosed and inform me whether there is an available remedy for this disease, and whether it can be communicated to the Grape-vine?

Orange, N. J.

E. H. C.

[This letter was referred to Professor Halsted, of Rutgers College, who replies that the whitish orbicular spots upon the leaves of the Virginia Creeper (*Ampelopsis quinquefolia*) are caused by a microscopic fungus which bears the name *Phyllosticta Ampelopsidis*. This minute fungus consists of very small threads or filaments, which run in all directions through the substance of the leaf and rob the leaf-cells of their vital fluids. Soon after the spot begins to be apparent from the dying of the leaf-tissue in the infested part, small spherical bodies appear which, after attaining full size, look like black specks upon the brown or sometimes nearly white spot. These dark bodies bear within a multitude of spores. These spores serve for the fungus the same purpose as do seeds among higher plants. It is, therefore, by these spores, which can only be seen with the high power of the microscope, that the leaf-spot fungus is propagated from year to year. With this fact in mind it is evident that, in order to destroy the fungus, all infested leaves should be burned.

The fungus is deep-seated and, therefore, does not make its presence in a leaf known until after a large part of its sapping and mining has been accomplished, consequently, it is not easy, as it is in some other mildews, to apply a remedy that will remove the fungus and save the part attacked. There is a leaf-spot of the Grape which is put in the same genus (*Phyllosticta*) with the one upon Ampelopsis. They are so much alike that it is not impossible that the plants upon which they grow are responsible for the difference. Professor Halsted is not sure that this disease can be communicated from the Virginia Creeper to the

vine, but he has recently seen it upon leaves of the "Boston Ivy"—*Ampelopsis tricuspidata* (A. Veitchi). Upon the same plant he has also observed the dreaded mildew of the Grape (*Peronospora viticola*). It is to be hoped that this useful Japanese creeper, which has hitherto been remarkably free from these pests, will not fall a prey to the many fungous diseases which now infest our native species.—Ed.]

Ribbon Grass.

To the Editor of GARDEN AND FOREST :

The "Ribbon Grass" (GARDEN AND FOREST, ii., 394) is common in most old gardens about Germantown. I enclose a specimen from an old farm-garden on my property, which was there when I bought it nearly twenty years ago. It does not often flower, but when it does, the upper portion of the culm bearing the flowers produce the green leaves of the normal form of the species. Upon the specimen the remains of the inflorescence, the green leaves and the lower striped leaves on the same culm can be plainly seen. "Gardeners' Garters" is a very common "common name" for this plant.

Germantown, Aug. 15th, 1889.

Thomas Meehan.

Notes.

Masses of *Pontederia azurea*, of an acre or two in extent, are found floating in the river Parana.

Kœlreuterias are blooming for the second time, and many of the panicles are as large as those of the first flowering.

Owing to the cool, damp weather, blooms of such Roses as *Perle des Jardins*, *Papa Gontier*, *The Bride* and *Niphetos*, now in market, are as large and full as they usually are in the middle of September.

Mr. W. Watson, assistant curator of the Royal Gardens, Kew, assisted by Mr. Bean, the foreman of the Orchid department, has commenced the publication, in monthly parts, of a treatise on Orchids, for the use of amateurs.

Some remarkably fine Lotus flowers from the pond in New Jersey, where they are naturalized (see GARDEN AND FOREST for April 10th), were lately sent to this office. The expanded flowers measured thirteen inches across.

Messrs. Siebrecht & Wadley have issued a catalogue of more than 200 pages, in which, for the convenience of amateurs, the plants are grouped into classes, according to their cultural requirements and adaptability to various special purposes.

Among the small trees now in bloom *Rhus semialata*, var. *Osbecki*, is conspicuous, being covered with white flowers in spikes fifteen inches long and six or eight inches in diameter. The rich, tropical-looking foliage is a glossy green, changing to bright colors in autumn.

The large white flower-clusters of *Hydrangea paniculata grandiflora* are now very freely cut and sold for decorative purposes. Not only do they remain without wilting for a week or ten days in a warm room, but they will dry on the stems and retain their cream-white color all winter. Half a dozen of these panicles on long stems in a large vase, with spikes of *Gladiolus* of some positive color, make a very effective group.

The Governor of New Hampshire has appointed Messrs. John J. Bell and John D. Lyman, both of Exeter, to represent the state at the annual meeting of the American Forestry Congress, in Philadelphia, October 15th to 18th, and the Governor of Tennessee has appointed the following gentlemen: J. M. Coulter, Dyer Station; John P. Buchanan, Murfreesboro; Tomlinson Fort, Chattanooga; Lucius Polk, Columbia, and P. C. Isbell, Manchester.

The city trade in such plants as Mignonette, Sweet Peas, China Asters, Sunflowers, and, lately, single and double Dahlias has been good all summer long. Many people who have no country seats at Lenox or by the sea buy flowers, not because it is the fashion, but because they love them, and they buy them more abundantly in summer because they are cheaper. When spikes of *Gladiolus* are selling at twenty-five cents a dozen they are quite as beautiful as when they cost seventy-five cents each.

A White Oak tree was cut near Scottsburg, Indiana, not long ago which measured, according to the *St. Louis Lumberman*, twenty-seven feet in circumference. The tree was ripped up by means of a cross-cut saw, and the owners got out one board

that was ten inches thick, five feet two and a half inches wide at the butt and four feet six and a half inches at the top, and thirty-two feet long. This board was loaded upon a broad-tread wagon, to which two yoke of oxen and eight horses were hitched, and it took one whole day to remove it one and a half miles.

Nymphæa Marliacea chromatella is a hybrid from *N. flava*, the Yellow Water Lily of Florida, the other parent being, as English authorities say, *N. tuberosa*. However that may be, the plant is now blooming with Mr. E. D. Sturtevant at Bordentown, New Jersey, and it seems to be an acquisition. The flower is yellow, considerably larger than that of the Florida plant, and a trifle larger than the northern pond Lily, *N. odorata*. Its odor is pleasant, but not powerful; it continues to bloom from June until late autumn, is more floriferous than *N. flava*, and, what is of greater importance, it is perfectly hardy in this latitude.

The New York Florists' Club have selected Mr. John Thorpe as the representative of their interests in the management of the World's Fair to be held in this city in 1892. Already the nurserymen and florists of the Old World, who have a rapidly-growing trade in this country, are inquiring as to their probable opportunities for a display, and if anything like a characteristic, complete and continually fresh exhibition in the line of floriculture is to be made the work of organizing it should not be deferred much longer. No man in the country is better fitted for such a place by natural aptitude and experience than Mr. Thorpe.

Colonel Pearson has visited the famous vineyards on the shores of Lake Keuka and of Seneca Lake, under instructions from the Department of Agriculture, and he reports that the Black Rot, as well as Anthracnose, and both the "downy" and "powdery" Mildews have at last attacked the vines in this region, where these diseases have been hitherto practically unknown. Discouraging reports of the Black Rot also comes from the Hudson River Valley. Of course, it is now too late to use remedies with any success, but the Grape-growers are eagerly studying the matter and preparing, as well as they can, to use preventive measures another season.

Rev. M. J. Berkeley, who was the first botanist in England, and for many years almost the only one, to give systematic attention to the diseases of plants, died on the 30th of July, at Sibbertoft, of which place he had been vicar for twenty years. He had a wide knowledge of almost every department of botany and natural history, although he was especially eminent in the field of cryptogamic botany, and it was through his discriminative knowledge of Fungi and their effects upon plants that he rendered most signal service to horticulture. Mr. Berkeley was a man of striking and dignified appearance and of straight-forward and manly character. He was eighty-six years old.

The dwarf trees which the Japanese horticulturists are showing at the Paris Exhibition are attracting much attention. Pines, Thujas and Cedars, said to be 100 or 150 years old, are only eighteen inches high, and with such specimens it would be easy to have a coniferous forest on a balcony. These arboreal deformities are produced by great labor, and, if the truth is told about their ages, this work of arresting the tree's development and forcing it into contorted forms must be persisted in by several generations of foresters. All this painstaking is hardly paid for by the beauty of the resulting abortions, but, as has been suggested, a look at these trees will explain where the fantastic forms come from which serve as models for the plants we see on the lacquered trays, bronzes and embroideries which come from Japan.

Next to the Yellow or Long-leaf Pine, the Cypress is the most important timber tree in Florida. Aside from the manufacture of shingles, for which it is so largely used, there is a large demand for this timber for boat-building and bridge-construction. Cypress is preferred for window sashes and outside doors, for inside work of brick houses, for water-tanks, cisterns, barrels, buckets, tubs and water conductors. It furnishes a good body for veneered furniture, and veneer itself made from Cypress burls is often of extraordinary beauty. For railroad ties this timber is unexcelled, and likewise for paving blocks. As there is much waste in sawing Cypress, and it is difficult to dispose of this waste, even by burning, the *Florida Times-Union* suggests that the manufacture of these blocks might be made most profitable in connection with a Cypress mill near some city like Jacksonville. Cypress blocks have proved very satisfactory for paving in that city. In Galveston, where no sap-wood is used, the sawed blocks of heart-wood show very little wear.

Problems in Horticulture.

THE letter from Rev. Lyman Phelps, on another page of this issue, gives some facts which confirm his belief in the immediate influence of foreign pollen on the constitution and quality of the Orange. The fruit on other trees in groves where certain strains of the Navel and Blood Oranges are growing is changed, according to his observation, in general appearance, form and flavor, partaking of the qualities of the two varieties named. Of course, it is not demonstrated that the change does not come from variation in the bud; but no one is prepared to say, with certainty, that changes in a fruit are never due to the influence of pollen from another plant. Practical cultivators believe that, with fruits, as a rule, no such change need be expected. Some varieties of our native Plums, when planted by themselves, bear sparingly, because, as it is assumed, their ovules are imperfectly fertilized. When, however, these trees are planted near others which yield abundant pollen, a larger amount of fruit is set. It is supposed that this is due to the fact that pollen from surrounding trees is conveyed to the stigmas of the flowers of the native Plums. But no one expects to find any change in the fruit. The Wild Goose Plum remains the same, no matter where the pollen comes from. Certain varieties of Grapes are also more productive when planted near vines which yield abundant pollen, but the fruit remains identical with that from self-fertilized flowers. Elaborate experiments have been made by Mr. A. A. Crozier and others in crossing Apples, Grapes, Pears, Plums and Squashes, and in no instance did the influence of the foreign cross appear the first season, and yet, in the absence of direct proof, we must admit that here is a problem which is not completely solved.

For several months an energetic discussion has been carried on in English horticultural journals as to certain alleged evils arising from the practice of grafting. The positions taken on either side of the controversy show how widely at variance are the views of practical propagators on matters which may be of vital importance in the history of the plant treated. Incidentally, many related questions are suggested. At what age does a tree furnish buds or cions which will prove the most healthy, long-

lived and productive? Will there be any difference in the result if buds or cions are taken from different parts of the same tree? Or, do buds taken from the leader of a nursery tree develop into trees which differ in productiveness or vigor from those originating in buds from side branches? Is there any difference, for grafting purposes, between the terminal bud and buds lower down; and how near the end of the shoot should we look for the buds which will make the healthiest tree? Questions like these are of practical moment. It seems to be admitted that improper selection of stock and cion will cause a deterioration of the plant, but many propagators have an opinion that buds and cions can be chosen and set so as to perpetuate the qualities we wish to retain. Can more than this be accomplished? In a late number of this journal, Professor Goff pointed out the fact that the Wilson Strawberry has improved under a system of propagation from offsets. In an address before the Pomological Society in Florida last winter, he also called attention to experiments at Geneva which seemed to show that potatoes can be improved by a certain method of selection. In view of these facts, it is not impossible that by some system of budding or grafting certain desirable qualities in plants can be actually increased.

But if it is assumed that the only hope of improvement in plants lies in the production of seedlings, a thousand other questions at once obtrude themselves upon us. If a seed which results from hybridizing or cross-fertilization is sown, what qualities are most likely to be transmitted from the pollen-parent and what ones from the mother plant? It has been suggested that a cross might be produced between *Prunus Simoni* and some of our varieties of the Peach with the possibility of securing a fruit of good quality that could be grown in more northern latitudes. In the same way, a cross between the Japanese Persimmon and our native *Diospyrus* might possibly yield a fruit approaching in size and quality the Japanese product, and equaling our native fruit in hardiness: In either case, which kind should we select as the pollen-parent with the greatest hope of success? Certain varieties of the Peach and Plum will come true from the planted pit; to what extent is it possible to secure the same result with Apple seeds, for example, from blossoms in which self-fertilization has been made certain? Some experiments by Dr. Sturtevant seem to indicate that Raspberry seedlings produce a better average quality of fruit when they originate from few-seeded berries than they do when they originate from many-seeded berries, and this suggests the advisability of making similar tests in other fields.

But there is no need of multiplying questions of this sort. What we desire to call attention to is that our knowledge of the principles which underlie ordinary horticultural practice is limited in every direction. Considering the nature of the subject, and the mystery which envelops all the processes of life, it is not surprising that we know so little, but it will be surprising if the spirit of awakened inquiry does not prompt students to more thorough and systematic investigation in this field than have been hitherto undertaken. There certainly is no lack of opportunity for our experiment stations to prove that they can be of practical benefit to all who have gardens and orchards.

How to Mask the Foundations of a Country House.—IV.

IT has been said that the color of their foliage, as well as their form, should be considered in grouping shrubs about the base of a house. The flowers which they bear likewise demand attention. A succession of bloom throughout the season should be secured, while the more common practice is to select only such plants as flower in early spring. Some favorite shrub, with very conspicuous flowers, like a Forsythia, is often repeatedly introduced in scattered positions, producing a restless, patchy effect of color that could be obviated by a little massing. It should be remembered, too, that a plant with pink or lilac blossoms will not often look well next

to one with yellow blossoms, while a white-flowering plant will harmonize with either.

Too much stress should not be laid, however, upon the flowering qualities of the shrubs as a whole. Qualities of foliage are more important, because more persistent, and because, after all, green is the color we chiefly want close to the house. A few evergreens are always desirable, but there should not be too many of them. If so, the summer-effect of the plantation will be sacrificed to the winter-effect; during the summer months it will have too stolid and heavy and gloomy a look. And even in winter this look is given by an over-use of evergreens. Leafless shrubs are beautiful, as well as those in leaf, and almost or quite alone can clothe foundation-walls to a degree that suffices when Nature at large is bare. Many deciduous shrubs have a peculiar charm in winter, while they do not fall behind their rivals at other seasons—Golden-twigged Willows, for instance, Red-twigged Dogwoods, and a multitude which carry their bright berries well through the inclement season. If some of these are selected, and evergreens are sparingly introduced, the effect of the winter shrubbery may be made extremely beautiful. Care should be taken, however, to mass the evergreens a little, so that when they are thrown into full relief by the fall of deciduous leaves they will not look as though spotted about at random; and a station quite near the walls is, for this reason, usually the best. If deciduous plants, with bright-hued leaves, are, as a general rule, to be avoided, so, too, in an even greater degree, are golden evergreens. It is especially desirable that whatever foliage we have in winter should be green; and a bright-yellow shrub has an even more distinctly spotty and obtrusive look in winter than in summer. The bright color of the twigs and berries on the deciduous shrubs just named is not open to the same objection, for the hue is then so delicate and airy that it cannot offend the eye.

The hardest task of all is to plant well around a house which is square in shape and encircled by piazzas. The absence of angles and recesses makes the grouping of plants very difficult, and it is difficult, too, to vary their upper outline agreeably when they cannot rise against a background of solid wall. Many suburban houses are built in this way, and are usually encircled by a line of flower-beds with annual creepers—Nasturtiums for choice—trained against the piazza-lattice and posts. A better device would be to plant hardy creepers against the posts, and very low-growing hardy shrubs elsewhere, grouping them with higher ones when an angle does offer, and carrying them out to meet higher plantations, if such can be placed a little to one side of the house. As very low-growing deciduous shrubs are so inconspicuous in winter, a freer use of evergreens may be recommended in cases of this sort. There are many kinds of Japanese Retinosporas, for instance, which grow from a foot to two feet in height, and are admirably adapted for the purpose. Anything hardy and anything green, however, is better than a flower-bed, which is too formal and too gaudy in summer, and which vanishes in winter, leaving that ugliest of all objects, a stretch of naked earth. Much pains and money are often expended, to very poor effect, in planting such beds. For example, we saw last May a large house flanked with piazzas, one side of which was bordered with, first, a thick line of bright Golden Elders, then a wide band of Iris in blossom, and then a broad bed, with a curving outline, filled with showy spring annuals. The first cost must have been considerable, and it was evident that more money and labor would soon be needed to replace the spring-flowers with others, and that when winter came there would be a wide, unattractive line of naked earth. And, meanwhile, the spring-effect itself was hideous in its formality and its gaudy, ill-arranged colors; and, far from uniting the house with its surroundings, the planting actually separated the two with a bolder, more conspicuous division than had there been nothing but green grass. Unity in color and variety in line were needed, but what was supplied was monotony alone and a crude diversity in color.

Naturally, however, a few flowers of certain sorts may sometimes be introduced with excellent effect on the edge of a shrubbery which encircles a house, or close to the house, between the masses of shrubs. Certain flowers of an architectural character, so to say, like Hollyhocks and Dahlias, Sun-flowers and Gladioli, never look better than when growing against a wall, only there should not be many of them, and their places, as well as their colors, should be carefully chosen. Accents of color will be welcome, but the look of a flower-border should be avoided.

In selecting shrubs for the purpose now in question, one other consideration should be borne in mind. This is the natural character of the site. The foundations of a suburban

villa on a flat piece of ground, which should rightly be treated as a carefully-tended little garden-landscape, and those of a cottage, we will say, on a rocky stretch of New England shore, should not be planted in the same way. In the one case, garden-shrubs will be appropriate; in the other, those native products of our woods and swamps, which are quite as beautiful, and almost as numerous. It would be undesirable to surround a villa with picturesque clumps of Mountain Laurel, Blueberry and Clethra, suggestive of really rural scenes; but such plants as these are just the ones to group about a picturesque cottage standing on a rocky site, and with Pines or other native trees in its vicinity. Of course, efforts are sometimes made to treat the whole extent of a place like this in the conventional, gardenesque way; and if the grounds, as a whole, are thus inappropriately managed, it matters little, perhaps, what is done with the house-foundations. But the tide of taste has turned. There is a growing desire to preserve the essential characteristics of a site, and to value them all the more if they are distinctly different from the regulation suburban type. And when this desire is felt, there is nothing more important than that, in clothing the foundations of the house, native local shrubs should be chosen instead of those appropriate to more conventional pleasure-grounds.

Miles Joseph Berkeley.

THE news of the death of Rev. M. J. Berkeley, the distinguished English mycologist, will be received with deep regret, not only by those specially occupied with the branch of botany in which he was pre-eminent, but also by all who are interested in the progress of horticulture and vegetable pathology, to which he constantly contributed during his long and busy life. He was born April 1st, 1803, at Biggin, in the parish of Oundle, Northampton, and, after a preparatory course at Rugby, entered Christ's College, Cambridge, where he graduated in 1825. Although destined for the church, he was much attached to the study of natural history while at the university. At first curate at Margate, in 1833 he assumed charge of two small parishes near Wansford, Northamptonshire, and was also rural dean of Oundle and Weldon. In 1868 he was transferred to the vicarage of Sibbertoft, a small village near Market Harborough, in which quiet and retired parish he passed the remainder of his life. During his later years he was a great sufferer from gout, and for some time had hardly been able to leave his house, or even his chamber. His death occurred on July 30th, at the ripe age of eighty-six years.

Berkeley's first work in natural history is said to have been on Mollusca, but his reputation rests on his wide knowledge of Fungi, in which he far excelled all his British contemporaries, and was a worthy rival of the distinguished Elias Fries, often called the father of mycology. His botanical work, however, was not confined to Fungi. In 1833 appeared his "Gleanings of British Algæ," a supplement to the English Botany, which is still regarded a classic work, and thirty years later he published a "Hand-book of British Mosses." His writings on Fungi were very numerous; a few of them in book form, but the greater part papers in botanical journals and the proceedings of learned societies. They were devoted especially to the descriptions of species from all parts of the world, for, such was his reputation as a systematist, that collections were sent to him for study from both continents—from the Arctic to Antarctic regions. The new species described by him must number several thousands. Of his books the admirable volume on Fungi in Hooker's British Flora, 1836, seems to us especially excellent. "The Outlines of British Fungology," 1860, was an attempt at a revision of the earlier volume with descriptions of the larger species and an enumeration of the smaller species. The "Introduction to Cryptogamic Botany," 1857, was the first general treatise on the subject in the English language, and contained a large number of original observations, especially with regard to Fungi.

Berkeley was for many years a frequent contributor to the *Gardeners' Chronicle* and the journal of the Royal Horticultural Society, to whose pages he gave many important original notes on plant diseases, besides many critical reviews of the work of others on this important subject. His contributions to these journals were often in a semi-popular form, and did much to extend the knowledge of a then much-neglected branch of botany.

The name of Berkeley is held in hardly less reverence by American botanists than by his own countrymen. For a period of nearly forty years after the death of Schweinitz, the first American mycologist, in 1834, scarcely anything was published on North American Fungi, except what came from the pen of Berkeley, who found a zealous correspondent and

fellow-worker in the late Rev. M. A. Curtis, of North Carolina. Not less than twenty-five papers, including these published conjointly by Berkeley and Curtis, contain notices of North American Fungi; the "Notices of North American Fungi" in *Grevillea*, 1872-76, alone having descriptions of over one thousand species, almost all of them new.

Berkeley was a man of a singularly sweet and frank nature, and, although, with advancing years and increasing bodily infirmity, he was forced to live in retirement, he was still the leader of British mycologists, beloved and respected by all. Those who knew him in his prime, or even in his declining years when unable to associate freely with scientific men, as was his wont, recall his unvarying courtesy, his constant readiness to aid others in their studies, his simple and cordial manner. With a large family, forced to depend on the modest income of a remote parish, we are compelled to admire the courage and energy which enabled him to accomplish so much for science, and only regret that he had not been placed early in life in some position where he could have devoted his whole activity to the pursuit of his favorite science.

Berkeley's personal appearance was very striking. His large frame, his dignified and intellectual face, admirably set off by his full, white beard and flowing hair, commanded at once the respect, which an acquaintance with his elevated character and unselfish disposition served only to deepen.

W. G. F.

The Fairbanks House at Dedham.

OUR picture on page 415 shows a house in the town of Dedham, near Boston, Massachusetts. It is one of the oldest houses in this country which is still intact and habitable, and undoubtedly the very oldest in which descendants of its builder live to-day. The builder of this house was Jonathan Fairbanks, a native of the West Riding of Yorkshire. He landed in America in the year 1633, lived for three years in Boston, and then built the house we illustrate in the year when the town of Dedham was incorporated. At his death, in 1668, he left it to his eldest son, John, and his offspring in the male line have since uninterruptedly inhabited it. The seventh generation now dwells within its venerable walls, and the care and good taste they display in its preservation are exceptional in this land of little respect for ancient relics and too-frequent desire for showy surroundings rather than for those which are harmonious and therefore beautiful.

The original house has never been altered, but now forms the central portion of the picturesque little group of walls and roofs. The wings were added about one hundred and fifty years ago, and although, perhaps, no conscious desire for good, architectural effect guided their designing, their presence greatly increases, instead of injuring, the charm of the simple first building. The shingled roofs, of course, have been repaired from time to time, but only as necessity compelled, and without disturbance of the weather-stains and lichens, which give a beautiful greenish tone that contrasts delightfully with the soft, unpainted gray of the walls. The house stands a short way back from the road, raised on a gentle little hill. This is covered with good turf, kept sufficiently neat, but not rolled and tended as a lawn might be about a more pretentious residence. A number of great Elm-trees overshadow the slope and the house itself, disposed in an irregular way, which under the circumstances could hardly be improved upon. They must be nearly if not quite as old as the house itself. The simple dignity of effect produced by this use of a single kind of tree, especially well adapted to its purpose, may teach a useful lesson to the owners of the villa and cottage of to-day. Now it is the custom to plant a variety of trees even when the grounds are as small as these of the Fairbanks house, and little thought is usually given to their grouping. Consequently we most often see a huddled, inharmonious result, in which the beauty of the individual trees disappears, and the place as a whole is deprived of character as well as of unity. But even when most carefully grouped it is a question whether the association of different trees in a very small place could be quite as beautiful—quite as simple, dignified, and harmonious—as is this company of wide-spreading Elms, so thoroughly expressive of shelter and of shadow, and each so admirably developed.

But perhaps the most noteworthy point in the attractive picture presented by this house and its surroundings is the way in which the shrubberies grow about it. Lilacs and other old-fashioned shrubs were planted long ago close to the foundations, and have been allowed to develop freely while kept from undue raggedness. Now, as will be seen, they overtop the humble walls in many places and group with the sloping roofs

in a fashion which must strongly attract the eye of every wandering landscape-painter. In summer, tall Hollyhocks and Dahlias grow in clumps close to the house, giving just the notes of brilliant color needed to complete the pretty picture it makes; but no formal beds or flaunting, "new-fashioned" flowers are allowed to introduce a discordant accent. No old English cottage seems a more integral part of its natural surroundings than does this little New England home, and none is more picturesque than this despite its characteristically American shape and material. Time, we see, can sanctify and beautify even a wooden house of the humblest proportions, if only the hand of man gives it a little aid in the way of tastefully planted trees and shrubs, and then does not interfere with its work. Here no inharmonious element has been introduced—each feature and detail suits all the others, and the general effect, although it is simply that of a small, unpretentious farm-house, lacks neither refinement nor true beauty. A single bed of *Coleus*, a single attempt to prune the luxuriant shrubs into a more "orderly" form, a single touch of crude paint on the house itself, a single architectural "improvement" of modern fashion, would ruin it all. Fortunately, nothing of the sort has ever been attempted; and it is to be hoped that, even when descendants of Jonathan Fairbanks no longer dwell beneath his roof-tree, he into whose possession it may come will prove himself possessed of as much reverence and good taste as they. So scarce and precious, indeed, are relics such as this in America that the town-fathers of Dedham might well desire to take it under their own protection, to assure preservation for as many centuries as its sturdy timbers can still endure.

The photograph from which our illustration is reproduced was made by Miss A. L. Rotch, to whom we are indebted for its use.

Notes Upon Some North American Trees.—VII.

125. *CRATÆGUS ARBORESCENS*, Ell.—This name was published by Elliott (Sketch of the Botany of South Carolina and Georgia, i., 550) in 1821. Linnæus' herbarium, however, shows that he knew this plant, and that it is his *Cratægus viridis* (Species Plantarum, 476). The specimen is in flower. It has no thorns, and exactly represents the common glabrous form of this now well-known plant. An almost identical specimen is found in the herbarium of the "Hortus Cliffortianus" preserved in the British Museum. Professor Gray, who examined the Linnæan herbarium in 1839, wrote in pencil on the sheet of *C. viridis* "certainly a distinct species, A. Gray," having reference to the fact that *C. viridis* has been referred by American botanists to *C. coccinea*. The fact, however, of its identity with Elliott's plant, at that time very little known, seems to have escaped his notice. It is not clear from whom Linnæus derived his specimen. The species is credited in the "Species Plantarum" to Virginia, but this tree is not known to grow now anywhere north of the valley of the Savannah River. Dr. John Garden, who lived in Charleston in the middle of the last century, was the only correspondent of Linnæus who resided anywhere near the locality where it is now known; and there is nothing to show that the specimens were sent by him. It is not altogether improbable, although rather unlikely, that the plant which has been called *Cratægus arborescens*, but to which I propose to restore in the *Silva* the Linnæan name, may extend as far north as the coast-region of Virginia, and that it was really from Virginia that the specimens upon which Linnæus founded the species were sent.

127. *CRATÆGUS COCCINEA*, L.—The Scarlet Thorn is the most variable, within certain limits, and the most widely distributed of the North American species. Two or three extreme forms appear at first sight to represent as many different species; but these pass, however, one into the other, and it is not always easy to distinguish them. Certain characters, however, are constant; and the brown bark of the young branches, the long, stout, and usually abundant chestnut-brown spines, the prominent glands on the serratures of the stipules and leaves, on the peduncles and acuminate calyx-lobes, and the bright scarlet fruit, always pendulous at maturity, are common to all the forms, and serve to distinguish *Cratægus coccinea* from *C. tomentosa* with which it has often been confounded. The stipules are

lanceolate and narrowly acuminate but on vigorous shoots often become broadly ovate and cordate. The number of styles varies from two to five, but the fruit except in shape and size, and in the number of seeds, which are strongly ribbed on the back with two deep grooves, is very much alike in all the forms of this species.

The principal forms may be arranged as follows :

1. Var. *TYPICA*, with rather small sharply serrate, or somewhat cut-lobed leaves, cuneate at the base and pubescent on the lower surface especially on the mid-rib and primary veins; few-flowered, pubescent corymbs of small flowers (half an inch across) with pubescent calyx, and round or sometimes pear-shaped fruit rarely more than half an inch in diameter.

2. Var. *POPULIFOLIA*, with more slender spines, thin, glabrous, sharply serrate, somewhat incised leaves, often truncate or slightly cordate at the base, borne on slender petioles, and small glabrous, or occasionally hairy three to five-flowered, small, narrow corymbs.

3. Var. *MACRACANTHA*, with very long, stout spines, thicker leaves, cuneate at the base and tapering into a stout petiole, sharply serrate, and incised above the middle, slightly pubescent on the lower surface when young or quite glabrous or with a few scattered hairs on the mid-rib and primary veins; broad many-flowered, pubescent cymes, and rather larger flowers and fruit than in number one.

4. Var. *MOLLIS*, with densely pubescent shoots, large-broad leaves, usually incisely cut into acute, narrow angulate lobes, cuneate, truncate or heart-shaped at the base, often somewhat scabrous on the upper surface, the lower more or less densely covered with pubescence, broad pubescent cymes, with large flowers (one inch across) and large spherical or pear-shaped, sometimes punctate fruit covered with a white bloom.

What I consider the typical form, that is the plant, which, as shown by his herbarium, Linnæus had before him when he established the species (*Species Plantarum*, 476), is common, from Newfoundland to Florida, and extends west to Minnesota, Missouri and Texas. It is the common Thorn in the valleys of the southern Alleghany Mountains and is not rare in the Gulf States. The leaves are sometimes quite glabrous. This is usually a stout, tall, or even a small shrub with intricate branches, or more rarely a small tree.

Var. *POPULIFOLIA*, Torr & Gray, Fl. i., 465 (*C. populifolia*, Ell. Sk., i., 553), appears to be confined to the south Atlantic States, although forms intermediate between this and No. 1 are found everywhere. It was described by Elliott as a shrub with slender branches, but I have never seen it growing; and I am not acquainted with the fruit. I have flowering specimens collected by the late Dr. Ravenel at Augusta, Georgia; and Curtiss' *C. coccinea*, No. 807, collected in Alachua County, Florida, belongs here.

Var. *MACRACANTHA*, Dudley, "Cayuga Flora," 33 (*C. glandulosa* ? Willd.), is widely distributed from the valley of the St. Lawrence to Manitoba, Colorado, and the western slopes of the Cascade Mountains in Washington. I have not seen it anywhere south of New York and Missouri. It is a small tree or shrub, with long, straggling branches, thickly armed with sharp spines often four to five inches long, and in the west, with thick almost coriaceous leaves. It is confounded in the eastern States, especially in New England, with *C. tomentosa* to which have been referred generally the red-fruited Thorns of the western Mountains, which all belong here.

Var. *MOLLIS*, Torrey & Gray, Fl. i., 465 (*C. subvillosa*, Schrader), is found from eastern Massachusetts, through western New York to Missouri and middle Tennessee, and south-westward through Arkansas and Texas to the Sierra Madre Mountains of northern Mexico. It seems to be wanting from the South Atlantic and Gulf States east of the Mississippi, and from the whole Alleghany region. This is the largest of our northern Thorns, and one of the largest of the genus, often reaching a height of thirty feet, with a clean, straight trunk and a wide, round head. The leaves vary greatly in the amount of their pubescence, being at the east sometimes nearly glabrous, while the amount and density increase in proportion as the climate

of the region in which the individual has grown, is deprived of moisture. This variety flowers fully a week earlier than the other forms of the species, and the fruit which falls as soon as it is ripe is several weeks earlier. The eastern, or less densely-pubescent form, is very well figured in Emerson's "Trees and Shrubs of Massachusetts" 2 ed., as *C. tomentosa*. Nos. 1, 3 and 4 may be seen growing together in the space of an acre, close to the north shore of Massachusetts Bay, in the town of Revere, and their different habit and appearance, contrasted. At this place the three forms are well marked and show no tendency to vary among themselves. In Berkshire County, on the contrary, where all three grow in great abundance, they have so inter-bred that it is almost hopeless to try to separate them.

C. S. Sargent.

New or Little Known Plants.

Tigridia buccifera.*

OF the discoveries made by Mr. Pringle last year in the mountains of Mexico there has already been figured in the GARDEN AND FOREST (Vol. I., Fig. 61) a new species of *Tigridia* belonging to the typical *T. pavonia* group. We now offer one of the *Beatonia* section, which are distinguished by smaller and more or less purple instead of orange flowers, and by minute terminal stigmas. From *Nemastylis*, which the species greatly resemble in habit, they differ in the inequality and dissimilarity in form of the outer and inner segments of the flower, and in the position of the styles, which are here opposite to the anthers, instead of alternate with them.

In the present species the flower is nearly two inches broad, with the saucer-shaped base, formed by the broad concave bases of the segments, of a pale, greenish-yellow, dotted uniformly with purple. The obovate blade of the outer segments is a clear light purple. The shorter inner segments are very peculiar in shape, being folded together in such a manner as to form a sunken longitudinal tube down the centre, the dilated sides at the outer end of the tube approaching each other in the form of two cheek-like prominences. These are colored white, purple and yellow, while the small, rounded, terminal blade is a deep purple. The anthers are erect and nearly sessile upon very short united filaments, the cells of each anther separated by a broad connective, as in some species of *Nemastylis*. The styles are closely united nearly as high as the top of the stamens, where the conical branches suddenly diverge, and are exerted in pairs between the anthers.

The flowers, as is frequently the case with plants of this order, are quite fugacious, lasting at the longest only for a single day. But while they last they are remarkably pretty, and a succession from the several spathes of one or two flowers each day is assured for several days. The drawing is a very faithful representation of a plant which bloomed in Cambridge in July of this year from bulbs collected by Mr. Pringle, in 1888, in the mountains of Jalisco, Mexico, and received from Mr. F. H. Horsford of Charlotte, Vermont.

Foreign Correspondence.

London Letter.

THERE were very few Orchids sent to the Committee of the Royal Horticultural Society at its last meeting, and the only one certificated was a lovely variety of the rare *Sobralia xantholeuca*, which has been named *Alba*, although it is not pure white. In the original the flowers are pale yellow with a deeper colored lip, and sometimes flushed with lilac. In this new variety the sepals and petals are very faintly tinted with

**TIGRIDIA BUCCIFERA*.—Stem a foot high, from a small bulb, branching, glaucous; radical leaves nearly as tall, plicate, three lines broad, the cauline bracts (three) more or less foliaceous; spathes of two unequal bracts one and a half to two inches long; perianth two inches broad, with purple-dotted, greenish-yellow base, the blade of the outer segments obovate, purple; inner segments tubular-folded in the centre, the dilated sides below the small, concave-rounded, deep-purple blade approximate in two cheek-like prominences; anthers nearly sessile, with broad connectives; styles as long, the conical branches widely divergent, exuded between the anthers.

sulphur-yellow, but the lip is primrose-yellow. The large size of the flower, equalling that of the common *S. macrantha*, and the graceful evergreen foliage render this one of the finest Orchids in cultivation. Two very pretty forms of *Cattleya Eldorado* were noteworthy. One named Painted Lady, from Sir Trevor Lawrence, had the sepals and petals snow-white, the labellum deep orange-yellow in the throat, and adorned with a small crimson-magenta blotch at the lip. The other form was named *Albo-splendens*, in which the lip was more highly colored. The variety named Wallisii, which is quite white with the exception of a yellow throat, was also shown. These *Eldorado* *Cattleyas* are particularly valuable, as they always flower at this season when Orchid bloom is scarce. *Dendrobium revolutum*, a small inconspicuous flowered species, but interesting botanically, was awarded a botanical certificate, as was also *Maxillaria fuscata* with reddish-brown flowers not unattractive.

One of the most important certificated plants was the new *Spiraea gigantea*, a hardy herbaceous plant from Kamtschatka, and said to be a form of *S. Kamtschatica*. It is a noble plant, rising with a stout erect stem fully eight feet high, clothed with large vine-like leaves nearly a foot across, and terminated by a long plume-like cluster of white blossoms after the manner of *S. venusta* or *S. Ulmaria*. It will be a grand addition to our list of plants that thrive on damp soil, by the margin of a stream or lake, and no doubt it will prove quite hardy with you. It was shown by Messrs. Paul, of Chess-hunt. Another first rate new hardy plant was Späth's variety of the Siberian Dogwood (*Cornus siberica Späthii*), shown by Messrs. Veitch. It is one of the most striking variegated shrubs I have seen, the leaves being of a bright yellow, broadly margined and marked with various shades of pale green. It showed no traces of sun burning in the foliage, so common among bright-leaved shrubs. In view of the hardiness and vigor of the Siberian Dogwood, this variety will most likely prove as valuable for

ornamental planting as any variegated shrub we have, and will be hardy, no doubt, in America. A good addition to single Bouvardias we have in the new sort, Mrs. Robert Green, shown by Mr. May, one of the leading market florists about London. It is a sport from the President Cleveland variety and pos-

sesses all the good points of that popular sort. It is dwarf and vigorous and produces large and abundant trusses of salmon-pink flowers—a tint different from that of old sorts. It will be a good plant both for market-grower and general gardener. Two exceptionally handsome new ferns worthily won certificates. One was a pendulous form of the common *Pteris serrulata*, named Plumosa. It has long fronds, crested or tasselled at the extremities, which hang in a graceful way on all sides of the pot, which is quite hidden by them. It is sure to become popular both for pots and hanging baskets. Mr. Coleman, of Tunbridge Wells, exhibited it. The other fern was *Cyrtomium falcatum Fensomii*, a handsome form of a well-known green-house fern, having bold, deep green, shining fronds. All the above were novelties, but a certificate was also voted to the old *Bigonia Cherere*, from Guinea, so as to emphasise the merits of a green-house climber, which was formerly more commonly grown than now. It is a strong climber with large foliage, and produces, at this time of the year, huge clusters of long trumpet-shaped flowers of a deep maroon crimson. The specimens came from Sir George Mackay's garden, one of the most beautiful in Surrey, teeming, as it does, with a wealth of beautiful plants out of the ordinary run. The lovely *Bigonia (Tecoma) jasminoides*, also a green-house climber with large clusters of trumpet flowers, white, with carmine

centres, was also shown in perfection from the same garden. An important exhibit was that from Mr. Anthony Waterer, of Knap Hill, consisting of about a score of seedling varieties of *Lilium auratum*, all different from the original form, and varying in color from a rich crimson to pure white minutely

Fig. 125.—*Tigridia buccifera*.—See page 412.

spotted with crimson. The finest forms were those much like the magnificent *L. Parkmanni*, raised in America about twenty years ago by Mr. Francis Parkman, and whose stock passed into the hands of Waterer. It has not, unfortunately, been put into commerce yet, so that lovers of Lilies have a treasure in store for them. A few of the seedlings now exhibited so much resemble Parkman's that they would pass for them, and perhaps they have the same parentage which is *L. auratum* crossed with a deep crimson form of *L. speciosum*. From these Parkmanni types of seedlings, all having petals tinted and spotted with deep crimson and edged with white, there was every gradation to the forms with white petals thinly spotted and not possessing the characteristic golden band of *L. auratum*. One was similar to, if not identical with, the variety *Rubro-vittatum*, which is still a rarity. Every one of the seedlings was beautiful, and we must look forward to the time when Mr. Waterer will be able to put them, together with Parkman's Lily, into commerce. Some of the seedlings would undoubtedly have been certificated by the committee if the regulation number of flowers (three) had been shown instead of one.

A group of ornamental trees and shrubs from Messrs. Veitch's Coombe Wood nursery included the following noteworthy kinds: A variety of the Hemlock Spruce (*Tsuga Canadensis*), named *Argentea*, with the tips of the branches of a silvery hue, though not so pronounced as in other conifers with variegated foliage. A more effective conifer was a golden form of *Retinospora pisifera*, in which the whole of the foliage, both old and new, is of a rich yellow tint. It is a favorite plant among those who have a special liking for gold and silver conifers. The golden variety of *Ulmus Dampieri* was shown in bright condition and displayed well the peculiar erect growth of this Elm. A much admired shrub was the cut leaved, scarlet-berried Elder (*Sambucus racemosa serratifolia*), which, as yet, is not generally known. The elegantly cut leaves, combined with the clusters of brilliant red berries, make it a most beautiful shrub, and, on account of its hardiness and vigor, it may be planted in any locality. But it is to be regretted that this beautiful plant does not produce berries in the south as freely as it does in the cool and moist parts of Scotland, and I imagine that your hot and dry summers are detrimental to the fruiting of this shrub in America also. Among other good things shown by Messrs. Veitch, were *Ceanothus azureus albicans*, with feathery clusters of whitish blossoms as plentiful as in the blue Gloire de Versailles; *Veronica ligustrifolia*, a narrow-leaved New Zealand shrubby Veronica; *Clematis coccinea* and *C. crispa*, the latter with flowers larger than those of *C. coccinea*, and of a pale purple; *Cytisus nigricans*, one of the best of midsummer dwarf shrubs, having long, slender spikes of yellow flowers; a dark-leaved variety of *Spiraea callosa*, called also *Sanguinea*, and *Philesia buxifolia*, a beautiful little Chilean shrub with flowers like a miniature *Lapageria*, which is almost hardy in the south of England.

Some of our florists are doing their utmost to anticipate autumn by showing us autumn flowers at midsummer. One showed a new early flowering Chrysanthemum with large lemon-yellow flowers named *Mdlle. Leonie Lassali*, and another exhibited a large gathering of Cactus-flowered and single Dahlias. Among the best Cactus sorts that flower early are *Panthea*, bright orange-scarlet; *Zulu*, blackish-crimson, and *Mrs. Hawkins*, yellow, flushed with pink. The single Dahlias represented some of the new picotee-edged sorts which were much admired last year. Among the best shown by Messrs. Cheal were *Duchess of Albany*, with fawn-colored petals, edged with mauve; *Victoria*, white, edged with scarlet, and *James Scobie*, yellow and scarlet. These new combinations of colors may revive the waning popularity of single-flowered Dahlias.

Cultural Department.

Some August-Flowering Shrubs.

THE Japanese *Hydrangea paniculata* in this latitude blooms for nearly a month from the middle of July. It has few sterile, showy flowers, but its large panicles of perfect blossoms with their stamens are much more pleasing when closely examined than the great paniced variety (*H. paniculata grandiflora*) of which it is the parent. The flowers of the *Grandiflora* variety, which are nearly all sterile, begin to turn white as *H. paniculata* is about done flowering, and from the middle of August until well into September it is the most conspicuous feature of many modern New England gardens and country places. As they become old the large, dense panicles assume a pinkish hue, and they are often collected

and carefully dried for winter adornment of the house. These plants like care and good cultivation, as they degenerate and become straggling if planted in poor soil and not cared for, or if early spring pruning is neglected.

The many varieties of the Althea, or Rose of Sharon (*Hibiscus Syriacus*), are popular August and September-flowering shrubs. They are shrubs which seem to thrive very well in small yards of city dwellings as well as in more open gardens. They are, as a rule, remarkably free from insect pests or disfigurement by fungus diseases, and they retain their smooth, shining, dark green leaves until late autumn. It would be almost useless to name varieties here, as the names and descriptions given in catalogues are so conflicting, but varieties with single or double white, purple, red, pink and variegated flowers are offered, and of these the single-flowered varieties are the most beautiful. The blossoms are odorless. In the climate of Boston the plants are not hardy if planted on low or wet ground, where growth is continued too late in the season and the wood does not get thoroughly ripened before severe frosts occur. If planted on dry ground, growth will not be so rapid, but success and hardiness may be assured. For fragrance as well as beauty, the terminal white racemes of flowers of the Sweet Pepper Bush (*Clethra alnifolia*) are the most prized at this season. Plants growing in moist, shady woods often continue blooming freely in September. *Clethra acuminata* from the mountains in the Southern States is hardy, and blossoms with our native species, but is not as attractive. Although seldom seen in gardens, both species are easily cultivated, and will do well in those regions where plants of the same class grow spontaneously.

While some species and varieties open their first flowers earlier in the summer, the low-growing Heaths are also reliable bloomers in August. Double, white, red and other varieties of the common Heath or Ling (*Calluna vulgaris*) are now cultivated, but they are almost unknown in American gardens. In this latitude they require a slight covering of leaves, coarse hay, or evergreen branches to protect them from the direct rays of the sun and the consequent alternate freezing and thawing which is so fatal to so many plants. Among other species of the family in full bloom the best are *Erica vagans*, *E. stricta* and *Daboecia polifolia*. These are more tender than *Calluna vulgaris*, but generally do very well when given the same protection. The story is often told by immigrants, or those who loved their native "moors" in the "old country," of their efforts to introduce the Scotch Heather or the Heath about their new homes, and the instances are rare when their treasures have grown and thrived. A limestone region, or a clay soil and limy water is often the cause of failure, for most plants of this family, *Droseras*, *Saracenias* and some others, rarely flourish in districts where there is much lime.

There are two types of Tamarisk which bloom freely in Boston and vicinity, although they are by no means common in gardens. There is much confusion in their nomenclature. Plants of the first type pass under the names of *Tamarix Africana*, *T. Gallica*, *T. Anglica*, *T. tetrandra*, *T. elegans* and *T. parviflora*, and all flower at about the same time, in the latter part of May and in June. If they have specific differences, they are so slight or inconspicuous to the general observer as to be unnoticed in the garden.

The second type is the most desirable. It comes into full bloom about mid-August, and then the masses of delicate, tiny, pink buds and blossoms among the fine foliage are very beautiful, and, when well grown, the whole aspect of the plant is unsurpassed in gracefulness by any other shrub at this season. This is the *T. Indica* of some writers, but, among other names, it is often found in commercial catalogues under the name of *T. Chinensis*. In the climate of Boston it is hardy where not too much exposed, and thrives best in a porous soil, especially in the vicinity of water. It will grow fifteen or twenty feet high, and, if cut back occasionally, it becomes wide-spreading and bushy. When planted in masses it gives a soft, pleasing effect, even when not in bloom.

On account of their minute leaves and pliant branches and stems, the Tamarisks are well adapted to withstand severe storms, and, for this reason, they are much planted along banks and sea-coasts in southern England, where they may be called evergreen. They are also much planted on the Bermuda Islands, where the fine, dense foliage is said to form a perfect shelter against the strong winter gales. They are among the best sea-side shrubs in this country. The Tamarisks are propagated more easily than Willows, and cuttings readily take root in any ordinary moist soil.

The shrubby *Potentilla* (*P. fruticosa*), with its yellow blossoms averaging nearly an inch across, has the merit of giving

very few of its flowers during June and July, and of making a more extensive show in August. It is at home all over the temperate parts of the northern hemisphere, and, although it is not a plant of great value in small gardens, it is very useful and ornamental as an undershrub in larger places, or in parks and woodlands.

Jamaica Plain, Mass.

J. G. Jack.

Native and Japan Plums.

SINCE the introduction of the Wild Goose Plum there have been many attempts to improve it, and other American varieties, but as a market fruit nothing has yet been produced to supersede it. If the Mariana ripened its fruit as early as it was represented to do, while being disseminated, it, no doubt, would be more profitable; but such is not the case, for while scattered specimens color up a little in advance of the Wild Goose, it spreads its time of ripening over a greater period, the main bulk of its fruit coming in at the same season. Nor is its quality as good, and it therefore brings a lower price. The tree is much better in form and habit, though, and, in my

are the only two that have proven satisfactory and profitable here. The trees of all the other varieties of this type on my grounds go down under our hot suns, blighting in the same way that Pear-trees do. There are some cross-breeds—neither true Chicasa or Americana in type, such as Wayland, Golden Beauty, Moseman, Miner, Forest Garden, Forest Rose, Reed and Indian Chief—that are perfectly hardy in tree and produce abundantly of fruit, varying in size, color and quality; but the season of their ripening tends to render them much less profitable than the Wild Goose, since they come some time after that variety, when Peaches are plenty in the market. To the grower there is a world of difference between four cents a quart and fourteen cents a quart, which last-named figure my Wild Goose Plums, in ten-pound baskets, readily brought in Baltimore market this season.

There are but three of the Japan varieties fruiting with me yet. Ogon is first to ripen; color, yellow; size, medium to large; quality, fair; not productive. Botan ripens with Wild Goose; large, red; quality, very good; very productive, trees bear quite young. This variety promises to be profitable. I

The Fairbanks House at Dedham.—See page 411.

judgment, the chance for improvement, by crossing this with other desirable varieties, is better than it is with the other. The Mariana is valuable as a stock on which to work other varieties, being almost entirely free from the annoying habit of suckering from the roots. This is especially valuable in districts infested with the Peach yellows (assuming that such a disease exists), because Plums are often worked on Peach stocks. Cuttings of the Mariana grow about as readily as those of the Orange Quince.

Lone Star, a Texas variety, ripens about with the Wild Goose, and when fully matured is nearly as good in quality, but as a market Plum is less desirable. Robinson, another Chickasaw Plum, ripens immediately after Wild Goose, but is smaller, and much inferior every way, except in productiveness. It is extremely prolific. The Newman, an older variety—also Chickasaw—approaches the Wild Goose nearest in all respects—except in time of ripening—of any other variety. It is a week or ten days later, a heavy yielder of fine-sized, bright-red fruit, which places it second in value as an orchard variety with me. Among the Chickasaws that have little or no value, commercially, I would name Cadd, Chief, Early Red, Yellow Transparent, Hattie, Arkansas Lombard, African, Coletta and Jennie Lucas.

Of the Americana type, Purple Yosemite and Deep Creek

am strongly of the opinion that it has been sold under the name of "Abundance," in New Jersey. For the honor of the trade, let us hope that the deception was unintentional. Kelsey is full of fruit for the first time, and at present looks as though Peaches would be pretty well out of market before it gets in. The trees go through our winters here unharmed, not even the terminals of small branches being injured.

Denton, Md.

J. W. Kerr.

Asparagus from Seed.

I LIVE in a locality not specially favorable to the growth of Asparagus, though much attention is given to planting new beds in sheltered spots in hopes to secure early cuttings. During the past forty years there have been changes in the method of its culture, and growers are still looking for improved methods. The first beds were planted here by dropping seeds in holes six inches deep, about one foot apart each way. Such a bed of three acres, now forty-two years old, is still in bearing.

