INDEX

TO THE SEVENTEENTH VOLUME OF THE NEW ENGLAND FARMER.

A.

Address before Concord Agricultural Society, 113; of Henry Stevens before Caledonia Agricultural Society, 193; of Josiah T. Marshall, 201; of Leonard Withington at Topsfield, 249; Hon. Lester Filley at Pittsfield, 305; of H. W. Bishop Berkshire Agricultural Society, 329; Col. C. S. Kentucky Agricultural Society, 315; Rev. H. Colman, 273-361.

Account current with a pig, 35.

Advice to parents, 195.

Alpine Mulberry, 157.

Agricola and answer to, 317.

Agricultural education, 25.

Agricultural school at Templemoyle, 35.

Agricultural meetings at the State House, 231, 254, 270, 273, 286, 294, 302, 313, 342, 350.

Agricultural geology, 255, 262.

Agricultural statistics, 325, 333.

Agricultural intelligence, 190, 366.

Agricultural improvements, 78, 85, 94, 110.

Agricultural Societies, cattle shows, &c., by H. C., 134, 142, 150, 157, 166, 174.

Agricultural fair and show at Berkshire, 137, 145.

Agricultural, Middlesex, Society's reports, 156.

Agricultural, Worcester, Society's report, 161.

Agricultural, Essex, Society's address, by H. C., 361.

Agricultural, Massachusetts, Society's Premiums, 134.

Agricultural, Massachusetts, Exhibition, butter and cheese, 182.

Agricultural, Massachusetts, Society's report on vegetables and grain crops, 255.

Agricultural, Massachusetts, Society's report on farms, 290.

Agricultural, Massachusetts, Society's report on inventions, 322.

Agricultural convention at Albany, 324.

Agriculture in Long Island, 47; in Maine, 65.

Agriculture, experimental, 70.

Agriculture of Dumfriesshire, 122.

Agriculture, what have the States done to encourage it, 132.

Agriculture, practicability and means of improving, 155.

Agriculture, practical elements of, 284.

Agriculture, State patronage of, 262.

Agriculture in Canada, 37.

Agriculture, board of, minority report, 300.

Agriculture and the clergy, 414.

American Agriculture, opinions abroad on, 19.

Ancients on agriculture, opinions of, 19.

Artificial showers, 208.

Apple Molasses, 197.

Apples, preserving through winter, 112.

Always behind hand, 176.

Arboretum, London's review of, 266.

Ashes, 259, 349.

Ashes, lime, &c., 321.

B.

Barre, rural festival at, 126.

Bees, longevity, 51.

Bees, cure of the sting, 51.

Bees, description of, 180; multiplying swarms of, 333.

Berkshire Agricultural Society's cattle show, 137, 145.

Bear story, boy taken by one, 184.

Bennett, Mr. N. S., answers to Massachusetts Agricultural Society, 357.

Beet sugar, important improvements in making, 291; by H. C., 230.

Beet sugar, in France, 192, 293.

Butter days coming, 208.

Beurre Copiamont and Frederick d'Wurtemberg Pear, 121.

Birds on farms, 404.

Biter Bit, 176.

Binn's, Mr., remarks at Agricultural Society's Meeting, Lancaster, Eng., 385, 393.

Bloody Murrain, 283.

Bone manure, 98, 253.

Books on agriculture, for schools, 12.

Book farming, 123.

Botanic Conservatory, exhibition of roses at the, 411.

Botis in horses, 82.

Bowditch, Dr Nathaniel, 24.

Bohan Upas, 180.

Boston Cultivator, notice of, 206, 222.

Board of Agriculture, minority report of, 301.

Bounty on silk, 302.

British Queen steamer, 403.

British corn market, 160.

Bridg-water cattle show, 128.

Bridgewater, list of premiums proposed by, 394.

Brown, Mr S. H., statement, 347.

Budding, inoculation or, 409.

Butter, making of, 29; making and salting, 261.

Buffalo berry, 62.

Bulbous roots, cultivation of, 131.

Bush cow, 200.

C.

Cattle show, Worcester County committee of arrangements notice, 82; at Concord, 110; at Bridgewater, 129; at Plymouth, 117; at Worcester, 118; at Pittsfield, 122; Northampton, 126; at Patuxet, 340.

Cattle, Devonshire, 42; marks of good, 61; choked, how to relieve, 325; feed for, 93.

Calves, wintering of, 351.

Canada, agriculture in, 357.

Capons, 30.

Capiamontpear, by Hon. J. Lowell, 81, 85.

Cabbage molasses, 211.

Cabbage cultivation of, 315.

Cauliflower, cultivation of, 252.

Carrot crop, John Moorhead's account of, 285.