The uplands are not sending Asparagus to market; it seems to flourish best in sandy loam near the river, where water can be reached from twelve to twenty feet below the surface. This would seem to indicate the necessity of water. The best stalks

I have seen I have discovered in such localities. Last season six or eight such sprouts I saw in a square foot of ground, self-sown, no doubt; and in the fence-row, which had been undisturbed by plow for many years and without manure in that time, I never saw so many fine sprouts grouped together. These things point to the conclusion that what *Asparagus* needs is not deep culture, salt or manure, so much as a comparatively undisturbed growth, both of sprout and root, with mulching. Whether fertilizers will supply the drain on the plant by the removal of sprouts repeatedly in spring cuttings is still a problem.

In watching the results of all present methods that are practiced in the culture of *Asparagus*, this course of nature has been followed imperfectly, if at all. *Asparagus* is found near the salt water, not for the salt, but for the water and for undisturbed root-growth. Secure this in the garden and the conditions will be perfect; and this is what I have set out to accomplish. In my newer plantings, seed is drilled thinly in rows one foot apart; the rows being in pair four feet apart; these double rows are covered with straw horse-manure in summer after cutting is done; this is to remain on the row as a mulch during the winter, and in the early spring is covered up on the rows with dirt thrown up from the spaces with a plow. After cutting is over, the dirt is again brought back into the spaces with a hoe, the rows are again mulched, and the rotation is complete. By this method of cultivation the crowns are undisturbed, and the roots, which run deep, are not injured by plowing in the spaces; the plant is mulched with fertilizing material eleven months in the year. In the summer months the weeds are kept down by the same means, and in the spring the rotted mulch is again returned to the spaces to enrich the soil after doing duty over the crowns at the time of cutting. The *Asparagus* is thus cultivated in a compact row, and the crowding of shoots does not of necessity mean small ones, as has been shown by its growth in the uncultivated state and in my experience.

I have seen two beds ruined by using a plow or cultivator over them to kill out grass and weeds, and these beds had been planted deeply with this in view. But the crowns were cut off, and the beds become thin and cuttings small and unprofitable. By the method here described, the seed is planted where the plants are to grow; there is no transplanting. The spaces between rows can be cropped for the first two years, and cutting may begin in the third year, after which the spaces should not be cropped. For the location of such a bed choose a spot now that is as free as possible from weeds, manure heavily this fall and again in the spring, plowing no deeper than usual. This is all the preparatory work needed.

West Springfield, Mass.

W. H. Bull.

Notes on Wild Flowers.

Pogonia pendula, now nearly out of flower, is a delicate little Orchid, growing only three to six inches high, from a small bulbous root, and bearing several small white or pale pink drooping flowers. The plant is not a showy one, but the flowers are very delicate and pretty. It is one of our rarest species, and, as its natural location is on high ground, it may be easily grown in loamy soil in the shade.

Zephyranthes longifolia, one of the Mexican Amaryllises, is now in flower. The plant comes from a small bulb half an inch or more in diameter, and usually grows from six to ten inches high, bearing, on short stems, a light yellow flower. The leaf is long and grass-like, and the flowers are not very large. The bulbs are easily wintered in dry earth in the cellar.

Allium scaposum, a plant of the Onion family now in flower, is about one foot high, bearing an ample umbel of light pink or white flowers, which are quite pretty. The bulbs are, probably, tender, and should be wintered in a cellar.

Habenaria psycodes, one of the purple-fringed Orchids, is now blooming. The usual height of this plant is about two feet, but it varies much according to its location. In the shade it is taller, more slender, and the flowers much paler than in the open sunlight. The spike of pinkish-purple flowers is often ten inches long, fragrant and very showy. It comes late in the season, when most other northern Orchids are past flower, and the flowers are quite durable. It likes moist soil and, though not strictly a bog-plant, it will thrive on the borders of bogs, and also on higher ground that is moist. When planting it on upland soil, unless quite wet and springy, plenty of peat or leaf-mould is needed about its roots, and also a mulch, or else it should be placed in the shade.

The Dwarf Cornel or Bunch Berry (*Cornus Canadensis*) is a pretty little plant, seldom more than six inches high, bearing in June a head of small flowers. These heads are surrounded

by a sort of involucre, which is white or slightly pinkish and resembles the petals of a flower, so that the heads appear as one flower nearly an inch wide. The plant is quite pretty in flower, but much more attractive at this season, when the bright red berries are ripe. These are in dense heads, and are very showy. The plant spreads from subterranean creeping stems, and when established in a moist but well-drained loamy soil soon forms dense beds.

One of the most conspicuous of our wild flowers at this season is the Great Willow-Herb (*Epilobium angustifolium*), which is quite common in many localities. The plant generally attains a height of two and a half feet, but in some places, where the soil is rich, it is over six feet high. The flowers are in long spikes, one to several on a plant, of a pinkish-purple color and very showy. In localities where the timber has been burned off this plant often seems to take complete possession of the soil, and, when in flower, displays wide spaces of color. There is little difficulty in establishing it in any ordinary soil.

Eupatorium aquatoides (White Snakeroot) and *E. purpureum* (Joe-Pye weed or Trumpet-weed) are both in flower. The former grows from two to four feet high, bearing numerous heads of pretty white flowers. The plant seems to thrive in any moist soil. *E. purpureum* is a variable plant so far as size is concerned, sometimes attaining a height of ten feet, but usually not more than three or four. The flowers are in dense compound heads, purple or flesh-colored, and quite pretty. The plant is common in low, wet ground, but may be easily grown in any ordinary soil.

Of the many Golden Rods now coming into flower, *Solidago juncea* is the first, and is one of the prettiest. The stalks are about three and a half feet high, bearing dense heads of bright yellow flowers. The plant is one of the easiest perennials to grow, and will thrive in any ordinary soil. Another Golden Rod, which flowers a little later, is *S. nemoralis*, a smaller species, usually one to two feet high, with a dense, somewhat recurved panicle of rich yellow flowers. It grows in dry, sterile soil. All things considered, we think this the most desirable species for cultivation.

Helianthus decapetalus, one of the perennial Sunflowers which bloom at this season, is a very showy plant when it attains its maximum size. The stems are branching, often six feet high when in rich soil, and bear numerous large, showy yellow flowers two or more inches wide. *H. strumosus* is a smaller plant, two to four feet high, but with flowers much like the former, except that they are smaller. Both plants are desirable for cultivation and may be grown in any loamy soil.

Charlotte, Vt., August 13th.

F. H. Horsford.

Orchid Notes.

Dendrobium rhodostoma.—This is an attractive bright-flowered hybrid, between *D. Huttonii* and *D. sanguinolentum*, very much resembling the latter in its growth. The stems or pseudo-bulbs are very slender, from two to three feet long, and from near the top of these the little bunches of flowers are produced. The flowers, which are about two inches across and well expanded, are white, with all the segments heavily tipped with rosy purple. Unfortunately, these do not last many days in perfection, but the plant is seldom out of bloom, for the old stems continue to produce racemes for many years. This plant grows very freely with liberal treatment, and is best suited to pot culture.

Cynoches ventricosum, popularly known as the Swan's-neck Orchid, is now flowering freely, and, though not a showy kind, is the most attractive of the genus and well worth growing, not only for the quaint form, but also for the pleasing perfume of the flowers. The growth consists of stout, fleshy bulbs about one foot long, terminated by several thin, lanceolate, light green leaves. The large greenish-yellow and white flowers are borne on drooping racemes which spring from near the top of the bulbs, and last about three weeks in good order. This Orchid, as well as its congeners, will give satisfaction when grown in rich, open soil, in well-drained pots, supplied with abundance of water, in the warmest house; a little liquid manure will also be beneficial. As soon as growth is finished the plants should be removed to a cooler house, with plenty of air and sunlight. Water should be gradually withheld until all the leaves have dropped, and after this no water need be given, except to prevent shriveling, until the new growths appear, when the plants may be shaken out and repotted in new soil.

Saccolabium caeleste.—This is a comparatively new species and proves a great acquisition, adding another to the all too small list of so-called Blue Orchids. The habit of the plant somewhat resembles *S. curvifolium*, but is much stronger. The leaves being broader and thicker, and of a deep green.

It appears to bloom very freely, producing dense-flowered, erect racemes about eight inches long. The flowers are white with all the segments heavily tipped with light blue, though some varieties are much deeper colored than others. It is an attractive Orchid, a robust and free grower, and rapidly establishes itself with the usual treatment accorded this class of plants.

Trichopilia (Pilumna) nobilis.—This Orchid can hardly be called a distinct species, as it is nothing more than a larger and better form of the well-known *T. fragrans*, nevertheless it is a choice Orchid, and by no means common. It is a native of Peru, and grows very freely with the *Odontoglossums*, and, like them, requires abundance of water, though a little less may be given after growth is finished. The habit of the plant is clustered, with oblong, compressed bulbs, terminated by a large, broadly oblong, acute leaf. The radical scapes bear four to five large, pure white flowers, excepting for a dash of orange in the throat. These are very fragrant.

Kenwood, N. Y.

F. Goldring.

The Hardy Flower-garden.—The garden looks especially gay just now with the Phloxes, Tritomas, Lilies, Gladiolus and many more all at their best. The double kinds of Delphinium, too, are remarkably fine. The named French ones are very double, and many are of good color, but they always seem to lack constitution, never living long, nurse them as we will. We are trying the plan of raising our own, and so far the results are good, fully ninety per cent. of the plants raised from the seed of double kinds producing double flowers, many of them equal to the best named kinds, and the plants are much more vigorous and produce longer and stouter spikes than imported ones. When selecting varieties for seed, it is best to pick off all the side branches and let the main stem remain. This will give it additional vigor, and the laterals usually produce flowers less double than those of the main stem. Our seed saved last year was sown in February, and the plants have now spikes of bloom two feet long. This success is, doubtless, due to sowing seed early and potting the plants off as soon as large enough to handle, and planting in their permanent places as soon as the weather becomes warm enough.

Of the Tritomas, John Benary, one of Lemoine's new ones, is always the first to flower with us. It has an immense flower of a bright crimson. The next best is *T. corallina*, with the most compact flower of all and the freest bloomer. The spikes are not so large as those of *T. uvaria*, but they are much more useful and effective for cut-flower work. The Hyacinth Lily, *Galtonia candicans*, is a valuable summer-flowering bulb; its tall spikes of pure white, pendent, bell-shaped flowers, make it a very conspicuous plant. We find it perfectly hardy; in fact the bulbs winter better in the open ground, provided it is well drained, than in the cellar. This is a plant readily increased from seed, and the bulbs reach flowering size the second year. Good bulbs produce as many as four spikes during the season, if the old ones are cut off as soon as they show signs of seeding, so that there is a continual show until frost puts an end to all out-door displays. One of the best things of recent introduction is *Platycodon Mariessi*, a dwarf form of the old *P. grandiflorum*; its distinctive qualities are that the flowers are as large again as in the old one, and that it does not exceed six inches in height. It is really a most useful plant. The great objection to the original form was that it was liable to produce flowers from the top only. This variety produces its blooms in abundance even on young plants; we measured some blooms which were two and a half inches in diameter.

Passaic, N. J.

O.

The Dwarf Cannas raised by French hybridists are rapidly gaining favor here. It is only a year or two ago that they were first seen here at the exhibitions, but now they are largely grown at all the best nurseries, and are becoming widely known throughout the country. For several weeks past they have been a great attraction in the conservatory at Kew, where many visitors make their first acquaintance with them. Their noble foliage is always handsome, and, when this is accompanied by the tall spikes of large and richly-colored blossoms, as curious in shape as any Orchid, they are extremely attractive; in fact I do not know any Orchid so brilliant in color as some of these Cannas. They can, moreover, be grown by everyone who owns a green-house. [In this country they grow perfectly well out of doors.—ED.] They require no attention in winter, as they die down to their fleshy tubers or rhizomes, and when in full growth do not occupy much space on account of their dwarfness which is one of their chief merits. In one of our leading nurseries I

made the following selections of sorts the other day after comparing them one with the other. One of the most striking kinds was *Capricieux*, flowers large, sepals broad, bright, orange-scarlet, margined with yellow; Admiral Courbet, citron-yellow spotted with scarlet, very showy; Louis Thibaud, brilliant vermillion; Victor Hugo, scarlet; Antonin Crozy, bright crimson; Geoffroy St. Hilaire, foliage stained with vinous purple, flowers vivid scarlet; Francisque Morel, crimson-red, and Madame Just, flowers, rich orange-yellow. There were several other sorts, but these, I thought, were the finest. All were vigorous in growth, and carried an abundance of bloom on spikes well overtopping the foliage.

Kew.

G.

Dwarf Herbaceous Phloxes.—There is a race of French herbaceous Phloxes little grown in gardens, but which deserve wider cultivation. The one great fault of the herbaceous Phlox is its tall, ungainly and untidy habit, but in this newer race we have a dense, bushy, spreading growth, the plants rising but about two feet in height, and, in a few varieties, so densely smothered with flowers as to hide the abundant rich-green foliage. We made notes of a few good kinds in the Broxbourne Nursery, among them *Bacille*, flowers large, mauve-lilac in color, and the plant not more than two feet high; M. H. Jacotot, white shaded magenta towards the centre; La Ville de l'Air, white, with a clear purple eye; Mars, bright red; Colibri, pink shaded rose; and Foutcheau (whatever that may mean), pink with a carmine eye. The last-mentioned is a good flower spoilt by a foolish name. Such a race should become common in gardens. One clump was clothed to the ground-line with foliage, and spreading out on every side more like a shrub than a hardy, herbaceous perennial.—*The Garden*.

Correspondence.

Conifers for Planting on the Plains.

To the Editor of GARDEN AND FOREST:

Sir.—I use the time between the arrival and departure of my freight-train to send a few notes made while passing through Nebraska, stopping here and there. My object on this trip has been to note the progress and promise of timber-claim planting, and by the way to observe what coniferous growth may be expected to do on these plains and prairies when real timber-planting—not simply tree-planting for ornament, shelter or shade, or for land speculation—shall begin.

Men of broad views, and with no tree-seedlings to sell, either nursery-grown or pulled at the river-side, begin to appreciate that re-foresting the plains must become a national or state affair; at least that it cannot be done by private enterprise within this generation, and certainly not in such a systematic manner as is necessary to insure the best results in climatic amelioration. Co-operation and concentrated efforts alone will accomplish that.

But these questions of more general nature are too fruitful of argument to be discussed in a letter. Which conifers promise well in this region can more briefly be treated, since our experience, so far, is only very meagre.

When I started from Washington I was almost ready, unconditionally, to urge American trees only for American planting. In fact, I had advocated, on theoretical grounds, the introduction into the plains of Rocky Mountain conifers, especially *Pinus ponderosa* and *Pseudotsuga Douglasii*, which thrive naturally under climatic conditions not dissimilar to those prevailing here, and had not expected to speak of the Scotch Pine again in connection with American forestry; but I am compelled to say that at the first place where I had an opportunity to observe it side by side with eastern and western forms, which was in Crete, seventy-five miles west of the Missouri River, the Scotch Pine was decidedly the most promising tree, and next to it the Austrian Pine. There were in nurseries, four to five years planted, besides these two, *Pinus Strobus*, *Picea Engelmanni*, *Abies concolor* and *Pseudotsuga Douglasi*. The Europeans were thrifty, while all the Rocky Mountain tribe had lost their leaders; their terminal buds had been killed not this year only, but every year since they were transplanted, giving the trees an unsightly, ragged appearance. Only a few *Picea pungens*, which had been specially cared for and coaxed under shelter, had developed fairly. In the same town are found many Pines of older growth, planted in 1873. The Scotch and Austrian are perfect, with annual shoots of two to three feet, as straight and well-proportioned as the best in their native land, without a flaw, and it would be difficult to tell which of the two to choose as regards thriftiness. There was also one White Pine, grown in the shelter of

the other Pines, which seemed to be just as much at home, while in the nursery the young plants had a jaded look, and were browned more or less under the hot blast which passed this region in May.

Thus discouraged, in regard to the Rocky Mountain trees, I went westward with little hope of finding much worth noting, but was most agreeably surprised at Franklin, fifty miles east of the one hundredth meridian, where an enterprising man has begun systematically to test the possibilities of Rocky Mountain conifers. Rev. C. S. Harrison is one of those hardy and hearty men of the West, full of vigor, will and push, bound to succeed, if success is attainable. The sight which met me at his nursery was astonishing, indeed, when the locality is considered. Here could be found more conifers in one spot than anywhere on the plains west of the Missouri. Nothing had been planted longer than four years, it is true, but here were not a few trial-plants only, but a nursery of conifers, in all stages, from the seed-bed to the six-year-old transplants. A space of 100 feet square protected all around by a loose board fence, and, shaded by a brush-roof, serves the purpose of starting the plants, either from the seed or from seedlings, carefully taken from their native haunts. Under this shed, as well as in the open, the Scotch Pines showed the thriftiest growth; the Austrians, though no beauties, were also well at home. Neither of these, and but few of the former, showed any loss of terminal-bud, the oldest transplants being six-year-old Scotch Pines, which had made this season shoots of from fifteen to twenty-five inches, and were now four to six feet high.

Under the shed the Engelmann Spruces were of the finest appearance, the Douglas Spruces next, while *Abies concolor* made only an indifferent show, and *Picea pungens* was, perhaps, still worse.

The sturdy *Pinus ponderosa*, which was present in many specimens under the shed, and freshly transplanted into the open, had not yet put on its best style, but when a lot of them were shown to me, neglected and overrun, almost smothered by grass, and yet as fine Pines as ever carried a head, I had to subscribe to Mr. Harrison's prophetic expression that this tree is destined to furnish the saw-logs of the coming forest of the plains.

I must not forget to mention the hardiest of the hardy, the ubiquitous Juniper, which, although hardly to be recommended as a forest-tree in this latitude, is probably the most reliable ornamental conifer here. The Rocky Mountains furnish it with a beautiful silver sheen added.

The last conifers met, save an *Arbor-vitæ* hedge, freshly planted by an enterprising settler at this place, were grown under the inspiration of the water-works of McCook, the "Magic City of the West," being fairly within the arid region, and yet converted into a garden-spot by its energetic population, who have spared nothing in ornamenting their homes and streets.

Two Scotch Pines at the depot, twelve years old, and several younger specimens in town, still recommend this species for ornamental planting. The White Pines, with the exception of one specimen, were all out of the race; a number of Norway Spruces, low and stubby, yet showed fairly well, while two stunted Blue Spruces had not been able to save their terminal-buds. This failure of the terminal-bud, which is the common injury, not only to the conifers, but to most trees in the plain, and which accounts somewhat for their crooked appearance Mr. Harrison hopes to overcome, by proper treatment and "schooling" under the shed and in the nursery for six years, having observed that this same loss is frequently sustained even in the native forest, and afterward outgrown. But while such treatment may be practicable for ornamental plants, for forestry purposes we would not be able to apply it, and it remains questionable whether the damage would be outgrown in time on the plains.

The Bull Pine (*Pinus ponderosa*) alone seems to be the one native conifer which, so far, promises to serve as a timber-tree of these wind-swept tables.

Stratton, Neb.

B. E. Fernow.

Direct Influence of Pollen on the Orange.

To the Editor of GARDEN AND FOREST:

Sir.—In spite of what some botanists set forth as Nature's unvarying law, the question of the immediate and direct influence of pollen on fruit should, in the matter of the Orange and Lemon and all Citrus fruits, be considered as one which has been settled.

For weeks each season I have been carefully examining the exterior and interior of oranges growing on Maltese Blood-trees and on the Imperial Blood of the St. Michael family,

which have a navel mark not common to either family. I have singled out these two families of the Blood Orange with the navel mark because I consider the three oranges as the best of all oranges, and have made careful experiments for years hoping and expecting to combine in one orange the superior points of the Blood and the Navel.

These Blood oranges having the navel mark are completely changed in outline, in their exterior and all through by the effect of the pollen of the Navel-trees. From being naturally oblong, they become somewhat flattened, the flavor is changed and the cellular form of the pulp is changed.

Of twenty oranges having a navel mark recently cut from a Maltese Blood-tree standing beside a Washington Navel-tree, only two of the oranges had a single seed, eighteen were seedless, while nineteen in twenty of the Bloods which were not marked by the navel had one or two seeds. Not always does the pollen of the Navel show its effect in the lengthened axis. Sometimes you find an orange shaped like the Navel except the umbilical mark is wanting on the outside. Inside there is no axilar centre; the inner orange has spread all through the fruit. There are two sorts of pulp, two sorts of fruit-cells and two separate and distinct flavors.

A few times I have seen an orange cut from a Majorica-tree, one side almost solidly colored, like an Imperial Blood, pulp dark as wine; the other side not a trace of rubricate, the divisions of fruit-cells as distinct and clear as though they had been fenced off by an impassable dividing-line. One side the decided piquant flavor, sub-acid, that a thirsty man gratefully remembers on a hot day; the other, the fruity-flavor of a Strawberry or Black-cap raspberry, with juice quite as dark as that of the latter berry. Such an orange I cut at Ocala, during the Exhibition, last winter, and observing visitors noted the difference in flavor as well as strong contrasts in color in the two sides of the same orange.

Sometime later I cut a Prata orange, such as L. W. Sherman, of Boston, sells for "whites," because the rind is a pale lemon color. I noticed before I cut it, longitudinal, single rows of rubricate oil cells, running from flower to stem as straight as the lines of longitude on a school globe. The opposite cheek of the orange had splashes of them, giving a beautiful contrast to the pale-lemon shade. I was not surprised to find in the pulp, usually as pale and white as a Villa Franca lemon, rubricate tints.

I then went to the row of trees on the opposite side of the Blood Oranges, and soon found on one of the outside branches of the Ribbed Du Roi, an orange well marked as a Du Roi save the blossom end, which was a well-defined Blood. I cut and found a more deeply-colored orange than the average Bloods with not a seed, although the Du Rois are not wanting in seeds.

Among the ornamental dwarf Orange-trees at Belair, President Berckmans, during a visit last winter, called attention to one found with rind not unlike the shell of the old Crook-neck squash when ripe, the exact counterpart of which he had seen on a tree in a distant part of the grounds. The distant tree originally came from Japan and has not been bearing more than three years. I know such oranges were never seen there on the tree on which he saw it till this one strange tree began to bloom and bear fruit. Now tracks of this ribbed and warty fellow are again and again seen on the other trees.

In March last I cut a cluster of five oranges from the tree sent me by Wm. Saunders, Superintendent of the Grounds of the Agricultural Department at Washington, labeled Bahia. The cluster looked precisely like similar clusters growing on an adjoining St. Michael tree. Cutting them all, I could see no difference in seed or flavor from the St. Michaels; the same sharp acid, the thicker, rougher and tougher rind than that of the Navels—not a thing to remind one that the sap of a Navel-tree nourished those five St. Michael Oranges.

Some years since I procured from A. W. Rountree, of New Orleans, the Double Imperial Orange. I budded a number of trees from the tree he sent. They bloomed fully for the first time last February and March. The past summer and autumn I found again and again oranges on adjoining trees so exactly like the real Double Imperial that the novice would say they were the same. This orange (the Double Imperial) has an exterior, as E. H. Hart says, *sui generis* and quite distinct from most oranges. It has as much pollen (yellow, too) as any Orange-bloom I ever examined. It is one of the coming oranges for Florida.

Meanwhile let me say, a race of oranges which can completely metamorphose whatever other variety its pollen touches must be most prepotent indeed. Out of the two strains, the Navel and the Imperial Blood, will come the future orange, which the intelligent lovers of the queen of

fruits will say are the best. Their price will depend on the conscience of the seller. Note that Palermo Imperial Bloods, on March 1st, sold in Boston at \$4.35 a box, when average Palermos sold at \$1.50 and less.

Lyman Phelps.

[The phenomenon of the direct influence of foreign pollen upon the fruit of various plants has long interested naturalists. It is a matter of much practical importance, too, to horticulturists, if certain fruits, especially those belonging to the Squash and Melon family, change and deteriorate, as some assert, by the influence of the pollen from other plants of the same family acting upon the ovaries from which these fruits develop. Persons interested in the subject will find a summary of what is known about it in a paper by M. Maximowicz published in the journal of the Royal Horticultural Society, new ser., iii., p. 161. See also Darwin's "Animals and Plants Under Domestication" (English ed.) i, 39; Asa Gray in *American Journal of Sciences and Arts*, 2 ser., xxiv., 442, and Darlington's "Fl. Cestrica," 2 ed., p. 555.—Ed.]

The Chinese Quince.

To the Editor of GARDEN AND FOREST:

Sir.—We send you a branch from one of our plants of this species in response to the suggestion (GARDEN AND FOREST, ii., p. 389) that "it would be interesting to know if this handsome plant is cultivated anywhere successfully in the United States."

When the senior member of our firm settled in Germantown, in 1852, he found a specimen possibly twenty feet high, and with a trunk eighteen inches thick—giving these figures from remembrance of the specimen only—on the grounds formerly owned by a Mr. Sickles, but about that time purchased by Mr. E. H. Butler, the founder of the well-known publishing firm of E. H. Butler & Co. It was a bushy specimen, with branches nearly to the ground. It produced its large oblong fruit but sparingly. From our subsequent experience with its rate of growth, that specimen must have then been at least twenty-five or thirty years old. No one could tell how it came there. It is remarkable that at that time there were found other rare Chinese plants in Germantown gardens. Among them the *Rosa rugosa*, which has again been introduced within recent years, and which is still growing where it then grew, on the grounds about the Chew House, so famous in the history of the struggle of the Colonies against Great Britain. We have always credited the old firm of W. R. Prince & Co. with these introductions, because some rare things have been traced there, planted in the early part of the present or toward the end of the past century.

The habit of the Chinese Quince is fastigate. Its great beauty is in the color of the autumn leaves, which is fully equal to that of the Tupelo, or Sour Gum, or Black Gum, as it is variously called. When our nurseries were founded in 1852, it was one of the first to go in the collection. It has been in every edition of our catalogue since that time, except our last, the compiler dropping it by a lapse of the pen through momentarily classing it with the "Pyrus," leaving out "*Cydonia*" in brackets, as often written. It is still there as *Pyrus Sinensis*, though that name properly belongs to the Sand Pear. Of the trees planted on our grounds prior to 1860, one remained to reach over twenty feet in height, when it fell a victim to public improvement, as it stood near the line of what is now Meehan Avenue in our city list of streets. There ought to be hundreds throughout the country distributed from our nurseries during the past thirty years. We fancy it must fruit freely in Virginia, as we frequently have specimens sent or brought from there by parties anxious for its name, as its large, delightfully-scented fruit attract the curious.

In conclusion allow us to thank GARDEN AND FOREST for the excellent work it is doing in bringing to notice the numerous beautiful things well adapted to our climate, of which a few have knowledge. There are probably between two and three thousand species or marked varieties of trees and shrubs that are hardy through the central states, the number, of course, increasing or diminishing as we go south or north, and which, if introduced and made known, would render American parks and gardens superior in variety to any others in the world. No nurseryman can catalogue or describe these properly. It would require the expense of a heavy volume. Only journals such as GARDEN AND FOREST, or societies such as the Massachusetts Horticultural Society, can do much in this line—and what both of these have done and are doing is worthy of all praise.

Germantown, Pa.

Thomas Meehan and Son.

To the Editor of GARDEN AND FOREST:

Sir.—Nearly twenty years ago Dr. George Thurber wrote in the *American Agriculturist* (December, 1871): "We do not know how so many Chinese Quince trees become distributed about the country without the owners of them having their names. For several autumns, including the one just past, we have received a number of fruits from different points in the vicinity of New York to be named."

"This year one of them remained on exhibition at our office for several days, where it attracted much attention from its novel shape. We have had the fruit and leaves engraved at about half the average natural size. The tree grows in a spreading form, and reaches the height of about twenty feet."

"The leaves are quite unlike in appearance to those of the common Quince, being of a dark green with a shining surface. The flowers are rose-colored with a violet odor, becoming darker with age, and makes the tree quite ornamental in spring. The fruit is irregularly egg-shaped, green and very hard and dry. We do not know that any use can be made of the fruit, but it is quite conspicuous and ornamental when upon the tree. The botanical name is *Cydonia sinensis*. We do not find the plant in any of the catalogues of our leading nurserymen, and cannot say where it may be procured."

Most of what is stated above is as true now as it was then. Many persons, otherwise well informed in horticultural matters, are entirely ignorant about the existence of this fruit. It is strange that a tree which combines so many good qualities is not more widely known. In Virginia and further South the tree reaches a height of some thirty feet. Under favorable conditions, the fruit grows to a very large size, single specimens reaching a weight of from two to two and a half pounds.

It has a very firm flesh, which, we are assured by reliable authority, makes an excellent preserve and jelly of a beautiful pink color. As the tree is a profuse bearer, it seems strange that its cultivation has been so much neglected. In Virginia and other localities where the fruits mature every year, the growing of the Chinese Quince and the manufacture of preserves from it could no doubt be developed into a profitable industry.

New York.

F. M. Hexamer.

Strawberry Plants for a New Bed.

To the Editor of GARDEN AND FOREST:

Sir.—The mode of growing superior Strawberry plants adopted by J. M. Smith, of Green Bay, Wisconsin, and detailed in full in GARDEN AND FOREST of August 7th, commends itself not only to the sober thought of all interested, but also agrees with the experience of those who have pursued the plan of propagating the new plants from strong and vigorous ones that have not been allowed to bear fruit and thus to partially weaken their reproductive force. There is no doubt that in all cases (other things being equal) this mode will produce better plants, and, consequently, a better yield of fruit the following season.

One of my neighbors has pursued this course for a number of years, and he has thus been enabled to retain in good bearing order and in a healthy condition that most excellent old variety, "Boyden's Number Thirty," when all the growers in the neighborhood of its early home, Irvington, New Jersey, were obliged to discard it on account of its deterioration. It is still true that like begets like, and in order to produce strong and hardy plants you must have vigorous stock to work from.

Newark, N. J.

C. L. Jones.

To the Editor of GARDEN AND FOREST:

Sir.—Referring to Mr. Horsford's note on the Swamp Milkweed (*Asclepias incarnata*), let me say that there is a variety of this species with white flowers. Not long ago I came upon a few plants of this sort, and the umbels of white flowers were most attractive.

Arnold Arboretum.

Jackson Dawson.

Recent Plant Portraits.

Botanical Magazine, July.

PANDANUS LABYRINTHICUS, t. 7063, a handsome species, native of the Malay Islands, which has flowered and fruited at Kew, its striking ovoid heads of fruit being particularly noteworthy.

SYRINGA VILLOSA, t. 7064, the Lilac from North China, which was figured in this journal (i., 521, fig. 83).

OLEARIA MACRODONTA, t. 7065, one of the Daisy trees of New

Zealand, and the most conspicuous one from the great abundance of broad white corymbs, which terminate every branchlet and cover the plant with a sheet of flowers. The tree is twenty feet high, with spreading branches, smelling faintly of musk.

DISA LACERA, var. *MULTIFIDA*, t. 7066, a beautiful blue flowered species.

ENCRYPHYA PINNATIFOLIA, t. 7067, a small, bushy Chilean tree, with pinnate leaves and flowers like large, single white roses. After the petals fall away the stamens persist, and are themselves very ornamental.

Notes.

The Japanese *Platycodon Mariessi*, of which mention is made in another column of this issue, is highly commended as a plant for the rock-garden in English horticultural papers.

Governor Green, of New Jersey, has appointed Andrew J. Fuller, Professor Byron D. Halsted and W. A. Stiles as delegates from that State to the meeting of the American Forestry Congress, to be held in Philadelphia in October.

The officers elected by the Society of American Florists for the year are as follows: President, J. M. Jordan, of St. Louis; Vice-President, M. H. Norton, of Boston; Secretary, William J. Stewart, of Boston; Treasurer, W. H. Hunt, of Terre Haute.

A National Chrysanthemum Society was organized last week, with John Thorpe, of Pearl River, New York, as President; William K. Harris, of Philadelphia, Vice-President; Edwin Lonsdale, of Philadelphia, Secretary, and John Lane, of Chicago, Treasurer.

The Society of American Florists presents the name of Dr. Hexamer as the executive head of the agricultural part of the World's Fair in 1892. Dr. Hexamer is widely known as editor of the *American Agriculturist* and as one of the leading authorities in the country on pomology. Mr. John Thorpe was, of course, recommended by the same body to represent the interests of floriculture.

A very neat plant for rock-work or border is *Plumbago Lar-penta*, which is now covered with its intensely blue flowers. It is perfectly hardy in this latitude, spreads rapidly and soon covers a large space, running with wiry stems in a half-prostrate way and never attaining more than six or eight inches in height. It starts late in spring, but begins to bloom here in early August, and continues to flower abundantly till freezing weather.

Plants of a so-called White Huckleberry (a variety of *Gaylussacia resinosa*) sent to the Arnold Arboretum last year by Mr. B. W. Westbrook, of Montague, New Jersey, bore a small quantity of fruit this season. When ripe the color is a yellowish-white on the under side, deepening to a pale crimson on the side exposed to the sun. As is the case with white or light-colored varieties of many other fruits, the berries of this are much sweeter than the typical black fruit which it resembles in size and other respects.

The London *Garden* protests against the irrational desire to increase the size of many flowers. One of the prettiest things that have suffered in this way is the Petunia; the most free blooming and constant of summer flowers is spoilt by this absurd desire for size. The huge flimsy blooms, too heavy to support themselves, are the perfection of ugliness, and show the flower in a false light. When a bed of this large-flowered strain is planted out in a somewhat exposed position, where the Petunia under ordinary conditions would do well, the thin, weak blooms cannot withstand the wind that would leave unharmed a strain of medium size and decided colors. The African Marigold is another case in point. The huge globe-like flowers are as ungraceful as it has been possible for the florist to make them, and yet he is not content even with this extreme and unnatural development, but aims at still further "improvement." It is the same with the Hollyhock, tuberous Begonia, Chrysanthemum, Pansy, Balsam and many another garden flower; all are in danger of permanent disfigurement by this crazy fashion.

At Headingley, not far away from Leeds, still stands an ancient Oak-tree "which is believed by devout antiquaries to have been part of the ancient forest which may have given its name to the town. The tree certainly gave its name to the 'wapen-take' Skyrack (Shire-Oak), and it may have witnessed in successive ages the horrible rites of the Druids, the assemblings of local crusaders, and the markets of thrifty cloth-work-

ers. Be that as it may, the Oak even in its decay is regarded with veneration. Winter storms have done much to shear it of its mighty proportions, for Whitaker's drawing in 1816 shows a more stately wreck than that of to-day. The last great branch fell in 1883; a portion of it was sold for £100 to furniture-makers, and the old man who owns the remains of the trunk has been offered £200 for them as they stand. His joy in the tree is more to him than the money, but there is some fear lest his successors may take a more mercenary view." An illustration from a recent drawing shows us an immensely massive and still lofty trunk, devoid of all but the stumps of branches and with a hollow, like a great arched doorway, yawning in its side, but still clothed to a considerable extent with fresh sprouting foliage.

In the *West American Scientist* Mr. Edward Palmer writes entertainingly of the fruit of the Opuntia, or *Tuna*, as it is called in Mexico, where it forms the principal article of food for many of the natives during several months of the year. The Tuna of the Mexicans must not be confounded with the Opuntias found in southern California and Arizona. Many valuable varieties of Opuntia are found growing in the Cactus-belt of Mexico, and seeds of some of the most desirable were furnished originally by the United States Department of Agriculture. When new varieties are produced by artificial crossing and selection as great improvement may be expected as has been made with other cultivated fruits, but the different varieties now have no distinctive names. This Cactus requires little care, and thrives on almost any soil, but it reaches its best condition on the table-lands of Mexico. A piece of the plant laid on the surface of the ground will take root and grow; it will endure considerable cold, and the most protracted drought only seems to increase the sweetness of the fruit. When gathered, the fine spines on the surface of the fruit must be removed, so that it can be handled without inconvenience. The skin is then removed, leaving the pulpy meat exposed in a most tempting manner. It is specially adapted to the breakfast-table, having something of the Water-melon flavor, with a suggestion of Strawberry. Tuna is abundant and cheap in the market from June till November. It is finding its way along the frontier of the United States, and is already on sale in Jacksonville and other southern cities.

The *Gardeners' Chronicle* reports that at the Paris Exposition many of the South American republics show specimens of the product known locally as Yerba Mate, or Paraguayan Tea, and derived from the torified leaves and stalks of different species of Ilex. It is exhibited in packets and in original bales of green hide. This is the dietetic beverage of about 20,000,000 in South America, and its popularity is shown by the exhibits in the various pavilions of the Argentine Republic, Paraguay, Uruguay, Brazil, Chili, Bolivia, etc. It is difficult to get at any reliable returns as to the entire traffic in this commodity, the production of which is carried on in such a desultory and wide manner, and extends over so vast an area of wild country where the Holly-trees flourish. In the Argentine Republic the consumption is over 35,000,000 pounds, against 5,000,000 pounds of Coffee. In Paraguay the production of Mate is about 5,000,000 pounds; from Brazil there is an export of 65,000,000 pounds to neighboring states, while the local consumption is about half as much. This is singular in the great Coffee-producing centre of the world, which sends into commerce annually more than half the entire production of Coffee. Strong efforts are being made to open a trade with it in Europe, especially in France, where shops advertise and recommend it. Whether this will succeed remains to be seen, looking at the increased production of Tea and the enormous increase in its sale in Europe. Approaching in its chemical composition to Coffee and Tea, it is asserted that it does not cause wakefulness or prevent sleep. In the rural districts, as well as in the smaller towns, this beverage is considered a regular form of diet, and not, like tea, a mere accompaniment of the breakfast-table. It is sweetened with sugar until it almost becomes a syrup. It is sold at twopence to fourpence per pound, and one pound will produce about twenty quarts of infusion. It is sometimes flavored with Cinnamon, Orange-peel or Lemon-juice.

Spring-Flowering Bulbs.

AT this season, when all the air is filled with the fragrance of ripening fruit, and flowers are still blooming in mid-summer abundance, it is difficult to recall the impression made on the mind by the hardy flowers that begin to appear, one after another, under the first genial influences of early spring. After the long northern winter, any evidence of renewed life is welcome, and early flowers could not fail to give delight for the cheerful promise which they bring, if for no other reason. But apart from this appeal to the imagination, and from the fact that they have few rivals, spring flowers in themselves are among the most beautiful which the year has to offer; so that every one who has any appreciation of grace and delicacy in form and color takes especial satisfaction in a spring-garden. The testimony is universal that one who plants a spring-garden provides himself and his friends with a store of unfailling and ever-increasing pleasure.

These thoughts are seasonable, for the time is at hand when preparations for spring flowers must be made, if we are to have them at their best. Without mentioning the hundreds of other flowers that have been spoken of in these columns earlier in the year as they came into bloom, we wish especially to call attention to the endless variety of bulbs in which the flowers for next year's bloom are already stowed away. Snowdrops and Squills, Snowflakes and Crocuses, Fritillaries and Erythroniums, Daffodils, Jonquils, Chionodoxas, Satin Flowers and many more—most of them in endless variety—should be secured early, or the dealers will have nothing but refuse stock to offer. It is true that most of these will bloom if not planted until November, but many of them lose their vitality when kept too long out of the ground. Those who wish to deal directly with the great bulb-growers of Holland, or to secure rare varieties from specialists, have no time to lose. Careful study of the catalogues should begin at once, for at least six weeks will elapse between the sending of orders and the arrival of the bulbs. The middle of October is late enough to plant any of them, and most of them will become better established if planted in September.

Even in our wild February weather the fragile Snowdrop will often pierce the frozen soil and open in a sunny ex-

posure, and, if a proper selection of bulbs is made, flowers can be had in constant succession through all the spring months, until the summer Irises appear. Now is the time to choose a proper position for each according to its habit. Most of the earlier and more delicate ones are out of place in masses or formal beds. Snowdrops, for example, can be snugly placed under the shelter of a wall or a boulder in the rock-garden. Tall Squills like *S. campanulata* are at home in the grass, which may be a foot or more high when they bloom. Daffodils will grace the borders of a woodland path. Yellow Crocuses are beautiful on the turf, as they open just as the grass is warming into tender green. Gay garden Tulips and Hyacinths are quite too civilized for nooks in the wild garden, but some of the species of Tulips, especially those of recent introduction, are not misplaced on the border of shrubberies, or in pockets of the rock-garden. There is no spot in wood or meadow, by the brookside or byway, among the rocks, or in a trim enclosure, where some of these flowers cannot be placed to advantage.

None of these spring-flowering bulbs are more generally appreciated than the almost numberless species and varieties of the Narcissus. The single Daffodil opens early in April, with the Bloodroot, and for six weeks some member of the family will be in bloom. Latest of all, and hard after the beautiful *N. biflorus*, comes the Poet's Narcissus, the hardiest and most useful of all. No flower is more effective in the border, in the rock-garden, or as an edging to the shrubbery. It can be naturalized even in a hay-field, and it never appears more beautiful than when shining among the grass, as in our illustration on page 427, which gives a view on private grounds not far from Boston. The foliage should remain till the bulbs have ripened well, and this is true of all other bulbs; but long before the grass is fit for the scythe the tops will have died down out of the way, and the bulbs will have multiplied for fresh flowers another spring. The Poet's Narcissus is not particular about soil or exposure, but it will multiply more rapidly in a deep, rich soil, and gratefully repay kind treatment. Many varieties have been produced by crossing and selection, which are interesting to those who take pleasure in noting minor distinctions among flowers, but for general effect none of them are superior to the original type, which can be bought for a trifle, and a few of them planted every year in vacant corners will soon furnish an abundant supply. Like most species of Narcissus, they do better when planted early, and then, if the soil is suitable, they only need to be protected from the ravages of the lawn-mower to keep on spreading and flowering year after year. No one ever had too many Poet's Narcissus or other spring bulbs of that adaptable kind which will brighten up out-of-the-way nooks in unkept parts of the garden, and no one ever enjoyed such flowers in full measure until he has seen them scattered along the wayside or among the grass, or grouped naturally in a wood border.

In an article on "The Lesson of Conemaugh," in the *North American Review* for August, Major J. W. Powell, Director of the United States Geological Survey, says that "wherever the chief precipitation is snow, forests are a disadvantage if the waters are needed in the valleys below for irrigation, for the forests keep the snow distributed over broad areas of ground and expose it to the winds on their trunks, branches and leaves, so that altogether the mountain evaporation is enormously increased as compared with the evaporation from snow-drifts and ice-fields." If there have been measurements which show that forests enormously increase evaporation, the facts would have a scientific interest for students of forestry, and we should be glad to see a full report of them. But whatever the loss of water from such evaporations may be, the extinction of mountain-forests usually involves the destruction of the mountains themselves, and of the streams which flow from them. If the forests are destroyed there will soon be no possibility of controlling and utilizing the water from the

denuded hills. Under such conditions the question of a greater or less quantity of water dissipated by forest evaporation is not important. The forests are an indispensable factor in a system of irrigation by mountain streams.

Major Powell adds that in low mountain and hilly regions of humid lands, forests about the sources of the streams are of advantage, because they "serve to hold back the water and thus equalize the flow through the year and greatly mitigate the floods." That is a very good statement of an important truth, and the forests will perform this office just the same whether the precipitation is chiefly snow or not, and for any kind of country, humid or arid, where forests can grow. The evil, difficulty and danger of this whole matter are in the fact that the disastrous changes which result from the destruction of mountain forests do not take place immediately, or with the spectacular suddenness of scene-shifting on the stage. When the country is obliged to recognize the fatal and irretrievable consequences of the extinction of the mountain forests of California and Colorado, the men who are now clamoring for their destruction will have gone out of sight, and we shall all be silent. But a civilized nation should be capable of foresight, of learning without the lessons of experiments so disastrous and fatal. It is matter of regret that Major Powell and the admirable young men associated with him are not more vitally interested in the preservation of these important forests. Their indifference gives aid and comfort to the enemies of their own work, and of our national civilization.

The Art of Gardening—An Historical Sketch.

IX.—Greece.

THE history of the few nations which we have already passed in review is enough to show that a stronger or weaker feeling for natural beauty was never the only cause which affected the development of gardening art. The literature of the Jews, for instance, proves that they had an exceptionally deep and poetic feeling for the beauty, grandeur and mystery of the inanimate world; but their gift for art was small, and they were not wealthy or addicted to luxurious living. In consequence, their use of gardens was comparatively restricted, while the Phœnicians, who were akin to them in lack of artistic capability, and were doubtless as inferior in a sentiment for nature as we know them to have been in moral intensity, practiced gardening more generally, because they were a richer and more pleasure-loving people.

As I tried to show in my last chapter, the Greek was not so devoid of a love for the beauties of nature as is commonly said. He may well have loved it in an equally poetic and an even purer way than the Persian, and he was certainly the superior of the Roman in this respect. If, then, his gardens were less extensive than those of Persia and of Rome, we must look elsewhere for the reason. In this case, of course, it cannot be found in artistic inaptitude. It lay partly in the fact that the Greeks were not a rich people and they were not ruled by kings and courtiers; but chiefly it lay in the fact that above all other men they were the exponents of action—of the constant, vigorous exercise of body and mind. The game of politics was their diversion, not hunting or feasting as with the Persians; the hippodrome, the theatre and the gymnasium were their favorite refuges from care, not the country home which so strongly attracted the Roman of the Augustan Age.

The Greeks got their first impulse towards the creation of gardens from Persia. In the early periods of their existence they had neither villa gardens nor stately city squares. Domestic life in the modern sense hardly existed, nor social life in the Persian sense; men met in public to exercise or discuss, not to enjoy themselves in idleness, and they went to their homes for scarcely more than to eat and sleep. Of course there were sacred groves around their temples, but these—the common property of all ancient nations—were religious, not artistic, in their origin. Even such a picture as Homer paints when he makes Nausicaä say to Odysseus that he will

"A never-felled grove find, that poplars crown,
To Pallas sacred, where a fountain flows;
And round about the grove a meadow grows
In which my father holds a manor-house,
Decked all with orchards, green and odorous,
As far from town as one may hear a shout,"*

* Chapman's translation.

—even so simple a picture as this can hardly have had its prototype in Greece when Homer wrote. He must have seen such homes on the Ionian coast, where Persian influence worked towards beauty and luxury at a much earlier day than in the peninsula itself. And all his other pictures of gardens suggest little more than useful plantations—orchards, vineyards and vegetable gardens.†

Cimon, we are expressly told by Plutarch, was the first who adorned Athens with gardens, and the influence of Persia was very potent in his day. He "first embellished the upper city with those fine and ornamental places of exercise and resort" which the Athenians "afterwards so much frequented and delighted in. He set the market-place with Plane-trees, and the Academy, which was before a bare, dry and dirty spot, he converted into a well-watered grove, with shady alleys to walk in and open courses for races." Doubtless the state in which Cimon found the Academy was the result of the Persian invasion; it must have been an agreeable spot when the Pisistratidæ were in power. But Plutarch's words suffice, at all events, to show that Cimon did more than had been done previous to his time. As described in later years, the Academy—which lay in the suburb Ceramicos—was surrounded by a wall and contained marble canals, fountains, long alleys, chiefly of Plane-trees, and narrower walks, called "philosophers' walks," embosomed in shrubbery, all thickly intermingled with architectural and sculptural forms. In addition to the main buildings, there were small temples and altars, and statues without number; colonnades, pavilions, and isolated seats for repose; and a long, oval, marble-bordered race-course.

On the north bank of the Illyssus was another similar resort, the Lyceum, with an exceptionally fine colonnade of marble decorated with paintings. Here Aristotle taught, as Plato had taught at the Academy. And at a third "gymnasium," called the Cynosarges, laid out for the use of half-Athenians and foreigners, Antisthenes taught in later days, and from its name, most likely, his scholars got their name of "Cynics."‡

Such were the places which, for the Athenian, represented the splendid palace-gardens and hunting-parks of the Persian. Beautiful they were, of course, but with an architectonic rather than a natural charm—scarcely gardens at all in the modern sense, for by no means places for repose and contemplation. Much the same was the magnificent "sacred grove" called Altis which surrounded the temple at Olympia—a "forest of bronze and marble statues," a veritable city of lovely buildings, embosomed in trees and set about with flowering plants. Carthage, too, had her public gardens, where marble and foliage met on equal terms; and even in rigorous Sparta the young men exercised beneath the shade of gigantic Planes.

The form which the private dwelling assumed in the cities of Greece is too well known to need description. Even in early times, no doubt, its courts were planted or adorned with flowering odorous shrubs in pots. Fruit and vegetable gardens must also have been commonly attached to dwellings of any pretension, and perhaps small flower gardens for the delight of the secluded wives. But only when in the age of Pericles power and wealth came in unprecedented measure to Athens do we read of pleasure-gardens in any wider sense. Domestic life, as we understand the term, still hardly existed; but the wealthy courtesans who met the men on equal terms, social and intellectual, possessed beautiful gardens in which much of their life was passed; and the famous "symposia" were usually held in gardens or in open colonnades facing a verdurous, shadowy enclosure. Now, too, we hear of gardens on the flat roofs, and of the importation of exotic plants to be cultivated in wooden boxes or woven baskets, or even in vases of silver, or of clay made still more precious by the touch of art. Gradually a line of villas with gardens behind them stretched out of the city almost as far as Eleusis; and, it is said, few hedges or walls separated one property from another, but the prospect was everywhere open and harmonious. The garden of Phryne is mentioned with especial praise, and Epicurus possessed a famous one near the Academy, where, in a favorable environment, he instructed his scholars in the philosophical system which bears his name. Pliny, indeed, says that "Epicurus, that connoisseur in the enjoyments of a life of ease, was the first to lay out a garden at Athens; up to his time it had never been thought of to dwell in the country in the middle of the town."

New York.

M. G. Van Rensselaer.

† "Of the gardens of Hesperides we know nothing singular but some golden apples. Of Alcinoüs, his garden, we read nothing beyond figs, apples and olives. The gardens of Adonis were so empty that they afforded proverbial expression, and the principal part thereof was empty spaces with herbs and flowers in pots."—*Sir Thomas Browne*.

‡ Vitruvius's famous restoration on paper of the Athenian Academy cannot be accepted as correct.

The Sugar Maple and Maple Sugar.

A FORCIBLE writer has aptly said: "Timber trees declare a dividend only at death, and there is constant and strong temptation to their destruction. The Sugar Maple declares annual dividends and the tree survives." It is difficult to induce men to plant or protect trees by urging their beauty or usefulness in modifying the climate. But in the case of the Sugar Maple a direct argument can be addressed to the pocket of the farmer. The value of the Sugar Maple, and the rare delicacy and excellence of the product derived from it, is so great, in my view, that on my own farm, a fertile and productive one, there is no portion which yields more satisfactory returns than does a forty-acre sugar-bush. Nor am I alone. Mr. Eugene Davenport, of Woodland, Michigan, states that his forty-acre sugar-bush pays a net profit of twelve per cent. on a high valuation. I believe he has not overstated the facts. There is a delicacy of flavor about Maple syrup that is equalled by no other sweet. Art cannot counterfeit it, and from the nature of the case it will always be a luxury. Therefore, we can count on a ready market at a high figure for a product that can never be depreciated by excessive competition.

Many persons make a mistake in clearing out too thoroughly the underbrush from the sugar-bush. We must remember that trees grown in thick forests have been protected by neighboring trees and brush-wood from the severe winds, and so have not deep running roots to resist the heaviest blasts. If, then, we cut away the other trees and the undergrowth, we shall almost certainly lose our trees. I thin out trees and undergrowth very sparingly, and have lost very few. Others pasture their sugar-lot. This should be done with caution. I have turned sheep into my lot, but they are watched very carefully, for it is my aim to protect the young Maples. And if the old trees, which have now been tapped annually for more than fifty years, should show signs of decline (they do not as yet), I shall have a vigorous young grove to tap instead of the old one.

No rule can be given as to date of tapping. For the past few years about the 20th of March has been a good time to begin in this latitude. The tendency is to tap too early. The evil of this is that the cut dries up, and when the season does fully open, it is not in condition to yield the best returns.

In early times we used to cut an oval in the tree with an axe. This was often two by four inches in diameter. A terrible wound, yet some of my best trees of to-day were tapped in this way for years, and stand as monuments of Nature's recuperative power. We next used a two-inch augur, cutting about half an inch deep, and, as before, cutting a second gash just below for a spout. This, though an improvement, was still a cruel practice. The wonder is that the trees stood it as they did.

We now use a half-inch curved-lip bit, which cuts a very smooth hole. We bore from one and a half inches to two inches in depth. While science seems to have demonstrated that depth, not size of hole, measures the amount of sap, yet experience in my bush proves that a two-inch hole gives more sap than a half-inch cut, though not enough more to warrant the larger wound.

If we desire to secure the very finest article, we must exercise great care and absolute neatness. The best spout is a close-fitting metallic one, which also holds the bucket. The buckets should be of tin, should "nest" or have flaring sides, and should hold not less than fourteen quarts. The bucket has a small hole through the side close to the top, by which it hangs to the spout. The past year I have used two spouts to a bucket, one passing just over the rim. Hereafter I shall use two spouts to all but my smallest trees. I use an inch pine cover, one foot square, to each bucket. It is painted red on one side and white on the other. The cover keeps out all filth, rain and snow from the sap, and is a very great aid in gathering. As we turn the covers each time we can see for rods by the color if we have gathered the sap from any bucket.

Sap contains cane-sugar, which varies in amount with the tree. I think the average is about one pound to four gallons of sap. The best syrup—that which has sufficient consistency to please the palate, and yet is not so thick as to crystalize in the cans—weighs eleven pounds to the gallon when hot. We aim to have all our syrup of this exact weight. It takes about thirty-five gallons of sap to make one gallon of such syrup. To make the finest sugar or syrup requires great neatness and dispatch. Any dirt affects the color, and possibly the flavor, and therefore the sap is strained through cloth at least three times. Delay in reducing sap to syrup or sugar affects both color and flavor. I suppose that ozone colors the product, just

as it colors a piece of cut-apple. Thus long exposure is to be avoided. Again, delay, especially if the weather is warm, and if the greatest neatness has not been observed, induces fermentation, which changes the cane-sugar to grape-sugar. This injures both color and flavor decidedly. Could all sap be taken just as it oozes from the tree, and converted quickly into syrup or sugar then, we would always have a product nearly water-white and of the highest flavor. In the syrup there is a variable amount of malate of lime. Often this is almost absent. Sometimes we get a pint in reducing six or seven gallons of syrup. This lime malate often incrusts the bottom of the evaporator, and gives much trouble. I use an evaporator so arranged that the back-pans (all are connected by siphons) can be changed each day, and there is no trouble from these incrustations. In other evaporators, if the bottom of the pan at the very back end be occasionally scraped with a pine paddle the lime is said not to trouble. When the syrup is strained through factory-cloth, much of the lime is removed. The syrup then stands for half an hour, when the lime so settles that but little is left in the liquid, if carefully turned off. This is at once sealed, while hot, in air-tight cans.

We have a very neat house in which to boil the sap. Even the wood house is separate from the boiling room so as to save or prevent dust. The "Champion" evaporator reduces very fast. Mine is twelve feet by four, and will manage the sap for 800 trees. It consists of four separate pans connected by siphons. We run off the syrup once every three hours, about seven gallons at a time, and this rapid work helps to make a very fine article.

Trees vary much in the amount of sap they yield. Sound, vigorous, large, and heavy-topped trees are the best. Seasons differ exceedingly. What we need for sap is a cold night, freezing the ground, followed by a warm, still day. The season that has many such days will be a good one. Sap from different trees varies in sweetness. Sap late in the season is usually sweeter than that which runs earlier. Sap which runs rather slow is richer than when it runs very fast. Trees tapped on the south-west side run fastest early in the season; those on the north-east excel later. The sap is all equally good till the buds start, when the syrup will be rank both in taste and odor. The old idea that the first run was best came from the fact that the buckets then were all neat and clean. It is important to wash out the buckets often with warm water, so as to prevent any possible fermentation.

Agricultural College, Mich.

Notes Upon Some North American Trees.—VIII.

129. *CRATÆGUS TOMENTOSA*, L.—This is one of the best marked and least variable of the North American Thorns. It may be readily distinguished by its large, ovate-elliptical leaves three to four inches long, narrowed at the base into a margined petiole, doubly serrate and sometimes incisedly cut towards the apex, glabrous, dark green and lustrous on the upper, paler and covered with soft pubescence on the lower surface; by the spreading, loose, pubescent corymbs of rather small flowers and by the small oval fruit, rarely more than a third of an inch long and always upright. It may be distinguished from all the varieties of *C. coccinea* by the absence of glands, and by the pale gray bark of the branches, which are generally unarmed. The thorns, when they do occur, are short and stout and of the same color as the branches. This species, with which a variety of *C. coccinea* is often confounded, does not occur in New England, or, so far as I know, anywhere east of the Appalachian Mountains; it is common in western New York, extends through southern Michigan to Missouri, where it is very common, and as far south as east Tennessee and Georgia. It is the latest of all our *Cratægus* to flower, with the exception of *C. cordata*; and the flowers emit an exceedingly disagreeable odor. This species is admirably figured in the "Arboretum Segrezianum," t. 22, under *C. leucocephalus*; and there is a doubtful figure in the "Botanical Register," xxii., 1877, under *C. pyrifolia*. But as these works are not very accessible, Mr. Faxon has drawn the figure, which appears on page 425 of this issue, which may serve to call the attention of botanists to this plant. I shall be glad of information of its geographical range, especially in Pennsylvania and in the states west of the Alleghany Mountains and south of the Ohio River. The specimen in the Linneum herbarium fixes the identity of this species and

settles, so far as concerns the oldest name, its rather complicated synonymy.

The plant which has been sometimes considered a variety of this species (var. *punctata*, Gray, Manual, 2 ed. 124.—Census Cat., 80) is, certainly, quite distinct from it, and one of the best marked and least variable of our species, always readily distinguished by the prominent primary veins of the leaves, and by the large, dull red or bright yellow pendulous fruit covered conspicuously with white dots. This plant is common in Berkshire County, Massachusetts; it extends west to Ontario, and southward along the Alleghany Mountains to the high peaks of North Carolina. The name which has been usually applied to it is that of Jacquin, *C. punctata* (Hort. Vindob., i., 10, t. 28), published in 1770; and this name can be retained, as the *Mesiphus cornifolia* of Munchhausen (Hausv., v., 145) is of the same date.

130. *CRATÆGUS CORDATA*, Aiton.—Walters name, *C. populi-folia* (1788), is taken up in the recent Catalogue of the plants of New York in the place of that of Aiton (1789). The oldest name for this tree, however, is *Mesiphus cordata*, Miller, "Figures of the most beautiful, useful and uncommon plants described in the Gardeners' Dictionary," i., 179 (1760), and "Gardeners' Dictionary," ed. 8, so that the oldest specific name being used it is fortunately possible and proper to retain the familiar *C. cordata*.

133. *CRATÆGUS BERBERIFOLIA*, Torrey and Gray.—This species, published in the "Flora of North America," i., 469, in 1838, had been discovered by Professor Carpenter on the prairies of Opelousas, in western Louisiana. Little was known of it, as the specimens were gathered after the petals had fallen and before the ovaries had grown perceptibly, and nothing more was seen of this plant until the spring of 1880, when I found it in eastern Texas, not very far from the original locality. I visited Opelousas for the third time four years ago, and fortunately met with the tree on the very spot, probably, where Professor Carpenter had discovered it fifty years before. The trees at this time were only in bud, but later, through the kind offices of Dr. Mohr, of Mobile, I obtained copious flowering and fruiting specimens and an abundant supply of seeds, which have been distributed among the principal European gardens.

An examination of this plant both in the field and in the herbarium makes it clear that it must be considered a pubescent form of *Cratægus Crus-galli*.* The Louisiana trees have the habit of *C. Crus-galli*, with the peculiar horizontally spreading branches, making the low, flat-topped head of that species. The bark is identical in the two trees, and I find no characters, except in the pubescence of the young shoots, of the leaves and of the inflorescence to distinguish it from the ordinary broad-leaved form of the Cockspur Thorn. The plant was described as unarmed in the "Flora of North America," but I have, thanks to Dr. Mohr, who purchased Dr. Carpenter's herbarium, one of his original specimens, which has stout, straight spines an inch and three-quarters long; and branches may be found on the same tree covered with thorns, or entirely unarmed. The fruit is ornamental, half an inch in diameter, and orange with scarlet cheeks. This plant grows quite abundantly about four miles west of Opelousas, on ground adjoining the plantation of a Mr. Pierre Pompon Petre. It is found among an open growth of Oaks and Hickories, associated with Hornbeams, Flowering Dogwoods and the Parsley Haw, close to the margin of the prairie, which is here bordered with a most luxuriant growth of the beautiful *C. brachyacantha*. Dr. Mohr sends what is evidently the same plant, collected on Black Creek, west Florida, in 1882, and Mr. Faxon, in 1885, found at Augusta, Georgia, *C. Crus-galli* with pubescent shoots and leaves which cannot be separated from the Louisiana plant. *C. Carrierei*, of which *C. Lavalleyi* is a synonym—a seedling which sprung up in the

garden of the Museum d'Histoire Naturelle, at Paris, is the same as our plant, except in its less developed pubescence.

135. *CRATÆGUS FLAVA*, Ait.—This, according to Karl Koch, is the *Mesiphus flexispina* of Moench (Verzeichniss ausländischer Bäume und Stauden des Lustschlosses Weissenstein bei Cassel, published in 1785). I have not this work before me, but if the reference is correct, the specific name of Moench must replace that of Aiton, which was not published until four years later, and *C. flava* become *C. flexispina*—a change which is less objectionable than many others, as the fruit is never quite yellow, and more often red than yellow-green. *C. S. Sargent.*

Foreign Correspondence.

London Letter.

AUGUST is usually the interval between the summer and autumn crops of roses, while as a rule it is too early for Dahlias and other autumn flowers. But this year, owing, probably, to a fine and warm early summer and an abundance of rain lately, our open air gardens are particularly gay with flowers, and the Royal Horticultural Society's show in mid-August was brighter and more crowded than I remember to have seen it at this season. The hall was lit up with masses of Dahlias, Gladioli, Roses, Carnations, Java Rhododendrons, Begonias, Orchids, a host of border flowers, specimens of hardy and ornamental trees and rich collections of fruits, including a marvellous array of Tomatoes from the Society's gardens. Here was a feast to suit all sorts and conditions of gardeners, but there was but a handful of admirers after all, and all these directly interested. The real flower lovers are those who have the best and most richly stocked gardens, and go to exhibitions only to see for themselves what is new and good.

There was an unusually large number of novelties at the meeting, and amongst them were some first-rate plants, and I was glad to see the new *Vanda Kimballiana*, shown splendidly by Sir Trevor Lawrence and Messrs. Low. It is, without question, a lovely Orchid, and a valuable addition to the small number that flower in late summer. The plants exhibited differed somewhat from those I saw before, the sepals being almost pure white, while the trilobed labellum was of a vivid crimson purple. The flower reminds me much of the pretty *V. Hookeriana*, being similar in size and form. Some of the specimens shown bore as many as seven flowers and buds. I hope it will prove a good grower, but the rounded quill-like leaves do not indicate robust growth. It was, of course, honored with a first-class certificate, as was also a new Cypripedium from Baron Schroeder's collection. This was *C. orphanum*, supposed to be a cross between *C. Drurii* and *C. barbatum*. It is handsome, but much resembles several other hybrids, *C. Harrisonum superbum*, for instance. It is one of the finest of its class, and will delight specialists in Cypripedia. A far finer hybrid is that named *C. Stoneo-superbiens*, indicating a cross between these two species. It so nearly resembles the beautiful hybrid named after the late Mrs. Morgan that it was re-labeled *C. Morgania*. The parentage of both hybrids is the same, and there might be, perhaps, some slight variation in form and color. It is the nearest approach among hybrid Cypripeds to the unique *C. Stonei platytanum*, and some look upon it as really handsomer, and certainly it is more free in growth and flower. The long, broad and drooping lateral sepals, richly spotted with black on a pale ground, gives distinction to the hybrid, while the rest of the flower partakes of the features of *C. Stonei*.

A great treat for Orchidists was a specimen of the grandest of all Cattleyas, *C. Hardyana*, which, when first exhibited, was supposed to be a natural cross between *C. gigas* and *C. Dowiana aurea*, but probably it is only an extraordinarily fine variety of *C. gigas*, or, as it is now called, *C. labiata Warscewiczii*. The flowers are as large and as fine in form as any variety of *C. gigas*; the sepals and petals are a very rich and bright rose-purple, while the broad labellum is of an intense crimson magenta, and adorned with two large blotches of bright yellow, and netted with the same color. This grand Orchid is still very rare, and probably does not yet exist in American collections. It is said to have cropped up, in a few instances, from gatherings of imported plants of *C. gigas*.

Among the other choice Orchids shown was a fine example of the blue *Saccolabium caeleste*, a small-growing species with short, dense spikes of exquisite little flowers, violet-blue and white; *Lælia monophylla*, of the size of *Sophranitis grandiflora*,

* *CRATÆGUS CRUS-GALLI*, var. *berberifolia*, arbor mediocris, ramulis horizontalibus, hornotinis pubescentibus, foliis oblonge cuneato-obovalibus, superne serratis subtus dense pubescentibus, 2-poll-longis; corymbis dense hirsutis.

and with similar flowers of a brilliant orange-scarlet, and the rare little *Oncidium triquetrum*, with modest little flowers of no great beauty. The Marquis of Salisbury's gardener contributed about a dozen spikes of *Saccolabium Blumei*, from eighteen inches to two feet in length, with glorious wreaths of tiny blossoms of lovely color and form and delicious fragrance. On seeing such Orchids as these one can understand how captivating they are to the public, who value flowers for what they are, and not for their rarity or money value.

so tasselled at the points as to make it quite different from the well-known old favorite. It received a first-class certificate, and it well deserved it.

Among the large number of florists' flowers, only those of superlative merit received awards. Most interest centred in a splendid collection of new Gladioli of M. Lemoine's raising, and shown by Messrs. Veitch. In addition to the hybrids raised by intercrossing *G. purpureo-auratus* and *G. Gandavensis*, M. Lemoine has now some crosses from *G. Saundersii*, a Cape

Fig. 126.—*Crataegus tomentosa*.—See page 423.

An extremely handsome new Pitcher plant named *Nepenthes Curtisii superba* was shown by Messrs. Veitch, who won for it a first-class certificate. The pitchers are of bold yet elegant shape, with a broadly recurved, grooved rim of dark crimson, the rest of the pitcher being of the same color, copiously marked with irregular blotches of very pale green. Some of the pitchers measured nine inches long, and the plant is a vigorous grower. A good market Fern will probably be found in the new *Pteris tremula Smithiana*, which has every frond

species, having large flowers, with hooded sepals of a bright scarlet. It is as hardy as *G. purpureo-auratus*, and, therefore, was well calculated to yield progeny possessing vigor of growth and hardiness. These Saundersii hybrids he has named *G. Nanceianus*, and two sorts were considered worthy of awards of merit. One was called President Carnot, with flowers four and a half inches across, and of a bright scarlet-red, the other, Comte Horace de Choiseul, with crimson flowers, freckled with white. Both are superb varieties, and will

certainly become popular. Of the other class of hybrids (those from *G. purpureo-auratus*) there were numerous sorts shown, three of which, named André Chenier, Alsace and La France, were distinguished by awards, while another, shown by its English raiser, and named Hippolyta, was also voted an award of merit. It has large and perfectly-shaped flowers of lemon-yellow, blotched with maroon-crimson. The growth is vigorous, and the spike long and massive. Next in interest were the double Begonias of Messrs. Cannell, who showed a really wonderful group of seedling plants, all raised from seed in February of the present year. The remarkable point about these seedlings was the very large size of the blooms, which looked more like double Hollyhocks than Begonias, so perfect were the rosetted blooms. Some may think they are too big, and perhaps so, to be really beautiful, but the amateur is always asking for larger and larger blooms, and so the business of the florist is to produce them. The colors of these new double flowers are exquisite, soft, yet brilliant, and one could trace almost every intermediate gradation of tint from a rich deep crimson through the palest of pinks to snow-white. The sorts to which awards of merit were given were named Litkie, pale salmon-pink; A. Blanc, rich cherry-crimson; Mrs. Cayzer, bright rose. Though only three won distinction, there were others equally fine, but the committee do not like to be too liberal with awards.

The Java Rhododendrons of Messrs. Veitch are always admired, and, now the firm whose peculiar specialty these greenhouse shrubs are, have taken to show cut blooms in boxes like Roses, so numerous have the sorts become. It is not often now that anything special is obtained in the way of color, but on this occasion they showed one, called Duchess of Fife, of a singular color—pink-cream, I heard it described—while the large blooms were perfect in form as well as large in truss. This race of greenhouse plants is becoming extremely popular now, as they do not require much heat to grow them to perfection, while they yield flowers almost throughout the year, in winter especially.

There was a first-rate new Chrysanthemum called Golden Shah, which the experts on the committee considered worthy of an award, as it is said to be finer than any other yellow early-flowering sort. It is dwarf, perfect in bloom, and in color bright and good. The crowds of new Dahlias exhibited sufficiently proves that the demand for them is as great as ever. I will not attempt to describe even those that struck me by the distinct colors or other novel point. Only two were certificated, as the committee are very careful now in dealing out awards to new Dahlias. Both were single, one, called James Scobie, is warm yellow, with a centre zone of crimson—a distinct break in color; the other is yellow, flaked and pencilled with scarlet. Single Dahlias seem to have had their day of popularity, the rage now being for Cactus-flowered sorts of the Juarezii type, and here were to be seen from such great growers as Ware and Cheal some beautiful sorts in color different to any shown before. Those I made special note of were Panthea, Charming Bride, Zulu, Empress of India, all first-rate. But we shall see Dahlias better later, when other things are less engaging. A firm of market-growers, Messrs. Hawkins & Bennett, think they have obtained the perfection of a double scarlet Pelargonium for the market-grower. This they call the Duke of Fife, with massive truss of brilliant scarlet and very double, and, lest it should be thought that it too much resembles that well-known and first-rate sort, F. V. Raspail, they showed some blooms of the latter for comparison. The Committee believed in it, too, for they voted an award of merit.

A Few Late Pears.

THE Abbott is a good pear for family use, though not much grown. It is a little smaller than the Bartlett in size, with a nice blush on the sunny side, and people who dislike the musk of the Bartlett would prefer the Abbott. The tree is a strong grower and yields well. Its merits have been overlooked.

Belle Lucrative is a pear of medium size and excellent quality when well-grown. It is an abundant bearer, and, if allowed to do so, will over-bear, to the detriment of the fruit, both in size and quality. The skin of the fruit is an unattractive green, and for this reason, among better-looking pears, it is apt to be passed without notice, but its buttery, juicy flesh amply compensates for any lack of good looks.

Golden Beurre is of medium size, and in appearance directly the opposite of the preceding, while approaching it in quality.

It is an abundant biennial bearer, but, for some reason, has not achieved great popularity.

Flemish Beauty is another large and exceedingly delicious pear, and of almost honeyed sweetness at its best, but it cracks and spots so badly over a large extent of territory, that it is absolutely worthless except in limited areas.

The White Doyenne or Virgalieu, with a dozen other names as synonyms, used to be the standard of excellence of the whole pear family, and would be to-day if it could be grown as well generally as it was forty years ago. At that time it was the pear of pears in the farmers' estimation in this part of New Jersey (but this was before the advent of the Bartlett or Williams' Bonchrétien, as it was sometimes called), but it also became subject to spotting and cracking, and is now so absolutely worthless that it is seldom seen, and is unknown to most of our younger people.

Howell, a large, handsome, light yellow pear, a good grower and bearer, is highly esteemed by many, but I never considered it quite good enough for a standard dessert fruit.

Louise Bonne de Jersey, where it succeeds, is a noble fruit, of buttery texture and juicy, but in this section it is gritty, astringent, and only fitted for cooking purposes. Of late years it has developed the fault of shedding its leaves so early that the fruit is seldom more than two-thirds grown, so that it is difficult to imagine that it could ever attain the degree of excellence which it reaches when grown in perfection.

Angouleme, or Duchess, as it is popularly known, is of the largest size and best quality, if well-grown; if not, it is just the reverse. The larger the specimen, generally, the better it is. The flesh is coarse-grained, but juicy, sweet and delicious; one of the most popular pears grown, after the Bartlett, and more largely grown as a dwarf on Quince-root than any other. It must have congenial soil, however, and high culture. On my soil, as a dwarf, it is like other dwarfs, of little account. It is said to prove satisfactory as a standard, but I have no experience with it as such. There are few advocates of dwarf-Pear culture left. The few successful orchards of dwarf-trees, are those which have rooted from the graft, and have become standards in fact.

Anjou is another large, popular pear of very good quality, when in perfection, and it will keep till November and December in good condition, if properly cared for. The tree is one of the best in health, foliage and growth, and should be in the smallest collection. This was Colonel Wilders' favorite.

Buffum, a pear of medium size and fair quality, is one of the most healthy, vigorous growers in the whole list, and an abundant bearer every other year. Sometimes the fruit is rather under-sized from over-bearing, a tendency in all pears, and some years, too, it is less juicy than others. It is then excellent for cooking. With approaching ripeness it assumes a yellow and handsome appearance.

Bosc is a long, slender-necked russet pear of the highest excellence, sweet and rich. The tree is a poor, open grower while young, and the fruit is borne singly or in pairs generally, and very evenly distributed. It is most satisfactory when top-grafted. This was Mr. Downing's favorite pear, and his judgment on this point seems to me eminently sound.

Claireau is a pear of the largest size, handsome and good, when in perfection. The tree is a fair grower and an early and abundant bearer, but it is liable to shed its leaves prematurely. When the foliage is held till October, and the fruit is fully matured, it ripens up handsomely, and the quality, to my taste, is much superior to that of the best Bartlett. This spotting and premature fall of our Pear-leaves is a more serious trouble with me than the fire-blight. The latter kills, and leaves no doubt as to the course to pursue, while the former leads on hopefully to certain disappointment in the end.

Sheldon, a round, russet pear of medium to large size, flesh granular, melting, sweet, juicy and aromatic, is a fruit of the highest excellence. The tree is a lusty grower and generally productive. It should be in the smallest collection.

Seckel is too well known to need description. The tree grows moderately slow, bearing its fruit in clusters, which should be thinned to single specimens, if possible. Its small size is its only fault.

Onondaga is a large, greenish-yellow pear of excellent quality. Tree vigorous and productive.

Lawrence is an American pear of great excellence. The tree is of moderate growth, very healthy and productive; the fruit of medium size, smooth, yellow at maturity when grown on young trees, but on old trees it is very apt to become cloudy or rusty. The skin is thick, flesh fine grained, buttery, sweet and juicy, and it will keep till Christmas with ordinary care, and, on the whole, is the nearest approach to a good winter pear I am acquainted with. The tree holds its foliage

with great persistency—a very valuable feature in any tree.

Winter Nelis is a small russet pear of excellent quality when well grown, but the tree generally loses its foliage early before the pears mature, and, therefore, they seldom reach perfection. The tree is a slow, slender grower, and should be top grafted on some more vigorous kind.

Dana's Hovey is among winter pears what the Seckel is among autumn varieties. The tree is a good, healthy grower, and produces fruit about the size of the Seckel, but better and more highly flavored. If it were only a little larger!

Sweetness is a prominent characteristic of most of the pears so far named. In Superfin we have an acid pear of large size, green at maturity, but sometimes ripening up a bright yellow. In the latter case the acidity generally be-

Urbaniste is another large pear, in quality equal to any named; skin, smooth, greenish-yellow; flesh, melting, buttery, rich and juicy. The tree is a fair grower, but is not popular among dealers and planters because, like the Tyson and some others, it is tardy in coming into fruit. The old adage about planting pears for one's heirs is not regarded with favor by tree-planters now-a-days; they are in a hurry, and would like the trees to commence bearing at once. When one has old trees of undesirable kinds, a new head of Urbaniste could be grafted on and this excellent variety would soon come into fruit.

I have grown many other pears, but the list is long enough to meet the wants of an amateur. I have mentioned only the leading and most popular varieties now before the public,

Poet's Narcissus flowering in the grass.—See page 421.

comes much modified and assumes a rich, vinous flavor that can hardly fail to please any palate not wholly partial to sweetness. Seasons and soils have much to do with the full and thorough development of this pear more so, perhaps, than any other. I have eaten it when I could desire nothing better, and again when it was disagreeably sour. Stewed or canned it is excellent, and needs no lemon or other flavoring as do the Bartlett's and other sweet kinds. The tree is a good, thrifty grower and a fair bearer.

Diel is another acid pear of large size and very good quality when in perfection. The flesh is more coarse, and sometimes gritty and less acid than the preceding. The tree grows well and bears well. But the fruit sometimes cracks and the leaves fall prematurely, and we cannot expect trees that do not hold their foliage till the fruit is mature to produce that fruit in perfection.

trees of which can be easily obtained. One who has a longing for the pears of his childhood had better get cions or buds and insert them in stock more easily obtainable.

And what about the Kieffer? Well, if one wants a handsome, strong-growing tree, and an abundant cropper of fruit for canning purposes, the Kieffer just meets his case, but as a table fruit it does not deserve planting. It is a valuable substitute for the quince, and, as it will produce fruit far more abundantly and cheaply, it is well worth planting for its excellence in taste and appearance when preserved.

A few trees on the smallest place can be made in a short time to supply a family with a great variety in sufficient quantity for all purposes, by making one tree yield several kinds of those least required. A little judgment in this direction would secure a greater variety, covering the season more effectually, and avoiding a useless and wasteful surplus of a single

variety, which is apt to occur when a tree gets into full bearing.

The pear is the easiest of all our fruit trees to graft successfully, and the merest tyro need not fail in so simple an operation.

Montclair.

E. Williams.

The Wild Garden in August.

SEVERAL clumps of *Clethra* in my wild garden fill the air with their delicious fragrance, and *Clematis Virginiana* is one mass of bloom. A tall, cedar post was set in the ground, and crooked, gnarled Grape-vine stems were nailed to it, which makes a support for its leafstalks, where they can clasp and climb in all directions. Long, pendulous branches are drooping from every side, loaded with white blossoms, which attract numerous butterflies and other honey-loving insects.

A very showy Sunflower has been in blossom since the middle of June. I found it on an island on the New Jersey coast, some four or five years ago, where it attracted my attention with its wonderful amount of bloom. I have called it a form of *Helianthus latiflorus*. But June is early for this or any other Sunflower to blossom. Its leaves are quite thin and smooth, not at all like the normal *H. latiflorus*. It is now full of flowers, and will continue so until frost, and when I look at this beautiful plant I am not surprised that so many persons favor its adoption as the national flower. The Narrow-leaved, Pine-barren Sunflower (*H. angustifolius*) is just coming into bloom. This is also a pretty species; but to do well it must be grown in a damp spot, which can be easily secured in any desirable place in the garden by sinking a tub in the ground and filling it with good soil and keeping it moist. My plan is to get oil-barrels and saw them through the middle, thus securing two good receptacles from one barrel. After they are sawed I set fire to the inside and burn out the oil and slightly char them, which makes them last an indefinite time. Groups of many of our most charming swamp-plants can be grown in these tubs as easily as a Morning Glory at our window.

One of the most remarkable plants in my collection is a *Rudbeckia*. At the base of each ray is a dark-brown spot, making the flower very handsome. It was brought to me in a bouquet this summer, and the young lady collector, having excellent observing powers, could tell exactly where it grew. On going to the spot we found the plant held several flowers, all marked in the same way, so we carefully removed it and planted it in one of the tubs in the garden, where it continued in bloom a long time, attracting much attention. It grew in a swamp, and has undivided leaves and a dark-purplish disk, but, according to Gray, this division of *Rudbeckia* ought to grow on dry soil.

The white and yellow fringed Orchids (*Habenaria blephariglotis* and *H. ciliaris* and *H. cristata*) are very beautiful through July and August. What is more attractive than a group of these plants in a half-shady nook, surrounded by low, cool-looking Ferns? This use of the sunken tub enables us to grow them in any desirable spot.

One of the most stately groups in my garden, among these wild swamp-plants, is of sedge (*Scirpus Eriophorum*). It is five feet in height, and each stem is surmounted with a large, graceful, drooping, umbel-like panicle of flowers. This sedge is lovely from April—when it first begins to throw out its long, rather broad, grass-like leaves—until November, when it is crowned with its persistent, drooping panicles of fruit.

The Arrow-head (*Sagittaria*) and Pickerel-weed (*Pontederia*) are among the bog-plants now in bloom. So is the bright orange-colored *Polygala lutea*, which flowers all summer. This species is the most showy of the Polygalas, and deserves a place in every garden.

Among upland plants the Eupatoriums are now quite showy with white and purple bloom. The Butterfly-weed (*Asclepias tuberosa*) is still brilliant with orange-red flowers, attracting hosts of butterflies. Many wild plants not in flower are lovely now in their mature foliage. The Sumachs are specially fine. The Stag-horn Sumach (*Rhus typhina*) was stripped of its flowers in June by the almost omnivorous Rose-bug, but I never saw its foliage more beautiful than now, while the Dwarf Sumach (*R. copallina*) is strikingly handsome, with perfect, smooth, shining leaves.

The blossoms of the Holly met the fate of the Stag-horn Sumach, but the prickly leaves were left intact, and their shining verdure will be a joy during the winter. The Bayberry and Sweet Fern are still handsome with perfect, fragrant leaves, which one cannot help noticing in this season of unusual insect-devastation.

The smooth Alder (*Alnus serrulata*) and *A. maritima* are both handsome shrubs which grow finely in my garden, and the

latter makes a small tree from eighteen to twenty feet in height. Their smooth, straight-veined leaves are as handsome as those of the Beech, which tree, to my regret, does not succeed in our soil, so the next best thing are these Alders, which grow luxuriantly and are attractive, even in winter, with their clean-looking bark and clusters of small, persistent, cone-like fruit.

Vineland, N. J.

Mary Treat.

The Ismenes.

ISMENE is now considered to be simply a sub-genus of *Hymenocallis* of the *Amaryllis* family. It differs, however, from the rest of the genus to such a degree that the old name is likely to stand for a long time among horticulturists. It is very desirable that plants should be known by their right names, for correct nomenclature is necessary to intelligent gardening, therefore, though the name of the sub-genus heads this article, I shall call the species by their proper generic title. Counting *H. deflexa*, there are seven species. Of three of these I write from experience.

All of the *Hymenocallis* have a central cup surrounded by six radiating segments, the cup in sub-genus *Ismene* being very much larger proportionally than in the rest of the genus. All of the species are natives of the Andean chain, from Ecuador to Bolivia.

H. Macleana is a very pretty species. Its flowers are of a decided green color, and give the species a distinctness which is very satisfactory to those who prize individual character in plants as well as general effect. The flower-stalks are about twenty inches tall, and bear frequently as many as ten flowers, the average being about six. As in the other species, these do not all open together, but at intervals of a day or two, so that the same cluster often presents fresh flowers for nearly two weeks. This species increases very rapidly by offsets. Last autumn I selected twenty strong bulbs and stored them in a cellar where the temperature averaged 42°, falling occasionally to 38°. Dahlias and Gladioli, stored in the same cellar, are now doing well, but the bulbs in question, planted on the same day with the bulk of my stock, wintered under a green-house bench, were fully ten days later in coming up; not one bloomed, and they now present a stunted and feeble appearance. I conclude, therefore, that cool wintering is not at all to their taste. I have never been able to get good seed from this species, which is the *Ismene undulata* of catalogues.

H. calathina is a much larger plant than the foregoing in all its parts. In the whole range of summer-flowering bulbs I do not know a more noble and stately one. The large cup is white, a little marked with green; the flowers are nearly as numerous in the cluster as in *H. Macleana* and last as long; their perfume is very pleasing to most persons, though a little too strong if brought into a close room. The foliage is so green, vigorous and erect that a row or cluster of the plants is very beautiful even after the flowers are gone. By careful fertilization seeds may be obtained, which are of the peculiar bulb-like nature observable in those of *Nerine*, *Brunsvigia* and *Amaryllis Belladonna*. They are of the color of a pea a little too old to cook, and of very different sizes, the largest being the size of a sparrow's egg. They are best sown on the surface of a pot of earth without any covering. In a short time a shoot is sent out which turns down into the earth and presently sends up the young foliage. June is the flowering time of both these kinds.

H. Amancaes is also a remarkably beautiful species, its broad flowers being of a strong deep yellow, somewhat striped with green, and very fragrant. It is a rare bulb, rated at a high price in catalogues, and usually not to be had if ordered. With me it is late to start and late to bloom. At the present time, August 10th, it is less than a foot high and shows no sign of a flower-stalk. The seeds of this species often make no growth above ground, but form a bulb as large as a swallow's egg, with no foliage at all until the second year. A lemon-colored hybrid has been produced by crossing this with *Calathina*. The "Botanical Register" contains an animated account of the annual fiesta in Lima, when great throngs of people, on foot or horseback, go out upon the hill of Amancaes to gather the blossoms of this bulb and spend the day in amusements.

H. Quitoensis, *H. Andreana*, *H. deflexa* and *H. nutans* are known to me only by figures and descriptions. They are all white-and-green-flowered, and not much unlike *Macleana* in general appearance. *H. deflexa* is ranked as a species by Mr. Baker, though it is a natural hybrid; Colonel Trevor Clarke has produced it by crossing *H. calathina* and *Elisena longipetala*.

Canton, Mass.

W. E. Endicott.

Lemoine's Hybrid Gladioli.—With the early and brilliant Brenchley's Gladiolus, this new race comes into bloom. The value and beauty of these Gladioli cannot possibly be overrated, and the more I see of them the more I am convinced that they will in time usurp the place long occupied by the more delicate varieties of the Gandavensis race, which few can grow well. Lemoine's are hardier and more robust in growth, and though they have not at present that massiveness of spike which characterizes the best of the Gandavensis hybrids, they rival them in diversity and richness of color. This race owes its hardiness chiefly to its parent, *G. purpureo-auratus*, which is quite a hardy bulb with us, growing strongly and propagating itself with singular freedom. The other parent was one of the Gandavensis race, but now, as elsewhere stated, M. Lemoine has hybridized with *G. Saundersi*, which is another hardy species, with large, brilliantly-colored flowers. I have just seen a collection of the newest hybrids, and out of two dozen the following were in perfection of bloom and extremely fine: Sphinx, deep crimson, with lower petals blotched with velvety maroon; Lamartine, flowers very large, cerise crimson petals, with white blotches on lower petals; Boussingault, pale pink petals, flaked with crimson, lower petals half bright canary-yellow, and half blackish-crimson, a very striking sort; Deleuil's Zélie, mauve pink, lower petals, blotched with white; Gainod, like Zélie, but larger; Enfant de Nancy, very rich and deep crimson, lower petals maroon. Other sorts not past their best were Mars and W. E. Gumbleton, both choice kinds. All these have flower-stems ranging from two and a half feet to four feet high, the spikes carrying from ten to fifteen flowers. All have the characteristic hood-like flowers of *G. purpureo-auratus* and *G. Saundersi*, but this peculiarity is not so marked in the later as in the earlier hybrids, and no doubt M. Lemoine will in time produce varieties with flowers as large and open, and as dense on the spike, as the best of the Gandavensis race, which now they quite eclipse in point of color.

W. G.
Kew.

Perennial Coreopsis.—These are among the best of hardy garden flowers as they require very little attention, reproduce themselves freely from self-sown seeds, and make a brilliant display from June until frost sets in. *C. lanceolata* has become in a comparatively short time one of the best known of the genus, and certainly no hardy plant produces more flowers throughout the season. Its large, bright-yellow flowers are of good substance, and stand well when cut. *C. grandiflora*, from the mountains of North Carolina, is equally good in all respects. The flowers are a trifle darker in color, more stellate, and the plant itself has a spreading habit. As soon as it begins to grow, *C. grandiflora* also begins to branch, so that, by the time the flowering period is reached, the smallest plant has become a dense bush some two feet in diameter. This plant deserves to become as popular as *C. lanceolata*. *C. verticillata* is a pretty species, with whorls of very narrow leaves, quite distinct from the preceding. *C. verticillata* is very floriferous, and a desirable plant. *C. delphinifolia* is a taller growing plant, well grown plants being often three or four feet high. The foliage, as the name implies, resembles that of the Larkspurs. The flowers are produced from the tops of the stems, and are quite showy, though not so large as those of the other species. *C. tripteris* grows from six to eight feet in height, and is suitable for the back row of the flower border, or for planting in shrubberies. The stems are clothed with elegant three-parted leaves, and just now the stems are surmounted by a branched panicle of very fragrant yellow flowers, the fragrance resembling that of the old English Wallflower. This plant may be effectively associated with Silphiums, *Helianthus orgyalis* and *Rudbeckia maxima*, all of which are of about equal height. All the above species of Coreopsis are perfectly hardy and perennial, and they would probably be far better known, were they exotic, and less easy to cultivate.

Lobelia splendens var. Victoria is a plant that has often been catalogued and sent out as a variety of the Cardinal Flower, *L. cardinalis*, with which, however, it has no specific affinity. It is a variety selected from the Mexican plant *L. splendens*, and, it may be added, that as a decorative herbaceous perennial it has no rival, the dark, purplish, crimson foliage resembling in color the Iresines so much used for bedding purposes. The flowers are similar in color to those of *L. cardinalis*, but they are three times the size. For fall effect there are few plants to equal this Lobelia, especially when planted in masses, or associated with some plant of variegated foliage. I once saw a large circular bed of this Lobelia intermingled with the variegated *Abutilon Thompsoni*, and the effect was charming. The hardiness of the Victoria Lobelia is not sufficient

to warrant its being left in the open ground in the eastern states. The crowns need lifting, and require protection from severe frost during winter. In spring these may be divided and replanted in the position they are to occupy during summer. Any one obtaining this plant as a variety of *L. cardinalis* would be led to suppose that it required a moist soil and situation, while, as a matter of fact, this would be extremely injurious. *L. splendens* needs a rich dry soil. The variety in question comes fairly true from seed, but its germination is somewhat erratic. We have found that plants may be looked for anywhere between six weeks after sowing and the end of the succeeding eighteen months.

E. O. Orpet.

Passaic, N. J.

Odontoglossum Schlieperianum.—This Orchid should find a place in every collection on account of the beauty and size of its flowers. Its nearest affinities are *O. grande* and *O. Insleayi*, to the latter of which Dr. Lindley considered it to be so closely related that he gave it the varietal name of *macranthum*, because the flowers were much larger than in that species. *O. Schlieperianum* has dull-green, ovoid, compressed pseudo-bulbs, each bearing two broadly lanceolate leaves, about five or six inches long. The flowers are usually borne in June on strong, sub-erect scapes; the oblong-ligulate sepals are of a bright lemon-yellow, covered with transverse blotches of reddish-brown, except at the slightly recurved tips; the petals, which are broader, and somewhat abruptly narrowed at the base, are of the same color as the sepals, but have a few reddish-brown blotches on the lower portion only. The oblong-ovate, emarginate lip is pale-yellow with chocolate bars at the base, while the conspicuous bright-yellow crests are spotted with crimson. Like most *Odontoglossums*, this species requires to be potted in a compost of peat and sphagnum moss, and should be placed in a rather warm corner of the house, as it is a native of Costa Rica. Water may be freely given during the growing season, which takes place after flowering, but must be greatly diminished during the winter months, when the plants are at rest.

The earliest notice of this plant appears to be in 1856, when it was sold in Covent Garden, London, with other Orchids from Central America. It flowered for the first time in Europe in the collection of Herr Schlieper, of Elberfeld, Germany, in honor of whom it was named.

Vanda teres.—For the last three weeks several plants of this species have been flowering one after another in quick succession, and the beauty of their flowers and peculiar appearance present an aspect quite distinct from other members of the Orchid family. With the exception of the beautiful *Vanda Hookeriana* and *V. teres*, most plants of this genus have distichous, strap-shaped leaves, some being very long, and others very short in proportion. *V. teres* has quill-shaped stems and leaves of a dark-green color, and a climbing habit. Two flowers are generally borne on a short raceme springing from the side of the stem opposite the leaves. The sepals are oblong-obtuse, the upper being generally erect and nearly at right angles to the roundly-ovate petals. Both sepals and petals are creamy white, tinged with pink or magenta, which color is usually much more intense on the petals than on the sepals. The lateral lobes of the handsomely-colored lip are folded over the column in the shape of a helmet; the middle lobe is spreading in front, where it is cut into two obovate divisions, and in connection with the two side-lobes forms a large conical spur at the base. The throat is orange-yellow, with radiating lines of crimson spots on each side, while the surface of the middle lobe is beautifully veined and washed with rosy magenta. There are several varieties of this species, which can only be distinguished by the color of the flowers.

It is not very difficult to grow *V. teres* successfully, provided that it be grown in a house with a warm and moist atmosphere, in a position exposed as much as possible to the rays of the sun. Here the plants are grown in a compost of peat and loam, with silver sand mixed, and all planted out close to the glass. During this warm weather they are syringed several times during the day, and receive a liberal supply of water at the roots also. Very little shading is given except when very hot. The plants may also be grown on blocks of wood with equal success, and placed in a pot three parts filled with charcoal, and covered with a layer of sphagnum moss, receiving abundance of water during the summer months, but much less in the winter, when the temperature for this species should be about 65°–70° Fahr. during the day, and from five to eight degrees lower at night.

Dr. Wallich introduced this Vanda from Burmah in 1826, but it is not, however, confined to this region, having been

sequently found in Khasya, Sylhet, and other parts of India, where it has been nearly always found growing on branches of trees exposed to the sun's rays. About ten years from this date it flowered for the first time in England in the collection of the Duke of Northumberland, at Lyon House, opposite the Royal Gardens, Kew, from which this place is divided by the river Thames. Now that the requirements of this species are better understood it is becoming much more popular than in former years, and a specimen of it will now be found in nearly every collection.

St. Albans, England.

John Weathers.

Correspondence.

An Interesting Wildwood.

To the Editor of GARDEN AND FOREST:

Sir.—Overlooking part of Lake Superior, the Nemadji Valley, the Bay of St. Louis, Fond du Lac and the Dalles of the St. Louis, from the north, are prominent and breezy terraced bluffs (some five hundred feet high), mantled with dense groves of Sugar Maple and Yellow Birch, with an occasional giant White Pine. From deep fissures in trap, gabbro and granite many little streams of cold, clear water trickle and tumble over mossy rocks, shaded by Vine Maple, Thimbleberry, Alder, Birch and Arbor Vitæ, through deep glens and park-like openings to the river and bay.

Shady groves on natural terraces, deep, clear pools with darting trout, or extensive views and fresh lake breezes are here at option within a few minutes ride of Duluth, a city notably barren of trees and shade.

This could have been said twenty years ago.

To-day, though not destroyed, this remarkably attractive strip of wildwood is marred. Pine and other timber have been cut; fires are killing bushes, uncovering streams to the sun, warming them and making them impure, while dead and blackened trees are standing as monuments of the past and warnings for the future.

During July and August of this year I have learned to value this varied wildness, because it has no equal short of the great mountain chains or some rocky sea coast, and because a quarter of a dollar car-fare and a short walk and scramble will furnish any one a lift out of and above the ruts of life.

Speculators have bought some acres in this region, seeing value in them for parks and pleasure-grounds. On one of these tracts recent cutting was noticed, with Pine-tops and broken hard-wood lying so thick as to kill most, if not all, the Birches and Sugar Maples left if fire should get in. Inquiry developed the fact that the owner, a speculator of Duluth, was holding the land for country residences and a park, yet he permitted a contractor who wanted piling to go there and cut as suited him, leaving the tract with anything but a pleasing appearance, and in great danger of being made worthless by fire.

The lesson I would draw from this is, that, while it may be for the best interest of holders of beautiful woodlands to keep them as woods, they are often unable to keep them, while many do not know how to keep them if they would. Yet the people should not loose the privilege of the woods, nor have to pay too much for the privilege. If men with capital to buy such tracts, and the knowledge to improve them, do not appear, then it is the duty of the men chosen by the people to look out for their interests to see that the benefit of such restful resorts are not lost.

Duluth, Minn.

H. B. A.

Trees Which Shade Dwellings.

To the Editor of GARDEN AND FOREST:

Sir.—How near a country-house is it safe and desirable to have Elm trees growing? I have recently purchased a house, the front piazza-steps of which are flanked on either side by a noble Elm about fifty feet high. Both trees have branches overhanging the house, and although it is situated on high ground, and in a location not exposed to dampness, still there is cause for much complaint on that score, and I am inclined to ascribe it to the proximity of the trees. I may add that both trees are sorely afflicted with the Elm-beetle. As a result the lawn is littered with dead leaves, and the Elms are, to all appearances, dead in midsummer. I saw the remedy for this beetle in GARDEN AND FOREST for June 19th, too late to profit by it this season. Being reluctant to cut down two such beautiful trees, even under the above provocation, I respectfully ask your advice.

Yonkers, N. Y.

H.

[Trees standing near a house, and especially on its

south side, may obstruct the light and check the breeze to an unpleasant and, perhaps, an unwholesome degree, and the lack of sunshine and ventilation would naturally aggravate any tendency to dampness in the house. The evil effects of trees in this respect are often exaggerated. This summer has been exceptionally humid, and even unshaded houses have been "damp." The Elm is usually a tree of open habit, so that it would offer, as a rule, comparatively little obstruction to ventilation. If the trees in question have been defoliated by the beetle they can do little harm this year. But, after all, no positive counsel in a particular case can be given until the premises are examined. If the trees are well placed, so far as the appearance of the "house-scene" is concerned, we should allow them to remain another year at least.—Ed.]

The Asparagus Beetle.

To the Editor of GARDEN AND FOREST:

Sir.—I observe that you recommend arsenites for destroying this pest, but Paris green has failed with me to check the beetle. I planted this year 3,000 roots, imported from Erfurt, and the beetle has made havoc with the plants in spite of lime, sulphur and other remedies. When Paris green was prepared for spraying the Potatoes I directed my men to spray half a dozen rows of the Asparagus plantation. A strong solution was used, and I expected to see both plants and beetles destroyed; but the plants were uninjured, and beetles and larvæ seemed to be enjoying the best of health.

My children have picked 500 to 600 beetles two or three times a week the whole season through, but the enemy is still here, though I think less numerous.

New Rochelle.

W. K.

[There is the difficulty of making arsenites adhere. We tried London purple this spring in a very fine spray, but most of it dropped off and very little poison remained. Where it did stick, it killed larvæ and beetles both. The best way of applying Paris green is to dust it on mixed with plaster or some other vehicle. The work should be done while the plants are wet with dew in the morning. Asparagus is hardy, and there need be little fear that the arsenic will burn it. Contact-killing powders destroy the larvæ or slugs, which, after all, do most of the damage and provide for future beetles. Pyrethrum acts very quickly when put on with a bellows, making a cloud of fine dust—but it is expensive; White Hellebore is good, but it acts more slowly and less certainly; Tobacco powders act rapidly and certainly, and a cloud of Tobacco dust blown over the plants once a week ought to be useful. It will kill nine out of every ten larvæ on the plants and will drive away all the beetles; the latter will return and lay more eggs, but the enemy can be held in check. The beetles may very easily have been imported with the roots for our correspondent's plantation. The larva pupates in the ground by the roots, and the beetles often creep in there to hibernate.—Ed.]

Recent Publications.

Japoneries d'Automne, by Pierre Loti. Paris: Calman Lévy. 1889.

Nothing is more difficult than to conjure up in words a vivid picture of unfamiliar lands. It can be done by no mere accumulation of facts general and particular, of statistics comprehensive and minute, of features great and small, of prosaic impressions abiding or transitory. How many big, instructive books we have had about Japan, and how little we know how the land would appear to us should we go there. Every traveler tells the same tale: he starts out equipped with what he thinks an exhaustive knowledge of the country, lands in a spot as strikingly unfamiliar as though he had never heard its name, and the longer he stays grows the more bewildered and surprised. Then he comes home and writes a book which shall really open in advance the eyes and minds of his successors; and then they follow in his track with an experience just the same as his.

But all this is because most men are *prosateurs* by nature, and merely reveal the fact more plainly when they set their pens to work. If they are intelligent, they learn facts wherever they go; if they are stupid, they think they do. But in

either case they do not receive real impressions, or they lack the power to convey them to others. Once in a while, however, comes an artist—a man born not merely to see but to feel, and dowered with the gift of adequate expression. Then, if his craft be painting, he shows us more than all the maps and diagrams and faithful prosaic paintings of generations have shown; and if his craft be writing, he tells us more than all the learned students and careful statisticians who had gone before him.