Chilblains, cure of, 195.

Chittendon, Mrs. and her workmen, 345.

Cheever's letters, 328.

Charcoal for diseased lungs in hogs, 122.

Cider, preventing from becoming sour, 43.

Claggett, W., on manures, 1.

Clay soils, best means of improving, 196.

Clergymen, their influence, 465.

Close of the year, 206.

Close of the Seventeenth Volume, 414.

Clover hay, curing of, 22.

Conversation between two emigrants, 35.

Cooper, Sir Astley, 72.

Colman's, H. C., address, Worcester Society, 273.

Colman's, H. C., address before Essex Agricultural Society, 361.

Convention, agricultural, at New York, 349.

Corn, great product in Montreal, 310; sample of early, 69; account of early, 85; large yield from a kernel, 95; disease of, 21; sowing broad cast, 53; experiment in harvesting, 179; crop of, by B. Slack, 278.

Corn stalk fodder, 266.

Cow, a Durham, 403; a good, 403.

Cows, disease in, 18; working, 390.

Crops in Pennsylvania, 340.

Cruelty to Animal, 119.

Crow and Wire Worms, 317.

Cuttings, 404.

D.

Dahlias, preservation of, 215; culture of, in France, 352.

Dana, S. L., on ashes, lime, &c., 321.

Dairy stock, 62.

Darby and the ram, 192.

Dearborn, H. A. S., on the culture of Tropical plants, 5; flowers, fruits, &c., 9; on Van Mons's experiment, 236; reply to J. Herrick on forest trees, 265; on J. H. Mery, letter to Captain Hunt, 297; on diseases on silk worms, 316.

Decomposition or putrefaction of vegetables, 13.

Deaf, dumb, and blind, 280.

Dennis Silk Manual, notice of, 350.

Diet, plain, 355.

Disputed territory in Maine, 293.

Dictionary of agricultural terms, 243, 268, 275.

Diseased hogs, 122.

Diseases in horses, 44; among animals, 23; of December, 224.

Domestic economy, items, 243.

Doctoring trees, 266.

Drainage, effects of thorough, 403.

Drainages, sewer, 402.

Drink for warm weather, 30.

Dry rot, 4.

Dress for farmers, 13.

Duties performed by a good farmer, 160, 224.

Durham cattle, 192.

Duration, probable, of human life, 408.

E.

Eastern railroad, 405.

Education, necessity of, 2; new system of, 58; self, 205; of farmers, 409.

Electricity, power of, 70.

Election week, 352.

Ellsworth, H. L., on sugar beet, 221.

Encourage one another, 205.

English, Irish, and Scotch, 312.

Eggs and poultry, 196.

Essex Agricultural Society's report on crops, 379; on mulberry trees, 377; on manure, 363, 370; on reclaimed meadows, 347, 348.

Errors, 310.

Example, good, in clergymen and men of influence and taste, 405.

Extravagance in the United States, 104.

Experimental agriculture, 70.

Experiment in manuring turnips, 115; planting potatoes, 185; on manures, 363, 370.

Exhibition of fruit and flowers, Massachusetts Horticultural Society's annual, 105, 107.

F.

Famine in India, 88.

Farming tools, care of, 245.

Farmers' work for July, 413.

Farms, size of, 46; subdividing it, 162; profit of, 397.

Farmers' garden, 3; employment, 43.

Farming, 170.

Farmers, education of, 409.

Farmer, a king, 171.

Farms, premiums on, 306, 331, 339, 356, 357.

Farrier, the pocket, 416.

Fat mutton, 411.

Feeding milk cows, 412.

Fertility of lands, means of increasing of, 89.

Finances of Maine, 277.

Flowers, fruits and trees, by H. A. S., 9.

Flowers, properties of, 244.

Flour, to test good, 229.

Fleischmann's memorial, 233.

Flax seed meal, 34.

Flemish Husbandry, 74, 172, 177.

Forest trees, hints on pruning, 45; review of Loudon's work on, 266.

Frozen ground, 325.

French, B. V., Esq., visit to his farm by J. B. 109.

French, Moses, statement on cultivation of crops, 379.

Fruit trees, protected from spring frosts, 412.

Frying pork, 413.

G.

Garden, farmer's, 3.

Geology of Massachusetts, 58, 69, 84, 92, 100.

Goodrich, Levi, statement of farm, 306.

Good wife, 256.

Gooseberries large ones, 163.

Grain Worm, essay on, 41, 49, 73, 161; curing of, 57.

Grain fly, to destroy, 68.