Such an artist is Pierre Loti, a young French naval officer, known in common life as Monsieur Julien Viaud. No one had heard of him until a few years ago, when he published the "Roman d'un Spahi," dealing with Algerian life, and the "Pêcheur d'Islande." He was not a writer by profession, but merely a born artist who had chanced to take to the sea, and now, inspired by strange foreign sights, showed himself at once a master in the art of writing. To say this is to say very much of a Frenchman. Almost every Frenchman is a born writer, as compared with Englishmen or Germans. A literary gift seems his by birthright, and when he does what would make instant fame for a man of any other modern race, he merely does what his countrymen expect of him if he dares to put his pen to paper. To say that the charm of Pierre Loti's style instantly gained him a place among the best of his contemporaries means, indeed, that he possesses an extraordinary talent. More than once before he published this present book he had spoken of Japan. But in "Japoneries d'Automne" (one must coin a word in order to translate and say "Autumn Japanesques") he gives us something more delicious than even "Madame Chrysanthème." It is but a little volume, a brief rambling account of an autumn ramble through a few districts familiar to every tourist. No one need turn to it who wants "information," much less statistics. Yet any one who wants to know how Japan appears had better turn to it than to anything else which we could cite. Pierre Loti's mood is that which has been cleverly called "detached sympathy"—the best of all moods for the non-scientific tourist. He neither tries conscientiously to put himself in the mental and emotional shoes of a Japanese, nor to don the shoes of a European bent upon understanding the point of view of Europe by the contrasts offered in Japan. He simply sees and feels with gay spirits, keen perceptions, a humorous delight in every oddity, and a genuine artistic enthusiasm for every charm. His impressions are incomparably fresh and vivid, and he reports them with incomparable vivacity, wit, good humor and literary skill, and, as an element in this skill should be noted, a brevity even beyond that which marks almost all French descriptive writing. It is impossible to translate any passages from his book; he is too Gallic in style to be Anglicized, even with as much success as one may translate such writers of an earlier day as Gautier. All we can do is to point our readers to the little volume, assuring them of a couple of hours' intense amusement, and a clear, abiding picture of Japan to hang in the gallery of their recollections. Of course, there would be no reason to do even as much as this in these columns had Pierre Loti not spoken of the gardens of Japan; but some of his most delightful chapters are devoted to them, and, though his treatment is superficial in the sense of being neither scientific nor categorical, he gives us a more interesting and more illuminative account of the Sacred Mountain of Nikko and the tombs of the Samourais than any one who had preceded him in these well-worn paths. Reading other writers we learn what there is in these places; reading him we learn how it all looks and what the sensitive Occidental feels as he is looking at it. The difference between the two results is immense, and Loti's we get through an hour or two of pleasure instead of through days of wearying study. This it is to be an artist. When will one arise to do the same service for those who read English only?

Meetings of Societies.

American Florists at Buffalo.

THE late meeting at Buffalo proved the most interesting yet held by the society. The attendance was full and the proceedings earnest and business-like from beginning to end. President May argued that more spirit should be infused into exhibitions to make them educational influences, and to the same end he counseled members to report their experience in the horticultural press. He also showed the advantage of raising new seedlings in America as more likely to give satisfaction than imported novelties.

Mr. W. C. Barry, in his essay on "Roses for Garden Decoration," said that of 334 varieties sent out in 1887 and 1888 there

were only fourteen which he considered worth cultivating in this country. He named, among those of conspicuous merit, Sir Rowland Hill, Madame S. Rhodocanachi, Vicks Caprice, Bonait, Max Singer, and the new hybrid, *R. Rugosa*, Georges Bruant, which has cream-colored flowers, borne in trusses of six to eight. He also mentioned, as likely to prove of great value, Mrs. John Laing, Dinsmore and Blanche Moreau, an almost perfect pure white Moss Rose.

Mr. Robert Craig, in an instructive paper, said that in the florists' business, as in other business, it was the specialist who won success. Boston and Philadelphia had been highly favored, as private persons had endowed their horticultural societies with fine buildings, and to this fact was largely due their high standing. He spoke in favor of the establishment of horticultural halls in every city, and urged the construction of a national botanic garden. Mr. John Thorpe advocated the establishment of an experimental garden for comparing varieties and species of plants, for testing various fertilizers and florists' seeds for making trials of insecticides, and pursuing investigations in every branch of horticulture. A business representing more than \$3,000,000 of capital and directly occupying the attention of 150,000 people, should be entitled to some governmental support. The result of this paper was a committee appointed to bring the matter before Congress. A paper on "Useful Summer-flowering Plants," by Mr. A. E. Whittle, of Albany, advocated the planting of many varieties of hardy plants for the decoration of American gardens.

Mr. Forstermann's essay on the "Habitat of Various Orchids" had a practical value in suggesting the proper temperature for their successful cultivation. For example, *Phalænopsis* houses are often kept at a temperature of from 80° to 90°, while in their native state they flourish in a climate which ranges in the growing season from 70° to 80°.

Other papers of importance were read by Edwin Lonsdale and H. H. Battles, of Philadelphia.

Mr. Wm. McMillan, Superintendent of the Buffalo Parks, read a paper on "Landscape-Gardening," from which we quote some of the opening passages. In a future number we hope to add further extracts from this paper, which was received with many marks of approval, and contained much sound doctrine.

"An ornamental landscape is not merely a composition of choice trees, shrubs, grass and flowers, but includes as well every inorganic element of Nature embodied in the scene. The 'lay of the land'—to use a familiar phrase—is in a double sense the ground-work of the composition. This includes every form or feature which the earth's surface presents to us, from the flat plain to the beeding cliff; every variety of hill and vale, ridge or dell, bare rock, sterile sand, or rich soil; and also water, flowing or still, of whatever volume, large or small. Even the atmosphere must be included as a part of every landscape, for the scene varies with every variation of sunshine or shade, dim haze or clear sky, still air or stirring breeze. The lights and shades of a landscape-painting are carefully studied, and whatever is appreciated in the copy is surely of greater value in the original.

"In the embellishment, then, of any grounds of sufficient extent to have a distinctive landscape-character, the gardener must take into account all the impressive and attractive natural elements of the place. The general aim of his work will be to make a harmonious combination with the dominant characteristics which Nature has already stamped upon the site. He will seek a fuller or richer development of the essential leading features, simply softening what is hard, clothing what is bare, filling out what is meagre, and enriching what is beautiful, all in harmony with the original type. He will thus avoid all novel conceits, all conspicuous eccentricities, all incongruous intrusions, and be guided by his understanding of the laws of Nature as enacted by the ruling Divinity of the scene, and his sympathy with them.

"I lay special stress on this fundamental principle, because it seems to be so commonly overlooked or ignored in ordinary landscape-gardening. In fact the very opposite rule is followed in much work that is done, and the result receives much popular approval. It is a common thing to value the decorative work on any given site in general proportion to the degree in which it is obviously artificial, new or peculiar. This unfortunate fashion seems to pervade every branch of landscape work. Instead of the artificial being subordinated to the natural, it is made specially prominent, and in some cases it even becomes the 'be all and end all' of the scene. For instance, drives and walks are made unnecessarily broad, or sinuous, or prominent, or intrude where not needed. A sharp terrace is formed mainly to display its bold lines, or a channel is dug for an artificial runnel, to give occasion for introducing

a bridge. Summer-houses, arbors, rockeries, pools, fountain basins and jets (usually dry), clumps of trees and shrubs, or beds of flowers and foliage plants, are stuck around promiscuously in conspicuous sites, without any fitting relation to the natural conditions of the landscape.

"A common phase of the same taste is shown in the popularity of the class of plants which propagators call 'sports.' This includes that numerous list which pads out the pages of most catalogues, the endless varieties with the leaves abnormally shaped or colored, or with a drooping or contorted or dwarfed habit of growth. Nearly all the plants of this class are less hardy and vigorous and healthy than the normal type. It is probable that their peculiarities in color or habit are due to some unhealthy condition of the sap or defect in the channels of circulation. But in spite of this relatively weak growth, sickly color or deformed shape, they are all popular favorites. The paler and feebler and more distorted the growth, the more they are liked and petted and pampered. A few of the best of this class may be sparingly planted as foils or specimens or curiosities merely, but never in proportions to rival those of the true type of each species. For general use the natural color and shape are more pleasing and satisfactory, not only because more vigorous and durable, but also because they are in accord with the true order of nature, while the others are not. Nature, in fact, disowns her 'freaks' of this sort by the general sterility of such offspring. Their reproduction depends wholly on artificial propagations. It were better to let them all die a natural death than to treat them as if they were Nature's finest productions. Her sanction to their continued existence is given only when the seed, if produced at all, is true to the parent.

"On strictly private estates, where chiefly the eye of the owner is to be gratified, he may ride to his heart's content any hobby that may please him. But in places exposed largely to the public eye, as in ordinary villa grounds, suburban gardens and public parks, novel ideas will be introduced modestly and not generally adopted till they have stood the test of the fullest criticism. This means more than the ready applause of the populace which mere novelty, if daring enough, is sure to elicit; more than the hotbed stimulus of fleeting fashion, however popular for a time."

Notes.

It is estimated that the forest-fires which have been raging in Montana for the past four weeks have caused a loss of at least \$100,000 a day.

Tigridia Pringlei, which was figured in this journal nearly a year ago (vol. i, p. 389), has bloomed this year at Kew, and its flowers of fiery scarlet and orange were considered very striking.

It is reported in a bulletin of the Florida Experiment Station that the annual Crimson Clover (*Trifolium incarnatum*) promises to be profitable in that state as a winter pasture plant, as material for ensilage and for dry forage.

Several correspondents have sent us the browned leaves of the Horse-chestnut, with inquiries as to the cause. The disease is the work of a fungus, *Phyllosticta spharopsoidea*, and it seems unusually prevalent this year. It is difficult to suggest any remedy, because the fungus, as now known, is an imperfect form, and we are unable to tell what its perfect condition is.

The leaf-blight of the Pear and the cracking of the fruit is caused by a minute fungus known as *Entomosporium maculatum*. Professor Halsted writes to the *Rural New Yorker* that the spraying of some copper sulphate mixture upon the trees in early spring may help to arrest its ravages, although this has not yet been demonstrated. The National Department of Agriculture promises to publish soon the results of some hopeful experiments in overcoming this disease.

The Cassava, which has already become a standard product in Florida, is now on trial in several parts of Louisiana, and Mr. J. L. Normand reports in the *Southern Cultivator* that it thrives and produces wonderfully in the latter state. In his judgment it will yield more to the acre than any other article of food. Many nutritious and delicate dishes for the table can be made from Cassava, while as a food for domestic animals—cattle, poultry, sheep and swine—it is invaluable in that region.

The Governor of South Carolina has appointed the following gentlemen to represent that state at the annual meeting of the American Forestry Congress in Philadelphia, October 15th to

18th: Hon. A. P. Butler, of Columbia; Dr. F. P. Porcher, of Charleston; Professor H. A. Green, of Chester; Hon. Walter Hazard, of Georgetown; H. E. Buist, Esq., of Greenville. The Governor of Ohio has appointed Hon. John B. Peaslee, of Cincinnati; Hon. Leo Weltz, of Wilmington; Hon. James Poindexter, of Columbus, and Hon. Adolph Lene, of Cincinnati.

The exhibition at the late meeting of the florists in Buffalo, was larger and more interesting than any former one. Some remarkably fine and distinct colored Asters, new Dwarf Cannas, Hybrid Tropæolums and Tuberous Begonias, together with numerous Palms and Ferns, and a collection of Orchids and Stove plants were greatly admired. The mechanical part of the exhibition was full of interest, the greatest competition being over the hot-water boilers. Twelve patterns were shown, some solely for hot water, others for steam, and others again could be used for either hot water or steam. The "Standard flower pot" which was adopted at the meeting in New York, seems to have been generally accepted by all the flower-pot makers in the country.

Last week many of the leading fruit-growers of the middle states and New England visited the nurseries of Stephen Hoyt's Sons, at New Canaan, Connecticut, to inspect the new Green Mountain Grape, which has been introduced by that firm. The vine is a strong grower, and bears abundantly large, shouldered clusters of white, or rather green, grapes, which are among the earliest to ripen. The berries are rather small, flavor good, and skin very thin. Considering the fact that this is a bad year for the vine, and that the soil and climate about New Canaan is not favorable to grape production, the visitors were favorably impressed with the quality and promise of the variety, and feel confident that it will prove a valuable addition to the list of earliest grapes.

An interesting exhibition of Tomatoes was on view at the seed warehouse of J. M. Thorburn & Co., in this city, last week. Eighty varieties were named, and although several of them were plainly duplicates, the diversity of form and color and texture was so marked that some fifty distinct types could be recognized. The smooth outline and solid flesh of some of the newer varieties, like Thorburn's New Jersey, proves what can be accomplished by patient selection; and yet the tomato which, perhaps, showed the most compact and yet the finest texture, was *Ignotum*, which, as its name implies, is from absolutely unknown parentage. The Peach Tomato, so called from its resemblance to that fruit in size, shape, color and even in an incipient down upon the skin, was a novelty to most visitors, and so was another variety known as the Station Tomato, because produced on the grounds of the New York Experiment Station by hybridizing the upright Tree Tomato with one of Livingston's varieties. The plant is upright, producing a fruit of fine quality, which begins to ripen much earlier than either parent.

A correspondent of the *Gardeners' Chronicle* observes that while many bulbs like the Emperor Daffodil are of inferior quality the first year, and gain strength the second season, other bulbs deteriorate, and especially the Tulip, for this reason: The outer coat or skin of the Tulip is exceptionally hard and tough, and does not readily decay, as do others with softer skins; and, further, their mode of increase is so rapid—for a fair-sized flowering bulb will produce in some varieties three and four "chickens" in one season, though all are not equally prolific—that the offsets, being encumbered by these hard skins, have not the chances of putting forth their roots into the soil and are thereby crippled; the bulb does not make half its growth, and a general weakness is the result. Thus it is that we see clumps of Tulips which have remained undisturbed for several years, producing, it may be, one or two sickly flowers where dozens might have been, if they had been annually lifted, cleaned and replanted. Next to the Tulips the English and Spanish Irises are, perhaps, the most liable to deteriorate when left undisturbed in the ground for a year or two. The coats of skin upon the bulbs are very thick, and to keep the bulbs in good health for any length of time they should be annually lifted, cleaned and replanted with as little delay as possible. Erythroniums are benefitted by lifting every second or third year, as by this time they become crowded and require separation. Lilies may, if in good health, be left for an indefinite period; but where replanting is deemed necessary, it should be done as soon as flowering is complete, because it is just at this time that the new basal roots are emitted, and to preserve these intact should be the aim of all cultivators.

A New England Rock Garden.

A BOSTON correspondent contributed to our pages early in the season a series of notes upon some of the interesting spring-flowering plants of his rock-garden, and now he has sent us a series of views of this garden, taken when the Poet's Narcissus was in flower. Two of these views are reproduced in this issue, for the purpose of showing how interesting and attractive a garden of this sort may be made, and how an ugly bit of waste ground may be easily brought to serve a good and useful purpose. The site of this garden, a few years ago, was an abandoned gravel-pit partly overgrown with brambles. A few old trees grew about the borders, and the lower side extended down into the low, wet, peat margin of a pond. The flight of rough stone steps, which appears in the picture on page 439, was carried up the steepest face of the gravel-pit to connect a wood-walk at the lower level with dressed ground above. Large stones, lichen-covered, when such could be obtained, were spread over the surface of the gravel-slopes to hold the soil, which was placed between them, from washing away and to make the "pockets," which are desirable to protect delicate plants from the encroachments of too vigorous neighbors. A few tall-growing shrubs were planted at the top of the now rocky hill to increase its apparent height; and a few low ones were scattered through the rocks to break the surface and avoid any danger of monotony. Then the remaining space has been gradually filled with spring-flowering plants—hardy bulbs of many sorts, hardy ferns, and such native plants as flower before the full development of the leaves on the forest trees, for as these shade the ground, except on one side, it is suited for early flowering plants only. These thrive here and make this small garden a spot of interest and beauty during the six weeks which follow the opening of spring; and then the ferns cover the ground during the remainder of the season, or Sedums or House-leeks, and other sun-loving plants, on the exposed side keep up the succession of flowers.

The view on page 438, taken from the low ground near the pond, shows a section of the garden open to the south-

west. The large tree to the right of the picture in the foreground is a Sassafras, with the deeply furrowed bark admirably brought out. This view shows the manner in which the rocks are arranged to hold the soil placed among them, and to prevent the water from pouring off from the surface. The whole secret of a successful rock-garden is in the manner the rocks are placed. If they are laid in such a way that they offer no resistance to the flow of water away from them, the moisture-loving plants, which properly belong to such gardens, cannot survive our hot, dry summers, but if they are arranged so as to resist the flow of water, they are of great service in increasing the humidity of the soil, not only by preventing the rain-water from flowing rapidly away, but also by checking evaporation. They are of great assistance, too, in forming barriers between different plants and in protecting the weak from the strong, and in keeping deep, cool recesses for the fine roots of Alpine plants. The number and variety of plants which can be grown in a small space, prepared in this way, is astonishing, and thousands of the smaller bulbous plants like Crocuses, the smaller Squills, and Dogtooth Violets, may be tucked away close to the edges of the rocks, or at the points where they join, without in any way interfering with the more prominent occupants of the larger spaces.

Certainly, there is no sort of garden which, in our northern climate, is capable of giving more pleasure than one, whatever its arrangement may be, in which the principal feature is the cultivation of the hardy plants which flower in spring.

The production of staves has been an important industry in the United States for more than a century, and vast quantities of the very finest timber produced in our forests have been consumed in this way. Virginia was for many years the great stave-producing state, but as good Oak became scarce in the accessible parts of that state, the business gradually spread west to Ohio and Indiana. Now Missouri and Arkansas and the region covered by the southern culmination of the Appalachian Mountain system produce the largest quantity. We gather from a recent issue of the *St. Louis Lumberman* some interesting information with regard to this industry. The wood preferred for stave-making is white oak. It is used for tight barrels, except molasses barrels, which are made of cyprus (*Taxodium*) or bass-wood. Barrels used for holding flour, potatoes, apples, sugar and similar commodities are made of elm, ash, red oak and other woods. There are three classes of staves, the classification being based on the methods used in getting them out. These classes are the "split," the "sawed" and the "cut." The first are used for beer, wine and other liquids, and are made from the best white oak. The sawed staves are also made from white oak, and are used in the manufacture of coal-oil barrels, lard tierces, white-lead kegs, well-buckets and other vessels intended to contain liquids. Cut staves are made by machinery, and are put into barrels used for solids. There is, in addition to the great home consumption, a large export of staves to England, and to France, Italy, Spain and other European wine-producing countries. The annual export is now estimated at twelve million pieces. The principal stave markets are New York and St. Louis. New York and New Orleans are the two principal export ports. The importance of St. Louis as a stave-distributing centre is of comparatively recent date, and is due to the exhaustion of the forests east of the Mississippi, and to the great development of barrel-using industries in the West, such as milling at St. Louis and Minneapolis; beer-making at Milwaukee, and especially the wine-making of California, for in all the territory west of the Rocky Mountains there does not grow a tree from which a wine-cask can be made. St. Louis now receives annually between 2,500 and 3,000 car-loads of staves, which are distributed all over the United States and Europe, although large quantities are used in supplying local factories. There are still

immense stretches of stave-timber in the United States; as some of the very best of it is not yet within reach of the railroads, but the vast increase of wine-production in California, and the fact that good stave-timber cannot be found now anywhere in any quantity, except in our Southern states, must have an influence upon the value of southern hard-wood lands, and must in time destroy the forests of Oak in these states, as it has in Virginia and in the valley of the lower Ohio River.

Drives and Walks.—I.

IT is generally thought that in planning a country-place, whether large or small, the main thing to be considered is the situation of the house. Aspect and prospect—the way the house will look to the passer-by or the approaching visitor, and the way the landscape will look from its windows and piazzas—are supposed to be considerations of such paramount importance that the choice of a site may well be made and the house constructed before anything else is arranged. Important considerations these are indeed, yet there is another of quite as much importance—one which must, indeed, be borne in mind from the outset, if aspect and prospect themselves are to be satisfactory in the end. This is the arrangement of the various drives and walks which run through the property. Convenience as well as beauty dictates that the position of the house and its dependencies should not be fixed until this arrangement has been mapped out.

If the grounds are large, and their surface is not perfectly flat and uniform, it may easily happen that the site which seems best to the architect is one where the relative positions of the high road and the entrance-front will be such that no good approach can be designed. For an approach to be good there must be an easy turn-in from the high road; the grade within the gate must be as gentle as possible; there must be no sharp turns, dangerous alike to meeting vehicles and to bordering turf; the house must be well displayed to advancing eyes; the ground must not be so intersected by the line of gravel as to interfere with a beautiful arrangement of its parts, and this line must not be a disagreeable object from the house. Too often in the approach not one of these necessities is fulfilled, although all might have been fulfilled had the house been properly placed. Sometimes even a change in position, so slight that it would not have perceptibly altered either aspect or prospect in general, would have made all the difference between a good approach and a bad one. It is folly, we know, to force a landscape-gardener to lay out a straight road where a curved one would look better, or a curved road where a direct one would be more sensible, and therefore more beautiful; to compel him to run it over a hillock which it might encircle, or down into a hollow and up again when it might pass to one side; to give him no convenient access to the high road except at a point where turning-in is awkward; to forbid him to take in a good point of view which might easily be shown from the drive, or to show disagreeable objects which might be concealed. And yet it would be easy to point to many new places where just such necessities have been forced upon the landscape-gardener by an error in the placing of the house, or where, to avoid them, he is compelled to spend a large amount of money, and perhaps to injure the general effect of the place, in altering the configuration of the ground. When the position of the principal entrance relative to the high road and to the varieties of surface in the ground is fixed, there is nothing left for him but to do the best he can with his approach; this often means something very different from the best that might have been done; and upon the character of the approach may depend the success or failure of the place as a whole.

In places of any size a curved entrance-drive is better than a straight one. Naturally, there may be a case when a wide straight avenue can, with advantage, be made in a direct line through a great estate and leading to a house the architectural majesty of which demands a very dignified approach. But such cases rarely, if ever, occur in America. As a rule, what we call a large place is not large according to English ideas, at least in so far as the ornamental grounds are concerned; and a house which we consider stately, an Englishman would be apt to call merely picturesque. Almost without exception, therefore, wide straight approach roads are inadmissible in this country except in public parks; a curved road is better, because less pretentious, easier to build and to drive upon, unless the land be perfectly flat, more beautiful in itself, more harmonious with the character of our buildings, and less strikingly artificial.

But as all roads and walks are palpably artificial, no matter how they may be designed or of what material they may be composed, it is not good art to make too palpable an effort to conceal the fact. The real reason for the existence of the drive—its utility—should always be acknowledged to the eye as well as practically secured. This means that, though the approach is curved, it should not circle about to an excessive degree, irrationally increasing the distance that must be traversed before the house can be reached, and, when its course is overlooked from the house, wearing an unmeaning, wandering look. English writers on landscape-gardening often deplore the fact that in the effort to make a display of magnitude in the estate or to show various effective points of view, an approach has been so laid out that it is positively irritating to the visitor; when he thinks he is near his destination he finds himself carried away again, and sometimes this process is repeated several times. In addition to the pretentiousness and inconvenience of such an arrangement it injures the place as a whole, for there is no more fundamental principle in the art of gardening than that the fewer the roads and walks the better, and the shorter their course, consistent with convenience and good lines, the better, too. A line of gravel is not a beautiful object in itself, it is conspicuous on account of its difference in color from the surrounding verdure; and wherever it comes it cuts a landscape composition in two as with a knife. Its virtue lies in being at once as useful and as inconspicuous as possible.

Old Mission San José Gardens.

CALIFORNIA has but few old gardens, although the Bidwell grounds at Chico, the Fox Nurseries at San José, and some of the old Oakland and Sacramento homesteads date back to the early fifties. Still older, belonging to a different régime, are the old Mission gardens of the last century. Some of these are still kept up; others have fallen into decay, but all are full of a tropical beauty of their own, because the Palm, Olive, and the Vine so much predominate. One old estate, within thirty-five miles of San Francisco, combines in a remarkable degree the charm of the Spanish gardens of the eighteenth century, and the charm of the early American gardens. I refer to the Gallegos grounds, near the Mission San José, planted chiefly by the Beards and Elsworths, thirty and forty years ago.

The estate of Juan Gallegos includes six hundred and forty acres of vineyard, besides large orchards and extensive pastures. The twenty acres or so that immediately surround the old mansion show as fine a lawn and landscape of native trees as can be found in California. Besides this, there are some trees which were planted by the Mission padres, old Pears and Olives of sixty years growth. There are avenues of Figs, and groves of Olives and Oranges, all large trees in full-bearing. There are many Palms, large Pines, and choice specimens of deciduous trees. On the hill slopes, east of the plateau, at the base of Mission Peak, where the home-grounds are situated, is an old avenue of Spanish-planted trees, Pears and Olives of nearly a century's growth, which rank among the finest relics of Mission gardens left in California.

E. L. Beard, a man of great ability and energy began farming in Santa Clara Valley at this old Mission in the days of '49-'50. He established a nursery here in 1852, sending an agent to the Atlantic states for seeds, scions and young trees, which were taken to California by way of Panama. In 1853 the ordinary price of a one-year-old Cherry, Peach or Pear tree was five dollars, and those who bought, and set out orchards, found that, in 1857 and 1858, the fruit brought twenty-five cents and more per pound. Mr. Beard, and his step-son, Henry Elsworth, developed an orchard and wheat-farm which extended over an area of two thousand or more acres, in and about the Mission San José. Their homestead tract, where plantings of ornamental trees began early in the fifties, was the tract that is now the heart of the Gallegos estate. We have seldom had farmers on the Pacific coast who showed the intense love of beautiful trees that Mr. Beard always did. His groves were on rich, well-watered and sunny slopes. To these he brought specimens of nearly all the native conifers of California, and of many of our finest deciduous trees and ornamental shrubs. His eastern connections enabled him to secure, and he planted here, all the Spruces, Firs and Pines, to be had in eastern nurseries. He also had Australian and Japanese correspondents many years ago, and planted Acacias, Japanese Persimmons, and other imported trees, ten years before any one else had them. He planted a great many Olives and Oranges in groves and avenues; large Fig groves, and many Palms. Chestnuts, Walnuts, and other nut-bearing trees were grouped

near bridges across the stream, and, behind his residence were large fruit orchards and vineyards stretching down the valley.

At present, after more than thirty years of uninterrupted growth, under most favorable conditions, the trees that surround the lawns and "opens" of the place are notable for size and beauty, even in California, and they attract many visitors. Mr. Juan Gallegos, the present owner, is a wealthy Spanish gentleman from Costa Rica, educated in England, and now one of the largest and best known of viticulturists in the state. He has greatly extended the ornamental grounds, and especially delights in plantations of Palms of various sorts, particularly the Date Palm, so that the estate is becoming more and more tropical in its appearance. He is passionately devoted to the old trees, planted by his predecessors, and to the still older Pear and Olive trees planted by the Spanish padres. The Orange-groves are now in heavy bearing condition; the Olives begin to yield well, and the vineyards are so extensive that he has sometimes carried a stock of one million gallons of wine in his cellars.

An interesting fact in reference to the Olive in this region deserves record. The trees of the old avenue of which I have spoken are of the Mission variety, so-called, the kind brought to this coast by the padres, and variously identified since with sorts still cultivated in Spain. The trees planted by the padres here, however, differ much in growth, and are probably seedlings of the Mission variety. Some ripen early, others are very late, and some are much better bearers than others. The old Pear trees were of two sorts, a small, early pear of russet color, ripening about with the Madeleine, and a large, bronze-colored, late, coarse pear. The grapes were all of the old Mission sort, the same grape that grows to-day in the vineyards of the lower Rio Grande, and is so famous in the southwest as the "El Paso Grape." I am told by an old pioneer who knew the Mission San José, before the conquest of California, that the quaint old Spanish garden contained in its exact centre a seedling Apricot tree, which was an object of superstitious fear to the Indian neophytes, for they were taught that its fruit was the fruit of "The Forbidden Tree." They always went by it with bowed heads, and crossing themselves. On three sides of the old garden towered an immense wall of *Nopal*, or Mexican Prickly-Pear, with adobe buildings, walls, and the church on the other side.

Niles, Cal.

Charles Howard Shinn.

Notes Upon Some North American Trees.—IX.

LYONOTHAMNUS ASPLENIFOLIUS, Greene.—This interesting tree was discovered by Mr. Barclay Hazard on Santa Cruz Island, one of the Santa Barbara group, in 1885, and was described by Mr. Edward L. Greene in the *Bulletin of the California Academy of Science* (i., 187, and ii., 149, t. 6). Mr. Greene visited the island a year later, and found that "this tree is no rarity on its native shore. There are a hundred fine groves of it distributed up and down the thirty miles of the island's northward slope, individual specimens often as high as thirty-five or forty feet. The wood, close-grained and hard, is called iron-wood by the men of the island. No other small tree of our coast equals this in grace of form and beauty of foliage. The flowers, too, are quite showy in their season, the larger corymbs often measuring a foot in diameter." Mr. Brandegee found *Lyonothamnus* last year on Santa Rosa, where "the trees are small and often distorted by the wind. This species always forms small groves of a hundred, more or less, trees. It sends up several trunks from one cone, and the whole grove probably is connected underground by its roots" (Brandegee in *Proc. Cal. Acad.*, 2 ser., i. 2, 210).

The genus *Lyonothamnus* was established by Professor Gray (*Proc. Am. Acad.*, 2 ser., xii., 291) for a shrubby plant, discovered by Mr. W. S. Lyon, on the island of Santa Catalina, in 1884—*Lyonothamnus floribundus*.

Lyonothamnus is the first representative of the Saxifrage family among the trees of North America.

TERMINALIA BUCERAS, Hemsley.—This tree was detected by Mr. A. H. Curtiss, on Elliot's Key, at the time of our visit to southern Florida in the spring of 1886; and a few specimens, forty or fifty feet high, were found in full bloom on the 19th of April. It is the *Bucida Bucas* of Linnæus, but the genus *Bucida* having been merged into *Terminalia*, the plant becomes *Terminalia Bucas*, and

the author who first used this combination of names is the authority for it. The author in this case, unless some earlier application has escaped me, is Mr. Hemsley, in "Bot. Am. Cent.," i. 402. We have never been able to find a good seed of this tree in any of the herbaria of this country or of Europe, or to procure one from any of the West Indian or Central American botanists, although it is a common and widely-distributed littoral species. The plate, therefore, for the North American *Silva* lacks the figure of the embryo, an omission which may still be rectified could a single perfect seed be sent to me.

147. *EUGENIA LONGIPES*, Berg.—This species, as it grows on No Name Key, in Florida, the only station known for it in the United States, is a slender, spreading bush with stems six or eight feet high, and with no tendency to assume arborescent habit. I propose, therefore, unless I can learn that it becomes under more favorable conditions really a tree, to omit this species entirely from the *Silva*.

ARALIA SPINOSA, L.—This species must find a place in the *Silva*. I have seen it on the western slopes of the Big Smoky Mountains of Tennessee, growing to a height of thirty or thirty-five feet, with a straight, clear trunk, eight inches in diameter, and stout, wide-spreading branches.

148. *EUGENIA PROCERA*, Poir.—Two Florida trees have been confounded under this species. The larger of these, a tall tree, almost entirely confined, within the United States, to a single hummock on the shores of Bay Biscayne, east of the mouth of the Miami River, with scaly red bark, narrowly-acuminate, coriaceous, shining leaves, which are contracted into a long, blunt point, small flowers in axillary clusters, and small, pea-shaped scarlet fruit, has already been described in *GARDEN AND FOREST* (vol. 2, f. 87) under the name of *Eugenia Garberi*, a name bestowed upon it in memory of its discoverer.

E. procera is a much smaller and a much more common and more widely-distributed tree in Florida, occurring on nearly all the Keys. It is rarely more than twenty feet high, with a perfectly smooth, ashy-gray bark, broader, much thinner and duller leaves than the last, larger flowers, and larger fruit, which is first yellow and red, finally becoming black when fully ripe.

Eugenia Garberi should stand in the catalogue immediately after the last species.

153. *NYSSA CAPITATA*, Walt.—An older name for this species is that of Marshall (*Arbustum Americanum*)—*Nyssa Ogeche*, published in 1785, or three years earlier than that of Walter. The orthography of Marshall's name, although it is not that now used for the river Ogeechee, had best be retained.

154. *NYSSA SYLVATICA*, Marshall. The various forms of *Nyssa* with clustered, fertile flowers borne on a long peduncle, were all united in the Census Catalogue under the name of *Nyssa sylvatica*, the Linnæan species *N. aquatica* being held to include both a form of this plant and the very distinct *N. uniflora*. It may, however, be convenient to retain as a variety the Water Gum of the south Atlantic States, which would then become *N. sylvatica* var. *aquatica*. This, owing to the fact, probably, that it grows in shallow ponds where the trunk is surrounded with water during a large part of the year, is generally a smaller tree; and these conditions would account also for the enlarged base of the trunk, as the stems of aquatic trees display generally this peculiarity. The leaves are often lanceolate or orbicular rather than oval or obovate, the form they generally assume on upland trees, and the peduncles are inclined to be rather shorter. These characters are not constant, however, and it is the manner of growth and the general appearance of the Water Gum rather than any characters apparent in the herbarium which must be relied on to separate it from the Tupelo of the New England coast and the Black Gum of the Alleghany Mountains and the Valley of the Mississippi, as these three distinct-looking trees are connected together by innumerable intermediate forms.

162. *GENIPA CLUSIEFOLIA*, Griseb. — This is a common, littoral plant on several of the south Florida Keys. It shows, however, no tendency to become a tree or to grow to a greater height than five or six feet, and should be dropped, therefore, from the North American Silva.

167. *ARBUTUS XALAPENSIS*, HBK. — Professor Gray, in his supplement to the "Synoptical Flora of North America," 2 ed., ii. 1, 396, proposed for this Arizona tree the name *A. Xalapensis* var. *Arizonica*. It is not easy to connect this plant, with its thick, white, scaly bark on the old trunks and thin, narrow, glabrous leaves, with the Mexican *A. Xalapensis*, which is known to me only through herbarium specimens, and through the figure in Hooker's "Icones" (t. 27); and it seems impossible to understand properly either the Arizona or the Texas *Arbutus* without more detailed information with regard to the Mexican species of this genus than is now available.

168. *ARBUTUS TEXANA*, Buckley. — Professor Gray proposed (l. c.) for this plant the name *Arbutus Xalapensis*, var. *Texana*. It was believed formerly to be confined to Texas, but two years ago I found a single plant on the Sierra Madre, near Monterey, in Mexico, where Mr. Pringle has since collected it. It may be expected, therefore, to be a widely-distributed Mexican species at the northern limits of its distribution in central Texas. The specimen collected by Parry and Palmer (No. 562) near San Luis Potosi, and referred to *A. Xalapensis* is certainly identical with the Texas plant. C. S. Sargent.

Entomological.

The Periodical Cicada.

A CORRESPONDENT in Essex County, New Jersey, writes that when the seventeen-year Locusts visited his region last he discovered that these insects were by no means as harmless as they had been described. Farmers were assured that they might prune orchards and forests a little, but would inflict no serious loss; but the fact was that many of the trees in a young orchard, set out the year before, were killed outright, and most of the remainder were injured beyond recovery. He adds the common belief that some of this army will appear a year or so ahead of schedule-time, and some may follow later, but thinks the main host will appear in 1894, and he adds that the years '92 and '93 will be dangerous seasons for setting out young orchards.

This letter expresses fairly well some of the beliefs on the subject of this, perhaps the most interesting of American insects. The fact that it appears every seventeen years is stoutly maintained by some, and as stoutly denied by others. Cases are cited of their appearing in the same localities at shorter periods, while in other regions the seventeen-year record is unbroken. To the scientific entomologist the problem has long been a settled one; but, somehow, the explanation has not become generally known. As a matter of fact, instead of one, or two, or three, broods, which are grudgingly admitted as possible by ordinary observers, we know positively twenty-two distinct broods, each brood with its own peculiar distribution, and each of them well recorded for several periodic appearances. Another fact not generally known is that in the more southern regions eight of these broods have become accelerated, from climatic causes, so that they appear at intervals of thirteen, instead of seventeen, years. These broods are just as true to their thirteen-year period as are the others to their seventeen-year term. In some sections the two varieties—for the thirteen-year brood is smaller than the other—overlap, and sometimes it happens that a seventeen-year and a thirteen-year brood will occur at the same time in the same place, as in 1885 broods vii. and xxii. appeared together along the Mississippi Valley. Of course, in such regions, there will be a brood thirteen years from that time, and another four years later. Such facts, incorrectly understood, give rise to the popular ideas of an irregularity in appearance. So, also, where two, or even more, broods occur in the same region, there will be an apparent irregularity in dates. This is instanced during the present year in Washington (brood viii.), where the cicada last appeared in 1885 (brood xxii.), only four years ago. A very full account of all the broods is given by Professor Riley in Bulletin 8 of the Division of Entomology, United States Department of Agriculture, and

a great deal of additional information in the report of the United States Entomologist for 1885.

New York is credited with six broods: 1889 [viii.], 1894 [xii.], 1898 [xvii.], 1899 [xix.], 1900 [xx.] and 1902 [xxii.]. It will be seen that for three years in succession some part of New York will be visited by the cicada.

New Jersey is credited with four broods: 1889 [viii.], 1894 [xii.], 1898 [xvii.] and 1902 [xxii.]. New York thus has all the broods appearing in New Jersey, and, in addition, two others.

The New Jersey broods do not overlap—i. e., there seem to be no places covered by two broods, and I have therefore received letters in abundance, and seen numerous notices in local journals, denying the appearance of brood viii. this year.

To be somewhat more specific, brood viii. (1889) has appeared in Long Island, New Jersey, along the Atlantic Coast to North Carolina and westward through Pennsylvania. The brood becomes scattering and small in number along the Atlantic Coast, and is very generally overlooked. In New Jersey it appeared in small numbers at the Palisades, at Princeton, Palmyra, Red Bank, and for some little distance along the line of the Cape May Railroad. Mr. Angell, a very reliable entomologist, assures me that he heard the insects at Orange, but I received no specimens. Long Island is the only New York locality recorded.

Without mentioning other broods, it only needs to be added here that the largest of the seventeen-year race, brood xxii., which covers the greatest territory and is also very numerous, does not appear here until 1902. In New York it appears only on Long Island, extends in small detached areas through middle New Jersey, until, in Pennsylvania, the main army is struck. It is somewhat doubtful whether the brood in 1902 will be very numerous on Long Island, for the sparrows assembled in force in Prospect Park when the Cicadas appeared, and spared very few indeed. So well was the work done that in a search for eggs I spent an entire day along the line of their appearance and found but a single punctured twig!

Brood xii. (1894) appeared last in 1877 and is a very numerous one. It extends along both sides of the Hudson as far north as Troy, and crosses Long Island. They were in 1877 most abundant on Staten Island, less so on Long Island, and I observed them within the limits of New York City. In New Jersey they were very abundant nearly all over the State, and this brood is the one most generally remembered by farmers, and to which most of the letters received refer.

The larva of the Cicada lives underground and subsists by puncturing the roots of trees and sucking their juices. The rate of growth is so slow that the damage done is never perceptible, and need scarcely be considered. The mature insect takes its food in the same way, puncturing branches only instead of roots, and its damage in this respect is very small. The real injury is caused by the female in ovipositing. For this she selects, preferably, the tender terminal shoots of trees, shrubs, or, where they appear in large numbers, even low bushes, and makes a series of deep longitudinal slits into which the eggs are deposited. Where the twig or branch is small, it soon loses vitality, and eventually dies. On large trees this amounts to a severe pruning only; but in small, nursery trees or a young orchard, it frequently, if not generally, means the death of the tree. The advice not to put out young trees just before "Locust year," is sound. In New Jersey this advice should be remembered for the 1894 brood, and so too the farmers along the Hudson should take warning. This is really the only brood occurring in damaging numbers in these States. No practical remedies against these periodical pests have been suggested.

Foreign Correspondence.

London Letter.

THERE are certain variegated and golden-leaved trees and shrubs that display much beauty of foliage in spring and early summer; but, after exposure to strong sunshine, they are often anything but beautiful; indeed, nothing in a garden is more unsightly than a tree or shrub with sunburnt foliage. There is now such a great demand for these gold and silver variegated trees and shrubs that every tree-nursery is crowded with them, and the nurserymen are always alert to add some novelty to their lists. In many cases I have asked for a Catalpa, but was told it was not kept in stock, while I could have any number of the golden-leaved variety. The same is true of the beautiful pale-green *Acer Negundo*. One who orders it will probably get the variegated form, now too common everywhere. There are many people who do not see the

least beauty in green-leaved trees, though the wide range of greens, from that of the Evergreen Oak to the tender green of the Negundo, is capable of producing far more pleasing effects in garden-scenery than a superabundance of bright gold and silver foliage.

The newest addition to gold and silver-leaved trees is the golden variegated Negundo, shown before the Royal Horticultural Society last week. Though it did not find general favor with the committee, it is interesting as an ornamental tree because its foliage is less glaring than the common silver-leaved kind. The yellow variegation is good, and blends pleasingly with the green of the leaf, and, no doubt, in habit of growth and vigor, it is identical with the older sort. It has been exhibited three or four times, and on each occasion its merits have been at once compared with its more showy relative. But Mr. George Paul, who showed it, tells me that those who see it in the nursery are much pleased with it, and that it is selling well, which, after all, is the test of the popularity of a novelty. Another new golden variegated shrub of decided value is a variety of *Ligustrum ovalifolium*, named *Elegantissimum*, which is very different, and much superior, to the older yellow-margined kind. The leaf of the newer variety is larger, of thicker texture, and the broad golden zone is more pronounced. It, moreover, keeps its color throughout the season. It was one of the most striking things shown by Messrs. Veitch in their great collection of ornamental trees and shrubs from their Coombe Wood nursery. Among other trees of this character at Coombe just now is the golden variety of your Hop-tree, *Ptelea trifoliata*, which is quite a cloud of soft golden-yellow, and, of course, it retains the picturesque umbrageous growth of the typical form. This golden variety is different from the golden variegated form, of which the late Charles Hovey sent me some specimens several years ago. In this, the leaflets are in most cases half green and half pale yellow, which, no doubt, would be effective on the tree, but I have not seen this form here yet.

Of the shrubs in flower at Coombe the most noteworthy, perhaps, are *Eucryphia pinnatifolia* and *Spiraea Bumalda*, the first because of its rarity, the other on account of its novelty, for, though it is not absolutely new, it is yet but very little known. The *Eucryphia* is a Rosaceous shrub from south Chili, introduced about a dozen years ago by Messrs. Veitch, and, like some other Chilean plants, such as Darwin's Barberry, *Buddleia globosa*, the Fuchsias and the Pernettyas, has proved quite hardy in these islands. It grows about a yard high, the numerous branched stems being clothed with deep green pinnate leaves. The flowers recall those of the large-flowered *Philadelphus grandiflorus*, having four broad, white petals and numerous stamens spreading out like a broad tassel. I do not suppose it would be hardy enough to stand your winters, but it is worth green-house treatment. The little *Spiraea Bumalda* is quite a gem here among flowering shrubs, and, although it is scarcely different in flower from the common *S. callosa*, its neat and dwarf growth, rising only about two feet high, tends to make it very popular, and in some of the nurseries it is a difficult matter to maintain a stock equal to the demand. The ordinary form of it has a dense, flat flower-cluster, pale pink on first opening, getting darker later; but this week Mr. Anthony Waterer sends me a specimen of a new variety he has in his nursery, the flowers of which are a deep crimson, richer even than the *Atrosanguinea* variety of *S. callosa*. It is quite worthy of a distinct name, and a good one would be *Fulgens*. Of other *Spiræas* now in flower there is none so pretty as the variety of *S. hypericifolia*, known as *Flagelliformis*. It is much more floriferous than the type, as its long and slender, curved shoots are perfectly wreathed with small clusters of white flowers. I rank it among the choicest of flowering shrubs, but it is rarely seen. The plants I saw came from Transon's, of Orleans, where it is largely grown. Another first-rate shrub, in bloom now, is the old *Hypericum oblongifolium*, from the Himalayas, which is quite hardy here, and never fails to assert itself in an attractive way every August. It is a thin-growing plant, about two and a half feet high, and has numerous clusters of large cup-shaped flowers of the richest yellow. It is a beautiful companion shrub to the showy *Hydrangea paniculata grandiflora*, which is now expanding its huge clusters of snow-white blossom in the open air. The two group well, the *Hydrangea* as a centre mass, then the *Hypericum*, and outside that the Rose of Sharon (*H. calycinum*), which forms a neat margin to a shrub group.

The Catalpa is, for the time, the glory of many an old garden. I say "old" because you very seldom see it planted in a new garden, except, perhaps, the golden-leaved variety, which, however, is generally cut down periodically so as to get large and vigorous foliage. In the old suburban gardens, such as

Sion, Claremont, Cienwood and Kew, the Catalpas are wonderfully fine this year, the great spreading trees being crowded with clusters of white bloom. The common kind is your *C. bignonioides*, which is hardier than the Japanese *C. Kämpferi* which has the finest leafage. *C. speciosa* promises to be hardier even than *C. bignonioides*, and in some nurseries it is being propagated in preference. It is quite distinct enough in growth to enable one to single it out when growing among the common kind. There is a good deal of talk here about the new hybrid Catalpa of Mr. Teas, described and figured in a recent number of GARDEN AND FOREST, in an article which has been copied into English journals. Its rapidity of growth, its vigor and floriferousness indicate a first-rate ornamental tree, and we hope to see it soon on this side. It is so seldom now that a new flowering hardy tree is introduced that it is quite a red-letter event.

Bulbs are, of course, now engaging the attention of gardeners, and I am reminded of this by the multitude of trade lists which the mails are carrying. My table is strewn with catalogues from all quarters, the Hollanders being particularly attentive in this respect. At one time you rarely saw a Dutch bulb-grower's list, but now each grower seems anxious to impress upon you the fact that it is folly for English people to buy their bulbs through the seedsmen here when they can get the same from him at wholesale price. The bulb trade with our nurserymen and seedsmen is not as profitable as it used to be, as the auction sales tend to keep prices low, but after all, really fine bulbs are more certainly secured through the best houses at home. The nursery and seed trade naturally resent the innovation of the Dutch grower in sending his catalogues broadcast in this country, but it has had a beneficial effect for those who habitually buy their bulbs from tradesmen at home.

London.

W. Goldring.

Cultural Department.

Shrubs with Conspicuous Fruit in August.

IN this latitude the month of August does not afford a great abundance of showy-fruited shrubs and trees. Of the economical or domestic fruits few are conspicuous in color, and these are chiefly early red and yellow varieties of apples and plums. As the fruit of these early kinds is not left on the plants to be admired, they do not come under the head of ornamental plants. But the coloration of many varieties of fruit in September and October certainly adds much to the autumnal beauty of New England landscapes.

Among all the handsome-fruited shrubs grown for ornament, none can surpass the Cranberry Tree (*Viburnum Opulus*) when well laden with fruit. This plant was mentioned as having noticeable fruit in July, and, as August advances, the berries, or drupes as they are called botanically, become bright red and remain brilliant through the autumn. The fruit of the Arrow-wood (*Viburnum dentatum*), of which the birds seem very fond, ripens about the middle of the month. It is blue in color and is borne on erect terminal cymes. This is followed by *Viburnum molle* which, though a more southern species, is quite hardy here. The plant, as well as the fruit, closely resembles *V. dentatum* in general appearance, but the fruit is usually somewhat larger.

Viburnum pubescens and *V. acerifolium* have oval blue-black fruit which is not particularly showy. The Wayfaring Tree (*V. Lantana*) holds its ripe yellow or red drupes until near the end of the month, when they lose much of their beauty by becoming dull and black. Towards the end of the month the broad cymes of the common Elder (*Sambucus Canadensis*) have become fully ripe and dark purple or black, and the branches bend over with the weight. The berries remain on the plant for a considerable time, and on this account, as well as for its handsome white flowers, it is very ornamental in shrubberies. A yellow or golden-leaved variety is very much admired by many, and its fruit is lighter in color than the type.

There are several species of Dogwood which are interesting on account of their fruit during the month. The fruit of *Cornus alternifolia* is blue-black and will remain on the plants for many weeks, if not devoured by the birds. It is a shrub more interesting for its succession of horizontally growing branches and neat habit than for beauty of fruit. The bluish-white fruit of *Cornus circinata* is generally too much scattered to be effective.

Cornus stolonifera is a handsome and pleasing plant, having deep-blue or metallic lead colored drupes, the color being somewhat faded or paler on the side exposed to the sun. They ripen from the middle to the end of the month, and with

those of the next species may remain on the bushes for some time. This species is worth planting for its conspicuous red stems, which are especially noticeable towards the end of winter, as well as for the profusion of white flowers which it bears in June. The silky Cornel (*C. sericea*) does not generally ripen its fruit until the end of the month, and in some situations not until September. In the Arnold Arboretum and vicinity the bright-blue fruit is produced in great abundance. *Cornus paniculata*, which is one of the most slender of the native shrubby species, bears a profusion of delicate white flowers in June followed by pale white fruit about the end of August.

If only one-fourth of the yellow early spring blossom of the Cornelian Cherry (*Cornus Mas*) developed into ripe fruit, the plant would again be a most beautiful object from the middle

small, slender-twigged, partly trailing shrub, from two to three feet in height, with deep green leaves, one or two lines wide and from one to two inches in length.

The fruit ripens early in the month, when the purplish pods open, disclosing the seeds enveloped in an orange-colored aril. This little shrub is quite hardy at the Arboretum, and is excellent in rockeries or for the borders of shrubberies.

The smooth Sumach (*Rhus glabra*) throughout the month bears velvety, crimson fruit, which is often collected for use in making vinegar or as a substitute for lime juice. It is not such a tall growing species as the Staghorn Sumach, which, in some respects, is to be preferred for planting in groups.

The well-known Snowberry (*Symphoricarpos racemosus*) ripens some of its large, white berries during the month and at the same time continues blossoming. Another plant with

A New England Rock Garden.—See page 433.

to the end of August. The drupes are oblong, from three-fourths of an inch to an inch long, and deep orange or bright scarlet, or cornelian colored (whence the common name), when fully ripe. They are edible, though somewhat acid, and in parts of Europe are made into marmalade and used in other ways. Unfortunately, in this latitude, even large plants bear very little fruit, and it drops to the ground almost as soon as matured. *Cornus sanguinea* is another European and Asiatic species sometimes planted in our gardens. It is a close, compact shrub, which will grow eight or ten feet high, and it bears small, terminal cymes of almost black, and not very ornamental, fruit.

Enonymus nanus (*E. angustifolius* of some catalogues), a native of the Caucasus, is the only species of the genus which fully matures its fruit here during this month. This is a neat,

the same habit of flowering is the Alder Buckthorn (*Rhamnus Frangula*), which continues to produce its ripe, shining, purple-black and inconspicuous flowers from July until well into the autumn.

Except *Rosa rugosa*, which ripens first, *Rosa Engelmanni*, recently described and figured in these pages (vol. 2, f. 121), and *Rosa acicularis* are the earliest species to become conspicuous with fruit in the Arboretum. The bright red fruit of *R. Engelmanni* especially is large and attractive.

Fruits of other species of roses also assume bright colors during this month as well as some species and varieties of Barberries. But as they are not always fully matured until September, and remain on the plants for a considerable time, they deserve mention later.

Jamaica Plain, Mass.

Memoranda From a Northern Garden.

RHUBARB is an easy plant to grow, and market-gardeners find ready sale for the leaf-stalks in spring-time, when there seems to be a very general craving for sharp, pure acids of vegetable origin. It does not take much time or much expense to establish a bed of this plant. The old-time fashion of trenching and deep intermixture of manure is as needless as with Asparagus. A coating of good stable manure, three to four inches thick, well plowed under, is sufficient. Strong, single eyes set this fall after such preparation, four feet each way, will make plants which will shade the whole ground the next fall, and be ready for cutting the succeeding spring. From such a bed I have cut ninety-three stalks which together weighed 100 pounds.

the raw state. Is it not significant that the Oldenburgh apple brings about as good a price as the Gravenstein in many if not in all our markets? Yet the former is strictly a culinary apple. But besides this, is the consideration that many of our choicest dessert varieties are either shy-bearers or very local as regards success; while others are unusually susceptible to the inroads of insects and fungi? Productive sorts of handsome appearance and fair medium quality are, in my opinion, the most profitable to plant. The pains-taking amateur, who is not thinking of profit, may find some pleasure (mixed with a good deal of vexation) in cultivating what are rightly styled "fancy" sorts.

It is the fashion to disparage the quality of Russian Apples, and I observe that our government pomologist, Mr. Vandeman, follows this fashion in his recent report. But in this he

A New England Rock Garden.—See page 433.

Should Asparagus seed be planted deeply, as often advised—say at the bottom of a hole six inches deep? It will come up, but, as with all seed too deeply planted, it will not grow so vigorously as from shallow planting. But about the cutting? Must there not be deep planting to get the white butts required in most markets? Not necessarily; ridging with the plow at the end of the second season's growth will accomplish the same end. If the hills are four feet asunder, both ways, the double mouldboard-plow will give either ridges or hills, as desired. In cultivation during the summer, after cutting is over, these are somewhat leveled; but are easily renewed at the last working, previous to which it is well to give a shovelful of manure to each hill.

Is it not a mistaken notion that all but fruits of the highest dessert quality should be disparaged by horticultural writers? It is safe to say that much more than one-half the crop of our tree fruits (excluding the Citrus family) is cooked before it is eaten. Some of the best for cooking are scarcely eatable in

is widely at variance with all those who have had the longest and most complete opportunity of testing these apples. It will take a good while yet to sift and thoroughly test the more than 300 varieties that have been introduced to this continent from eastern Europe within the last twenty years. Suppose a similar number of the best American varieties had, within the same time, been on trial even in so comparatively small a country as New Zealand, would not a large proportion have been condemned? But probably others would find acceptance and prove of great value. It has been abundantly shown that the apples of western Europe and their American seedlings are not suited to our colder states and Canada, where almost the whole Russian list are at home. When we come to consider dessert quality alone, I think a sufficient number of Russians are already known to possess that quality to a very encouraging extent; while in vigor of growth, early and free bearing, size and beauty of fruit, they decidedly excel most American apples. Their great lack is in long keeping.

This is, no doubt, due to the fact that the Russian orchard region lies about 600 miles north of our northernmost settlement. There the growing season is proportionally short, and a short autumn is quickly followed by steady cold weather. But from these Russian fruits it is highly probable that American seedlings will appear which will supply this single lack.

It is conceded that in climate the eastern coasts of Asia and America are much alike, and many fine species and varieties of trees and plants from northern China and Manchuria already flourish among us. I am inclined to believe that we shall yet find something of value to us among the fruit trees of the same region. At any rate, we may hope that it will yield "iron-clad" species and varieties which will prove useful in modifying and improving our native species, and the species of northern Europe. What a magnificent field for work is here opened for the young and ambitious staff of our experiment station! They should not hesitate a moment in entering upon it with energy and persistence.

T. H. Hoskins.

Seasonable Hints about Foliage Plants.

AS the cooler nights and heavy dews of Autumn are at hand some changes in treatment will be found beneficial to this class of plants, particularly as regards watering and syringing, for some of them will suffer more from carelessness in these operations at this season than they do in the winter, when the stronger fire-heat removes the moisture more rapidly. The better plan is to give water in the morning, and on most days to syringe at the same time, simply dampening the walks and benches in the afternoon, if the air seems too dry, so as to avoid the excessive condensation of moisture on the foliage during the night. Such condensation is decidedly injurious to many of the more delicate Palms, and causes the tips of the leaves to decay, and Pandanus suffers in the same way. *Pandanus utilis* and *P. heterocarpus* (otherwise known as *Pandanus ornatus*) will be found particularly susceptible to injury from over-watering, and, consequently, water should be given sparingly, both at the root and overhead during the short days of the year.

On the other hand, Caladiums will still be in full growth, and when in this condition should receive a copious supply of water at the root, with an occasional application of liquid manure to increase the size and heighten the coloring of the leaves. If intended for exhibition they should be given plenty of air, so that they may be able to stand changes of atmosphere without the necessity of staking each leaf to prevent its falling down on the pot, as the careful arrangement of a small forest of stakes in a specimen of this class (or any other) will not prove a point in its favor when examined by competent judges.

Most of the Marantas will yet be in active growth, and will take a liberal supply of water, but as the growth becomes slower, the allowance should be slightly diminished. They should not be allowed to get very dry, however, or a loss of foliage will surely result, and it should be remembered that a moist atmosphere and a shaded house are among the requisites for the successful cultivation of most of them, with the possible exception of a few of the stronger constitutioned sorts like *M. zebrina*, which grows very well out-doors in the summer as a vase plant, if placed in a somewhat sheltered position. With all of the above-mentioned, and, in fact, with stove plants in general, a reasonable amount of ventilation at night will be found advantageous, if care is taken to prevent draughts, and if the night be very cool, a little stronger fire-heat may be given to correct any deficiency in temperature.

If any of the Palms are pot-bound they should be given a shift at once, so that they may become well-established before winter, for though these plants do not come to a full stop in growth during the winter, yet their root-action is so much slower then, that there is greater risk of over-watering if they have been potted very late in the season. Of course, when it is desired to grow young Palms very rapidly, they may be potted whenever it is found necessary, without much attention being paid to the season of the year, because, when given extra heat and attention, they may be kept growing during the whole year, and this practice is common among trade growers, who often find it needful to grow their plants under high pressure in these days of sharp competition.

Cyanophyllum magnificum and *Sphaerogyne latifolia*, two of the handsomest stove-foliage plants in cultivation, should be found in every collection where there are facilities for growing them. But to keep these two species in good condition, liberal treatment is required, both as to pot-room and moisture, for, if neglected in either of these essential points, the

foliage soon becomes stunted and disfigured. If they are becoming pot-bound, an occasional watering with liquid manure will be a help, pure guano being probably the most effective fertilizer for this purpose. This should be used with caution, however, a two-inch potfull to an ordinary can of water being sufficient, if the guano is pure. The *Cyanophyllums* and *Sphaerogyne*s both being shade-loving plants, and also natives of the tropics, they should be furnished with somewhat similar conditions when under cultivation, but while giving them plenty of shade it will be found best to keep the plants within a short distance from the glass, so that the growth will be short-jointed, thus making the plants appear better furnished. These two plants are readily propagated by means of single-eye cuttings placed in bottom-heat and kept rather close until rooted, which is usually in from three to four weeks' time, after which they should be potted off into moderately light soil, and repotted as often as they become well-rooted, so that the growth does not at any time suffer a check, else the symmetry of the plant may be injured.

Holmesburg, Pa.

W. H. Taplin.

Crooked Norway Maples.—It is the general experience of nurserymen that the Norway Maple does not grow as straight, when young, as the Sugar Maple. In the majority of cases there is a bend at the beginning of each year's growth, which shows in the trunk until the tree attains a considerable size. What is the cause of this crookedness? The young shoots of the Norway Maple are as straight as those of the Sugar Maple. The normal habit of growth is a true perpendicular, but next spring a side-shoot takes the lead with a curve. It is evident, then, that the central terminal bud of the Norway Maple has suffered injury in some way. This has not been caused by the cold of winter, for it is the most hardy of the maples. Every nurseryman has observed that the growth of young trees of this species stops in the latter part of July, the shoots becoming very short-jointed, and the leaves showing injury with tips crisp, as if scorched by the sun. In previous seasons I have been uncertain of the cause of this stoppage. I have occasionally found flying thrips, much resembling, and perhaps identical with, the vine fretter, but these were so few in number that I had supposed them inadequate for such a sweeping result.

Early in July of this season I found occasional thrips on the tender terminal shoots of the Norway Maple, which flew immediately upon my touching the leaf. I at once had all the leading shoots of this variety dipped in a weak solution of the kerosene emulsion. This process has been repeated three or four times in as many weeks, and the result is that the shoots have continued to make a healthy growth. I have no doubt that the terminal bud will start next spring, as straight as an arrow; and I have no longer a doubt that the thrips has been the sole cause of the stunted growth of previous years. The Sugar Maple does not seem to be affected by this pest. Neither have I found the Schwedler and the Reitenbach maples troubled by it, although they are varieties of the Norway. The Sycamore Maple does suffer to a considerable degree. But the remedy is easily applied on small trees, and on large trees it is unnecessary.

Newton Highlands, Mass.

W. C. Strong.

Rhododendron odoratum, which is said to be a hybrid between *Rhododendron Ponticum* and one of the deciduous hardy Azaleas, was one of the chief attractions in the open-air garden at Kew for late July, when there were large masses of it flowering in great profusion. In growth it resembles the deciduous Azaleas or Swamp Honeysuckles of North America, though its foliage is somewhat different, being larger, of thicker texture and a deeper green. The flowers are Azalea-like in size and form, and are gathered into moderate-sized clusters. They are of a delicate mauve-lilac tint in the main mass of plants, but a few have as deep tinted flowers as *R. ponticum* itself. They are deliciously fragrant, and this heightens the value of the plant for the garden. Another point of value is, that it flowers at a time when the majority of the other Azaleas are on the wane, and it lasts three or four weeks in bloom. It grows well in any ordinary peaty soil, kept tolerably moist. Loudon enumerates it in his arboretum under the name of *R. azaleoides*, and he says it is the variety subdeciduum of Andrews' Botanical Repository. It is also known as *A. fragrans*. Though an old and well-known shrub at Kew, it is rarely seen in even the large tree nurseries, but now that its character is so well displayed at Kew attention may be directed to it.

Kew.

W. G.

Pyrethrum uliginosum is now at its best and is without doubt one of the very best plants we have for cut flowers, and for garden decoration in autumn. We find that plants in moist

situations produce much larger flowers than those in dry sandy positions, and as *P. uliginosum* is a gross feeder, it needs division every second year when the soil should be well enriched with decomposed manure. If this treatment is given, the stems grow five feet high, and from the axils of every leaf a flower stem is produced, bearing a cluster of flowers, each of which is four inches across, with petals pure white, and a bright yellow disc. This plant is thoroughly hardy, and is by no means new, although we received it as such, three years ago, from Switzerland. Twenty years ago it was quite common in English gardens, but its present popularity comes from its re-introduction with so many other fine old plants that had been under a cloud during the reign of the bedding system. *P. uliginosum* is easily increased by division of the stolons which are freely produced from the old stem, and with us seeds are matured in good seasons and germinate much better when self-sown than when sown under glass. The Great Ox-Eye Daisy deserves a place in every collection of hardy plants.

Clematis paniculata, as it is here, is worth going a long distance to see. There are over 200 plants, and although only nine months old, they are from seven to eight feet high, and covered with the large panicles of fragrant white flowers. Their fragrance, in the early morning, especially reminds one of that of the Hyacinth. This plant is being distributed also under the name of *C. robusta*, an appropriate name enough, for there is no *Clematis* in cultivation of stronger habit, but the name *C. paniculata* is now nearly 100 years old, and it ought to have right of possession, but this is probably only another instance of an old plant under a new name. In addition to the free flowering qualities of *C. paniculata* the foliage is large, of a shining, dark green, and the plant is an excellent climber, perfectly hardy, and needs no pruning in spring, except to cut off the old flowering stems. As a plant for the decoration of the piazza there can be no better, for after the flowers are over, the prettily-awned seeds are almost equally ornamental, especially when they take on their peculiar bronzy tint.

Passaic, N. J.

O.

Osbeck's Sumach.—The Japanese variety of *Rhus semialata*, known as the var. *Osbeckii*, again flowered profusely at the Arnold Arboretum, and when in blossom, with its many large panicles of greenish-white flowers, it was one of the most conspicuous of small-sized trees in this latitude. With the exception of the Japan Sophora (*S. Japonica*), which blooms at the same time but continues some days longer, it is the latest to flower of all the woody plants which assume the true arborescent form. The plant, like its American congeners, is a fast-growing one. With large, pinnated, dark green leaves, and broadly margined or winged petioles, it is handsome and interesting all through the summer, and in the autumn it assumes the brightest yellow and scarlet colors. A panicle of the small, greenish-white flowers is borne at the end of each branch. The panicles average nearly a foot and a half in length, with a lateral spread almost as great. The flowering period is rather short, the first flowers opening this season about July 29th, and the last August 15th. The large plant in the Arboretum bears staminate flowers, but, occasionally, pistillate or perfect flowers are borne also as the panicles sometimes produce a very few scattering fruits. This small tree gives promise of being quite hardy where the winters are much colder than at Boston.

Arnold Arboretum.

J.

Orchid Nomenclature.—Since Lindley's time almost every Orchid has been described by Professor Reichenbach, and, as no one else appears to have preserved authentic specimens, and the herbarium of the Hamburg professor is sealed up for twenty-five years, it is difficult, in many cases, to decide what has already been described and what is really new—a difficulty rendered greater by the fact that "his papers," as the *Gardeners' Chronicle* says, "are not only extremely numerous, but scattered through a wide range of publications, in almost all European languages."

Kew has stepped forward to fill the gap. We notice a letter setting forth that the director of that establishment is willing to assist cultivators of Orchids in naming their plants in cases where difficulty arises in their correct nomenclature. A second letter points out that many of the plants described by Professor Reichenbach still exist in gardens, and requests that specimens of the same be sent for preservation. By this means a considerable number of types might be recovered, if the suggestion is acted upon, which seems likely to be the case. Orchid-growers have learned a lesson—not to send all their specimens to a private herbarium again.

A suggestion has recently been made that the Royal Horticultural Society should appoint a Professor of Orchidology, who shall look after the naming and describing of new Orchids, and to whom all questions relating to their nomenclature shall be referred. Another proposal is that a committee be appointed to determine the principles on which they shall in future be named. It seems hardly likely that the first suggestion will be acted upon, as the expense of getting together the necessary herbarium and drawings would be no inconsiderable item. The second proposal is good in its way, provided always that the decisions of the Committee are accepted and acted upon, though we do not remember that the former conference, at Liverpool, led to any very practical results. Certainly the nomenclature of Orchids is in a good deal of confusion, and is likely to remain so while growers insist upon having a name for every slight variation which occurs.

The genus *Cattleya* furnishes a very good illustration. The *Gardeners' Chronicle* has seen fit, after a long interval, to continue its "List of Garden Orchids," and this genus is now just completed. Turning it over we note no less than twelve varieties of *C. guttata*, whose characters are briefly given, but on reaching the very polymorphic *C. labiata*, such an array of names present themselves as to be perfectly bewildering. About nine geographical varieties are recognized, and under several of these a host of variations or polymorphisms are given. The variety *Mossiae* seems the most polymorphic, having something like forty-seven sub-varieties, or polymorphisms, or whatever else they may be. The variety *Trianae* follows closely behind, with something like forty-one. We wonder how they all differ, for the characters are not given—perhaps on account of want of space, as they take up something like a column and a half as it is. However, those who wish to know will now be able to find them, by the references given and the list of published figures. We note such delightful combinations as *Cattleya labiata Mossiae Peetersii* and *C. Reineckiana superbissima*, whose correct name would appear to be *Cattleya labiata Mossiae Reineckiana superbissima*. Such names, we should think, require a good deal of regulation.

Forests and Civilization. The North Woods.—VII.
To the Editor of GARDEN AND FOREST:

Sir.—There have been marked changes in the thought of the people in the Adirondack region since I first began to observe things here. At that time nearly everybody thought the forests were inexhaustible, boundless and everlasting. It made no difference how much timber might be destroyed, or how great areas might be burned over and ruined, there were still illimitable, uninvaded wilds. There was then hardly any care among the guides about putting out fires, and if a visitor wanted his fire extinguished when he broke camp in the morning, his suggestion was often regarded as an impertinent and absurd interference with the affairs of the people of the woods. When a squatter wished to clear a potato-patch for the next spring's planting he fired his brush-piles in the time of greatest drought, and sent the flames roaring away through leagues of forest, not caring how far or how long they might burn. The region was being rapidly devastated by fire, and there were extensive and open depredations on the timber of the state lands. Visitors from the cities often displayed a most thoughtless and uncivilized enjoyment in destroying as much of the woods as they could during their summer stay here. There was little sign of forethought, or sense of responsibility, anywhere, regarding the value or the destiny of these mountain forests.

All this has been greatly changed. There have been few extensive fires during the last few years, and there has come to be a very general feeling among the people who live in the woods and from them, that injuries to the forests are injuries to their own means of subsistence, and are therefore to be avoided. Camp-fires are generally carefully extinguished, and the wanton destruction of trees by campers is discouraged. The old superstition that the woods are inexhaustible, has given place to the sense that things are coming to an end; that the very existence of this great summer resort is threatened, and that the permanence of its peculiar industries and revenues is no longer secure.

There is a rapidly developing feeling that the region ought to be taken care of, and that something should be done to prevent the complete extinction of the woods. These changes in the thought of the people here have been brought about, partly by the extension of the railroads into hitherto inaccessible parts of the wilderness, and the increased cutting for lumber everywhere, and partly by the influence of recent

discussions in the press. Since papers of influence have declared that "the only plan by which threatened injuries can be averted, and means provided for the permanent conservation of these invaluable forests, is the acquisition by the state of the entire Adirondack region," the minds of the people here have been turning more and more in the direction of such a change. A valuable educational work has also been carried forward among the woods-people by the chief Forest Warden and his subordinates. They remind everybody that unless the forests are preserved, the occupation and livelihood of the inhabitants of the country here will be gone. "No woods, no tourists, no living for you." The most intelligent and observant men here are coming to be in favor of the gradual acquisition of the entire region by the state. But nobody wants the state to buy the land before the timber is cut off! The lumbermen want the existing crop for themselves. But some arrangement could doubtless be made to purchase considerable tracts for the state as soon as the timber now standing on them is utilized. Then, if fire is kept out, the forest will soon come back again, and the state can take care of it if her people are wise enough.

There has been comparatively little depredation upon timber on the state lands during the last few years. Some ne'er-dowells steal a tree or two at a time for shingles, or to sell, and some lumbermen still buy logs from men who are known by everybody not to own a foot of land or a stick of timber anywhere, but the pillaging of the state timber lands has greatly declined. The Forest Commission has successfully prosecuted some offenders, and has successfully discouraged others. The Bill providing for a change of venue in suits for trespass on state lands, which the Commission brought forward in the Legislature last winter, was a good measure, and should have become law. Such cases cannot always be fairly tried in the vicinage where the depredations were committed.

The extensive and increased cuttings which thoughtful men deplore is, of course, not on state lands but on those of private owners, who have a right to cut their own timber whenever they choose. They have also a legal right to cut it as they choose, and to destroy forest-conditions all over their own territory, if they are so unintelligent as to wish to do that. What observing and public-spirited men regret is, that so much of the forest is cut off with so little thought of the future and its needs. There is really no sound objection to cutting off the woods if it were done in the right way, for they would soon be reproduced. But much of it is done thoughtlessly, carelessly, stupidly; without the application of judgment, intelligence or common sense. I think we shall have to interest, engage and educate the lumbermen, and get them to help us in the effort to establish a more enlightened and practical policy and method in cutting off timber, and maintaining permanent forest-conditions, so as to have a succession of crops. They ought to feel more interest than most other people in the permanent preservation of the forests as a source of revenue and profit to themselves individually and to their children, but, unfortunately, they do not always act from enlightened self-interest, any more than the rest of us.

While these mountain forests are in the hands of private owners we must expect that they will be utilized, as other property is, for their benefit, and it is not reasonable to denounce them for managing their possessions for profit, as other people do. Here are two lines of work, the encouragement of forethought and wise management among lumbermen and private owners of forest lands, and the discussion of the policy of the gradual extension of state ownership of land in the Adirondack region.

The Conemaugh catastrophe has had a distinct influence here in stimulating thought about the relation of mountain forests to streams and their flow, and the effect of mountain denudation in producing destructive torrents and freshets, and intelligent men in the wilderness, and in the towns along the Hudson, are giving these subjects more attention than ever before. It is not quite plain to them just how this disaster teaches the lesson drawn by my friend Major Powell, "that forests are a disadvantage to irrigation where the chief precipitation is snow." But the question of the quantity of water that might be saved, by destroying the mountain forests of California and Colorado, is not practically important. If forest-conditions are destroyed on the mountains, in which the streams to be used in irrigation have their sources, evil and destructive forces which no human power can control will be liberated and set in motion. The soil will be carried down from the mountain slopes. The irrigation reservoirs will be filled up, and the fertile lands below buried under sand and gravel. The streams will be ruinous torrents for a short time each year, when the snows melt, or the rains fall, and their channels will be dusty chasms during the season when water

is most needed. The air will be filled with dust from the perpetual erosion of the hills. The regions which might be the permanent seat of vast and prosperous populations will be wrecked, desolate and accursed. The laws and forces of nature will not make exceptions in our favor, though we are a great country.

But why should our friends, the geologists and hydraulic engineers be eager for the destruction of the forests on our western mountains which still belong to the nation? The forests are not in their way. Their permanent conservation and proper management will in no way interfere with the great expansion of engineering and constructive work for the storage and distribution of water, upon which it is evident that we are about to enter. There will be plenty of business for the engineers for a great while to come, and vast revenues will be appropriated for its cost. The magnitude of the possibilities before us is indeed stimulating to the sanest mind, and it will not be wonderful if some enthusiasts conclude that arid lands are better for agriculture than those to which nature has given an adequate rainfall, and that the world is to be saved by being sufficiently dammed. But the fact remains that mountain forests are the natural storage reservoirs for the water that falls upon them, and that they are indispensable to the integrity and permanence of the streams which have their sources in them.

J. B. Harrison,

Lower Saranac, New York.

Cor. Sec. American Forestry Congress.

The Practicability of an Improved Use of Popular Plant-Names.

To the Editor of GARDEN AND FOREST:

Sir.—Popular plant names are a part of a great mass of descriptive terms, applied to familiar or conspicuous natural objects, and form an important part of every language. They seem to be as necessary to the people at large who want names that easily become familiar, as "scientific" names are to the student who must have a universally understood system and mode of expression.

Botanists pay less attention to popular names than ornithologists, entomologists and other students of natural science. Why they should may perhaps be explained by circumstances connected with the early history of botany. The study of plants, first confined to the physician, who considered them for their real or supposed medical virtues, was for a time thrown into great confusion from lack of means for identification. Later students began to work out a system of classification and at length botany was established as a science apart from medicine. But in the mean time the early physician had degenerated into the herbalist, with his quackery and superstition, and both he and his vocabulary were held in contempt by the botanist. This early antagonism resulted in a separation between the popular and scientific names of plants.

Some popular names have come to us from a very early time, while others, more recent, can be traced to many different sources. We have not the various dialects that are responsible for many of the seemingly trivial names in English books, but from all parts of the world names have come to us with the plants to which they belong; while others have become attached to new plants. Purely American names have been adopted from Indian languages or corruptions of them, and many have originated among our people.

There are many common names which are used without practical confusion or inconvenience of any kind; such, for instance, as Quince, Elm, Wheat, Cabbage, Cocoanut. That there is a much larger number in the use of which there must be uncertainty and consequent confusion, is not a sufficient reason for outlawing all such names. If it were, scientific names must also be outlawed by the same reasoning, for even the best botanists often make changes in what is regarded as the correct name of a plant, and often append to the name of a particular plant a long list of synonyms.

Considerable attention has been given to popular plant names in England, and several books are published there on their origin, meaning and use; but the more important of these are written from the standpoint of the philologist and archaeologist, and while all deplore the uncertainty and confusion in the use of these names, little is done to correct it. It is often added to when a great number are given, by not specifying those worthy of general use.

We, in America, stand well to lead in establishing the correct use of popular names, for our text books and catalogues agree in the use and application of many of them, and we are comparatively free from complications that perplex our English friends.

The superceding of the system of scientific names by a system of popular names is not to be urged.

The ultimate object should be to establish for every plant one name which for good and sufficient reasons shall be known as the standard common name; all others for the same plant being made subordinate of it. Among the reasons for adopting the standard name would be that it is more frequently and widely used than another; that it does not conflict with the name adopted for another plant; that it has special fitness as a descriptive term; that it is descriptive of peculiarities in the structure and manner of growth of the plant or that it indicates its association with some interesting event. Priority should also be considered but would not necessarily establish the use of a name.

Most conspicuous or familiar plants have popular names, but if botanists, when describing a new plant, would publish with the scientific name an appropriate native appellation, or if necessary invent a name for popular use, they would do much to aid the purpose. A translation of the botanical name which is usually an abbreviated descriptive term, is often awkward and unweildy and would seldom be the best popular name that could be selected.

If the introducer of a new plant proposes a good and appropriate common name, the distributor will commonly be glad to adopt it, well knowing the value as a matter of trade of such a name. If one in use in its native habitat or elsewhere, or one given by the discoverer or botanist who classified it, is not available, it would be the duty of the distributor to invent one, short, easily understood and pronounced, descriptive of the plant in some particular, or referring to some association. If the botanical name only is used it is copied at first, but if the plant is widely distributed and popular it is sure to receive a popular name, often several in different localities.

A complete botanical name with a generic and specific name of the same character is seldom if ever used in a popular way, but the generic is often adopted, and with it an English prefix to distinguish it from other species. Such names when established are popular names, and often very serviceable, but it does not seem that the union of Latin and English can be as desirable as simple and expressive English names which may be, and so often are, used to express the same things as Latin generic and specific names.

When a cultivator creates a new variety and gives it a reasonable name, that name should be respected by everybody, and it should become odious for anyone afterwards to attempt to give the plant a new name, especially if this is done for a commercial purpose. A person who applies to a plant already having a good and sufficient name, one that better suits his individual fancy, and publishes it, should be held guilty of an inexcusable act. Only when a plant has a very conspicuously unfit or inelegant name should an attempt be made to give it another, nor should it even in such a case be made except with the approval of some notable body.

We need a work in which every name in use among the people to any considerable extent will be recorded and explained. Such a work would be valuable for reference for every one wishing to determine the meaning and application of unfamiliar names, but its highest value would be in its establishing a standard. It might be the work of an individual but better of an organization. However undertaken, the help would be needed of many specialists in sympathy with its objects, in every branch of botany and horticulture.

Brookline, Mass.

Warren H. Manning.

[A uniform vernacular nomenclature for all plants is, of course, desirable, but the difficulty of learning and using scientific names is greatly exaggerated. *Kalmia* for example, is now used almost as generally as Laurel, and is not more difficult to remember, and, when it is used, there is no doubt as to what plant is intended, while Laurel is used to designate at least half a dozen different plants. In one part of this country Ivy means *Kalmia*; in another it means *Ampelopsis* or *Rhus*, while the true Ivy is an entirely different plant. That Latin names may be learned and used generally, is shown by such names as *Spiræa*, *Paulownia*, *Rhododendron*, *Azalea*, *Euonymus*, *Fuchsia*, *Dahlia*, *Coleus*, *Coreopsis*, *Weigelia*, *Victoria*, *Begonia*, *Allamanda*, *Stephanotis*, *Cattleya*, *Mahonia*, *Ailanthus*, *Arbutus*, and so forth. Such names are as familiar and just as easily remembered as many vernacular names which are used indifferently, sometimes, for a dozen distinct plants, and, therefore, when used, do not convey any clear idea of the object

spoken of. Latin names only appear pedantic when they are unfamiliar, and while it is, of course, undesirable to substitute a Latin for a common name, which has become a recognized part of modern language, it might be a misfortune if English names were invented for all newly discovered or introduced plants, in addition to the Latin ones, bestowed upon them by scientific botanists, and as easy to learn as new English names.

In the case of new varieties of garden plants, an English name is preferable to a Latinized one, and the custom of giving such names now prevails, or should prevail. One reason for this is that these varieties may be distinct, for garden purposes, while they are practically identical in botanical characters, so that they do not deserve distinct botanical names.—Ed.]

Bits of Color.

To Editor of the GARDEN AND FOREST:

Sir.—We all return to the city too soon for the full glory of the foliage, but in August, even, there is much beauty to be seen. Autumnal coloring is not an effect of frost; it is rather a ripening as of the cheek of an apple. Frost withers, oxidation colors, so, at this comparatively early season, one will note elegant bits of color. A Sugar-Maple, otherwise green, will show one branch of glowing crimson. We have no Oaks, or Walnuts, or Chestnuts here, but the Elms grow yellow or russet. The wayside Ferns are rich in umber or sienna. The Ostrich Fern throws up its rigid plume of dark olive-green.

Some of the deepest colors I have noticed are afforded by the leaves of wild Sarsaparilla (*Aralia nudicaulis* and *A. racemosa*). These are of a very sombre purple. The same is true of the Virginian Anemone, whose tall fruit spikes along the roadsides look not unlike cannon sponges. In any account of autumnal colors the Golden-rods must be included. Here they abound and give a mellow glow to whole hillsides. They nod over the borders of forest-trails, and are of infinite variety of form, strict spikes, graceful wands, or broad, flat cymes. The Asters, too, begin to light up their pale stars of blue or white. Among the fruits we have the scarlet of the ever-present Bunch-berry, the fine red globes of the *Viburnum Opulus*, the deep-blue clusters of the *Clintonia*, or the single glowing pod of the *Trillium*. Some flowers have a second blooming. Thus we see everywhere the acrid or tall Butter-cup in flower, and we have even found the dwarf Cornel and the pretty *Linnaea*. Its English name of Twin-flower, it shares with the *Mitchella*. Everywhere before the houses here there is a tree of Crab-apples, very rosy and charming. They are, apparently, grown only for ornament. Regretfully we record a bit of vandalism: the ruthless mowing down of the wayside shrubbery. It is with a pang that we see this reckless destruction of lovely masses of foliage, the graceful Sumach, the feathery Ferns, young Alders, Osiers, *Viburnums*, Elders and Cherries. What a misapplication of the word improvement! Last year, in Orange County, New York, we were told that such destruction was enforced by law. If such is the case it is time to look after the law-makers.

Sugar Hill, N. H.

W. Whitman Bailey.

Recent Plant Portraits.

Botanical Magazine for August:

STAPELIA GIGANTEA, t. 7068; the great flowered species discovered thirty years ago in Zululand, and more lately found in Namaqua Land, on the opposite side of the African Continent. The corolla is twelve to fourteen inches broad.

CATASETUM GARNETTIANUM, t. 7069; one of the Orchids which have so much scientific interest on account of variation of the perianth, due to sexual dimorphism.

GREVILLEA ASPLENIFOLIA, t. 7070; a species sent from New South Wales early in the present century, and well-known in green-houses.

BERBERIS ANGULOSA, t. 7071; a rare Himalayan species with the largest flowers and fruit of any of the thirteen species found on that range. In Sikkim it is a shrub four feet or more in height, and growing at elevations of from 11,000 to 13,000 feet, where it forms a striking object in autumn from the rich golden and red coloring of its foliage. The fruit is edible and less acid than in the common species.

ANOIGANTHUS BREVIFOLIUS, t. 7072; an acceptable addition to cultivated Cape bulbs. The perianth is a bright yellow, an inch to an inch and a half long.

Notes.

The occurrence of morphine in *Eschscholtzia Californica* has been recorded by Baudet and Adrian.

It is noted in several instances this year that where Potatoes were fertilized with potash salts the blight has been less prevalent.

Professor Bailey reports in the *American Garden* that the Crandall Currant has decided merits as a fruit for the home garden. It is hardly a "fixed" variety, however, and only the best plants should be used as stock for propagating.

Colonel Pearson writes that the copper sulphate mixtures have again proved themselves preventive of both rot and mildew even in this exceptionally wet summer. The grape-crop about Vineland is, however, almost a total failure, even where the clusters were bagged, and bagged early.

A black-seeded Maize, with cobs of various colors, from Bolivia and Mexico, interests American visitors at the Paris Exposition. In Bolivia this grain is used for making *chica*, the popular fermented beverage of the country, as, indeed, of most of the South American republics.

The annual Chrysanthemum Show of the New Jersey Floricultural Society will be held at Orange on the 12th, 13th and 14th of November. The President, Mr. James R. Pitcher, of Short Hills, New Jersey, has sent us a schedule of premiums, which are liberal, and the exhibition promises to be one of exceptional merit.

Professor Arthur has discovered that the red Wheat-rust is not a stage of the black rust (*Puccinia Graminis*), as has been generally held, but of *P. Rubigo vera*, a rust which does not need the Barberry go-between for its reproductive stages. This relieves mycologists from some awkward attempts to explain how there happens to be so very much rust on the grain where there are so few Barberries.

The French Government has made Professor C. V. Riley a Chevalier of the Legion of Honor as a deserved compliment for his effective studies in economical entomology. His researches have not only been of advantage to the farmers and fruit-growers of the United States, but he discovered that the phylloxera was an American insect, and identical with the pest which had proved so disastrous to French vineyards. He also introduced into France the spraying-nozzle which bears his name, and which, with certain modifications, is used in that country to counteract the mildew of the vine.

Professor Beal finds that the peculiar markings in birdseye Maple do not occur in young trees up to about three inches in diameter, nor very high up in trees which are very much pitted at the base. A specimen taken fifty feet above the ground showed no trace of birdseye, while another from near the base of the same tree was very strongly marked. If the cause of these formations could be discovered and used to produce the marks it would add greatly to the market value of the timber, for the wood of this Maple and of other trees somewhat similarly marked is comparatively scarce and in great demand for veneers.

Mr. Charles H. Shinn warns us that when the California papers give accounts of immense Redwood trees that have been cut, they too often refer to the giant Sequoias. There are many specimens of *S. gigantea* in the Sierra forests of Fresno and Tulare, and they are being destroyed rapidly and their timber sold as redwood in the San Joaquin Valley. The so-called Redwood which was stated to be twenty-eight and a half feet in diameter was probably one of these trees. The famous Felton Redwood is twenty feet in diameter and 366 feet high; and, although there may be stumps of Redwood with a diameter exceeding this, Mr. Shinn does not know of any larger tree of this species, *S. sempervirens*, now standing in California forests.

The first section of the Charles River Embankment, an important feature of Boston's public park system, is completed. It lies between the two lower bridges to Cambridge, with a length of half a mile. It adjoins a crowded quarter chiefly occupied by the tenement-house classes, and is of great sanitary value. Mr. Olmsted's design is appropriately simple; it comprises the elements of a wide promenade along the river-wall, adjoined by slopes of turf with masses of trees and shrubbery, mostly of common native species. There are two landings, with floats for boats and steam-launches. At one end of the embankment is a public open-air athletic institution, called the Charlesbank Gymnasium, the first of its kind in

America; it has already proved a great success. At the other end an exercise place for women and girls is to be laid out.

A correspondent, whose patience has been tried in the matter of labels for such plants as Gladioli, Irises, and the like, writes that her gardener has hit upon a contrivance which has proved a great comfort. He takes a stout bit of telegraph-wire, some two feet long, bends it to a ring at the top, which is secured by a few spiral twists, leaving a straight, slender metal rod, with an eye at one end. This is thrust down deeply beside the plant, and a wooden or metallic label is attached to the eye with a fine copper-wire. The rod and eye is not a new device (*GARDEN AND FOREST*, vol. i., p. 146), but this method of constructing it will be new to many readers, and they will find it better than tall wooden sticks, which get pulled out or broken off. There are many plants to which labels cannot be satisfactorily attached, and if the wire is set in firmly it will remain as long as the plant by its side.

Professor Scribner read a paper, at Toronto, before the Society for Promoting Agricultural Science, in which he spoke of the Grasses on the bare summits of the southern Appalachian Mountains. These treeless domes, concerning which Professor Plumb not long ago wrote an interesting letter for *GARDEN AND FOREST* (p. 382), are called by the inhabitants "Balds," or "Grassy Balds," and are highly prized as grazing lands. Professor Scribner found twenty-five species of Grasses on Roan Mountain, many of them, as for example Timothy and Orchard Grass, evidently introduced, but now naturalized. The greater portion of the turf, however, was formed of Mountain Oat-grass (*Danthonia compressa*). Where this grass occurs in quantity in New England it is taken as a sign of poor or worn out land, but on these mountains it deserves the highest consideration. The condition of the stock which grazes on these meadows among the clouds proves the value of this grass as a food, and an analysis made by Dr. Stone, of the Tennessee Experiment Station, shows that it contains forty per cent. more of protein and fifty per cent. more of fat than Timothy or Orchard Grass.

Professor Burrill has detected a new bacterial disease of Indian Corn which shows itself first in a dwarfed condition of the young plants over areas varying in size from a few square rods to an acre or more. After the tassels are formed, the disease may be found scattered throughout the field in single plants; the affected stalks, and especially their lower leaves, being yellow and smaller than the healthy ones. In anything like severe cases, at least half of the roots are injured and often dead, the lower portion of the stalk will be found dead or dying, and presenting a dark color when split. The disease organisms are found in great numbers on, and within, the affected parts, in many cases collected in gelatinous masses consisting of the bacteria held together by a stiff mucilaginous substance which they exude. Too little is known of the disease to suggest any remedy, but as it is probable that the germs live through the winter in the soil, the young Corn would be liable to suffer more if planted in fields where the disease had prevailed the year before. It is noted that the disease is usually the worst where Corn has succeeded Corn. •The disease is a very prevalent one, and may have existed for a long time. It is not always destructive enough to attract attention, but not infrequently it occasions very serious loss.

Mr. B. E. Fernow, Chief of the Forestry Division, read a paper at the late meeting of the American Association for the Advancement of Science, at Toronto, on National Interest in National Resources—a subject suggested by recent action on the part of the Government in regard to irrigation and persistent inaction in regard to the forests of the national domain. Mr. Fernow showed very clearly why our forests constituted one of our national resources, which demand the continued care and fostering administration of the state. In commenting on the fitful and illogical way in which the nation deals with its resources, Mr. Fernow said: "While our Government is ready to go to war in order to protect its fisheries, it has never even known the value as food-supply of the game which has been killed. Whole races of animals have been extirpated before there was population enough to require the meat. While with one hand we pay exorbitant prices in land and wasted energy to get the plains re-forested, and that with poor success, with the other hand we offer a premium for forest-destruction in mountains by leaving them without proper administration. And now we propose to establish irrigation-systems, neglecting to provide first for those conditions which assure a regulated water-supply—namely, by forest-preservation."

The Landscape-Gardener and the Architect.

MONSIEUR Edouard André, one of the foremost landscape-gardeners in Europe, not long ago wrote for the *Révue Horticole*, of which he is joint editor with Monsieur Carrière, an interesting article on "Ornamental Buildings for Parks." He seems to feel that the English, with their love for the picturesque in architecture, have attained greater skill in this direction than the French, who are closely wedded to monumental and symmetrical forms of construction. The building in Sefton Park, Liverpool, which is illustrated in the *Révue*, does not, however, seem very excellent to American eyes; and if it is a fair representative of its class we may believe that foreign students could learn much by studying good examples of rural architecture in this country. But the passages to which we invite special attention are those in which M. André speaks in a general way of the relations of the landscape-gardener to the architect. To arrive at the perfect realization of those ideals which should guide in the design of lodges, pavillions, bridges, kiosks, and other buildings needed in a great park, it is needful, he says, that the landscape-gardener should be informed with regard to the principles of the art of building; otherwise he will be in a false situation and his influence will be null. He then proceeds to say:

"I know that here I touch upon a delicate point which has often embarrassed my confrères as well as myself. It has often happened—it happens constantly—that they find themselves in rivalry with architects who are averse to considering the designers of parks and gardens as true fellow-artists, or to treat with them on conditions of amicable equality. If the client, confiding in the taste of the landscape-architect whom he employs, asks him to furnish the architect charged with the construction of the dwelling with ideas relating to the accessory constructions in the park, it happens very often that the latter exhibits an evident, or dissimulated ill-will. Either he will execute badly, if he has no talent, the projects of the landscape-architect, or he will refuse to translate the ideas of another, and will secretly recast these projects in order to impress upon them his personal touch. What is the remedy for this?

Plainly to force respect and confidence by one's individual merits. If landscape-gardeners prove themselves to be sufficiently instructed in the art of building; enlightened by an elevated artistic sentiment, the fruit of their studies, their travels, and the comparisons and applications which they have drawn from them; capable of defending their projects to specialists, and able also to carry them well into execution, the opinion of architects will change, and my fellow-workers will advance in public esteem. I may add that our clients and their parks and gardens will likewise profit through a more fitting adaptation of ornamental details to the general effect by means of works in which science and taste will everywhere appear closely united."

Now it is true that the landscape-gardener should know something of architecture. Much of his work in connection with buildings is more closely related to architecture than it is to gardening. But there certainly is an equal necessity that the architect should acquaint himself with the principles of designing gardens and with the landscape-gardener's ideals, processes, and needs. In the discussion which followed the address of Mr. Eliot before the Massachusetts Horticultural Society, from which we quoted at length a few weeks ago, one gentleman argued that the proper way to secure unity in the "house-scene" is for the same artist to design the house and lay out the grounds. But this remark shows an imperfect appreciation of the requirements of both the arts in question. We can conceive it possible for the same person to be skilled in both, but the genius and industry which would be required to master and successfully practice two such complicated arts will rarely be found. What is really demanded is a hearty recognition of the importance of each of the two by the masters of the other, and the development of a spirit of brotherly concord, with an intelligent appreciation of both on the part of the client.

The architect, at least, should know enough of the scope and purpose of landscape-gardening to know that he can be materially aided by an artist trained to look at a building and its surroundings primarily from a different point of view from his own. There need be none of the antagonism suggested by Monsieur André in an associated plan of house and grounds. If a landscape-gardener first makes his study of the ground and suggests the proper location for the house, gives reasons why certain rooms should look in a given direction, and explains why the main entrance should be in a particular place, this need not limit or fetter the architect, but rather furnishes him with a secure basis upon which to make his own studies. In examples of actual practice which have come within our knowledge the result of such co-operation has not only been most successful as a whole, but the architect has recognized the fact that he has been aided to do more effective work in his special department. If either artist is consulted before the other, the landscape-gardener has the prior claim, especially when the grounds are of considerable size or when they are rugged and broken, as they are apt to be in the suburbs of eastern cities after the smoother and more regular lots have been occupied. We recall one instance where the approach-road to a suburban villa was constructed before an architect was selected. But, of course, the preferable method is to associate the landscape-gardener with the architect in the preliminary studies, so that there will be no discord between the designs of the dwelling and of its surroundings, but a unity of purpose which will not only make the place more attractive to the eye but more completely adapted to the wants of its owner.

It should be added that co-operation of this kind saves expense. By this we mean more than is meant by the mere statement that it pays as certainly to secure the advice of a landscape-gardener as it does to employ an architect. What a competent artist gives is always worth more than it costs. But, besides this, there will be usually found a direct saving in matters of construction—even in details of the building, and especially the adjuncts of the building. How much might have been saved is too often measured by the costly work which needs to be done when

the landscape-gardener is called in and asked to adjust its surroundings to a house after it has been built. This attempt to correct errors that might have been avoided is the most unsatisfactory and thankless of tasks. Too often these mistakes are beyond any sufficient remedy, or the expense of even partial correction may be excessive, and in either case the reputation of the artist and his art is unjustly called in question.

The *American Cultivator*, of Boston, under the title of "Practical Forestry," publishes some remarkable statistics from the pen of Mr. John D. Lyman, of Exeter, New Hampshire. "Taking," he says "the present forest-area of the United States as given in the latest reports of the Agricultural Bureau, and leaving the vast forest-covered regions of Alaska out of the question, and only reckoning 5,000 feet board measure to the acre, and assuming that our population is now 60,000,000, we have now ready grown and fit to cut 40,500 feet of lumber to every man, woman and child in the United States, or 222,700 to each family." Of the lands considered forest-covered, in the returns made to the Department of Agriculture, a considerable portion, such, for example, as the wood-lots connected with farms in most of the settled parts of the United States, contains no merchantable timber whatever; while in those sections of the country, still little changed by settlement or cultivation, the stand of timber over large areas of so-called forest does not average anything like 5,000 feet to the acre. Mr. Lyman must have discovered somewhere within the limits of the United States some unusually heavy timber to bring up his average to his moderate amount of 5,000 feet an acre. We should have supposed fifty feet an acre, taking the whole area covered with trees, to be nearer the mark. But Mr. Lyman is evidently accustomed to big timber, for he goes on to doubt, speaking of economic tree-planting in Massachusetts, if there is a man "in the state who has grown from seed or from trees set out 50,000 feet, or even 25,000 feet, of good timber to the acre." As it is less than sixty years since the first large plantations were made in Massachusetts, Mr. Lyman is probably correct. But such statements are hardly necessary to enforce Mr. Lyman's position that "the timber-crop per acre can be increased by the practical arts of forestry, the same as our grain supply has been increased, simply by knowing how to do it. The work, however, needs to be done on existing forests, and on lands adapted by nature to forest-growth." No one who has studied the forest-question in the United States will now deny that the care and improvement of existing forests, growing upon lands unfit for any purpose but the production of timber, is vastly more important than the creation of new forests by planting trees on lands adapted to other crops of more immediate productiveness. But while the forests are being made more productive, there is not a family in the United States, which will not feel happy at the thought that its quota of merchantable lumber is 222,700 feet board measure.

Drives and Walks.—II.

IT has been shown that, except in rare cases which are not likely to occur at all in this country, it is better that the approach to a country house in a place of any size should be curved rather than straight; but also that it should not meander about in an irrational way, injurious alike to convenience and beauty. It should not look as though the display of the various beauties of the property or the formation of graceful curves were its main object, while the conveyance of visitors to their destination was a secondary one; nor, on the other hand, should it be laid in a mathematical line, straight towards this destination, with a rigid disregard for surrounding objects. A happy mean between these two extremes is what is wanted—a line that is direct enough to seem sensible, and yet curved enough to be beautiful as well as easy for wheels.

Sometimes its bends will be dictated by conspicuous irregularities in the surface of the ground, or by existing trees, which

it is desirable to preserve. Then they will be evidently rational, and, if well drawn, entirely pleasing to the eye. But sometimes there will be no such reasons for curvature, and yet curvature will be necessitated by convenience in driving and the general desire to avoid too stiff a line. In such cases a good landscape-gardener will make the curves seem natural by some device of his own—by altering the surface of the ground or by planting. When his work is done, and time has assisted it a little, the effect should be the same as though nature had prescribed the line of his drive. The road may have been the first consideration, and the objects which govern its course merely later adjuncts; the curve may have been the necessity, the hillock, the tree, or the group of shrubs a device to excuse it. But the eye need not realize the fact—the surface irregularities and plants may be made to seem the cause, and the curve the natural consequence. To secure such a result is one of those artifices which are inexcusable if they fail of the right effect, but which are the highest art—the art which conceals art—if they produce this effect. It is an artistic defect to make too palpable an attempt to disguise the utilitarian character of a road as a means of transit from one given point to another; but it is an artistic triumph to make it look as though, while affording such transit with reasonable directness, it had chanced to take a course that is beautiful, too. Of course, while the careless observer will be deceived by the apparent naturalness, and its methods and results, the student of art will know that chance has had nothing to do with the matter; but his eye will accept the appearance of happy accident and his mind will enjoy it all the more for knowing that the hand of an intelligent man has been at work.

But to make the curves of a drive look natural it is not sufficient that they should have some visible reason for existing. The objects which supply the reason must themselves look natural or the artificiality of the whole arrangement will at once be plain. To throw up a hillock or plant a tree or a group of trees or shrubs in a spot where it will deflect the road will be futile, unless it looks as though, for other reasons, it ought to be there, and to look thus it must compose well with the features around it and play an acceptable part in the general aspect. The hillock must blend and harmonize with the general conformation of the ground, and the plants must form agreeable masses—not too large for their places, nor so small as to look as though they had been dropped down by accident—and must usually be supported by other plantations in their vicinity. On a lawn, which is large enough to be crossed by a road at all, there will be space for other trees and shrubs besides those which may immediately border the road; and all should be so arranged that the eye will be convinced that if the individuals which seemingly force the road to curve had been removed the effect of the remainder and of the prospect as a whole would have suffered. They should seem to have stood, before the road was built, in places where they were needed as items in an harmonious picture; and the road should seem to have respected them for this reason. Nor is it needful that every deflection in the road should be excused in just this way. For example, the approach may diverge to the right to avoid a beautiful tree; if it must then turn again to the left to reach the house in a convenient and pleasing way, this fact is its own sufficient explanation and excuse.

Whatever the objects chosen to justify the bends in a road, they should not be flower-beds. Anything which forces a carriage to turn from the direct path should be a real and a permanent obstacle—something over which wheels could not pass, and which could not be removed without destroying it. To make a flower-bed play the part of an obstruction to vehicles gives a deplorable look of triviality and wilfulness; yet there are few objects so often seen in the bend of a road that crosses a lawn. The truth, probably, is that the road has been curved without thought of supplying a reason for the curve, simply because it could not be carried straight or because of a belief that a curve, managed in any way, would be beautiful; and then the flower-bed has been thought of because the elbow in the grass seemed to offer a "good place" for it. But its trivial, ephemeral nature is not the only reason why a flower-bed is unsuitable in such a position. A lawn which is large enough to be crossed by a road has a somewhat park-like character, and in a park-like landscape a flower-bed is utterly out of place. The crude bright spot it makes is disagreeable enough in a small expanse of lawn, but doubly disagreeable when there is so much space that an effect of broad unity, of rural repose and peace might be secured. And where a flower-bed is out of place, so, too, of course, are small, isolated plants, and especially those which have evidently been brought from the green-house and must soon be returned to it.

The Art of Gardening—An Historical Sketch.

X.—Greece (Continued).