Green's straw cutter, 65, 266.
Grasshoppers, &c., 69; flight of, 69.
Grass and grass seed, 162.
Great discovery, 205.
Grand Duke and the Jew, 216.
Grape and strawberry, 165.
Grouching, 173.
Grub worm, 368.
Grubs, 412.

H.

Haying and hay, 38.
Harvesting corn, experiment in, 179.
Hawthorn hedge, 238.
Hazen, N. W., report, 347.
Hall's letters, 225.
Herrick, J., on forest trees, 265.
Hedge fence, 246.
Hints for July, 13.
Hogs, management and diseases of, 52; better coaxed than driven, 147; Berkshire, China, and other breeds, 277.
Horse rake, 66.
Horses, directions for purchasing, 29; bots in, 82; racing, strong facts in regard to, 35; diseases of, 171; hin a for preventing disorders, 44; feeding with grain, 219; treatment of wounds on, 77; singular operations upon, 329.
Holt, Joseph S., on mulberry trees, 377.
Holbrook, J. letter on education, 398.
How, Joseph on manure, 370.
Horticultural Society's exhibitions, 14, 30, 38, 46, 54, 62, 67, 77, 85, 94, 102; annual exhibition, 105, 117; 123, 131, 158, 170, 179, 198, 211, 219, 229, 237, 251, 254, 267, 283, 307, 366, 374, 390, 393, 403, 411.
Human life, probable duration of, 408.
Hydrophobia, cure of, 88.

I.

Ice and ice houses, 171, 293.
Illinois, 296.
Illinois and the West, 320.
Improvement, 374.
Important to farmers, 155.
Indian corn, suckering of, &c., 22; more than a hundred fold, 90; early varieties of, 115; H. C. remarks on, 190.
Industry and economy, rewards of, 8; effects on Michigan soil, 37; and indolence, 67; and promptness, 264.
Intelligence, effects of, 405.
Inoculation or budding, 409.
Invention, useful, 62.
Indolence and industry, 67.
Instinct of animals, 72.
Irrigation, 98, 388, 398.
Ingersol's piggery, 201.

J.

Johnson, Cuthbert William, on manures, 395, 401.
July, hints for, 13; farmer's work for, 413.
Jackson, Dr C. T. on influence of lime, 313.
Judson, Mrs., notice of, 384.

K.

Kenrick, William, on Buere Capianmont, &c., 121, 220.
Keep, Dr N. C., on manures, 358.
King, Daniel P. on irrigation, 389.

L.

Lambs, early, 189.
Land sales at the west, 396.
Lake fisheries, 152.
Letters from the east, 352, 363, 376.
Lime fences, 216.
Life in the Prairies, 304.
Little's, Tristram, statement on cultivation of crops, 379; on manure, 307.
Lilies, 215.
Lime, theory of the action on soils, &c. 33.
Lime influence in amending soils, by Dr Jackson, 313
Lime and Ashes, by S. L. Dana, M. D., 321.
Locusts, 59.
Lowell, Hon. John, on the Capianmont, Report, 81, 85.
on Lucerne grass, 80.

Lowell, Hon. John, comparison of the seasons, 371.
Lucerne grass, 90.
Lucerne and sainfoin, 111.
Lucerne, on sowing, 225.

M.

Marrow squash, 309.
Manures, by W. Claggett, 1; materials and sources of, 6; materials for, 17; circular, 323; liquid, 386; farm yard and proper management, 50, 116, 147, 386; what quantity should be applied to the acre, 124; N. C. Keep on, 358; D. Putnam's statement on, 363; experiment on by Joseph How, 370; their use and application, 395, 401.
Marshall's, Josiah T., address, 210.
Massachusetts Agricultural Society's premiums, 134.
Massachusetts Agricultural Society's report on vegetable and grain crops, 285.
Massachusetts Agricultural Society's exhibition of butter and cheese, 285.
Massachusetts Agricultural Society's report on farms, 290; on inventions, 322.
Massachusetts Horticultural Society, 403.
Mexican corn, 90.
Meadows reclaimed, 347, 348.
Middlesex Agricultural Society's report, 156.
Milk, preserving of, 5.
Miller, 221.
Milk cows, feeding, 412; soiling, 413.
Mines at Pictou, 400.
Mildew or rust, causes and prevention of, 124.
Moon, influence on timber, 35.
Moorhead, John, account of carrot crop, 285.
Morus Multicaulis speculation, 178.
Morus expansa, 344.
Mount Vernon Farmer, 169.
Montagne coal, 319.
Molasses from cabbage, 211; from apples, 197.
Mowing, 404.
Murrain, cure or prevention of, 194.
Mutual improvement, 172.
Mulberry tree culture, 26.
Mulberry and sugar beet, report on, 10.
Mulberry tree, Essex Agricultural Society's report on, 377.
Mulberry, new variety, 57.
Mulberry trees for sale, 175.
Mulberry trees, &c., 181.
Mulberry fever, 182.
Mulberry fantasies, 239.
Mutton, fat, 411.