FROM what has already been said with regard to the paucity of descriptive writing of any kind among the Greeks, it will be understood why it is difficult to divine just how their gardens were disposed. That they were largely formal in arrangement cannot be doubted. Such was clearly the case in public gardens like the Academy and Altis at Olympia; and the nature of the Greek mind, the way in which it conceived all kinds of beauty, indicates that the art which entirely conceals art could not have been its ideal even in the most private pleasure-ground. But by a Grecian orderliness and balance we need not understand an Egyptian rigidity of design. A certain measure of symmetry and architectonic dignity must have been desired; but grace, too, was essential to the Greek, and the symmetry he loved did not exclude variety. Even a discreet degree of picturesqueness may well have added charm to his garden effects, as is implied, indeed, by the fact that grottoes were used no less than formal basins in which swans disported themselves. From the character of his other works of art we may believe that he planted his trees now in parallel lines, but now in well contrasted varied groups; that he never clipped them into unnatural shapes, and never objected to a graceful irregularity of growth if it did not pass into patent eccentricity or combine in awkward ways with the omnipresent architectural forms.

The favorite ornamental tree with the Greeks was the Plane, on account of its thick, wide-spreading shade. The Pine and the Cypress stood next in favor as garden-trees. The funereal significance of the Cypress, recognized by all the ancient peoples, as well as by the Orientals and Europeans of our day, probably had its origin in Persia. Here it was believed that the first Cypress came direct from heaven to Zoroaster, and the tree was regarded with peculiar reverence as symbolizing by its pyramidal shape the flames which were worshipped as themselves the emblem of the "principle of light." In Greece, as elsewhere, the Cypress was constantly planted by tombs, and was prominent along those suburban streets which were lined with the monuments of the honored dead. But it was thought no less appropriate for pleasure-gardens, where its formal outlines harmonized well with architectural features. It appears, too, that tombs were sometimes placed in gardens. Lycurgus, the orator, is said to have been buried in a private garden at Athens.

The Oak was another favorite and sacred tree; so, too, the Poplar. The reverence bestowed upon the Olive, and its part in the story of the founding of Athens, need hardly be referred to. But it may be explained that Olives and fruit-trees of all kinds were regarded by the ancients as garden-trees, and often formed the temple grove. No such line as we draw to-day was then drawn between useful and ornamental trees, or even, it seems, between vegetables and flowers. Plutarch even declared that the best way to show the beauty of Roses and Violets was to plant them, for contrast, among Cabbages and Onions. No shrub was more beloved in Greece than the Myrtle and the Laurel, needed for many religious rites, and no flower more than the Violet, the flower of Athene, the emblem of Athens itself, the "City of the Violet Crown."

It is impossible to decipher from the curtness of contemporary records just where or how flowers were grown for sale in Greece, although mention is made of their cultivation near temples, and flower-markets were held at stated intervals in the squares of Athens. It was only in later days, however, that they were profusely used. The simple taste of early times desired no more striking ornament than a crown of leaves. Coronals of flowers, says Pliny, were not employed until about the 100th Olympiad—B. C. 380. Nor at any time had the Greeks a great variety of flowers. Roses, Lilies, Hyacinths, Violets, and the blossoms of fruit-trees and shrubs were those with which they were most familiar.

By the time of Alexander, the Persian love for gardens and parks, with many other forms of luxury, had obtained a strong foothold among the Greeks, especially in their wealthy colonies; and wherever the conqueror's footsteps are followed we read of admiration for the works of the Persians and of a desire to imitate them in new constructions. When Harpalus was left governor of the province of Babylon he was desirous, says Plutarch, "to adorn the palace gardens and walks with Grecian plants, and succeeded in raising all but the Ivy, which the earth would not bear, but constantly killed."*

* "But such digressions," adds Plutarch, "the impatient reader will be more willing to pardon if they are kept within a moderate compass." The modern reader would be less impatient if the compass had been wider! Diodorus, by the way, tells that when they were returning from India, where likewise the Ivy did

When the city of Alexandria was laid out "in the form of a plethrum or military cloak," its vast palaces and public buildings were surrounded with squares and gardens to such an extent that, buildings and grounds together, a third of the space within the walls was absorbed. Dinocrates (or Dinocrates) was the architect to whom the work was confided; and it was he who conceived the idea of carving Mount Athos into a statue of Alexander "with a city in the right hand and a reservoir of mountain streams in the left." Is such a scheme entitled to be ranked among landscape-gardening designs? And if not, where shall we place it? for it can hardly be called engineering, since beauty, not utility, was the main object in view. At all events it remains the most ambitious idea that was ever conceived with regard to the adornment of the surface of the earth.

Lucian tells us that at Cnidos there was a great pleasure-ground dedicated to Venus, where even "distinguished citizens" enjoyed themselves on the verdant meadows, and where the common people came in crowds on holidays; and he mentions its Cypresses, Planes and Myrtles. In Sicily, where luxury went hand in hand with tyranny, gardening seems to have been practised in an especially sumptuous way. Dionysius of Syracuse had famous gardens where his feasts were held; one of the Hieros built a war-galley in which the poop-deck was covered with earth and beautifully planted; and some modern writers have thought that the famous quarry-pits near Syracuse, where the Athenians perished in agony, were afterwards planted as pleasure-gardens.†

About 300 years before Christ, Kotys, King of Thrace, "took his pleasure by a cool stream" in a forest through which he had built "level roads." A hundred years later, near Athens itself, Herodius Atticus possessed a villa surrounded by large forests, which is spoken of by Aulus Gellius in his *Attic Nights*; and when Xenophon retired from his native country to Scillus, near Olympia, he erected an exact copy, on a smaller scale, of the temple of Diana at Ephesus, surrounded it with a similar "grove of cultivated trees bearing whatever fruits are eatable at the different seasons," and had spacious hunting-grounds in its vicinity.

Notes Upon Some North American Trees.—X.

172. MYRSINE RAPANEA, Roem. and Schult. This plant does not appear to assume anywhere in Florida an arborescent habit, and there seems no reason for retaining it in the American *Silva*.

180. BUMELIA SPINOSA, A. DC. Professor Gray, in the second edition of the "Synoptical Flora of North America," reduces this so far as relates to the Texas and Arizona plant to a variety of *Bumelia lanuginosa*,—the var. *rigida*.

182. BUMELIA CUNEATA, Sw. The Florida and west Texan tree, which has been referred to this species of Swartz, is not, it appears (Gray, *l. c.*), that plant; and Professor Gray has, therefore, taken up for it Nuttall's name, *B. angustifolia* (Sylva iii., 38, t. 93). *Bumelia reclinata*, Torrey (Bot. Mex. Bound. Surv.), not of Ventenat, a small tree of the Rio Grande Valley (Harvard in *Bull. U. S. Nat. Mus.* viii., 510) is referred to this species.

FRAXINUS CUSPIDATA, Torrey. This handsome Ash of the section *Ornus* must find a place in the *Sylva* immediately before *Fraxinus Greggii*. Often a shrub, especially towards the northern limits of its distribution, in Texas, notably in the mountain cañons of Chihuahua, it becomes a handsome tree, with a trunk six to eight inches in diameter (C. G. Pringle, in *GARDEN AND FOREST*, i., 142); and I have seen it nearly of the same size in the neighborhood of Saltillo.

189. FRAXINUS GREGGII, Gray. This species is abundant on the high slopes of the Sierra Madre, near Monterey, where it becomes sometimes a handsome small tree. Our illustration upon page 451 of this issue, made from a photograph taken last summer by Mr. Pringle in these mountains, will serve to give an idea of the habit of this tree and of its surroundings on the Sierra Madre.

not grow, Alexander and his body-guard made a long excursion to see a mountain where it flourished, and spent a day in Bacchic ecstasies and banquets, so great was their pleasure at beholding it again—a statement which certainly implies a strong love for the beautiful products of nature.

† Franz von Löhner: "Sizilien und Neapel." For a description of the present aspect of these quarries and their luxuriant vegetation see Symonds's "Sketches in Italy and Greece."

199. *FORESTIERA ACUMINATA*, Poir.—This plant, which I have seen growing with great vigor and luxuriance in different places in western Louisiana and in eastern Texas, hardly merits the title of tree, which was given to it in the Census Catalogue. It is rather a tall, broad shrub, with slender, spreading and recurving branches. It may be properly dropped from the *Silva* of North America.

Foreshiera reticulata, Torr., is reported by Dr. V. Harvard to grow as a small tree on the rocky slopes of the great cañon near the mouth of the Pecos River.

216. *NECTANDRA WILLDENOVIANA*, Nees. The oldest name of this plant seems to be *Laurus Catesbyana*, Michaux (Fl. Bor. Am., i., 244), for the *Laurus sanguinea* of Swartz (Fl. Ind. Occ., ii., 707) includes, according to Meisner (Prod., xvi., 165), two different plants; and it does not appear that *L. cyathifera*, Vahl. (Meisner, l. c.), has been published. *Nectandra Catesbyana* would seem, therefore, unless some older specific name can be found, to be the one to adopt.

219. *DRYPETES CROCEA*, var. *LATIFOLIA*, Müller. This is a very different plant from *D. crocea*, with snow-white bark, larger, thicker, and more lustrous leaves rounded at the apex, flowers with a single stigma, and oval, large white fruit an inch long, so that the original name of Vahl. (Eclog. Amer. 2, 119) *Drypetes glauca*, to which it was correctly referred by Nuttall (Sylva ii., 68) must be restored to it.

220. *SEBASTIANA LUCIDA*, Müller. The perianth of the male flowers is rudimentary in our plant, so that it must be restored to *Gymnanthes*, and so becomes *Gymnanthes lucida* of Swartz, the first name under which it was described.

223. *ULMUS FULVA*, Michx. Walter's *Ulmus pubescens* has been considered to be this species. The name is much older than that of Michaux, but Walter's characters leave it uncertain what plant he had before him, and his name cannot safely be taken up.

229. *FICUS AUREA*, Nutt. A specimen in the Kew herbarium collected by Brace (No. 356) in New Providence in 1879 shows that this common south Florida tree is also, as was to be expected, an inhabitant of the Bahamas.

230. *FICUS BREVIFOLIA*, Nutt. There appear to be only two indigenous Fig-trees upon the Florida Keys, *F. aurea*, with leaves pointed at both ends, and sessile, or nearly sessile, fruit, and a plant with cordate leaves and small, flattened pedunculate fruit, which is first yellow, but becoming scarlet at maturity. The peduncles vary considerably in length on the same plants. It is represented with yellow fruit in Nuttall's *Sylva* as *F. pedunculata* (t. 41), and with red fruit on shorter peduncles as *F. brevifolia* (t. 42). But the *F. pedunculata* of Nuttall is not the *F. pedunculata* of Aiton, but the *F. populnea* of Willdenow (vide Herb. Kew), the name which, unless some older one can be found for Willdenow's plant, must include *Ficus pedunculata* and *F. brevifolia* of the Census Catalogue and of Chapman's "Flora of the Southern United States."

232. *MORUS RUBRA*.—The variety of the Red Mulberry, first described by Rafinesque (Flora Ludoviciana, 113), with the under surface of the brighter green leaves covered with white tomentum (although the fruit is certainly not white, as Rafinesque described it),—the var. *tomentosa*, Bureau in DeCandolle's "Prodromus," xvii., 246, is common in western Texas. This is the large Mulberry-tree which abounds on the banks of the San Antonio River near its source; and I have collected it at Boerne, on the Guadalupe. The large Mulberry-tree (probably planted) in the Public Square at Laredo, on the Rio Grande, is of this form.

233. *MORUS MICROPHYLLA*, Buckley.—This Texas plant is not distinguishable from the common Mulberry-tree of Mexico and Central America, *Morus celtidifolia*, HBK, which is very common in the valley of the lower Rio Grande south of the river; and Buckley's name should disappear except as a synonym, although the Texas plants, as is natural, have generally smaller leaves than those on trees growing in the moister and more fertile Mexican valleys.

New or Little Known Plants.

Aster Lindleyanus.

THE handsome Aster which is figured for the first time upon page 449 of this issue is one of the latest additions to the flora of New England, having been first detected within its borders three years ago by Mr. Faxon, at Shelburne and Franconia, in the White Mountain region, and last year by Mr. E. L. Rand on the Island of Mount Desert, off the coast of Maine.

*Aster Lindleyanus** is a showy species, with stout stems ten to twenty inches high, the lower leaves ovate and obscurely cordate, with winged petioles, the upper oblong-lanceolate, the uppermost sessile and acuminate at both ends. The flowers, with pale violet rays a quarter to nearly half an inch long, are large and comparatively few, in loose panicles terminating the stems. This species is found from Labrador to the northern shores of Lake Superior, the Saskatchewan and the borders of British Columbia. It was first made known many years ago, from plants raised in England from seeds gathered in Labrador, but it has probably long ago disappeared from gardens.

Foreign Correspondence.

The Lindens for City-Planting.

THIS is the first warm summer we have had for many years. Grapes ripened before the month of August, and rye was harvested before the end of June; and, in places where the rains have not failed, vegetation is extraordinarily rich and luxuriant. I have never seen the Ash and the Oak more brilliantly decked with green. But there is a reverse to the medal. In the streets and public squares of Berlin, the Lindens, one of their chief attractions, present the sombre spectacle of a premature autumn. Their foliage, browned and withered by the heat of the sun, is already falling. The tree which has proved itself best adapted for city-cultivation—the tree so delightful for the richness of its verdure and its bloom in spring and early summer, seems no longer able to play its part in great centres of population. Yet, is it wise to banish the Linden from our cities and substitute everywhere the Elm, as some suggest? Let us consider the question a little.

Many people—let me say most people—know of but one Linden. Among us, the most common and most widely cultivated is *Tilia intermedia*, DC., commonly known as the Dutch Linden, since the Holland nurseries supply it in abundance. It possesses every good quality of the genus, but is extremely susceptible to heat. Even artificial watering fails to preserve its greenness. The same is true of *Tilia platyphylla*, Scop. Each of these species has a period of extreme beauty, lasting some months, which is followed by one of melancholy decadence. This again, toward the autumn, gives place to a partial re-leaving, never, however, as in the case of the Horse-chestnut, carried to the point of a second blossoming within the year.

For its ornamental qualities *T. ulmifolia*, so common in its wild state in the north of Germany, is superior to its congeners. It has not their fine flowers and foliage, and it falls behind them in growth, but it better resists heat and drought. To be convinced of this I have only to look out of my window upon Leipzig Square, where stand the noblest Lindens of Berlin. The leaves of this species are of a bluish tint. Looking at a single specimen, almost lost among the crowd of its neighbors, I am forced to concede to it a superiority in some respects. This particular specimen has also lost some of its leaves, but it is not an eyesore like most of the others around it, which, besides their suffering from drought, have been preyed upon for two years by voracious caterpillars (*Bombyx dispar*, *Daschyra pudibunda*, and a third species, whose name I do not know). I remember having noticed similar ravages among the trees in 1883, when, as early as the beginning of July, a long drought caused the blossoms of the Dutch Linden to fall in such quantities that they were swept away in heaps. The proper remedy for this trouble is not found in the substitution of another tree for the Linden, but in the employment in future plantations of a Linden different from the species now generally planted.

The species I recommend is the Crimean Linden (*T. dasystyla* = *T. euchlora*, K. Koch). Little known as a wild tree, it

**Aster Lindleyanus*, Torr & Gray, *Flora N. Am.*, ii, 122—Gray, *Syn. Flora*, i, 2, 182.

Fig. 127.—*Aster Lindleyanus*.—See page 448.

began to find its way into Germany about twenty years ago. It grows rapidly. Its top, while young, assumes a broad pyramidal form. The stout texture of its leaves, and their glossy surface, seem to have predestined it for intra-mural

plantations. The specimens which have come under my observation have remained unharmed, while other *Lindens* have suffered seriously. It would be advisable to make a trial of the Crimean Linden in America, where its advantages

would, probably, be even more apparent than they are here.

The beauty of all Lindens is great and incontestable. In the case of the Crimean Linden, this beauty is heightened by the lustre of the leaves, which resemble those of the Beech. It also has the advantage of blooming as late as the last week in July. The tree must attain a considerable age before it blooms, which it did in Berlin for the first time in 1873. My trees at Scharfenberg are fruiting well this year, and we shall have an abundance of seed.

We have here, also, some specimens of a variety of *Tilia platyphylla*, which is remarkable for the yellow color of its young branches and buds, a peculiarity which disappears in summer, but is very noticeable in winter and early spring. This is the variety known as Aurea. I mention it here because I have learned something as to its origin. It was discovered before 1829 in a forest of Alsace, near the outskirts of Bollwiller, by M. Baumann, who also first distributed it.

Notes on Hypericums.

THE Hypericums, or St. John's-worts, embrace more than 160 described species of herbaceous and woody plants, and there are, probably, a good many more still unknown. Of the known species only a comparatively small number are of much value to the florist or gardener, although all may be interesting or beautiful from the botanist's point of view. Except in very rare cases, in which the blossoms are white, the flowers of all the species are yellow, and they vary in size from very minute ones on slender annuals, an inch or two high, to the large golden yellow blossoms, several inches in diameter, of some of the cultivated species.

They are chiefly found in North America, Europe and Asia; but a few are tropical, and some inhabit the southern hemisphere. In Europe a few of the tender species are thought worthy of green-house culture. The name of St. John's-wort is said to have been derived from the fact that the common people of some European nations, especially the English and Germans, used to gather large quantities of the flowers and ornament their dwellings with them on St. John's Day, as a supposed protection from evil spirits. The species chiefly used for this purpose and to which the name was first given was the common St. John's-wort (*Hypericum perforatum*), which is found all over Europe and a large part of Asia, and which, having become naturalized in America and spread over a large area, is now looked upon here as a troublesome weed. It is a perennial herb, and when in full bloom is certainly as handsome as some of the occasionally cultivated herbaceous or half-shrubby species. The deep yellow flowers, in large corymbs, are over an inch in diameter and crowned with many stamens, and the leaves have very distinct pellucid dots, which are plainly seen when held up to the light. These dots on the leaves are characteristic of this genus, but they vary in number and size on different species, and are often black instead of pellucid. They secrete aromatic resinous juices and a volatile oil.

The Hypericums are generally not difficult to cultivate and propagate, yet very few classes of hardy ornamental plants are so little known and so poorly represented in American gardens generally. Some of the group are particularly valuable, because they flower after most shrubs and early summer-blooming perennials have past their best condition, and before other autumn flowering kinds have developed much of their efflorescence.

A number of shrubby and half-shrubby species of Hypericums, grown in England and the warmer parts of Europe, cannot be relied upon for hardiness to withstand the winters of our New England or Northern states. But among those tested at the Arnold Arboretum are some which are thoroughly satisfactory, and others that have promised well in the short time that they have been in the collection. They have been grown in an exposed situation where there was little protection in winter and no shade in summer, and where it was, perhaps, too wet in winter and spring to give the best results.

Of the low-growing, half-woody species, *Hypericum calycinum* is decidedly the most interesting and satisfactory. The stems are less than a foot high, and although killed back to the ground every winter, new flowering shoots arise from the creeping, woody rootstocks. The large, smooth, green leaves are ovate or oblong, and have very small, pellucid dots. Rarely more than one flower is developed at the top of each stem. The handsome flowers are bright yellow, from two to three inches in diameter, and crowned with many long sta-

mens. This species is easily propagated by root-cuttings, or cuttings of ripe wood in late summer. The roots spread and ultimately make large clumps, and the plants will thrive very well either in the open sunlight or under trees, if the soil is not too poor. In the Arboretum this Hypericum begins to flower early in July, is in its best condition during that month, and bears a few flowers in August, or even later. It is a native of south-eastern Europe. This and all the other Hypericums bloom later and for a longer time if grown in a cool, partly shaded place.

Hypericum hircinum, though not so handsome as the preceding species, is a very free bloomer and is easily cultivated. The stamens are very long and of varying length, the longest being about one and one-half times the length of the broad, pale yellow petals, which are three-quarters of an inch long. The stems are killed almost to the ground in winter, and come up again each year to nearly two feet in height. It begins to flower about the second week in July and continues until near the end of August. The form known as the Minor variety is simply smaller and more compact in every way, and it seems to flower somewhat later.

H. multiflorum grows taller than the last species, which it much resembles in foliage and flower. It is more shrubby, but its blooming season is shorter, lasting for only about two weeks in July.

H. oblongifolium, a native of high altitudes of the Himalayas, has not proved very hardy, but should be further tested. It has large leaves and very handsome, golden-yellow flowers from two to three inches in diameter. Another Asiatic species is *H. patulum*, with somewhat smaller leaves and flowers. It has usually proved hardy, but, with some others, was killed last winter. *H. Androsæum*, the Tutsan or Sweet Amber of England, requires further proof of hardiness before it can be recommended here. Some of these species, as well as some others, may thrive with little care in the climate of the middle states or further south, but here they require a good deal of protection in order to give very satisfactory results.

But among the thirty known North American species are several which are perfectly hardy and also very bright and effective as ornamental garden shrubs. By far the best of these is the beautiful *Hypericum aureum*, of which a description and figure were given in a recent number of GARDEN AND FOREST (pp. 184 and 185). In cultivation it is a bushy, very much branched shrub, three to four feet high, and often more in diameter. Several flowers are usually produced on the end of each branch and branchlet, although in a wild state the flowers are often solitary. The flowers are an inch and a half, or sometimes nearly two inches in diameter, and the petals are very thick and firm, and pale yellow or orange in color. The stamens, of which a careful count shows a thousand in a well-developed flower, are a little more than half the length of the petals, and of a golden-yellow color. When the flower is first open the stamens are so arranged that they have a beautiful dome-like shape, but, after repeated visits by humble-bees, which eagerly collect the pollen, the stamens lose their anthers, become more spread out, and have something of the appearance of a broad square-faced brush. The color gradually changes to an orange-brown, and after the third or fourth day the filaments become brown and are ready to fall with the first wind or rain. Although a native of Tennessee and other southern states, this species proves perfectly hardy about Boston, where it continues blooming from the first or second week in July until the middle of August, or later if the plants are young, or are grown in a moist or partly shaded place.

Hypericum prolificum is a species found from New Jersey southward, and also westward in Minnesota, Illinois, etc. It is the American species which is perhaps most commonly cultivated in European gardens. Between this species and *H. Kalmianum* there appears to be no very great choice as to ornamental value. The latter was originally found in the vicinity of Niagara Falls, and extends over the region about the Great Lakes, and within a few years it has been reported from Middle Tennessee. In its native habitat it varies in size from a few inches in height in exposed places to a couple of feet or more in favorable situations. In cultivation it will grow about as large as *H. prolificum* which attains a height of three feet or more. Both species are quite hardy. Perhaps *H. Kalmianum* being found so far north would do best in localities where the winters are very severe. The leaves are narrow, one or two inches long, and the thin petalled golden-yellow flowers are about an inch across, and produced in single or compound clusters at the ends of the branches. The leaves of *H. prolificum* are usually larger, and the flowers more numerous, though somewhat smaller, than

in *H. Kalmianum*. Botanically the chief distinctions between these two species are the five styles and five-celled capsules of *H. Kalmianum*, and the three styles and three-celled capsules of *H. prolificum*, but, in cultivated seedlings, these divisions appear to be by no means constant, and the capsules of specimens grown as *H. Kalmianum* are sometimes three, four, five, or six-celled on the same plant or branch.

These two species and *H. aureum* have been grown together in the Arboretum, and the seedlings produced from them have shown a tendency to variation, which seems very strongly to indicate hybridization. This might result from the work of bumble bees, which, in collecting the pollen, fly indiscriminately from one species to another. These plants do not seem to be very long lived and though they may do well for eight or ten years, or more, renewals should be made every six or seven years. Young plants from seed may begin to flower the second year if well grown. With a little trouble they may be propagated by cuttings, and in this way a particularly fine form might be best perpetuated.

Hypericum densiflorum is closely related to *H. prolificum*, of which it was classed as a variety in Gray's Manual. It is said to grow five or six feet high and to have more numerous, though smaller flowers. *H. Buckleyi*, a rarer species, is found in the mountains of North Carolina and Georgia, and is described as a branching shrub about a foot in height with flowers about an inch across. These two species have not yet been grown at the Arboretum. They will probably be quite hardy, but, horticulturally, not an improvement upon, or more desirable than the species already cultivated. *H. fasciculatum*, a plant three to six feet in height, has extremely narrow leaves. It has not yet been tested thoroughly at the Arboretum.

H. sphaerocarpon,* another southern species, is hardy, though dwarf, and not very shrubby. It has large cymes of rather small flowers followed by dark brown fruit. It cannot be called a very ornamental species, and is hardly more interesting than the troublesome *H. perforatum*.

The largest fruited American species is *H. pyramidatum* which Prof. John M. Coulter, in his "Revision of North American Hypericaceæ" (*Botanical Gazette*, vol. xi, 1886, p. 83), refers

to *Hypericum Ascyron* as it is found to be identical with that European and Asiatic species. It is herbaceous, and, though interesting in a general collection, is hardly ornamental. In cultivation the stems grow five or six feet high, the flowers are large with pale thin petals, and the large conical capsules are three-quarters of an inch or more long, and half an inch in diameter.

Arnold Arboretum.

J. G. Jack.

Border Carnations.

THE specialists in Carnations and Picotees held their meeting and exhibition as usual this year in London, but the

plain fact is that florists of the ancient type—those to whom a faultless circular outline to a flower and a smooth, flat petal are matters of momentous interest—are fast dying out, and with them the cunning art of "dressing" and "tweezing" flowers so as to make them artificially conform with the models of perfection they set up for themselves. But while we see the gradual decay of the old type, we are, at the same time, witnessing the rapid and vigorous growth of the modern florist and a flower-loving community caring less for highly bred varieties, distinguished by perfect "points," than for sorts of vigorous habit, great floriferousness, and the rich and distinct colors which characterize the modern race of border Carnations, which every year become more and more popular, not only because they are so beautiful, but because everybody can grow them without extra care and coddling. Consequently we see little or no improvement among the Flaked and Bizarre Carnations year after year, while each exhibition brings to the front numerous beautiful border varieties, rich and varied in color and with strong perfume. These self-colored sorts are

Fig. 128.—*Fraxinus Greggii*.—See page 447.

infinitely more beautiful than the striped flowers, and at the exhibitions the self and fancy Carnations and the Picotees seem to win the most admirers, and at the last show this was particularly noticeable. Since the border Carnation has become such an important flower in the cut flower trade, it has been the aim of every Carnation grower to raise the best white, the best yellow, or the best scarlet, or raise some new and striking color that will take in the market. We have many good scarlets and not a few good whites, but there is still room for yellows of various shades. Pride of Penshurst, Germania and

*Since this was written, Prof. John M. Coulter, in *Botanical Gazette* (p. 200), states that *H. sphaerocarpon*, of Michaux, must now be called *H. cistifolium*, of Lamarck.

Will Threthfall are good, but we want more pure yellows, both of deeper and paler shades. We have a host of what are called yellow-ground sorts—that is, those in which the body-color is yellow, striped or edged with red or some other tint—but these are not nearly as popular as the pure colors. Among the finest whites is Gloire de Nancy, a clove-scented sort that is now as common almost as the old Crimson Clove and the Blush Clove. Probably the greatest hit that has been made of recent years in point of color was that by the raiser of the Mrs. Reynolds Hole variety, its color being distinct from any other. It is popularly described as terra cotta, but its more definite description would be apricot red. It is among Carnations what W. A. Richardson is among Roses—a color admired by every one.

Since the above was written I have found at the Messrs. Veitch's nurseries some fine novelties. One of the most distinct new whites is Elaine, whose purity of bloom and vigor of growth is admirable. A very fine scarlet is Defiance, though it is not such an acquisition as a new white or yellow would be, since there are some splendid old sorts of a similar color. A very rich crimson sort, named William Toby, is likely to prove an extremely fine hardy border plant, being free in bloom and strong in growth, while a splendid purple is Purple King.

The Clove Carnations are the best of all town-garden sorts, and the gardens of the Thames Embankment have been enriched this season by glorious masses of the old Crimson Clove, the White Clove, and Blush Clove, the latter being the most remarkable because less common. There is much discussion about the new Crimson Clove, named Paul Engleheart, on account of its sturdiness of growth and dwarfness, which does away with the necessity of staking, which is one of the objections to border carnations. If we can get a race of dwarf Carnations of various colors that would hold up their flower-stems without stakes, it would indeed be a boon. I first saw Paul Engleheart some three or four years ago, and since then I find it has become widely distributed, even reaching American gardens. I was pleased to see Mr. Gerard's favorable mention of it in GARDEN AND FOREST (p. 332), and I hope it may lead to a wider knowledge of the plant. Other sorts of similarly dwarf growth would be welcome. Mr. Robinson, the editor of *The Garden*, is devoted to the Border Carnation, and at his garden in Sussex he grows every sort worth knowing. He offers prizes for the finest novelties so as to encourage raisers, and he receives, throughout the Carnation season, an enormous lot of blooms from all directions, but he can rarely find a dwarf habited sort like Paul Engleheart.

Kew

W. G.

Notes on Wild Flowers.

THE Swamp Rose Mallow (*Hibiscus moscheutos*), still in bloom, is well worthy of cultivation, and in rich soil will grow to a height of over five feet. The plant somewhat resembles the Single Hollyhock, both in the measure of its growth and the shape and appearance of its flowers. We have heard it called the "Wild Hollyhock," which, we think, is a good name for it. The flower is rose-colored at first, changing to a paler hue, and nearly six inches wide. The leaves are two or three inches broad, nearly round, numerous, and form a pretty contrast with the large showy flowers.

The Button Snake-roots or Blazing Stars (*Liatris*) are, several of them, in flower, and their long showy spikes of purplish flowers are very pretty. *L. spicata* is the finest species we have seen. This plant grows about four feet high in cultivation, and the long, loose spikes of lightish purple flowers frequently form more than half the length of the plant. *L. scariosa* is somewhat similar in its appearance, but does not generally attain over three feet in height under cultivation. Another small species, about fifteen inches high, is *L. cylindracea*. All seem to be easy of culture. They like open sunlight and a light loamy soil. *Lobelia cardinalis* (Cardinal Flower) is one of our finest plants for cultivation. Few species equal it in richness of color. In cultivation the flowering spike is frequently over a foot long, and thickly set with its flowers. The plant is usually nearly two feet high, as seen growing naturally along our brook sides, but fully a third taller under cultivation. *Lobelia syphilitica* (Great Lobelia), also in flower, is two to three feet high, with light blue flowers in loose spikes about a foot long. The leaves are about four inches long by half an inch or more wide, and are quite numerous along the stem below the flowering spike. The plant seems to do well in either shade or sun.

The Whorled Milkweed (*Asclepias verticillata*) is nearly past flower. Under cultivation it grows about eighteen inches high,

bearing in numerous small umbels its purple and white flowers. The numerous leaves are long and narrow, tapering to a pointed end. The seed pods are erect, nearly six inches long. The plant is quite pretty and easy to grow.

Cassia Chamæcrista (Partridge Pea) is an annual which, in rich soil, often grows two feet high. The plant is spreading in its habit, branching from the bottom, and bearing in great abundance its bright yellow flowers, which are about an inch wide. But the beautiful foliage of the plant, which is very delicate, is quite as much of an attraction as the flowers. The leaflets, a dozen pairs or so, have an odd habit of folding themselves up at night, and then opening out again in the morning at sunrise. It is easily grown from seed, and is a valuable plant.

Another beautiful annual is the California Poppy (*Eschscholtzia Californica*). The decumbent stems are about eighteen inches long. The foliage is a light green, delicate, and very beautiful. The flowers, which are borne in great abundance, are nearly two inches wide, bright yellow, with a reddish centre, somewhat resembling those of a yellow Calochortus. Few annuals of our choicest collections can be compared with this for beauty when grown on a rich and moist sandy loam.

Many of the Wild Asters or Starworts are now in flower, and they give us much more variety of color, though scarcely more numerous in kinds, than the Goldenrods. One of the finest is the *Aster laevis*, which generally grows from one and a half to three feet high, bearing a loose head of beautiful sky-blue flowers, which are three-quarters of an inch, or more, wide. It grows on sandy soil, and takes readily to cultivation. *A. Nova-Angliae* is a stout species, often seven feet high, very leafy throughout, and bearing a large corymb of violet-purple flowers about an inch wide. The plant is a very showy one when at its best. *A. ericoides*, fully a week later in flowering, has firm, light green foliage, and a profusion of pretty white flowers half an inch wide. This species grows about two feet high, and, planted in beds, forms a solid mass of fine foliage and flowers quite attractive.

The earliest Aster in this section is the large-leaved species *A. macrophyllus*. The curious root-leaves of this plant are very conspicuous, often nearly a foot long by half as wide. One point in which this species seems to differ from most others is that only a small portion of the plants flower. We often find large beds of apparently strong plants, and perhaps not more than half a dozen will be flowering. When in flower the plant is usually about two feet high, and bears a corymb of white, or bluish-white flowers. It is a desirable species, both for its foliage and flowers. *A. cordifolius* is another fine species, quite variable in size and the color of its flowers. Its prettiest forms are very beautiful, and under cultivation it attains a height of three feet or more. *A. undulatus* grows on dryer soil than most species and should be a valuable plant for dry situations. It has pretty light blue flowers, and attains a height of about two and a half feet.

Autumn Work in the Flower Garden.—When any alterations in the flower-garden are contemplated, many of these can always be made in autumn, and whatever is done in the way of shifting plants should not be delayed too long. The fall is the only proper time to move such early flowering plants as German Iris, Pæonies, Phloxes of the Subulata section, Narcissus, Camassias and all others that bloom in the early summer months. Plants lifted carefully at least six weeks before the advent of frost have ample time to make enough young roots to carry them through the winter, as the soil is still quite warm, and wherever it is sufficiently moist, action is by no means suspended. Lilies may now be transplanted as soon as the foliage and stems show signs of ripening, as this is the only time when they take a rest, and but a short one at that. A little later, roots will be starting from the base of the bulbs to carry them through the winter and until such time in the spring as the shoots are far enough advanced to supply their own feeders. Many failures result from planting Lilies in fall, because the bulbs have no chance to establish themselves before all growth is arrested by frost, and they are in a poor condition to meet the demand upon them in spring, when the young shoots should be produced. It is often the case that bulbs remain dormant a whole year from this cause. Any one who has grown Lilies is always in a position to report failures with some one or other of his pets, and this is not to be wondered at when it is considered that bulbs are received from their homes in all parts of the world and all are expected to thrive satisfactorily in the same spot and under the same treatment. Here in the East the Japanese Lilies grow without any trouble, but there are many of the California kinds that require

protection, and this is easily provided. They should be planted with others of the more tender kinds, such as *L. giganteum*, *L. Krameri*, *L. excelsum*, *L. longiflorum*, *L. Dalmaticum*, *L. Szovitsianum*, all near each other, where they may be shaded from the mid-day sun, and when the ground begins to freeze up a frame may be placed over them, filled with dry leaves and covered with shutters to keep out rain and sun-heat. In this way many delicate plants may be cultivated successfully. We never had *Anemone fulgens* so good as when thus treated. In the early part of May the bed was a perfect blaze of color. *Sternbergia lutea*, too, may be grown and flowered well, and many other things that cannot be trusted to the tender mercies of an Eastern winter. The frame should be removed as soon as the shoots are above ground in spring and all danger from spring frosts is passed. If the soil be heavy, and of a retentive nature, the addition of a little sand for the choicer Lilies will be an advantage, and we find powdered charcoal excellent to place around the base of the bulbs themselves. This promotes healthy root-action and assists in keeping away worms and grubs. If the soil is poor and it is necessary to add manure, care must be taken that it does not come in contact with the bulbs, which latter should first be covered with two or three inches of soil. The manure, which should be well decomposed, or, better still, decayed leaf-mould, should then be applied. In a position shaded from hot sunshine, and where tree-roots are not liable to rob the soil, it is not too much to expect that almost all the known Lilies can be successfully cultivated in a very limited space, year after year. The care and time bestowed upon these most beautiful of hardy flowers will be amply repaid by the abundance and richness of bloom and, eventually, by the increase of bulbs.

E. O. Orpet.

Roses and the Larvæ of the June-bug.—Much complaint has been made among Rose-growers during the present season of the ravages of the cockchafer grub, so-called, the larva of the well-known June-bug, *Lachnosterna fusca*, and, while this is not an unusual complaint, yet it seems to be especially loud this year. More or less damage is caused by this insect to newly-planted Roses, under glass, every season, and the loss is considerable in some large establishments. In several instances brought to my notice during the past month, from two to three hundred plants have been destroyed, while the loss of valuable time during the best growing season is really of more serious importance than the money value of the plants that have been destroyed. This grub seems to do its work in a rather indiscriminate manner, apparently cutting off the plant nearest to it without any regard to its being a strong plant or a weak one, and, unless captured after the first offense, it immediately proceeds to the next plant and continues its work of destruction, sometimes spoiling four or five plants in succession. Its usual method is to cut off all, or nearly all, the roots just at the base of the plant, or else to girdle the stem down near the base. Either plan is very effectual in killing the plant, which only survives the attack for a few days.

The first sign of injury shown by a Rose, after having been bitten by this pest, is usually its wilting under the influence of sunlight, which proves that something is wrong with its roots (providing the soil be in a proper condition as regards moisture), and, when such a manifestation is made by a previously healthy plant, it is well to examine the roots at once, and make a careful search of the surrounding soil to find the grub, which is usually not far away. It is not easy to prevent this loss, although it is safer to plant Roses in a compost that has been prepared for a year or so, because the eggs of the June-bug are deposited in the grass, and, after having been hatched out, the larvæ descend a short distance into the soil. In this way they are carried with the sod to the compost heap, and, if this compost is used immediately after mixing, it is reasonable to suppose that more of the grubs are brought into the houses with it than would be brought if it were allowed to stand for a year when many of the larvæ will have finished their growth and disappeared in the form of perfect beetles. This grub being of comparatively large size (from one to one and a half inches in length), is readily seen among the compost, and should be watched for when the benches are filled or the beds made ready for planting. In this way many may be destroyed before they have a chance to do injury, and the slight additional labor will save many plants, besides preventing the discouragement which is sure to visit the grower as one after another of his young Roses suddenly falls while it is making an apparently vigorous growth.

W. H. Taplin.

Orchid-Culture, Past and Present.—A very interesting paper bearing this title was read by Mr. Harry J. Veitch, of Chelsea, at a meeting of the Royal Horticultural Society, on June 11th last, and is published *in extenso* in a recent issue of the Society's Journal. A perusal of the same is not only interesting, but very instructive, and, among other things, reminds us that the commencement of what may be called the period of modern Orchid-culture dates from only a quarter of a century ago. Prior to that period, cool treatment was practically unknown, and cool Orchids were killed off as rapidly as imported by the incredible folly, persisted in, of cultivating them in hot stoves, in a climate to which they were as great strangers as to our severest winter frosts. It was in 1863 that three different collectors were sent out to New Granada to obtain living plants of the beautiful *Odontoglossums* of that region, which were then chiefly known from dried specimens. A few species had previously appeared in cultivation, *O. bictonense* being the first to reach England alive, as early as 1835; but it was not until the later period, when the conditions under which these Alpine Orchids grow became understood and imitated in gardens, that the Andean *Odontoglossums* became common in cultivation. The same may be said of cool Orchids generally, and what a large proportion of them modern collections contain is patent to every one. If the cultivators of an earlier period could see some of our best modern collections, how great would be their astonishment and admiration.

Half a century ago a considerable number of Orchids were successfully cultivated, most of them, however, found at low elevations in the tropics, and for these, warm houses must be provided at the present day. But a little earlier in the century profound ignorance as to the requirements of an Orchid seems to have reigned, and it is very instructive to observe the gradual evolution of our modern system of culture.

The earliest recorded instance of the flowering of a tropical Orchid in Great Britain dates from over a century and a half ago, but is not mentioned by Mr. Veitch. It appears that Peter Collinson received a dried specimen of *Bletia verecunda* from Providence Island, in the Bahamas, in 1731, and not despairing of life in the tuber, sent it to the garden of one Wager, where it was placed in a warm bark-bed during the winter, and produced its flowers during the following summer. In this single experiment we may see the germ from which modern Orchid-culture has been developed.

The Vanilla appears to have been established in cultivation prior to 1768, being mentioned in the second edition of Miller's Dictionary of Gardening of that date, but of *Epidendrum* the same author remarks that "the plants cannot by any art yet known be cultivated in the ground, though, could they be brought to thrive, many of them produce very fine flowers of uncommon form." Three species sent from America were planted with care in pots and placed in a stove, where they flowered, but soon afterward perished. *Phajus grandifolius* and *Cymbidium ensifolium* were introduced from China about 1778; *Epidendrum cochleatum* first flowered in this country in 1789, in the Royal Gardens at Kew, where also flowered *E. fragrans* in October of the following year. In 1794, fifteen species, chiefly West Indian *Epidendrams*, are recorded as being in cultivation at Kew, "in very great heat, and with fragments of half-rotten bark at their roots." A number of species from temperate regions were introduced previous to this date, but these may here be passed over.

The first Epiphytal Orchids received in England were brought from the West Indies by naval officers and captains of the merchant service, who gave little information respecting them beyond the fact that they grew on trees. Hence they were believed to be parasites like the Mistletoe, as will appear from a note by the editor of the *Botanical Register*, when figuring *Epidendrum nutans*, at plate 17. He there remarks: "The cultivation of tropical parasites was long regarded as hopeless; it appeared a vain attempt to find substitutes for the various trees each species might affect within the limits of a hot-house."

Messrs. Loddiges, of Hackney, who commenced the cultivation of Orchids for sale in 1812, were among the more successful cultivators of the period, and it is interesting to note their methods. The compost was made of rotten wood and moss, with a small quantity of sand. The Orchid-stove was heated by brick flues to as high a temperature as could be obtained by that means, and by a tan-bed in the middle, kept constantly moist by watering, from which a steamy evaporation was rising at all times, without any ventilation from without. Well might it be remarked that it was as dangerous to health and comfort to enter one of these houses as it was into the damp, close jungle in which all tropical Orchids were then supposed to have their homes; and no wonder they seldom lived long

under such treatment. England could not well be anything else than "the grave of Orchids" until a more rational system was adopted. We hope to return to this interesting subject in a future article.

London.

Calypso.

The Vegetable Garden.—Lettuce-seed sown now will give plants in time for setting in cold frames before winter comes, and, if the winter be not too severe, many of the plants can be used before spring, for they will grow if only protected from frost. Spinach, for early spring use, should also be sown now. After the plants are of good size, and before hard weather sets in, a mulch of manure will be beneficial. A few plants of Watercress may be set in a frame where the soil is damp, and, if the frost can be excluded, they will make a new growth, which will prove an agreeable relish in winter.

The Forest.

The Douglas Fir in Scotland.

AMONGST the exotic timber trees which have been introduced into Europe during the present century, the Douglas Fir has attracted more notice than any other species, owing to its remarkably quick growth during early youth. Specimens growing in free positions are believed to have laid on a mean annual increment of as much as three cubic feet, while only one cubic foot, at the outside, could be expected from a Larch tree; and even in a few fully stocked woods the increase appeared exceedingly great.

More than a year ago a Scotch paper drew attention to the oldest pure wood of Douglas Fir, situated at Taymount, in Perthshire, on the estate of the Earl of Mansfield. The plantation in question was spoken of in glowing terms, but only a few scanty measurements were given, so that it is difficult to arrive at any definite idea on the progress of the plantation, whereby it can be compared with that of indigenous timber trees.

Such general statements are often misleading, and therefore a correspondent of the *Gardeners' Chronicle*, no less an authority than Mr. W. Schlich, late Inspector-General of the India Forest Depot, measured, in July last, a sample plot in the Taymount plantation, and also measured, by way of comparison, a sample plot in an adjoining Scotch Pine plantation. The results of these measurements are not only of interest to forest-planters in Scotland, but they well illustrate certain general principles which should be borne in mind by planters in every country who propose to plant forests of exotic trees.

The plantation of Taymount is situated in $56\frac{1}{2}^{\circ}$ northern latitude, and at an elevation of about 200 feet above the level on the sea. The locality may safely be set down as of the best quality for the growth of trees. The rainfall is placed at twenty-eight inches annually. The area of the plantation amounts to eight acres, and was planted in the spring of 1860, in the following manner: Douglas Fir, four years old, nine by nine feet; Larch, four years old, one between every two Douglas Firs, and an additional line between every two lines of Fir, so that the plants stood four and one-half by four and one-half feet, each acre containing 2,151 plants, of which 538 were Douglas Fir and 1,613 Larch. The plants of Douglas Fir were two years' seedlings and two years' transplanted. The plantation took a good start, and the Firs are said to have taken the lead at once. The Larch were gradually thinned out, until the last disappeared before the year 1880, since which time the plantation was one of pure Douglas Fir. The first regular thinning of the Douglas Fir occurred in 1887. Before that thinning about 277 trees remained per acre, the remaining 261 having gradually disappeared during the previous twenty-seven years. Of the 277 trees, seventy-five per acre were thinned out in 1887, so that now, in 1888, the countings showed 202 trees per acre.

On a sample plot of average appearance all the trees were measured at a height of four feet six inches from the ground, and a selected tree was felled and its cubical contents accurately determined. Without giving the tables in detail, it appears that the sample tree could be taken as equal to the average tree in all dimensions, and estimating its growth, the result showed that, leaving out of account the amount of wood removed in previous thinnings, an acre of Douglas Fir had given an annual increase, during the twenty-eight years since the trees were planted, of 133 cubic feet of wood.

By way of comparing these results with the production of an indigenous tree, the trees on a sample plot of one-tenth of an acre—in a very uniform plantation of Scotch Pine, situated at a short distance from the Douglas Fir plantation—were meas-

ured. This Scotch Pine plantation had been established in a somewhat elevated spot, which was formerly of a swampy description. The locality is of second quality only, compared with the locality in which the Taymount Douglas Firs grow. It was drained and planted in 1847—that is, forty-one years—with four years' old plants of Scotch Pine; it has been thinned four times.

The result of the careful survey showed that an acre of Scotch Pine had given an annual production of 122 cubic feet of wood, against a production of 133 cubic feet made by the Douglas Fir. This difference is not great, and it is less important than it appears, when we consider that the quality of the soil in the Scotch Pine wood is decidedly inferior to that of the soil in the Douglas Fir wood.

Unfortunately, Mr. Schlich had no opportunity of measuring a Larch wood in the vicinity of Taymount, but it is well known that, up to an age of forty-five years, at any rate, Larch produces a greater volume than Scotch Pine, so that he does not hesitate to say that, "If grown in a well stocked or crowded wood and in localities of equal quality, Douglas Fir is not likely to produce more solid wood during the first thirty or forty years than the Larch, and probably, also, not more than the Scotch Pine."

The explanation is, that although the individual Douglas Fir develops more rapidly in diameter and in height than a Scotch Pine or Larch, it requires, at any rate in Scotland, much more space; and, consequently, an acre of land will hold only a much smaller number of trees. Moreover, the stem is more tapering than those of the important European conifers.

On the other hand, the growing stock of a Douglas Fir wood consists of much larger trees (though smaller in number) than an equally old Larch or Scotch Pine wood, and this is a great advantage where big timber fetches higher prices than moderate-sized timber. This advantage will, however, to a considerable extent, disappear with advancing age, when the indigenous timber trees of Great Britain reach the size usually demanded in the market.

The Taymount plantation gives some valuable data for comparing the Douglas Fir with other trees in the early stages of its development; but, of course, it gives no information as to its further production. The rate of increment of various European conifers is well known, but of the Douglas Fir, even in its native home, no accurate measurements are available. Mr. Schlich proceeds, however, to gather such additional facts as he can from the following data:

(1) Two Douglas Firs, planted on the same estate, and now fifty-seven years old, are ninety feet high.

(2) Dr. Mayr found the tree in its best estate in the moist valleys of the Cascade Mountains, where the average height of full-grown mature Douglas Firs, grown on soil of the best quality, amounts to 213 feet, with a diameter of six and a half feet, measured at six and a half feet above the ground. In the same locality, on gravelly soil, the trees only reached an average height of 148 feet, and a diameter of two and six-tenths feet. Again, in the Rocky Mountains, in Montana, at the same elevation and degree of latitude as on the west coast, the Douglas Fir reaches, on best soils only, the same dimensions as on the gravelly soil of the Cascade Range Mountains—that is to say, a height of 148 feet, and a diameter of about two and six-tenths feet. The part of the Cascade Range where the Douglas Fir grows has an annual rainfall of about thirty inches, while in Montana only twenty-four inches fall, and Dr. Mayr believes that the development of the Douglas Fir is proportionate to the rainfall.

(3) A cross-section of a Douglas Fir was sent from America for exhibition in Europe; it was then made over to Kew, and by the kindness of the Director was lately presented to the Cooper's Hill Forest Museum. The section shows a total diameter, including the bark, of seven feet nine inches, and the counting of the concentric rings indicates a total age of 515 years. An examination of this tree shows that it was still making good increment at an age of 515 years, which is higher than that usually attained by the European Larch, Scotch Pine, Spruce and Silver Fir. Secondly, it shows that the enormously rapid increase of the diameter during the first twenty-five years is suddenly followed by a much smaller and an approximately even increment during each of the following nineteen periods of twenty-five years. Thirdly, that the sectional area increases, on the whole, steadily. The periodic increment increases up to the age of 400 years, when it commences to fall. Taken by centuries, the fourth century yielded the largest increment. And finally, the rate of growth indicated in the section up to the year thirty resembles that of the average tree in the Taymount plantation in a striking degree.

So far, then, the trees in Scotland may be considered to have done as well as those of the same age, under good conditions, in their native home. Assuming, therefore, that they will continue to increase as rapidly as did the great tree whose section was sent to Kew, the conclusion is reached that under a rotation of seventy-five, and perhaps of eighty, years, the Larch will yield as much solid wood as the Douglas Fir whenever they are grown in regular, fully stocked woods, and in localities of equal quality—with this difference, that the material yielded by the Douglas Fir will consist of a smaller number of trees per acre, with a greater mean diameter per tree.

It may be added that the Douglas Fir would yield a larger amount of wood in a rotation of from 100 to 120 years than it would in a longer or shorter rotation. The difference, however, would not be great, and planters are not inclined to wait so long for returns.

As to the quality of the timber, the wood of the Douglas Fir has a great reputation, and in America its quality is believed to be equal to that of Larch timber. In how far the Douglas Fir grown in Scotland will come up to that standard remains to be seen. The larger sized trees so far cut on the Scone estate have been freely bought at the same rates as those usually paid for Larch, but sufficient time has not elapsed to show the comparative merits of home grown Douglas Fir and Larch timber.

As to the safety of production, it is an undisputed fact that Douglas Fir can, in Scotland, only be successfully grown in sheltered localities, because its leading shoot, and even the lateral branches, are very liable to be broken by wind. This reduces the area suitable for its cultivation very considerably. Then there can be no doubt that the Douglas Fir, in order to yield large volume returns, requires good, fertile, and fresh, or moist, soil—in fact, soil on which any other species will produce a large volume of timber. Such land can, moreover, be used to greater advantage for field crops. What is specially required is a tree which will do well, or at any rate fairly well, on lands which are not suitable for field crops.

Finally, it has been said that the Douglas Fir is not exposed to any disease, while the Larch, for instance, suffers so much in this respect. But it will be remembered that the Larch disease did not show itself in Scotland until about sixty years ago.

No doubt exists now that the Larch cancer is the result of the ravages of a fungus, and Dr. von Tubeuf has lately described a similar one which is parasitic on the Douglas Fir. It is found, as a general rule, that those Douglas Firs were especially attacked which grow in fully stocked areas, so that the branches of the trees interlaced; and in these cases the lower branches were more attacked than those higher up. This means that the Douglas Fir must be grown in thin, open woods, and if so, farewell to any high returns per acre, such as Silver Fir, Larch, or even Scotch Pine, will yield.

Mr. Schlich concludes by saying that there is encouragement to plant the Douglas Fir in Great Britain and Ireland, and he hopes that experiments may be continued. He only writes to sound a warning against extensive plantations until it has been demonstrated that it really deserves to supersede species hitherto cultivated. Great things were expected of the White Pine in Great Britain, and probably the Douglas Fir will not revolutionize sylviculture in the United Kingdom. It is one thing to nurse a single tree in a fine soil and under most favorable conditions, and another to grow trees on a large scale for economic purposes. In the former case only exceptional results are seen; in the latter case averages must be looked for and reckoned with.

[The result of Mr. Schlich's investigations upon the Douglas Fir in Scotland should be carefully considered by all persons in this country interested in planting, especially by those living in the Northern States east of the Rocky Mountains, where it is believed that this tree may prove valuable in forest-planting. Little is known yet, however, of its behavior in eastern America. The young trees which were planted here first were imported from Europe, where they had been raised from seed gathered in Oregon or California. They proved hardy only in very favorable situations. Dr. C. C. Parry visited the Rocky Mountains of Colorado during the summer of 1862, and found the Douglas Fir growing there at high elevations. Seeds from these trees were sent by him in the same year to the Botanic Garden in Cambridge (with seeds of *Picea pungens*, *Picea Engelmanni* and *Pinus Balfouriana*, all discovered by Dr. Parry), and a few plants were raised. The largest of these are now more than twenty feet high, and have pro-

duced cones. A comparatively large number of seedlings have been raised in recent years from Colorado seed, and in one or two places in New England they are being tested now on a considerable scale. The young trees promise well, and grow much faster than White Pines planted in similar soil—a light, dry and very porous drift—but not as fast as European Larch. Such experiments, of course, prove nothing yet, except that the Douglas Fir raised from Colorado-grown seed is hardy in New England, while seeds from the same trees, long subjected to the moister and warmer climate of the Pacific coast, do not produce plants which can support the climate of that part of the country. The facts which Mr. Schlich brings out—that the Douglas Fir must have space in order to develop rapidly, and that it requires shelter to protect its comparatively brittle leader and branches—will no doubt prove as true in the United States as in Scotland; and while enough is not known of this tree to justify any one in believing that it is more valuable than the White Pine or some other native trees, or in planting it in the eastern part of this country upon any large scale, there is enough known to make further experiments with it in forest-planting very desirable. As an ornamental tree, few hardy Conifers, of course, can equal or surpass the Douglas Fir.—Ed.]

Correspondence.

Storage-Reservoirs for Irrigation.

To the Editor of GARDEN AND FOREST:

Sir.—I was greatly interested in the article on "Mountain Reservoirs and Irrigation," but, in considering the danger of fatalities from broken dams, it should be remembered that the conditions under which reservoir-construction is to be undertaken in the arid region are radically different from those which obtain at the East. Remembering, too, that the average annual rainfall in the arid region is less than twenty inches, and that this is spread over the entire twelve months, it will be seen that the danger from such a tremendous downpour as that which caused the Johnstown disaster is quite remote. Excessive and sudden cases of rainfall are of rare occurrence in California. In that portion of the state in which irrigation is required, the average rainfall does not exceed twelve inches annually, or one inch a month. Under such circumstances, a dangerous precipitation is well nigh impossible.

But the builders of the reservoirs now in existence have taken care to guard against any contingency on this account. These reservoirs are never established in water-courses liable to heavy floods. The most expensive affair of the kind in California is the immense reservoir known as Lake Yosemite, in Merced County. This is fed from the Merced River, a stream familiar to all visitors in the Yosemite Valley. Instead of being formed by the damming of that stream, this reservoir is situated at a distance of several miles from it, occupying a depression in the foot-hills. It is supplied with water through a canal 100 feet wide and ten feet in depth, and the flow of water is regulated by a massive and substantial system of head-gates, by which at no time, even when the water in the river is at its highest, can more than is desirable find its way into the reservoir. The lake, as it is called, was formed by the construction of an earth embankment, 4,000 feet long, across the lower side of a depression in the rolling foot-hills. This embankment is 250 feet thick at the base, and tapers gradually until, at the crown, the width is twenty feet. The highest point is some sixty feet above the plain below. The water-face of the embankment is rip-rapped so as to prevent erosion. It is estimated that over 300,000 acres of land can be irrigated from this reservoir, upon which something like two million dollars was expended.

The most remarkable irrigation storage reservoir in the state is that at Bear Valley, San Bernardino County. This occupies the site of an ancient lake, high in the San Bernardino range of mountains. By some convulsion of nature the mountain that walled in one end of the lake was riven, and the water escaped through a narrow and tortuous channel toward the sea. By throwing a dam across this chasm the valley was again tilled with water from the winter rains and snows, which was utilized for irrigation in the valley twenty miles away. The only sources of supply are three or four rivulets, too small to be called brooks. There are never any violent storms which might cause the water in the reservoir to rise at such a rate as to be dangerous to the dam, which is a massive arched stone

structure, with abutments dovetailed into the solid mountain. This dam is remarkable as being the first adaptation of this arch principle in the United States. The gorge where it is located is perhaps seventy-five feet wide at the base, with rocky walls sloping to 300 feet at the summit. The dam is a granite and cement wall, arched up-stream with a radius of 335 feet. It is sixty feet in height, and with the water at the tifty-foot mark, it forms a lake five and a half miles long and from half a mile to a mile and a half in width.

A structure of similar character is the Sweetwater dam in San Diego County. This, too, occupies a narrow gorge, behind which lies a wide valley traversed by a small stream. Such a thing as a flood or dangerous rainfall has never been known here.

It should be remembered, too, that these reservoirs are constructed fully as much to distribute water as to preserve it. It is of the first necessity, therefore, that the means for drawing off the water shall be equal to those for holding it. Consequently, if there should be the least apparent tendency toward overflow, it is an easy matter to open the outlets and at once afford egress for any surplus water that may accumulate during seasons of extraordinary rainfall. The schemes of reservoir projectors do not contemplate the damming of streams which are subject to danger from overflow. Where such must be utilized, it will be after the manner pursued at Mercer, where the flow from the river can be regulated to an inch.

San Francisco.

G. F. W.

Notes.

Mr. Charles Anderson, of Flushing, considers Paul Neyron and Mrs. John Laing the only hybrid perpetual Roses which deserve to be named as autumn bloomers.

The Pecan bears abundantly, and makes a fine ornamental tree in the upper valley of the San Joaquin River, California, and the *Visalia Times* speaks of two trees in that city from seed planted nineteen years ago that are fifty feet high and seem better adapted to that climate than the English Walnut.

In the Jardin des Plantes at Paris stands an old Locust-tree (*Robinia Pseudacacia*), said to be the first one planted in Europe. It was planted in 1636 by Vespasien Robin; and now the old trunk, in its decay, is so mended with mortar and cement, that little of it can be seen; but there is life in the branches, and it may last for years.

The *Pacific Rural Press* speaks of a Bamboo grove on the grounds of General Kirkham, of Oakland, which was started twenty years ago with some plants brought from China. Every year the shoots come up stronger, and some of this year's growth are forty feet high and four or five inches in diameter. They sometimes make the growth of an eight-inch joint a day.

The Atlanta Perfumery Company is preparing to build a factory this winter in the Orange belt of Florida, where such flowers as Orange blossoms, Rose Geraniums, Roses, Yellow Jessamine, Tuberoses, Magnolias, and many other fragrant flowers can be had in large quantities. The plant will be of sufficient capacity to make use of 200,000 pounds of flowers in the season.

Professor W. F. Massey writes to the *Philadelphia Weekly Press* that when the Moravians settled the town of Salem, North Carolina, a century ago, they had the rare foresight to dedicate a large tract of Oak forest as a park forever, and this now contains trees hard to match. The great buildings of the college for girls are embowered among noble trees in a park which, for picturesque beauty, has few equals.

Dwarf White Asters were recommended for winter blooming by Mr. A. Giddings, of Illinois, at the florists' convention in Buffalo. They can be grown among Roses in beds near the glass and will bloom when only four inches high. They yield better than Carnations, and can be grown more profitably, for as soon as one lot of plants is through blooming, another can be had in readiness to take their place.

How much more at home our Pacific coast conifers are in England than in our eastern states can be inferred from a sentence or two in a description of the Pinetum at Hardwicke Hall, which appeared in a recent number of the *Gardeners' Chronicle*. After noticing a specimen of the Atlas Cedar as the most remarkable tree in the collection, on account of its remarkably rich glaucous color, the writer goes on to say: "The next tree to command notice is a Redwood *Sequoia sempervirens*, a perfect specimen, standing at least seventy feet high, and clothed down to the ground with healthy spreading branches and foliage. Near by is a Wellingtonia [which means *Sequoia gigantea*], sixty-five feet high at least, and some

nine to ten feet round the trunk, and several specimens of the Douglas Spruce over seventy feet high."

The Blue Spruce is now the recognized popular name in England for the glaucous form of *Picea pungens*, which has an established reputation as one of the handsomest and, at the same time, the hardiest of ornamental conifers suitable for European gardens. The blue variety differs only from the type in the bluish color which covers every twig and leaf, giving the tree, in its finest examples, the appearance of frosted silver. It has been known in England for a few years only, but now every tree-lover is talking about it, and if he has not planted it longs to do so. A correspondent writes that at Knap Hill Nursery the tree is one of the choicest treasures, and Mr. Anthony Waterer claims to have the finest stock of it in Europe. But, as he says, there are Blue Spruces, and Blue Spruces so-called that are not blue. The Knap Hill specimens stand in long files totally distinct from any other Spruce, the perfection of symmetrical growth and of a uniform silvery hue that captivates all who see them. Apart from its landscape beauty, the tree will doubtless prove good for shelter and screen-planting in England. It possesses what is most desired, and that is a sturdy and vigorous growth, and commences to grow late in the season after damaging frosts are past. We may add that our own nurserymen are beginning to appreciate the value and probable demand for this tree. We were recently informed by one who had visited the nursery of Robert Douglas, at Waukegan, Illinois, that the stock of Blue Spruce there, in large sizes, seemed exceptionally strong and handsome.

A series of charts of exceptional interest and value has been prepared by Mr. J. R. Dodge, statistician of the Department of Agriculture, which present graphic illustrations of certain facts in relation to the farms of the country, and their products. The first chart shows, that, taking the country over, 289 acres of every 1,000 are farm-lands, leaving 711 unoccupied. The most surprising result displayed here is the large amount of unoccupied land in the Southern, Eastern, and Middle states. Of the 289 acres of farm-lands, 153 acres are improved, 103 acres are in woodland, and thirty-three acres are unproductive, although much of the latter is capable of improvement. It is stated that in former censuses only the forest-lands in farm areas have been reported, so that it is estimated that the forest-land, including the portion not divided into farms, would approximate 250 acres to every thousand. The second chart shows the relative proportions of tillage-lands, grass-lands, woodlands, and unproductive lands in the farm area only. The range of woodlands is very wide, ranging from one per cent. in Utah, to sixty-two per cent. in North Carolina. A third chart illustrates the distribution of Corn, varying in the different states from less than ten acres to more than a hundred acres to the thousand. Similar maps show the distribution of Wheat and Oats, representing both acreage and average yield. A series of five maps illustrates the number and value of farm animals, horses, milch cows, other cattle, sheep and swine. The fourteenth chart represents the proportion of population in different states in all gainful occupations related to agriculture. Chart fifteen illustrates the value of farm-lands, showing a range in different states from \$65.16 to \$4.19, the general average of the entire United States being \$19.02. The last chart indicates the relative proportions of proprietors, of tenants who pay rent, and of tenants who pay a share of the produce, from which it appears that seventy-four per cent. of all farms are cultivated by their owners. The rate of yield of the three principal cereals shows so wide a variation as a result of climatic adaptation, different soils, and methods of culture, that the charts illustrating these facts are worthy of special study, while the average values of farm-stock in different sections are equally suggestive of differences in breed, degree of improvement, and the effect of distance from market. The results here set forth in this graphic way are certainly worthy of such a presentation.

Catalogues Received.

The Proper Use of Public Parks.

LARGE open spaces of public land within the limits of compactly built cities offer a constant temptation to persons who feel that they hold a joint ownership with their fellow-citizens in such property; who feel, too, that a portion of this property is needed for some purpose in which they are specially interested, and which appears to them of vital importance. Urban parks will never be free from the danger of assaults upon their integrity, and of perversion to purposes destructive of their highest usefulness, so long as any considerable body of citizens remains uninstructed as to the fundamental reasons which justify their existence and control their design. It would be hardly just to charge with utter selfishness the owners of trotting horses who desire to cut a speed-road through Central Park. They know that such a track would minister to their chosen recreation, and they fail to comprehend that it would defeat the chief end of the park, which is to furnish another and a nobler recreation for everybody else. The same can be said of those who have endeavored to convert the Meadows of Central Park into a military parade-ground, and of almost all other persons who have been eager at one time or another to condemn the park, or some portion of it, to illegitimate use. The storm of indignant protest which was aroused by the first suggestion that Central Park should be selected as the site for the Exposition of 1892 seemed a hopeful sign that public sentiment was becoming more enlightened in this direction; but, unfortunately, lamentable proof has since been given that there are still men of intelligence and public spirit who are willing to see the park turned into desolation for years and probably forever for the sake of a temporary show. It is a discouraging fact that so small a fraction of the population of the city really comprehend the special function in our civic economy which the park is designed to fulfil, and understand that when, for the advantage, real or assumed, of any class or sect, or cause or interest, it is diverted to some use which interferes with its legitimate office, the entire community suffers a wrong.

The fact that every man in a city has a right to its park, as a park, implies, that no one has a right to it as anything else than a park. This view is not held by certain labor

organizations in Boston who insist on using Franklin Park as a place for holding mass meetings, and who resent the refusal of the authorities to surrender the park for this purpose as an abridgment of the right of public assemblage. Of course, this last charge would have no foundation even if a piece of public ground, admirably situated for the purpose, had not been offered, as it was offered, to the labor organizations for their proposed meeting. The pity of it is that these men fail to discern that they have an especial interest in saving the park from any intrusion that even remotely threatens to impair its efficiency, or limit its capacity, of furnishing recreation for themselves and their children. Franklin Park was designed to offer the most practical and natural and perfect relief from the confinement and pressure and wear that are inevitable where men and women are crowded together under the strain of city life. As a direct antithesis to all this, the park furnishes the freedom of spacious meadows and open skies, the contact with pure nature, the tranquilizing influence of pastoral scenery, and invitations on every hand to rest or play. The millionaires of Boston have less need of the recreation offered, for they can spend the entire summer in their villas, on the mountains, or by the sea. But it is for those who have no country seats, and who take no vacations, and for their children, that this delightful picture of rural peace stands ready to furnish rest and healing, both to the mind and body. The men who are striving to reduce the hours of labor are precisely the ones who should avail themselves of these privileges during their hours of recreation. Of course a meeting or a demonstration in favor of some movement is utterly out of harmony with the spirit of the place. It would bring into the park the very conditions from which the park was designed to offer a relief and an escape—the jostling throng, the commotion, the stress and heat of excited discussion. It is plain that such assemblages are incompatible with restfulness and peace. Their avowed purpose is agitation, and this means essential antagonism to the purpose of the park.

It follows without argument, that if the representatives of one movement or cause are allowed to use the park for meetings, other bodies are entitled to a like privilege, and the play-ground will become the chosen spot where reformers of all sorts can indulge in a vociferous advocacy of their pet projects. A body of worthy clergymen who form the Evangelical Alliance are even now seconding a demand to permit preaching in the park, and this would encounter, besides the objections already mentioned, the special ones which arise from the sensitiveness of many persons and classes in matters of religion. To permit the use of the park for purposes that would be offensive to any considerable number of those who resort there would be a manifest injustice. Wandering sectarian preachers are none too gentle, as a rule, when they are characterizing other creeds than their own, and they can easily succeed in making themselves disagreeable. A large proportion of the working people who most need the park are Catholics, and why should they, for example, be forced to hear their faith attacked in their own pleasure-grounds? And if one sect is allowed to preach, the same privilege must be granted to all others. The spectacle of a dozen sects conducting services at the same time might give pleasure to the hoodlum element, but it would hardly minister to the enjoyment of those who were seeking the reposeful influences of rural scenery.

But urban parks, as we have said, will never be secure against destructive invasion so long as such dense ignorance prevails as to their appropriate purpose. Casual remarks of several wealthy and accomplished gentlemen of the committee to select a site for the world's fair in this city prove that they have not the slightest feeling for the beauty of natural scenery, nor the slightest appreciation of its value in a city park. They propose to obliterate what is altogether the most valuable and lovely portion of Central Park and speak of the part they hope to confiscate as "waste ground," and talk of "improving" it by

cutting down the trees, and making a desert of its stretches of greensward. The future of the city parks in this country is by no means secure—nor will it be, until the people generally understand that these parks have a function to fulfil which is quite as distinct as that of churches and schools and libraries, and until it comes to be a general and unquestioned belief that these pleasure-grounds are absolutely indispensable to the well-being of those who are subjected to the complex conditions of modern city life.

Drives and Walks.—III.

IN a preceding chapter we discussed the laying-out of a road on a place where the lawn is large enough to be crossed by it. When is this the case? Only when the lawn is so extensive that the drive will not be conspicuous from the house, or, at all events, from the principal side—when a wide space in front of the house can be left undisturbed by its intrusive, artificial line. That is to say, a drive should really never cross a lawn, although it may divide one lawn from another that can be treated as an almost independent picture. As a feature in a picture a road or walk is always to be deplored; but as a frame which encircles a picture it may be made inoffensive, and sometimes, with its bordering plantations, actually advantageous. Too wide and open a prospect is not desirable any more than one too cramped and crowded; while plantations are often needed to justify the course of the road, they are also needed to adorn it to the eyes of those who pass over it. Trees and shrubs may explain its curvatures, and it may explain the presence of shadowing foliage and attractive lower masses of green. Each helps the other by giving it a reason for existence, and both together may be beautifully brought into the middle distance at the side of a landscape picture, framing the foreground and affording glimpses, more attractive than a wholly unobstructed view, into the landscape beyond.

To preserve a wide expanse of lawn in front of a house is in itself sufficient excuse for carrying the road to one side. If a minor curve is justified by the wish to preserve a fine tree, so a general deflection from the direct line of approach is justified by the wish to secure that broad stretch of green which is the most beautiful of all possible adjuncts to a house, which is the indispensable foreground in any natural picture where utter wildness of aspect is not desired. A carefully clipped and tended lawn is the first thing to be secured where there is any comparatively level ground; where the house is anything but the simplest cottage, and where the rest of the place is to be "kept up" by the gardener's hand. If place and purse are so modest that the expense of turfing and clipping cannot be incurred, then a stretch of meadow left in its natural condition is essential; and in either case it is equally necessary that, to produce the right effect of breadth and peacefulness, the grass should be kept as free as possible from roads and walks.

To secure a good lawn where it can be most enjoyed—to keep the approach from cutting into two parts what ought to be an harmonious picture opposite the chief windows—it is best not to have the entrance front of the house and the lawn front the same. Even though the highway may lie opposite the front where the lawn must be made, the approach ought, if possible, to be carried to a door which lies in another side. There will be no look of caprice in such an arrangement, for where the front door is, there, of necessity, the road must go. It will not suffice to carry the road to one side, leaving an agreeable expanse of lawn, and then bring it along close by the house to a door in the lawn-front. This is a very common arrangement but a very bad one. If a road crossing the lawn in full sight of the chief windows and piazzas is offensive, still more so is a road running between the house and the lawn, forming a barren streak in the immediate foreground of the picture, and preventing that union of the house-foundations with the grass which it is so important to secure. Worse than anything else, however, is the wide sweep we constantly see, where, between house and lawn, a road returns upon itself. No one would ruin a fine painted landscape by pasting a strip or great circle of gray paper over the lower part of the foreground; yet this is just what hundreds of owners do with strips and circles of gray gravel in their natural landscapes. And how much pleasanter is it for the foot to step from door or window or piazza directly to the grass than to be obliged to cross a stretch of dusty or muddy road!

In these last paragraphs we find another reason why, as was

said in a former paper, the house should not be planned or placed until the roadways have been mapped out. A want of consideration in placing the main entrance may easily ruin the chance, not only for a good approach, but for a good lawn as well. Neither architect nor owner can always tell where it will be best to make the lawn any more than where it will be best to run the roads. The front-door is the end of the approach, and not to consult the landscape-gardener with regard to its position is to strike, without his consent, the keynote which must govern his whole arrangement.

What has been said with regard to the length of roads applies also to their width—the less there is of them in either direction the better. A drive where vehicles meet should be wide enough to allow them to pass without danger to themselves or the borders, but anything in excess of this should be studiously avoided; and if a turning-place must be provided near the house, the oval should be made as narrow as convenience will allow, or the road should be carried around a plantation of some sort. Here again, however, the plantation should not be a flower-bed. It should not look as though it had been put in to fill up a sweep which had been made too large; it should not look as though it existed because of the road. The road should look as though it took the encircling curve because there was an obstacle to its turning short upon itself which it was desirable to preserve. And the exact character of this obstacle should be regulated by surrounding things, and especially by those which lie opposite the door. If it is well to shut out something unattractive, then a shrubbery or low-growing tree may fill the space; or, if it is well that the eye should have free passage, then a tree with higher branches may be chosen.

A Cypress Avenue at Verona.

THE avenue of Cypress trees shown in our illustration, on page 464, forms the most conspicuous feature of the garden of the Villa Giusti, in the city of Verona. The villa itself, a Renaissance building, is not of great architectural importance, nor are the gardens very extensive, covering, perhaps, an acre and a half of ground. But they are beautifully laid out in the true Italian style, and there is nothing in all Italy finer in its way than this Cypress avenue. The trees are probably some four hundred years old, and most of them are in fine condition, although one of those shown in the picture died a few years ago. At the end of the avenue is a series of marble terraces, each affording a more beautiful view than the last of the lovely, ancient city with its wide river, Roman amphitheatres and soaring mediæval towers. Beyond the balustraded top, as we see, still other Cypresses are planted. In Goethe's "Italian Journey" he speaks with enthusiasm of the situation of the Giusti gardens and of their unrivalled Cypresses, and fancies that the pyramidally-clipped Yews of northern Europe may have been imitations of such admirable natural forms. Yet the Romans had clipped the Cypress itself to form "verdant walls" in their gardens, and cut it into the most fantastic shapes—representing, for instance, fleets of ships and hunters following their prey.

The genus *Cupressus* includes a number of species which are natives of southern Europe, Asia, Mexico and California; and the vernacular name "Cypress" is also given to other coniferous trees which are not true Cypresses, the most familiar example being *Taxodium distichum*, the deciduous or Bald Cypress of our southern states. The tree shown in our illustration is the best known of all the true Cypresses. It is the one constantly referred to by ancient authors and constantly used in modern poetical imagery—the symbol of grief, gloom and death, as the Oak is of strength, the Laurel of triumph, and the Myrtle of festivity. It is *Cupressus sempervirens*, peculiar for its fastigate or pyramidal shape. Its branches grow in an upright direction close to the stem, giving the tree a tapering, pointed outline, which is even more conspicuous among trees of ordinary habit than the shape of the Lombardy Poplar. The branchlets, growing in frond-like forms, are set thick and close together, and covered with very small, smooth, shining, scale-like leaves of a dark yet yellowish-green. These are evergreen, remaining on the tree for five or six years. The cones are oval, about two inches in length, and borne singly on short stalks. The usual height of the Cypress in its native homes—Greece and the islands of the Archipelago, Turkey and Asia Minor—is fifty or sixty feet, although it sometimes grows to a height of 100 feet. It is hardy in the southern counties of England, yet flourishes in Algerian gardens. Nor is it particular as to situation, growing sometimes in moist river-bottoms and sometimes on dry rocky precipices. Its best development occurs, however, "in soils which are deep and sandy,

rather dry than moist, somewhat sheltered, and at no great elevation above the sea."*

The Bible tells us that the Cypress grew in the Holy Land, and associates it with the Cedar in dignity—"I am exalted like the Cedar of Lebanon and like a Cypress on Mount Sion." The Egyptians knew it well, the Assyrians also, and the Greeks and Romans. It is now found in an apparently wild state in Italy; but Pliny assures us that it was not native to his country but had been introduced from Greece and first planted near Tarentum.

The Cypress, like the Lotus, was an emblem of immortality in all ancient times. But the interpretation put upon this common significance of the two plants seems to have varied as widely as their aspect. As a symbol of life after death, the Lotus was held sacred to Osiris, the god of generation, but as a symbol of the same thing the Cypress was consecrated to the dead and held sacred to Pluto and Proserpine. Ideas of joy and hope were associated with the Lotus, ideas of sorrow and bereavement with the Cypress. The reason of the difference is not hard to find. The Lotus is beautiful, graceful and gay in aspect, the Cypress is solemn and dignified and never seems more appropriately placed than when, like the Yew of England, it stands in a place of tombs. It was chosen as an emblem of immortality because it was an evergreen, and also because it would immediately rise again to an upright position if bent down by the wind or by manual force. Its association with ideas of death was explained by the fact that, if cut down, it throws up no suckers from the root. But such significations were always explained among the ancients by some poetic legend, and with reference to the mournful meanings of the Cypress, Ovid tells us that a youth named Cyparissus, a favorite of Apollo, having shot, by accident, a pet stag, grieved so deeply that he prayed he might visibly mourn forever. He was thereupon transformed into a Cypress-tree, and Apollo,

"Sadly sighing, cried:

'Be then forever what thy wish implied,
Be moaned by me, in others grief excite,
And still preside at every funeral rite.'

All Oriental nations still plant Cypresses in their burial-grounds, and the Turks place one at either end of a grave. They are so numerous, writes Loudon, "at Scutari that the cemetery there resembles one vast forest of Cypress. This magnificent burying-ground extends for miles in length; and among high and turbaned tombstones, gold-lettered inscriptions, and graves ornamented with flowers, the tall evergreen Cypress has a very striking effect." As we remember this cemetery, however, it is anything but magnificent in effect. It is, indeed, of vast extent, and some of the tombs, when examined, are very beautifully carved. But they are crowded so close together that it seems as though one body must often encroach upon the resting-place of the next; hundreds of the tall stones are out of the perpendicular, giving a painful look of neglect and decay, and the Cypresses, too, are pressed so close together that the dignity of their forms is less conspicuous than the deep and mournful gloom caused by the density of their shade. The Cypress is not a tree to plant thus in groves. It looks its best when seen in isolated examples or when arranged in avenues, like the one portrayed in our picture. But its dark and spiry outlines, rising everywhere from the court-yards of the houses, give great individuality and beauty to the general aspect of oriental towns. Constantinople, as seen from the harbor, covering its hills with its masses of white walls and its domes and minarets, would be far less beautiful were the general whiteness not relieved by innumerable lofty Cypress-trees, now standing singly and now forming little clumps or long lines, high above the house-roofs.

In mediæval Persia the Cypress was especially honored. Its pyramidal outline was thought to resemble a flame, and it was, therefore, planted near the temples of the fire-worshippers. A legend, which Firdusi versified, tells that the first Cypress came direct to Zoroaster from Paradise, and was planted by him in front of the temple at Kischmer, in Khorasan. When it was cut down by the Mohammedan caliph, Motewekkil, it was believed to be 1,450 years old. In India the Cypress is one of the most conspicuous of cultivated trees, standing, as usual, near tombs, or forming avenues similar to the one at Verona. In China, too, we read* that ancient grave-yards are laid out in squares and contain "tablets innumerable, Cypress-trees, gates, walls and bridges." The tomb of Confucius lies north of the city of Kio-fou-hien, "at a distance of about a mile; a fine avenue of old Cypress trees leads direct from the

north gate to the burial-ground;" the grave itself lies in a "forest of Oak, Cypress and other kinds of trees, enclosed by a high wall;" and everywhere in the neighborhood is "the unfailing Cypress." The grounds of the chief temple in the city itself are likewise filled with Cypresses, and one of them is said to have been planted by Confucius himself. "Its gnarled and aged trunk bears evidence of its great age;" but if it was, indeed, planted by the sage, it must be no less than 2,540 years old!

One of the most remarkable Cypresses in the world stands—or still stood not long ago—at Soma, or Somma, in Lombardy. According to some accounts it was planted in the year when Christ was born, but others declare that it was a tree in the time of Julius Cæsar. It is 121 feet in height, and twenty-three feet in circumference at one foot above the ground. Francis I., of France, drove his sword into this tree in his rage at having been defeated at the battle of Pavia; and Napoleon respected it sufficiently to deflect the line of one of his great highroads rather than do it harm. Near Shiraz, in Persia, stands a Cypress which is said to have been planted by the poet Hafiz or to have sprung up on his grave. At Chartreux are some famous Cypresses which were planted by Michael Angelo. The trunk of the largest, when measured in 1817, girthed about thirteen feet. Many writers have celebrated *Los Cypresses de la Reyna Sultana*, which form an avenue in the palace-gardens of the Generalife at Granada, and are connected with the history of the massacre of the Abencerages by the last Moorish king of that province. They are supposed to have been large trees at that time—1490—and were still flourishing in 1832. It would be interesting to know what is now their condition.

Modern folk-lore tells us that the Cypress brings ill-luck, especially when it comes to us in dreams. The wood of the Cypress is very durable, and in many different ages has been used for coffins. Thucydides says that Greeks who died for their country had their ashes preserved in Cypress-chests. Pliny refers to a statue of Jupiter in the Capitol, at Rome, which was made of Cypress-wood, had existed for 600 years, and was still in perfect condition. He adds that the doors of the temple of Delphi, likewise of this wood, had the appearance of being quite new when they had hung for 400 years. In his own time the wood was much used for rustic purposes, and, as plantations of Cypress could be cut every thirteen years for poles, vine-props, etc., they were esteemed so valuable that they were given as marriage portions, and hence the tree itself was sometimes called *dos filiae*. Plato had his code of laws engraved on Cypress-wood, and, in the fifteenth century, A.D., Leon Alberti found the wood of an ancient ship which had been submerged for 1,300 years, as he declared, to be chiefly of Cypress and still perfectly sound. The doors of old St. Peter's, in Rome, were of Cypress, and in admirable condition after they had lasted 1,100 years. Mediæval popes were often buried in Cypress coffins.

The balsamic odor of Cypress-wood and of the growing tree is constantly referred to by ancient writers, and it is said that oriental physicians used to send consumptive patients to the Island of Crete, where the Cypress grew in great abundance, on account of the healing qualities of the air, as in modern times they are sent where Pine forests abound.

Notes Upon Some North American Trees.—XI.

CARYA.—The first author to separate the Hickories from the Walnuts and to place them in a genus by themselves was Rafinesque. His first attempt was made in 1808, in the *Medical Repository* (v., 352), in which in a single paragraph he simply enumerated after the word *Scoria* the specific names, in parenthesis, of five Hickories. It has been suggested (Britton in *Bull. Torrey Bot. Club*, xv., 275) that *Scoria* was simply a misprint for *Hicoria*. This may well have been, but it is not important, as no characters having been indicated by Rafinesque at this time for his proposed new genus, or any reasons assigned for separating the Hickories and Walnuts, *Scoria* or *Hicoria* of the date 1808 cannot be considered. Rafinesque, however, in the "Flora Ludoviciana," published in 1817, clearly defined, on page 109, the characters which separate the Hickories from the Walnuts, under his account of *Hicorius amara*, and it is evident that he was the first to propose in print a separate genus for these trees, the *Carya* of Nuttall not having been published until a year later (1818); and it is just and correct therefore to discard the now familiar *Carya* of Nuttall and

* Loudon: "Arboretum."

* Loomis: "Confucius and the Chinese Classics."

take up the equally appropriate *Hicorius* of Rafinesque, for there can hardly be a question that the name should be written as Rafinesque wrote it when he defined the characters of his genus, and that an earlier generic name without characters cannot be considered. I propose, therefore, to follow in the main, with the substitution of *Hicorius* for *Hicoria*, the nomenclature which has been carefully elaborated for this genus by Dr. Britton (*l. c.*), although the rejection of *Hicoria* will add another to the heavy load of synonyms with which these trees are encumbered.

241. *CARYA OLIVÆFORMIS*, Nutt., will become *Hicorius Pecan*, Marshall's specific name (*Arbustum Americanum* published in 1785), Pecan being the first published and four years older than Wangenheim's (*Amer.* 54, t. 18. f. 43) *Juglans Illinoensis*.

242. *CARYA ALBA*, Nutt., becomes *Hicorius ovatus*. The different species of Hickory were not distinguished by Linnæus, but his herbarium shows that the tree which it has become the habit to call *Carya tomentosa* was really what he meant by his *Juglans alba*, and that the oldest post-Linnæan specific name for the Shell-bark is that of Miller (*Dictionary* ed. 8. 1768) *Juglans ovata*.

Carya microcarpa of Nuttall was considered in the Census Catalogue a synonym of *C. alba*. This was probably a mistake, but there still exist doubts about the true position of this tree to be cleared up. Dr. Britton (*l. c.*) would retain the Nuttallian species and places his *Hicoria microcarpa* in a section with the Pig-nut. His specimens gathered on Staten Island, where this tree is not rare, seem to me to belong to a not uncommon form of the Pig-nut with small compressed globular nuts, which were familiar to the younger Michaux (*Silva*, i, 196, t. 38) and to Emerson (*Trees and Shrubs of Massachusetts* 198). But it is not quite clear that it was this small round nut that Nuttall had in mind when he wrote the characters of his *Carya microcarpa*. He described the nut as "partly quadrangular;" and in the figure in his *Silva*, the exocarp is represented as thick, while the nut although small is strongly four-angled like a Mocker-nut, as his description, "nucē subglobosa subquadrangulata", implies, as does the following sentence, "by the leaves it appears to be allied to *C. glabra*, but the nut on a small scale, is that of *C. tomentosa*, or the common Hickory." Some further investigation of the Pig-nut group of our Hickories made in the field, especially in the neighborhood of Philadelphia where Nuttall found his tree, is desirable, and necessary to clear up the doubtful points of their specific limitations. It was this small fruited Hickory that Marshall described as *Juglans alba odorata* in the "*Arbustum Americanum*" as Nuttall has pointed out in the *Silva*. So that if it is found that the species must be kept up, the name for it would appear to be *Hicorius odoratus*.

243. *CARYA SULCATA*, Nutt., becomes *Hicorius sulcatus*.

244. *CARYA TOMENTOSA*, Nutt., becomes *Hicorius albus*.

245. *CARYA PORCINA*, Nutt., becomes *Hicorius glaber*, this species having been first described as *Juglans glabra*.

246. *CARYA AMARA*, Nutt., becomes *Hicorius minimus*, this species having been distinguished first by Marshall (*Arbustum Americanum*) as *Juglans alba minima*.

247. *CARYA MYRISTICÆFORMIS*, Nutt., becomes *Hicorius myristicæformis*.

The Nutmeg Hickory was discovered west of the Mississippi River much earlier than has been generally supposed. A specimen preserved in the Torrey Herbarium of Columbia College shows that Fremont on his third expedition found it at Camp 24, "near the Creek," on the 3d of July, 1845. The known range of this species was greatly extended last year by Mr. Pringle, who found a few trees in one of the cañons of the Sierra Madre in the vicinity of Monterey, Mexico.

248. *CARYA AQUATICA*, Nutt., becomes *Hicorius aquaticus*.
C. S. Sargent.

The Shell-bark Hickory.

THE Hickory is purely an American tree. The eight species which are known all belong to the southern half of the North American continent, with the headquarters of the genus, as represented by the greatest number of species in any one locality, in the valley of the Red River, in Arkansas, with one species pushing far south along the Mexican Sierra Madre. No other country or region of the earth can boast of an indigenous Hickory-tree, although it is quite within the bounds of possibility that one, and perhaps several species may still be found in the unexplored mountain districts of central China, so similar are the floras of our eastern states and of eastern Asia in actual composition, and so closely related in their descent from remote common ancestors. The Hickories, at least some of the species, are among the most valuable trees in the world. There has never been a boy or girl brought up in any part of the country east of the Missouri River who has not early learned the value of the pecan, or the hickory-nut, or the mocker-nut; and the wood which some of these trees yield has no equal, and certainly no superior, for certain purposes. There is no wood at once so tough and strong and true. It is the Hickory-wood in its handle which has carried the American axe round the world, driving, wherever it is known, all other axes out of the market; and it has made possible those light carriages, which in turn have made possible the American trotting horse, one of the marvels of these modern times, and probably the best example of what can be accomplished, by careful breeding and persistent selection, in the development of domestic animals for a special purpose. No other tree is known whose wood is tough enough and strong enough to stand the strain imposed upon the American trotting-sulky, and without the modern sulky and its heavier forerunner, neither breeding nor training could have produced that race of horses which every American looks upon in his heart of hearts with joy and admiration. As a nation we owe much to the Hickory-tree, and we have good and just reason for being proud of it. It is a tree known to many people; next to the Oak and the Pine, more Americans know the Hickory-tree when they see it than any other of our trees. That is, they know, generally, the Hickory, without distinguishing the different species, which is hardly surprising, since botanists themselves are often perplexed over questions concerning the proper limitations of these species. Nor are these questions ever likely to be settled quite satisfactorily, for it is probable that several of the species are inclined to hybridize one with another and so produce those individuals of doubtful characters which are the despair of people who expect to be able to fit exactly every plant they encounter with the printed description of it in some book.

The Shell-bark Hickory is considered, generally, the most valuable of the genus. The nuts, of course, are not esteemed as highly as pecans, and they are, perhaps, rather inferior to and considerably smaller than those of a western representative of the genus, (*Hicorius sulcatus*), the wood of which is equal to that of the Shell-bark. Still, the Shell-bark, perhaps, is the tree which people have in mind, generally, when they think or speak of a Hickory-tree; and the peculiarity of the bark which separates into great thick, loose scales, gives to this tree a distinctive appearance which makes it easily known and recognized.

The Shell-bark, as it is now seen in the eastern States, is generally an obconical, square-topped tree, with rather small branches, produced low down on the trunk. Such trees have grown generally since the land was first cleared for settlement and agriculture, and there are not now many people living here at the east who, unless they know the forests of the Mississippi Valley, and more especially those found on the higher Alleghany Mountains, have an idea of what a large Hickory-tree is, growing as it grew naturally before the white man disturbed and changed the natural condition of this country. Our illustration of a fine tree in

southern Indiana will give an idea, at least, of the dimensions to which this tree can attain under favorable conditions; and brings out admirably the peculiar character of the distinctive bark, to which habit is due the popular and familiar name of the species. The Shell-barks in this particular region, Mr. Ridgway notes (*Proc. U. S. Nat. Mus.*, 1882, 77), are sometimes 150 feet high, with trunks four or five feet in diameter, and bare of limbs for seventy or eighty feet; and even larger trees can be found in the western and still almost untouched forests of eastern Tennessee and western North Carolina. But these large trees are doomed, and before many more years have passed every Hickory-tree of sufficient size and proper quality will have been sacrificed to supply the ever-increasing demands which the industries of men make on this tree. The area of the region in which the Hickory grows to perfection is really small in comparison with the demand for it; and when no substitute can be found for a particular wood it must in time be exterminated however abundant the natural supply, unless measures are taken to increase and perpetuate it artificially. And it would appear that of all our trees the Hickory is the one which should be planted wherever suitable land can be spared for it; and it should be protected and cherished, in view of the ever-increasing demands the world is making and must continue to make on this tree.

Entomological.

A New Enemy of the Elm.

(*Gossyparia Ulmi*.)

IN the last (August) number of *Insect Life*, Mr. L. O. Howard has an interesting paper, accompanied by some excellent figures, on this new Elm-pest, belonging to the Coccid or "scale insect" tribe. The article is entitled "A Newly-imported Elm Insect," and it gives a good summary of what is known of the life history of the insect which is considered as having been introduced from Europe on European Elms, and which has been found in several places in New York State and also about Boston and in Washington. Near Boston it was first noticed in the Arnold Arboretum, in the summer of 1887. Since then it has increased very much, and has been found quite abundantly in many places in the vicinity of the city. Although first found on the Slippery Elm (*Ulmus fulva*), it has latterly been more frequently observed on the American Elm (*U. Americana*) than on any other species. It also attacks *U. racemosa* as well as the European species, *U. campestris* and *U. montana*.

The accompanying illustration from a photograph will be of assistance in recognizing the pest, and will give an idea of its appearance at one stage of its existence. The photograph was taken about June 20th, which is the season when the coccids may be most readily detected, and it represents fully grown females on the bark of a young Slippery Elm. The round of their existence may be described as follows:

These females are viviparous, and, in this vicinity, reproduction begins about June 20th. All the females do not mature at the same time, so that the young continue to come forth for a couple of weeks. The young larva is elongated, oval in shape, and of a clear yellow color, and, under the microscope, a number of spines on the back and sides may be seen, as well as the six-jointed antennae. As soon as they escape from the parent body the young begin moving actively about upon the trunk and branches, and sometimes collect in great numbers on the under side of the latter. Most of them soon find their way to the leaves, where they fix themselves and become quiescent, feeding upon the juices for four or five weeks, or, in some cases, for a much longer time. On some trees, which have no pubescence or bristles on the young shoots or twigs, many of the insects settle about the crevices of the buds, etc. On the leaves they are often found on both the upper and lower surfaces, either in the crevices made by, or close along the sides and angles of, the midrib and principal veins. On *Ulmus Americana* and *U. racemosa* they are found most abundantly upon the under surface, and in other species they occur on the upper or lower surface according to the amount of pubescence which prevails. They are less numerous where it is densely bristly. Late in July and during August they cast their skins, assume a permanent reddish or brownish color, and become active once more. The main color is often much obscured by a fine and easily-removed gray or white waxy powder, which is secreted by, and carried upon, the many spines with which the back is covered.

Nearly all of them return to the branches and trunk, where they settle themselves in crevices of the bark. Here they remain during the autumn and winter. If the days are warm in late April and early May they begin to move again, and soon afterwards changes of skin take place and small white cocoons are made, or, as Mr. Howard says, "the females cast their last skin and the males form their cocoons."

They issue forth within a week or ten days. Two forms of males have been noticed; the first, about two millimeters (say .08 of an inch) in length, has rudimentary or unexpanded wings, but appears to be perfectly developed in other respects, and the other, which comes forth a few days later, has broad, perfectly developed wings, and also differs from the imperfect male in having a more slender body and two long, slender, white filaments projecting from the anal segment. Soon after this the females fix themselves for the last time to the bark of the trunk or branches and continue to suck the sap of the tree and increase considerably in size, especially in diameter.

A white waxy substance is secreted, which afterward becomes so abundant as to form a sort of cushion beneath and around the sides of the insects, giving them the conspicuous appearance seen in the illustration. Here they remain, and in the latter part of June the living young begin to swarm forth; the mother insect gradually becomes smaller, shrivels and dies, and, after a time, the waxy cushion becomes dull and wears away, although traces of it may remain for many months.

During all the feeding period of their existence the coccids throw

Fig. 129.—*Gossyparia Ulmi*.—Full-grown females.

out a sort of "honey dew," in very minute drops, which, falling upon the trunk, branches and lower leaves of the tree causes them to become blackened, and many ants, wasps, flies and other insects are attracted to the sweet food. When dry this may be scraped from the leaves in sooty-like flakes.

Trees that are much infested with these insects make their presence known at a distance of several rods by a peculiar sweet, somewhat pungent, though not unpleasant, odor. An odor much like it may be noticed when drying green leaves of *Ulmus fulva*. On old trees the insects cannot get nourishment through the thick, corky bark of the trunks, and so ascend to the higher parts and branches, where they are not easily discovered. In some cases they may be a cause of the unhealthy appearance of trees. When abundant, they greatly injure the vitality of young trees if they do not destroy them.

No systematic experiments with insecticides have as yet been tried, but an application in June of whale-oil soap and kerosene, made pretty strong and applied with a stiff brush, appeared to kill all that were thoroughly washed, but some on the small branches escaped, so that enough were left to thickly colonize the tree again within a year or two. Thoroughly spraying the trees with kerosene emulsion, at a season when the insects are active and tender, might lead to more satisfactory results, but the chances are that some would escape.

It has been noticed that a few of the insects sometimes remain on the leaves until they fall in the autumn, and in this way they could be carried from one tree to another. When active they may easily be carried to widely-separated localities upon the feet of birds.

Arnold Arboretum.

Foreign Correspondence.

London Letter.

AT last we have bright sunshine and summer warmth again, and, in consequence, autumn flowers of all kinds have come out amazingly during the past week or so. Owing to this the last August exhibition at the Royal Horticultural Society's meeting was exceptionally large and interesting. It was remarkable, also, for the large number of novelties submitted, and no fewer than two dozen certificates were awarded. The chief feature of the meeting was a magnificent collection of *Gandavensis* Gladioli from the celebrated nurseries at Langport, which is undoubtedly the headquarters in Europe for these splendid flowers. There were about two hundred spikes shown, representing all the colors through which the Gladiolus ranges, and every spike was massive and set with large flowers of faultless shape. In some instances I measured spikes fully eighteen inches long, with only two or three unexpanded buds. But, unhappily, Messrs. Kelway's splendid success is not a reflex of Gladiolus-culture throughout the country. Failure in fact is more common than success, and no one can deny that the highly-bred Gladioli of the *Gandavensis* race are delicate in constitution, requiring exceptional treatment and favorable conditions of soil and climate. Though I have seen them grown in private gardens as fine as the Langport specimens, the prevalent complaint is that they are disappointing. But a new era in the culture of this flower is at hand, and in a few years success will be more frequent, and this will be brought about by the intermixture of hardier blood with these delicate strains. M. Lemoine's recent triumphs with the *Purpureo-auratus* race have convinced Messrs. Kelway at last of the importance of these new hybrids, for they have begun to raise them at Langport, and at this exhibition they showed us one fine example, at least, of their work. This variety is one called Leonard Kelway, in which we see the characteristic features of *Gandavensis*, the large spike and open flower combined with the growth and habit of *G. purpureo-auratus*. It is of wonderfully rich color, some of the petals being a deep maroon-crimson, others rose-pink brightening to scarlet. Now that Messrs. Kelway have made a fair start, we hope to see next season numerous new hybrids of the same stamp, which will be most welcome. They showed a large number of new sorts of the ordinary *Gandavensis* type, but as they reached perfection with these years ago, one cannot appreciate the difference between the old and the new; now and then there is a distinct "break" in color, but neither of the two certificated were exceptional in this respect. They were called Duke of Fife, a brilliant crimson, flaked with white, and Vulso, a pale salmon-pink with white centre. In both, the flowers were quite up to the florist's standard, and the spike was long and massive.

Turning from the Gladioli to the Dahlias we find novelties in every section, but in most cases it is a difficult matter to intelligently describe how they differ from old sorts, especially in the large, double, show kinds. There was a large collection of these from the famous raisers, Keynes & Co., of Salisbury, and four were selected as worthy of awards of merit. These were Crimson Globe, brilliant crimson—almost scarlet; Reliance, yellow-buff, flaked and tipped with crimson; John Hickling, a warm yellow, and Alice Emily, orange-yellow marked with carnation-red. All these were, of course, the acme of size and form. Among the Cactus section, which seems to be now more popular than any other, there were some very beautiful new sorts, and one named Panthea, a large spreading flower of a vivid flame color, won an award. The others that pleased me much were Asia, a delicate blush-pink; Empress of India, maroon-crimson; Lady Marham, cherry-crimson; H. Patrick, the best white Cactus; Honoria, the best yellow; Mrs. Hawkins, yellow, flushed with pink, and Amphion, buff and reddish-brown. The only single sort certificated was named F. L. Temple, in compliment to an American nurseryman now travelling in England. His namesake is like the old Paragon, the best of the earliest sorts, but larger, and the deep maroon and crimson edges seem brighter. It was shown by Mr. Ware, of Tottenham.

Among other certificated plants were three good Orchids, two of which were varieties of the popular *Loelia elegans* which flowers at this season. One variety was from the Duke of Marlborough, at Blenheim, and was named The Duchess. It is very distinct from the ordinary form, and beautiful, the sepals and petals being rosy-purple, and the broad, middle lobe of the labellum rich crimson, fading to almost white, while the lateral lobes are quite white. Another form called Cook's

variety is at once recognized by the smaller flowers, their symmetrical shape, and the brilliant crimson hue of the labellum. These two were the best of a number of varieties of this *Loelia* exhibited, which exemplified clearly what a wide range of variation exists in the cultivated forms of this beautiful Orchid. The other certificated Orchid was the old *Angraecum Chaillu-anum*, discovered thirty years ago by the great African explorer Du Chaillu. It is still rare, and by certificating it the committee stamp it as a good Orchid. It is small in growth, and produces a long spike of greenish-white flowers with long narrow sepals and attenuated spurs. Messrs Veitch showed, for the first time, a new species of Phajus from the Philippines, which has been named at Kew *P. Philippensis*. It is interesting, but not a striking beauty, the flowers being small and poor in color. Some fine examples of *Satyrion* (Terrestrial Orchids from South Africa) attracted notice, as they are so seldom seen in a flourishing, much less flowering, state. *S. carneum* has a dense spike of pink flowers, and *S. aurantiacum* has flowers of a rich orange-yellow.

A beautiful old half-hardy bulb from the Cape, known as *Watsonia rosea*, was certificated because of its value as a garden plant. It has Gladiolus-like growth, and a tall and slender spike, thickly set with open flowers of a clear rose-pink color. Mr. Ware exhibited it in splendid condition, showing what a fine plant it is when well grown. Mr. B. S. Williams was awarded a certificate for a new species of *Carludovica* belonging to the *Cyclanthaceæ*, and allied to the Palms, which they resemble. This new species is *C. palmifolia*, and is of graceful growth, with tall recurving fan-like leaves. It will make a first rate decorative plant. A new *Sarracenia*, named *S. decora*, was shown by Messrs. Veitch. It is a hybrid between *S. variolalis* and *S. psittacina*, and has curved pitchers about six inches high, richly colored with deep red, and variegated with white and green veins. Another form of *Pteris serrulata*, with crested fronds, called Densa, was shown by the market Fern grower Mr. May. It is very dense and compact in growth, and as crested as curled Parsley. The committee did not hesitate in awarding a first-class certificate to it. The same grower won a certificate for a new *Bouvardia* called Double Hogarth. It is precisely like the single Hogarth in color and growth, and the flowers are very double. Another was shown, but it was inferior to President Cleveland. Mr. Ware won an award for a pale straw-colored variety of the Iceland Poppy (*Papaver nudicaule*). It is called Sulphureum, which appropriately describes its color. The only new early *Chrysanthemum* was a shoot from the yellow *Précocité* with flowers of a deep bronzy-yellow. It is called Maud Pitcher, and being dwarf and compact in growth, and a free flowerer, is regarded as a good thing, and therefore was certificated. From a large number of varieties of Java Rhododendrons, from Messrs. Veitch, the committee selected for an award one called Ophelia, a lovely variety, with large flowers of perfect shape, and of a pale clear pink color. The importance of these beautiful green-house shrubs is being fully recognized now, and people have found out that they are among the most reliable plants for yielding an almost perpetual supply of the loveliest flowers one could wish, and, no doubt, their popularity will spread to American gardens. There was a large gathering of hardy ornamental trees and shrubs, but the only novelty was a golden tinted variety of the old *Taxus adpressa*. It came from the Handsworth nurseries under the name of Variegata. It is decidedly golden, and I can imagine what a big spreading tree of it will look like in future. It is a first-class novelty, and the committee, by awarding it a certificate, showed that this was their opinion of it. The new Clematis, Baron Veillard, was again shown, and though a freely-flowered specimen was shown, the committee did not seem to appreciate the color, which is a purplish-mauve, hardly bright enough for a Clematis.

Cultural Department.

Fertilizers for Ornamental Plants.

IN floriculture, the application of fertilizers may be made with three purposes in view: (1) effect on bloom; (2) effect on foliage; (3) effect on seed, bulb or other parts for propagation. The first and third purposes generally go hand in hand, and, if we secure the first, as a rule the other is attained.

Much space in the agricultural and horticultural journals is devoted to the recommendation of a plenteous application of manures to plants, but rarely do we find any testimony from experience except in the most general way. The past winter and spring I had under test in the university green-house some interesting work with manure for the purpose of ascertaining,

Fig. 130.—The Shell-bark Hickory.—See page 460.

in a measure, the effect of special and general manures on foliage plants and on flowers. In the first place, two lots of *Coleus*, one being red and the other green, received special application of mineral fertilizers. Five hundred milligrams (about 7.7 grains) of each of the following fertilizers were applied to a plant at intervals: (1) nitrate of soda; (2) sulphate of iron; (3) acid phosphate; (4) muriate of potash; (5) a complete fertilizer. The last three had been analyzed in the laboratory, and were good specimens of fertilizers; the other two were standard brands.

In beginning the experiment, six plants were selected for each manure as nearly alike as possible, excepting that three were red and three green. The plants were small, not having more than two nodes each; they had been cut back twice, and were in three-inch pots. They occupied a bench on the south side of the green-house, and had good sun exposure. Water from the same source was used in watering each set of plants. The soil the plants were grown in was as even in character as I could secure. The most striking effect from the fertilizers was seen in the application of nitrate of soda. The

plants treated with this became either very dark red or green in color and assumed a robust growth of unmistakable character. The complete fertilizer had an effect almost as marked, and produced deep color and strong growth. To my surprise the sulphate of iron did not give the depth of color that other experiments would seem to have warranted us to expect in this case. The plants appeared strong and healthy, but there was nothing unusual in their color. I think that the muriate of potash ranked third in effectiveness. The acid phosphate was not effective. The color of the foliage remained light, and the plants did not make a growth equal to those treated with the soda, potash and complete fertilizer. The iron and phosphoric acid had much the same effect.

These fertilizers made themselves felt for a few weeks, when their influence appeared to wear off, and all the plants began to once more take on a similar foliaceous coloring. Again the applications were made, and once more the same effect of the different plant-foods was made manifest. Future experiments were repetitions of the first two; whenever these fertilizers were applied the same results followed.

To me, the most pertinent application of what I saw in this, was the benefit to be derived from the use of sodium nitrate in bringing out strong foliaceous coloring, and especially in plants with bright-colored leaves. If the beauty of a *Coleus*-bed lies in its color of leaf, its effectiveness, in my opinion, may be materially heightened by the use of proper fertilizers.

In another direction I experimented with manures on roses. I procured sixteen two-year-old *La France* Roses of as nearly the same size as possible. These were separated into four lots of four plants each. Before planting, the soil was carefully washed from the roots of each plant. Lot one was planted in pure, washed river-sand, and fertilized once a week with liquid cow manure. Lot two was planted in sand like one, and treated once a week with liquid horse manure. Lot three was planted like lots one and two, and fed *Floralis* (a preparation procured from J. M. Thorburn & Co.) once a week. Lot four was planted in our regular rose-potting soil, and fertilized weekly with liquid cow manure, such as was used with lot one. All of these plants were placed in eight-inch pots.

First and most important, the plants grown in ordinary soil thrived best and produced the greatest number of buds.

At this writing they will average larger to a noticeable degree than will the others. The effect of the *Floralis* was injurious at first, but because too strong in application, though directions were followed; as a result one plant was killed, and the foliage removed from all. However, with reduced application, three renewed their growth and, before the season was over, yielded a fair showing of buds. In both lots where cow manure was used, more Roses were secured than from the others. The flowers were extra fine in all cases, but I have not at my disposal, the number of blooms produced by each lot.

The reason why sand was used in three lots was to see if the effect of manure could be better shown, where the soil was comparatively clear of fertilizing matter at the start. In each case, the amount of liquid manure applied was as nearly of the same quantity and quality as I could make it. The manure used was comparatively new and free from straw. This work is still in progress, and will be further reported on, so as to be accessible to those interested.

I cannot close without referring to another fertilizer test, on a more practical basis, if you please. A portion of one of our

A Cypress Avenue at Verona.—See page 458.

green-house benches is planted with Roses. The soil consists of turfy loam well mixed with solid cow manure. Late last winter our gardener, a rather intelligent negro, informed me that he had heard that sheep manure would make the plants show their color, and begged me to secure him some. In a short time a quantity was obtained and made into a liquid and

applied twice a week to the roses by Andy. Certain it is, our Roses did unusually well last spring. I shake my head in a questioning way as to the responsibility of the sheep manure for this, but Andy only laughs, and says: "Sho', P'fessor! Didn't I tell you that sheep manure 'ud do it?"

University of Tennessee, Knoxville.

Fern Notes.

SPECIMEN Ferns should now be in their best condition, as in most instances the growth will be fully developed, and showing the characteristics of the perfect fronds, whether fertile or barren. And, when the fronds are fertile, it will be well to select some from which the future stock of young plants may be raised. In this selection of fronds it will be found most satisfactory to cut them as soon as the spore-cases begin to open, because when taken in this condition a fair supply of spores are usually obtained; whereas, if they are allowed to remain on the plant until the spores begin to drop, much of the best of the crop is frequently lost. But owing to the great differences in the arrangement and appearance of the spores on different species of Ferns, it requires the exercise of some judgment in gathering them to ensure success, and in this operation as in most others connected with the growth of plants, experience is the best teacher.

It seems hardly necessary to repeat that the fronds gathered for seed should be wrapped in clean paper and put in a dry place for ten days or two weeks, at the end of which period the spores may be shaken out and sown, or else stored away in small phials for future use. The month of September is a good time to sow Fern-spores for an early spring crop, for though the seedlings do not make rapid growth during the winter, they will progress far enough to be in good condition for an early start in the spring.

Good use may be made of an odd corner in the green-house by planting out a few Ferns for cutting. They may be either on the bench or underneath it, but it is preferable to grow them on the bench, as they are better under control, and the fronds are stiffer and have more substance than those grown beneath where the light is less distinct. In growing Ferns for this purpose it is best to plant them in a comparatively stiff soil, as the fronds thus grown are harder and consequently stand better after they are cut.

The following species and varieties are well adapted for this purpose: *Adiantum cuneatum*, *A. Wiegandii*, *Pteris serrulata*, *P. Cretica magnifica*, *Onychium Japonicum* and *Nephrolepis pectinata*, and all of them may be readily grown in a green-house temperature. Water should now be given quite early in the day, and the moisture kept off the foliage as much as possible by free ventilation. As much air at night as the weather will permit should be given, because when kept too close some of the foliage is sure to damp off.

Among the easiest to be injured by moisture on the foliage are the Golden and Silver Ferns (*Gymnogrammas*), several of which grow best under stove treatment, while some few varieties flourish in a green-house. Of those most susceptible to injury from excessive moisture on the fronds, three or four are among the finest varieties, for instance: *Gymnogramma Peruviana argyrophylla*, *G. Laucheana magnifica*, *G. Laucheana grandiceps* and *G. Wetenhalliana*, the latter being considered by many persons one of the finest of the genus, although it is not always easy to handle. While speaking of *Gymnogrammas* we should not neglect *G. schizophylla*, a charming basket Fern with very delicate, feathery foliage, and possessing a notable peculiarity among its relatives of this genus, its fronds being proliferous, and producing young plants on or near the apex of the mid-rib.

In the treatment of many of the stronger-growing Ferns an occasional watering with liquid manure of medium strength will be found beneficial after the plants become pot-bound, tending to keep up the rich green of the fronds, but unless the plant is quite pot-bound it is just as well without any special feeding, and if the drainage of the pot is defective it is very easy to overdo the application of stimulants in this manner. Probably the best manure to use for the above is cow-dung, it being not so likely to injure the roots, though at all times discretion should be used in its application. It is useless to give liquid manure to a weak, over-potted Fern in the hope of inducing it to break into growth, and it should be remembered that this liquid should never be given to a Fern while it is very dry, else more harm than good will result.

Those pests of the Fern-grower, slugs and snails, are usually present in considerable numbers at this season, and especially so in old green-house structures, and should be carefully hunted for at least once a day. The use of Cabbage and Lettuce leaves as traps for the slugs is about the simplest remedy, and, by a regular examination of these leaves morning and evening, many of these troublesome enemies may be destroyed.

As the time for the various horticultural shows is near at hand, some thought will be given by growers to Ferns for exhibitions, and preparations will be made for these competitions.

It should be remembered that the tasty arrangement of an exhibit is always a point in its favor, and to this should be added clean pots and correct and neat naming of the specimens shown, the latter being absolutely essential to a good exhibit. In the preparation of the plants for this purpose it will be found necessary to stake up the fronds of some species; but in doing this as few stakes as possible should be used, and due consideration should be given to the natural form of the plant, so that its gracefulness may be retained. A stiff and formal arrangement of the fronds of a Fern is an abomination from an artistic standpoint, and should be utterly condemned.

Holmesburg, Pa.

W. H. Taplin.

Orchid Culture, past and present.—This subject is of such interest that I venture to offer a continuation of the notes sent last week.

The profound ignorance which prevailed on the subject of Orchid culture during the early days of the present century is well illustrated by the following extract from the *Botanical Register* for 1817, under plate 220: "Air plants," for such were Vandas, Aërides and Saccolabiums then called, "possess the faculty of growing when suspended so as to be cut off from all sustenance but that derived immediately from the atmosphere. Plants of other genera of this tribe, and even of a different tribe, are endowed with a like faculty; in none, however, can such insulation be considered as the state of existence which suits them best, but merely as one they are enabled to endure, as a carp is known to do, that of being suspended out of water in a damp cellar." On reading this, one cannot help thinking of the days when birds of paradise were supposed to be altogether devoid of legs and to spend their whole lives upon the wing.

The part which the Horticultural Society of London took in obtaining information on the subject may here be mentioned. Owing to the want of success which had attended the cultivation of Orchids, a stove was set apart for their exclusive culture, but we read that "the first experiments were unsuccessful; the plants were lost as quickly as they were received." This led Lindley to inquire more closely into the conditions under which Orchids grew in their native countries, and thus to supply data for more successful cultivation. These data were chiefly obtained from the lowlands of Brazil and from India, and from them Lindley concluded that high temperature, deep shade and excessive humidity are the conditions essential to the well-being of the plants. These conclusions, published in 1830, he subsequently had reason to modify, but they appear to have been generally followed for many years afterwards.

Various travelers, who had seen the plants growing at considerable altitudes on tropical mountains, gave utterance to monitory warnings against the folly of subjecting Orchids, which naturally grew in a temperate climate, to the stifling heat of an Indian jungle, and these views were gradually adopted by a few gardeners of intelligence. Cooper, at Wentworth, adopted a lower mean temperature, and admitted fresh air into the house. Paxton, at Chatsworth, added an improved method of potting to secure sufficient drainage, and occasional watering of the paths and stages of the house, so as to secure a moist atmosphere. In 1838, Lindley wrote, "The success with which epiphytes are cultivated by Mr. Paxton is wonderful, and the climate, in which this is effected, instead of being so hot and damp that the plants can only be seen with as much peril as if one had to visit them in an Indian jungle, is as mild and delightful as that of Madeira."

One of the causes, however, which entirely revolutionized the cultivation, not only of Orchids but of all kinds of exotic plants, was the substitution of heating by hot-water pipes for the old system of hot-air flues, with its attendant evils of smoke and other noxious vapors escaping through the cracks and fissures of the flues into the atmosphere of the house. This change had been gradually effected at a still earlier period, but deserves to be mentioned as one of a combination of circumstances which gradually brought about a more rational treatment of Orchids generally. To us, who are familiar with the modern system of cultivation, the wonder seems that the change should have been brought about so very slowly. But the fact remains that, up to about 1860, the numerous beautiful Alpine Orchids of New Granada were killed almost as fast as they were imported by the barbarous treatment they received, and which Lindley, towards the end of 1859, confessed to be "a deplorable failure."

There yet remain a number of refractory subjects. Mr. Veitch enumerates *Cattleya citrina* and a few *Loelias* and *Epidendrums* from the Mexican highlands, the *Barkerias*, some Brazilian *Oncidiums*, several fine *Dendrobiums*, the *Bolleas*, *Pescatoreas* and others, as examples of plants not yet rendered amenable to cultivation, but which gradually dwindle

away and finally perish outright. The causes of failure he attributes to our imperfect acquaintance with their native surroundings, or the difficulty of approximately imitating in our houses the climatic conditions under which they grow. Doubtless this view is the correct one, and the enormous advance made during the past quarter of a century inspires the hope that many of those which still remain refractory subjects will yet prove amenable to cultivation as the conditions under which they grow become better understood. Let us hope so.

Calypso.

Vegetables under Glass.—Market gardeners usually have a plant-house, and during the fall and the early winter it is practically empty, with the exception of the cuttings in the forcing benches and the stock plants to be kept over winter. It is possible to use this vacant space for two or three months, especially with vegetables for salads, without detriment to the plants. I have a span-roof house thirty-three feet long and twelve feet wide, heated with a smoke-flue under the benches, which are four feet wide on each side of the house, with a path down the centre. The soil used for vegetables is loam, eight inches thick, on benches; into this is dug fine horse manure. Lettuce should be set six to eight inches apart on the benches. A good variety for this purpose is the Grand Rapids Lettuce, a new kind which does well in green-house benches; Lettuce will not make perfect heads in the cool winter months, but for home use very nice plants can be raised. The house should be fumigated once a week with tobacco smoke, to kill the green aphids that would soon destroy all growth if not kept down.

Water-cress grows nicely in the bench, from slips of plants in their natural home. They should be dibbled in the benches about four inches apart each way, and, of course, watered well. A luxuriant growth of tender cress can be had in about six weeks, and when this is broken off a new growth will start, and this can be repeated as long as wanted. Mint roots will grow here nicely. Chives also do well, and fresh cuttings can be put in as often as they are removed. Seeds of French Breakfast Radish, sown in rows five inches apart, will produce edible roots in about six weeks from the time of planting.

If you have no garden Dandelion growing, go to the fields and gather roots of the common variety, digging them up full length, if possible, or at least not breaking them off within six inches of the leaf. They should be placed in boxes of earth with the tops uncovered, and not too closely cut. It is better to defer the digging till the ground is ready to close up for winter, and the roots can be kept in the box till February, in a place not cold enough to allow the earth to freeze, but cold enough to prevent the plants from making any growth. They should be kept damp, but not wet. About four weeks before Dandelion greens are wanted, the roots should be set in the benches in rows, and the growth will be a matter of surprise and pleasure. They grow quickly, especially when the house is kept warm. They will yield but one cutting, and the roots must then be thrown out. Parsley roots can be set in the benches in the same way, and will give cuttings all winter.

W. H. Bull.

Chrysanthemums.—This is a busy time with fanciers of Chrysanthemums, who must now be looking forward to the storing of plants inside at the first indication of frost, to the final training of specimen plants, and the thinning of the buds, besides the general care incident to the opening of another campaign. I have my specimen plants in quarters where they can be covered with sash in ten minutes. It may be that we shall not have frost enough to hurt the buds before the middle of October, but it is wiser to be on the safe side. The final housing of specimens will depend upon the conditions of the weather. Early-flowering kinds may be left out-of-doors a week longer than the later kinds, provided they can be protected during frosty nights. The final touches should be given to specimen plants as early as possible, for after the buds are set, and the wood begins to harden, all tying looks rough and unkempt. The thinning of flower-buds is of the greatest importance for specimen bloom. Three flowers are deemed sufficient on a single-stemmed plant, while on specimen plants three flowers should be left on each leader. Even when plants are grown in the ordinary way the flower-buds should be severely thinned. Of plants on which I am growing flowers for market I take from eight to twenty buds from each shoot, according to the variety. It is a mistake to think that thinning reduces the amount of color-effect. On the contrary, it augments it. All plants will require judicious watering when first taken in from out-of-doors. For the first two or three days it is best to be on the dry side, as, seemingly, the plants are much affected by their sudden confinement.

Weak liquid manure of any kind should be given at every other time of watering.

Carnations.—It is time that Carnations for winter-flowering were housed, and the planting, whether in pots or on open benches, should be done well and firmly. Any light, friable soil seems to suit the Carnation. A thorough watering should be given as soon as the planting is complete, and then on very sunny days the plants should be slightly syringed two or three times, the last time early enough to allow the plants to get dry before dark. The watering, after the first soaking, should be done very carefully, so as not to have the bed saturated for a week at a time. It is well to remember that each day, from now until the 1st of February, evaporation grows less and less. Carnations should be staked neatly as soon as potted or benched. The ties should be neat, and they should not be very tight around the body.

Pearl River, N. Y.

John Thorpe.

Caryopteris Mastacanthus.—In the first volume of GARDEN AND FOREST (p. 20) Max Leichtlin calls attention to this beautiful and interesting plant of the Verbenaceae family. To the same enthusiastic botanist and collector of new and rare plants the Arnold Arboretum is indebted for a specimen of the plant which is just now, and will continue to be as long as frost does not interfere, the most attractive flowering shrub in the collection. This plant was kept in a pit last winter, so that its hardiness has not yet been tested here, but it is well worth a little trouble and care. The small lavender-blue flowers are borne in large clusters at the axils of the opposite leaves, and as the branches grow, new flower-buds continue to develop with each pair of leaves, so that the plant would bloom for a long period if not checked by frosts. It was originally found in China by Robert Fortune, but it is also a native of Japan. If introduced from its most northern habitats it may be as hardy as *Vitex incisa*, which does very well here, without artificial protection, in some favorable situations.

Correspondence.

Forests and Civilization.—VIII.

To the Editor of GARDEN AND FOREST:

Sir.—Since the publication of my report on forestry matters in Pennsylvania was begun in GARDEN AND FOREST, I have had many letters from all parts of the country inquiring whether cutting off the woods had any effect in aggravating the recent great floods in that state, or in causing the disaster at Johnstown. Some of the writers think the catastrophe should be made use of at once as a most impressive lesson regarding the consequences of forest destruction, and various things which have been written since the occurrence indicate that some vital considerations have not been adequately recognized. We have reached a stage in the discussion of forestry subjects in this country when discrimination, moderation of statement, and dependence upon actual investigation by competent observers are more and more desirable.

It is certain that the destruction of forest conditions over any considerable portion of a water-shed causes the water from rainfall or melting snows to reach the channels of the streams in a shorter time. The water runs down the slopes more rapidly, and there is, consequently, more of it at any particular point in the course of the stream at one time, and the stream is higher than it would be if the water descended more slowly to the river-bed from the hills. This is one of the most important principles of the subject of forestry, and it should be familiar to all intelligent persons. Its truth may be easily ascertained by direct observation in any mountain forest region, where considerable areas have been entirely denuded by the effects of pasture or fire following the removal of the trees. But cutting off the forest does not, in itself, destroy forest conditions. If the ground is protected from fire and from pasture the forest-floor is not destroyed, and the trees will soon grow again. Water will not run any faster down a hill-slope which is still covered by the sponge formed by the network of living root-fibres, decaying leaves, and the accumulation of vegetable matter usually found on the floor of a forest, merely because the trees have been cut off. Forest conditions are still maintained if the land is so protected that another generation of trees has a chance to grow. It is not the cutting off of the trees that causes mischief, but the breaking up of the forest-floor, and of the succession of the forest, by fire or pasture.

During my recent examination of the mountain forests of Pennsylvania I had excellent opportunities for observing the effects of very heavy rainfall, and of comparing the rate of descent of the water over hill-side areas covered with forests,

or where forest conditions prevailed, with the rate on areas of equal slope where the forests had been removed, and the tract denuded by fire or pasturage. I went into the woods several times while it was raining heavily, and again after the rain had ceased. I had made similar careful observations here in the Adirondacks many years ago. In both regions I found that on denuded hill-side areas the water descended to the brooks and rivers much more rapidly than where the forests were still standing, or where, if they had been cut off, the forest-floor was still intact. After a heavy rain the denuded areas became dry much sooner than those of similar slope on which forest conditions had been maintained. The rate of descent of the water over hill-side areas of equal slope is in exact proportion to the smoothness and impenetrability of the surface.

As all the water-sheds of the Pennsylvania mountain forest region have been partially denuded, the floods resulting from unusually heavy rains are certainly somewhat more sudden and disastrous than they would be if forest conditions had been maintained over the whole drainage area. But there were sometimes great floods while the forests were yet unbroken, and there would be now if they covered the whole country as of old. The relation of forest destruction to recent freshets cannot be determined even approximately without much more careful and thorough observation than the matter has yet received. The entire drainage area of a stream, lake, or reservoir would have to be examined with scientific accuracy, and the proportion of forest areas and of denuded lands ascertained. Such investigations, if conducted by competent men, would probably make plain the necessity for some proportion of forest in every large water-shed or drainage area in mountain regions, and the places at which forests would be most needed for the protection of the streams and valleys could also be determined.

Until the methods of scientific investigation are thus applied to the subject, it can hardly be discussed intelligently or fruitfully, except in a very general way. Such application of scientific methods to the study of forestry subjects in this country would require a considerable advance in thought. While forestry was wholly a matter of theory for us here, it was necessarily only something to talk about, a topic for essays and addresses, and, of course, anybody could talk or write on the importance of the general subject. The method of treatment at this stage was inevitably somewhat vague and sentimental. All the illustrations were drawn from the history of the countries of the old world, and there was a natural tendency to assume that we might adopt the methods and ideas of European forestry, and put them into operation without taking the trouble to study actual facts and conditions here. This stage of library and office forestry was inevitable, but it was always plain to thoughtful Americans that it was only a stage, a degree of progress or advance, and that we should pass beyond it whenever we began to apply the methods of scientific observation to the subject in our own country.

The fact that our government is a democracy, that all the people participate in it, makes the psychological element the most important factor in this, as in all of our national problems. Everything depends upon the character, intelligence, temper, and degree of civilization of the people. Nothing greatly in advance of these can be done or established here. This is often deplored by men who wish to bring about various special reforms, yet it is not only a natural but a wholesome feature of our national condition and life. No institution which is not the product and expression of our national character can be successfully planted in our soil. If introduced from without, brought hither from alien lands, it could not be made vital or permanent. It would be artificial, parasitic, and of transient duration. The propagation of ideas, after we have the right ideas to propagate, the education of the people by the diffusion of knowledge, thus becomes the chief instrument and means for all that we have to do in this country for the advancement of our civilization, and the permanence of our national life. Many reformers are far too much disposed to rely on legislation and on government action without sufficient attention to the preparation of the public mind for the work of sustaining the laws and aiding in their efficient administration.

Real knowledge and sound practical judgment regarding forestry interests here can result only from direct, patient, and continuous observation and study of the subject, in all its aspects and relations, as a feature of the life of our own country. The labor and time required to gain such knowledge, through familiar acquaintance with the woods and streams of our country, must be paid for. Each of our principal states should have a competent officer or agent, whose work shall be out of doors, not in an office at the state capital, and who shall acquaint himself and the people with the condition of the

forests and streams of the state, and with their functions and value in all their relations to the life, civilization, and welfare of its inhabitants.

The Potent Pollen of the Navel Orange.

To the Editor of GARDEN AND FOREST:

SIR: The experience of Rev. Lyman Phelps, noted in No. 79 of GARDEN AND FOREST, will doubtless prove a stumbling-block to those scientists who do not believe in the direct influence of pollen upon the forthcoming fruit. That such a difference of opinion should exist among biologists indicates a *terra incognita* in the realms of botany as worthy of exploration and mapping out as the heart of Africa.

Discarding the theory of chance, there would seem to be only two ways in which so-called sports can occur—one by atavism, or reappearance of ancestral traits, and the other by the influence of foreign pollen upon the fruit, and through this upon the wood. So what we call sports are generally the freaks of pollenization.

Perhaps no family of plants is more readily affected in this way than the Citrus, and the infancy of Citrus culture in this country may account for the ignorance of many of our botanists respecting phenomena often observed by intelligent and studious Orange growers. The same phenomena are familiar to the Orange and Lemon cultivators of the Old World. A letter from one of them, published several years since in the *Florida Dispatch*, strongly condemns the intermixture of all varieties of Citrus trees in one plantation as tending to produce numbers of unsaleable hybrid fruit. And this caution is given, not as an unestablished hypothesis, but as a fact well known to all. My own experience in Florida, however, would not, from a commercial standpoint, warrant such extreme caution. The venerable Col. Davey, of Orange Mills, Florida, stated that he had sometimes seen perfect lemons on Orange trees, where both had been planted together, and I have seen fruits, closely resembling an orange, produced on Lemon trees. There could be no reappearance of ancestral traits here, and these so-called sports can only be attributed to the pollen, since it is presumable that, had no Lemon trees existed near by, a lemon would never have grown upon an Orange.

No sweet oranges differ more widely than the Brazilian Navel and the Maltese Blood. Geographically and structurally they are, in a measure, the antipodes of each other. If the pollenization theory be false, then, whenever a Blood orange bears the Navel mark, it would internally and externally maintain the characteristics of its kind. Contrary to this, when Navels and Blood varieties are planted together, the Blood oranges bearing the Navel mark are often scarcely distinguishable in shape, flavor and texture from the Brazilians. How could a Maltese orange be metamorphosed into a Brazilian except through the influence of pollen? When we reflect also that there are distinct varieties of Navels, and their almost exact counterparts occasionally appear upon other trees, the evidence becomes overwhelming. So much for chance examples—deliberate experiments do but confirm what chance suggests. Rev. Mr. Phelps carefully crossed the Mandarin orange with the Navel. Mandarin oranges of the typical shape appeared with the broad seal of the Navel impressed upon the apex. When Navel trees exist in any considerable number in a grove, the peculiar mark appears freely upon other trees, and I have in mind in my own grove several young trees of a hybrid Mandarin, not a Navel, on which, this year, every fruit is stamped with the broad seal. And yet some microscopists argue a lack of energy in Navel pollen, from its often too profuse shedding of bloom, when this pollen is so marvellously prepotent as to leave indubitable traces wherever it falls.

We may go still further and note that not only is the fruit directly affected by foreign pollen, but also the wood of the same growth, in its young state, at least. Some curious hybrids, in which the traits of both parents were strongly apparent, have been created by using buds from this cross-fertilized wood. The same principle prevails, perhaps to a less extent, among other genera of plants, and variations of Roses, called sports—I think the American Banner is one—not unlikely came about in the same way. I have before me an apple, with a broad stripe of deep crimson Baldwin peel, extending from stem to apex, which grew on a McLellan tree planted among a lot of Baldwins.

Can the doubting Thomases explain how that Baldwin streak came there?

Federal Point, Fla.

E. H. Hart.

To the Editor of GARDEN AND FOREST :

Sir.—I have read with interest Mr. Phelps' notes on the immediate influence of foreign pollen affecting the orange, and I am led to ask if he has a Washington Navel tree that from its own inherent nature or peculiar surroundings produces pollen so abundantly as to impress the fruit of surrounding trees to the extent he mentions? If so, he has a valuable tree to experiment with. The Washington Navels on Indian River are notorious for being poor bearers, and ringing, girdling and cutting has been resorted to, in vain efforts to induce greater fruitfulness. I concluded last winter from an examination of the blossoms, that the trouble was due to the fact that the blossoms were all pistillate, as I failed to find a single flower producing pollen. I also tried to fertilize hundreds of flowers by hand, using pollen from other varieties, carefully applying it to the stigma of the Navel blossoms, with complete failure, though the attempt was continued at intervals for two weeks. It is quite possible that the Navels here may produce an occasional flower with a grain of pollen which fertilizes its own pistil, but that they are able to furnish enough to visibly affect other trees is a revelation which I was unprepared for. Standing as these Navels do, surrounded by trees producing abundant pollen-bearing flowers, in bloom at the same time, and yet persistently failing to produce the least fraction of a crop, all this, together with my own unsuccessful attempts at cross-fertilization, seemed to indicate a lack of affinity on the part of these trees for the pollen of other varieties. The subject is an interesting one, and worthy of further experiment and careful, scientific study. If we could secure for the Navel the fruitfulness of other varieties it would have no rival. As for its influence on surrounding trees, I can only say that I have rarely seen an orange with the Navel mark in our Indian River groves, although Navel trees are abundant among them.

E. Williams.

Montclair, N. J.

Notes.

Bambusa Metake has proved hardy in Mr. Hunnewell's gardens at Wellesley, Mass.

At Penny Hill Park, near Bagshot, England, is a specimen of the Japanese Umbrella Pine (*Sciadopitys verticillata*), which is nineteen feet high, and has a circumference of branches of forty-six feet at three feet from the ground.

Mr. E. S. Carman reports that the Berckmans grape, a variety with compact clusters, resembling the Delaware in color and quality, but a little larger, has ripened perfectly on his grounds this year, while the Delaware lost its leaves early, so that the berries failed to ripen.

The members of the Forestry Commission appointed by the Governor of New Hampshire under the joint resolution of the Legislature, published in GARDEN AND FOREST a few weeks ago, are Joseph B. Walker, of Concord; J. B. Harrison, of Franklin, and George B. Chandler, of Manchester.

It is estimated that the wine product of California will not exceed 12,000,000 gallons this year. This is a reduction of 8,000,000 gallons from early estimates of this year's vintage. The reduction is due partly to damage by sunburn and mildew, but more especially to the fact that the drying of wine grapes will absorb probably 2,000,000 gallons, while 4,000,000 will go into the still. The state will probably produce 1,000,000 gallons of brandy this year.

It should not be forgotten that arsenic will kill bees as well as the curculio and the larva of the codling moth, and, therefore, Apple-trees should not be sprayed with insecticides before the blossoms fall. This is not an imaginary danger, for reports from many bee-keepers show heavy losses of bees in all stages, the imago, as well as the larva and pupa, being destroyed. This loss is not confined to the apiarist, for the bee, by aiding to distribute pollen, is a recognized help to the fruit-grower.

A correspondent of the London *Garden*, who accompanied the Scottish Aborigicultural Society during their recent journey to Sherwood Forest, mentions an Oak, which, in 1724, had an arched opening cut in it, that the then Duke of Portland might be able to win a bet by driving a coach and six through "a tree on his estate." The Duke won his bet, but destroyed the Oak, which, however, every year gives proof of its vitality by sending forth a thick crop of leaves on its shored-up limbs. The tree is forty-five feet high, its girth is thirty feet at five feet from the ground, and thirty-one feet round the base.

In Kirk's recently published "Forest Flora of New Zealand" three species of *Fuchsia* are mentioned, although the genus is

otherwise restricted to America. The most remarkable of the three is *F. excorticata*, which sometimes attains a height of forty-five feet, with a gnarled trunk up to three feet in diameter. The Central American *F. arborescens* is the only species that equals or approaches it in dimensions. *F. excorticata* has medium-sized flowers, at first of a greenish color streaked or blotched with purple, and finally of a dull red, with very small, almost black petals. The tube of the calyx is very much constricted immediately above the ovary, and there is a second constriction a little higher up. That this *Fuchsia* yields "one of the strongest and most durable timbers in the colony" will be news to most people. But, as the trunk is often crooked or gnarled, it is difficult to procure logs exceeding eight or nine feet in length, and its commercial value is therefore greatly diminished. Mr. Kirk says the wood is hard, dense, compact, and even, and deep brown in color, relieved by streaks of a paler shade, and short, narrow, waved, black markings. When much waved, it is of a highly ornamental character. Further, it is almost indestructible even by fire, except in a closed furnace.

The curculio has destroyed the plum crop in many places this year, notwithstanding applications of London purple in the form of spray. Carbolized plaster, applied in the proportion of one pint of crude carbolic acid to fifty pounds of plaster, has not been efficient, as it has proved in former years, to repel the insect. This failure is explained by the frequent rains, which have washed away all applications. In view of this experience, Professor A. J. Cook, in a paper read before the Society for the Promotion of Agricultural Science, comes to the conclusion that in case of very frequent rains the jarring method will not only be cheaper, but much more effective against the curculio. Again, as our wild fruits are more cleared away we must have plums in our orchards to protect the apples from the curculio. When apples are seriously stung they become so gnarled and deformed as to be worthless. It will pay, then, to set Plum-trees near by or among the Apple-trees. Then we will escape mischief among our apples, and will only need to spray our apples once, to destroy the codling moth, and can treat the Plum-trees three or four times with Paris green or carbolized lime in case we have only occasional showers, or can jar the trees when the rains are very frequent. If the carbolized plaster is preferred, it should be thrown freely over the trees, so as to strike every plum on the tree, which is being treated.

Professor J. B. Smith, entomologist of the New Jersey Experiment-station, in a recent bulletin, tells the farmers and gardeners of the state how they can help him in his investigation of insect pests. His first counsel is to be prompt, instead of waiting till the damage is done and the pests have disappeared, and he adds: "Do not waste time in describing insects. Send specimens, and send plenty of them. If an insect is really injurious, it is as easy to get a dozen as it is to get one, and it makes it a great deal easier for the entomologist. He wants two or three to put in alcohol, so that he will know them next time; the others he wants to bring to maturity, or to describe or figure so as to complete his knowledge of them. Such specimens, if dead, should be packed in some soft material, as cotton or wool, and put into a stout tin or wooden box. They go by mail for one cent per ounce. Never send insects loose in a letter! The postal clerk always smashes them flat, so that they are never of any use as specimens, and frequently not recognizable. With the specimen send also, so far as possible, a sample of the kind of injury caused by it—a bored twig or root, or gnawed stem, fruit or leaf—anything to show how the insect works. If at all possible, send the insects alive, along with a supply of their ordinary food sufficient to last during the journey. Pack them in a tight box, and do not punch air-holes into it. Insects need very little air, and the tight box keeps the food moist. Send with the insect an account of what you know of it; how it works—whether on leaves, twigs or fruit; whether above ground or underground; how long you have known it; how much damage it has done; what experiments looking to its destruction have been made, and what the result has been. Such facts are often not only of the highest scientific interest, but also of the greatest practical importance."

A Crisis in the History of Central Park.

THE Central Park of New York is one of the most interesting creations of American genius. No other city in the world has within its borders a work of landscape-art which equals it in originality of conception, in simplicity and beauty. It is worthy of the noblest civic pride, and it especially deserves affection and jealous care, because no other public work of the city approaches it in dignity or value. If New York is to have a great Exposition in 1892, nothing in the display could be more attractive to visitors than this park arrayed in all its summer loveliness. Nothing more distinctively or characteristically American can be imagined than the upper portion of the park, where the broad, free sweep of hill and valley permitted a more natural treatment of the original features of the land than was possible among the frequent narrow ridges of rock in the portion south of the reservoir. The gently undulating meadows, with their perfect turf; the projecting point of rock, with its clustering Pin Oaks; the recesses in the wood border, where the limits of the green-sward are lost in shadows; the sense of mystery and spaciousness which is given by the skillfully broken line of foliage which encircles the whole; the natural forest which sweeps up the long slope toward the northern boundary: all these constitute a picture of pastoral rest and peace which has no rival in the heart of a great city.

It is this most delightful portion of the park, and as much more of it as they may consider necessary, which the Committee on Sites have voted to cover up with carpentry. Even if it were probable that the wounds thus made could be healed within a reasonable period, this would mean the obliteration of the most beautiful bit of scenery on Manhattan Island at precisely the time when all the world is invited here, and it would advertise the vandalism of a city which failed to appreciate its noblest possession. But the hope that only temporary damage would be inflicted by such an invasion is a delusion. There can be no difference of opinion among persons familiar with park work as to the probable extent of injury to the park, if the proposed buildings, with their necessary approaches and surroundings, are placed on the North Meadows. Not one of them will dissent from the view of Mr. Olmsted, who writes:

"I am positive that no such structure could be provided for without involving a devastation that could never be repaired. I do not believe that it could be done without an enormous waste of the value of the park for the purposes to which it has been dedicated, and for which it has been prepared at great outlay." But we are not left to conjecture in this matter. Mr. Russell Thayer, who was Chief Engineer and Superintendent of Fairmount Park at the time of the Centennial Exposition, has written these words of warning, which are of singular value, because they are a record of actual experience:

In my opinion, it is impossible to erect the large structures required without destroying great numbers of the finest trees in the park, and, at the same time, doing almost irretrievable damage to the present shape of the grounds. Foundations will be required for all the structures, which will completely alter the present contour of a great portion of the present beautiful surface of the park and make it almost impossible ever to restore it to its present condition. The greater portion of the drainage system of the park would, of course, be destroyed, and, in many places, it would be necessary to level off the small hills and fill in the valleys in order to provide proper grades for the floors of the larger buildings. Besides the destruction of the greater portion of the trees, which would unavoidably interfere with the proper laying out of the buildings of the Exhibition, most of the shrubbery in the portion of the park devoted to the object would necessarily be destroyed. In fact, it may be stated that the greater portion of Central Park would be so changed after this Exhibition had been held therein that it would not be recognized as a public park. . . . The section of Fairmount Park occupied by the Centennial Exhibition was, previous to that event, almost totally unimproved, the greater portion being merely farm-lands. And even there, after the removal of the hundreds of buildings which composed the Exhibition, the grounds were a perfect desert of clay and gravel, upon which not a blade of grass could be made to grow for several years. Therefore, I am obliged to state as my candid opinion that, if the Exhibition is held in a highly cultivated park like the Central Park, the damage thereto will be almost incalculable.

The park is still young, but it has taken thirty years to grow into the beauty which now invests it, and a generation would be needed to restore it after the Exposition converted it into a desert. Oaks and Hickories, Chestnuts and Beeches, like those which were growing in the natural wood before the park was planned, can be replaced only after years of patient waiting. But what ground is there for hope that any resolute effort would be made to restore the park. If there is not enough public spirit in the city to preserve it now, when in the prime and freshness of its beauty, what encouragement would there be to begin over again, with the very surface of the ground scarified and blasted, until not one of its original features could be recognized? Even if any attempt at restoration were made it would soon be abandoned for some new invasion, because the clamor for space to be used for one purpose or another will grow louder as the population becomes more dense. The probabilities are that if the park is thrown open to this celebration, it will be left an entirely different and inferior work, and that its most impressive landscape features will be obliterated forever.

We cannot believe that the city is to suffer such a wanton spoliation, or that the park is doomed to ruin long before it has attained its mature beauty or has approached the full measure of its usefulness. When the intelligence and public spirit of New York have been appealed to on capital occasions, they have never failed to repel any assault that threatened the park with serious injury. They have erected barriers of precedent all around it against every form of destructive intrusion, and, foreseeing that these barriers might be prostrated before some sudden gust of passion or of enthusiasm, they have deliberately enacted a law to meet such emergencies. Beyond all doubt the present dangers to Central Park are more grave than any it has heretofore encountered. Its very existence as a park is in jeopardy. But the people of the city can be trusted to redeem their solemn obligations to hand down this peerless pleasure-ground without impairment to posterity.

Drives and Walks.—IV.

IT has been said that it is far better that no approach or other drive should cross the lawn in front of a country house. But, of course, the arrangement which is ideally best cannot always be made. In many cases where the road can be kept away from the immediate vicinity of the house-front, it will have to pass it at a greater distance. The road may then be masked by low plantations, which will, at least, be less disagreeable to the eye than the line of gravel. But plantations will often be undesirable as obstructions in what ought to be a simple extended view, or a broadly treated landscape. It is better, when possible, to sink the road, or to raise the lawn in a gentle slope towards it to such a degree that the eye will not perceive it, so that the stretches of lawn on its hither and further sides will seem to unite without a break.

If the place is so large that the house is not seen until after one has entered the approach-road, attention should be paid to the first view thus afforded. There is much in initial impressions, and a house may never redeem itself wholly in a visitor's eyes if it fails to do itself justice when they first light upon it.

With regard to walks, the same general principles hold as with regard to drives. There should be no more of them than are needful; they should neither be so straight as to lack beauty, nor so meandering as to lack ordinary directness and they should be as narrow as convenience will permit, for gravel streaks are not charming objects in themselves, and the greater their breadth the more they decrease the apparent size of the place. They should not be so narrow that two persons cannot pass with comfort, except in retired situations, where pedestrians will certainly be few; but anything in excess of this should be studiously avoided. A walk six feet wide, where one of three would have sufficed, will dwarf its surroundings to a much greater degree than most owners realize.

A lawn can be injured almost as much by foot-paths as by drives when they cut across it. A properly kept lawn is as delightful to walk upon as to look at, and, in our dry summers, the days are few when it will be too wet even for a lady's shoe. Of course, there may be cases when some distant object—a summer-house that is constantly used, a boat-house or tennis-court—will so constantly attract the feet that, unless a walk be provided, a ragged path will be worn across the grass. Then, a made walk is naturally better, for anything is better than a look of untidiness and neglect in grounds which ought to be carefully kept. But it should, if possible, be carried around the lawn, and, if this is not possible, its presence should be accepted as a disagreeable necessity.

Paths should never be made across a lawn, simply to give access to flower-beds, for the flower-beds themselves have no business there. A lawn is a place for grass. Its object, whether it be large or small, is to afford a simple sheet of verdure to delight the eye with its reposeful breadth and to supply a proper foreground for the plantations beyond it. To spot bright beds about is to ruin its peacefulness and its unity. There are thousands of country-places in America, from large estates to suburban villas, which would be immeasurably improved could all the flower-beds on the lawn, all the fountains and vases, and all the paths—leading nowhere but back to the house again—be once and for all turfed over. Flowers can usually be introduced in sufficient quantities in other ways—scattered among the shrubberies or arranged in massed beds behind the house or in borders disassociated from the lawn. Or, if they are the prime consideration and the place is not large enough for a lawn and a flower-garden both, it is better to give up the lawn altogether and arrange in front of the house an old-fashioned garden with as many beds and walks and Box-hedges as the space will allow. Such a design is consistent and sensible and may be made very pretty, while the more common device of trying to unite a lawn and a flower-garden is illogical and can never result in anything but an artistic monstrosity.

If there is a lawn, large or small, care should be taken that no walk, as well as no drive, runs between it and the house. Let the grass come up to the house-foundations, and unite the two by planting a few vines and shrubs. Then the house and its site will be connected and harmonized; the walls will seem to spring from the soil almost like a natural growth, and the picture seen from the lawn will be as charming as that which the lawn presents when seen from the house. Whether there are mere door-steps, or a porch, or a piazza, no path is needed, for this entrance should be used only by those who wish to stroll upon the lawn or to cross it to some spot not otherwise accessible. And even on those sides of the house where a path is needed

it should not be allowed to run close to the walls. Sufficient space should be reserved for planting against the walls, and thus, if the further side of the path is properly planted too, from a little distance the eye will see only the masses of verdure which connect the house with the landscape about it.

Although curving roads and walks are best in a place of any size, straight ones should usually be preferred in a small villa-lot. Then every inch of space is valuable, and, of course, a straight path occupies less ground than a winding one. The straight lines formed by the house and the street cannot be for a moment forgotten, and it is, therefore, good art to accept them as the basis of the whole scheme and make the paths within the gates correspond with them. Then, too, there should be no drive at all unless there be a stable behind the house. In this case it is best to leave the front free and carry the road in at the end of the lot to a door in the side of the house whence it may continue to the stable-yard. Place for a lawn is thus reserved in front, and the line of gravel will be least conspicuous from the principal windows. But it is better, when there is no stable, to sacrifice comfort a little in the interests of beauty—to leave the carriage in the street and let but a narrow pathway approach the house. The sacrifice will be a small one, and the gain in the aspect of the place as a whole may easily be great.

The suggestions in these chapters have not been made with the idea of making "every man his own landscape-gardener." On the contrary, they have been written to show how many things must be considered in the building of the simplest country-house, or the designing of the smallest place; and how desirable it is, therefore, that the aid of an artist should be called in at the outset.

Native Shrubs of California—II.

Cercocarpus betuloides, Nutt. (Low & Gray, Fl. i. 427), bears some likeness to the shrubby birches, but has sparser foliage, and, consequently, little beauty to recommend it. This prevailing shrub or small tree of the Coast mountains of the Pacific states is, however, of much botanical interest and possibly of considerable economic value. Known to the mountaineers and miners by the name of Wild Mahogany, its wood is the heaviest and hardest we have; and the leafy twigs have a sweet birchy flavor, rendering them choice food for cattle in late summer and autumn when the annual grass-crop has failed.

Under the name of *C. parvifolius*, with which species it has been confounded by those botanists who have seen dried twigs only, this shrub is credited with a range in California from San Diego to Lake County, or through the southern and middle parts of the State; but it is equally common southward on the Lower Californian peninsula, and northward on the Siskiyou Mountains in Oregon. That it is a good species, better than Nuttall the author of both of them knew, I indicated some years since, in my paper on Santa Cruz Island.* The larger, proportionally broader and nearly glabrous leaves, on which characters Nuttall seems to have relied, are indeed insufficient; they are inconstant. Small-leaved states of *C. betuloides* are often met with; but, over and above a certain constant difference in the general bearing or habit, easily seen at a glance, but not easily defined, the stem and bark of the two are strikingly unlike. *C. parvifolius*, which, by the way, occupies an entirely different region of country, *i. e.* the Rocky Mountains and adjacent interior districts, not reaching any part of California or Oregon, has a dark-colored, thick, persistent and fissured bark. *C. betuloides*, on the other hand, often much larger every way than the best developed states of *C. parvifolius*, presents, at most seasons of the year, a clean, smooth trunk with gray bark, and this outer bark is deciduous, falling away in irregular flakes in early autumn. On this character alone, *C. betuloides* will rest securely as an excellent species. By the pioneer collector, Mr. Douglas, and by the authors of the Botany of Captain Beechey's Voyage, the small-leaved state of *C. betuloides* was mistaken for the real *C. parvifolius*, and thus began that confusion of the two species which has continued, in our books, to the present.

During my vacation journeyings of the past summer, I, for the first time met with the curious *Fremontia Californica* (Low, Plantæ Fremontianæ, p. 6. t. ii) in its native wilderness. Particularly attractive to all botanists as being nearly related to the celebrated Hand Flower Tree of southern Mexico, eminent systematists considering it as nothing more than a second species of *Cheiranthodendron*, I had not, from the numerous herbarium specimens I had seen, inferred its highly ornamental character. The foliage, as in most shrubs of our arid mountain districts,

* Bulletin Calif. Acad. ii., 396.

is sparse and small. When the Rev. Mr. Fitch, the first after General Fremont to observe the shrub, described it to Dr. Torrey as having very much the appearance of an ordinary Fig-tree, he must have had in view the mere outline and texture of the leaves. In these points only are the leaves like fig-leaves; for they are commonly only an inch in diameter, and rusty tomentose beneath. The bark of both main stem and branches is, indeed, smooth and much like that of the Fig-tree, but darker, even blackish on the older trunks. But the beauty of the *Fremontia* is in the crowded profusion of its red and yellow Hibiscus-like flowers. Each wand-like branch, at flowering time, is simply a long, solid wreath of bright yellow, tinged with a rusty red; and the arrangement of the branches—the head of the tree—is as far from the conventional as the structure of the flower is unique. Growing along the steep and jagged rocky slopes of the mountains, the dark, smooth trunk will rise erect, while all the long-flowering branches, not rarely six or eight feet long, will hang on one side, it may be; or they may spread out in several directions, forming a flat-topped, or umbrella-like body; but the bush or small tree, not rarely twelve feet in height, is always attractive if in bloom and the flowering season is not brief. Or rather, the showy corolla-like calyces, of great firmness of texture, remain fresh a long time, and finally wither, almost without change of color, and remain attached to the growing fruit for some weeks.

Attaining its best development among the arid hills which shut in such almost rainless and overheated regions as the Mohave Desert, it is not likely that the *Fremontia* could be made well at home in gardens even in the milder regions of the east. In its more northerly habitat, the upper Sacramento valley in California, it is smaller and less beautiful by far than under the comparatively rainless skies of the southern interior. But any lover of shrubs, at once odd and beautiful, having once enjoyed the sight of this one in flower, will wish he might add it to the ornaments of home.

Notes Upon Some North American Trees.—XII.

254. *QUERCUS OBTUSILOBA*, Michx.—A much older name than that of Michaux (1801) for this tree is that of Wangenheim (Amer. 78, t. 6., f. 15, 1789).—*Q. stellata*; but Marshall's *Q. alba minor* (1785) is older still, and if such names of Marshall's as *Juglans minima* and *Juglans odorata* are to be taken up there seems no escape from *Quercus minor* as there can be no doubt of the identity of the species to which he applied this name.

The variety of this species with almost entire or undulate somewhat angled thin leaves is common on the sandy west coast of Florida, reaching at least as far south as Tampa, where it grows into a tree twenty to thirty feet high. The oldest name for this plant appears to be *Q. parvifolia* of Chapman; so that it would become if it is considered a variety of the Post-Oak, with which it is connected by intermediate forms, var. *parvifolia*.