N.

Newspapers, 96.
New England Farmer, remarks upon its course and influence, 406, 414.
Neat cattle, cleansing of, 147.
New year, 214.
New England Farmer Seed Store, 222.
Newhall's statement, 318.
New York Agricultural Convention, 349.
Nobility of labor, 128.

O.

Odesa wheat, 355.
Old maid's first offer, 336.
Onto, valley of, 359.
Onions, cultivation of, 165.
Osborn, William, statement, 347.
Ornamental trees, 163.
Ox, the great American, 413.
Oxen, Spanish, 390.

P.

Parley's Cyclopaedia of Botany, notice of, 83.
Painting roofs, 102, 414.
Patronage to agriculture, 149.
Pawtuxet Cattle show, 346.
Pear trees, wash not to be used, 162.
Pelletier, J., on soils, 241.
Peas, early 338; to raise early, 325.
Peasobest farming, 251.
Perry, Rev. Mr., statement, mulberry trees, 377.
Pine trees, summer transplanting, 37.
Pig, every family should keep one, 168.
Pig and piggery, 188.
Piggery, Ingersol's, 201.
Planting trees, 268.
Pleasants, J. S., on silk culture, 153.

Plums, 37, 86.
Ploughs, trial of, at Hoboken, 54.
Phillip, R. J., statement, 348.
Potato, preservation of, 118; climates adapted to, 219; Planting early sorts, 283; Quaddy blues, 229; Bagoa, 245; Dillingham, 318; Rohan, 83, 132, 133, 163; large return from, 317; blossoms, 133.
Pocket Farrier, 416.
Poultry, 196, 226.
Pomroy, William, answers to Agricultural Society, 341.
Poetry. Spring and Summer, 8; Lines to Poverty, 16; Hymn of the Farmer, 24; Child at Prayer, 48; the Confession, 56; Pudding and Beans, 65; the First Yellow Leaf, 104; the Summer bloom is past, 112; Vadis Harvest Hymn, 120; New England, 128; Autumn Sonnet, 136; to my Wife, 144; American Boy, 152; our Yankee Girls, 184; the Ivy, 192; Lament, 200; Thanksgiving day, 208; my Father's half bushel, 224; Try, try again, 232; Massachusetts, 248; Receipt for making cakes, 256; What a good Farmer hates, 256; Farmer, 264; what a Farmer wants, 272; North Wind, 280; Washing Day, 296; Grease, 212; Evergreen, 376; Nature, 384.
Profit of farming, 337.
Provisions, high price of, 366.
Prince and Sons, on Mulberry, 157.
Preserving winter apples, 122; pear and plums, 93.
Planting forest trees, 45.
Prospectus of the N. E. Farmer, 198.
Probable duration of human life, 408.
Private correspondence, 203.
Premium crops. Timothy Robert's statement, corn crop, 299; John Moorhead, carrot crop, 301; Levi Goodrich, farm, 306; Tristram Little, compost manure, 307; Peter Fay, farm, 314; William Backmaster, 331; Caleb White-bee, 339; J. F. Southwick, 338; Tristram Little, 338; William Pomroy, 341; J. Lawton, 356; N. S. Bennett, 357; William Wells, 364; William Salisbury, 365.
Pudding made of green corn, 73.
Pumpkins, on their culture, 91.
Putnam, D. on manures, 363; public health, 94.

R.

Rats in grain, to prevent their ravages, 37.

[NO. 1.]

AGRICULTURAL.

For the New England Farmer.

MANURES.

To the friends of our country's prosperity, it is a matter of gratulation, that our farmers are beginning to turn their attention to the all-important subject of making manures. As is the blood which circulates in our veins, to the human body, so is manure to our farms. Manure is the grand desideratum—the one thing needful—and wholly indispensable to agricultural production. It would be just as irrational to expect to have fat cattle without giving them food, as to hope for good crops without first supplying the peculiar kind of nutriment which each kind of plants or vegetables requires. Although this is a position too self-evident to be doubted by any intelligent farmer, yet it cannot be too strongly impressed upon the minds of all. The first object, therefore, in farming, is to make manure enough, richly to fertilize the soil. Until this is effected, the profits of the farmer must be very small. It is true, that in the first settlement of a country like ours, after the forest has fallen before the axe, the soil, having been enriched by the decomposition of leaves and other vegetable matter in the course of ages, and also by the ashes after burning over the cleared fields, may for many years continue to be fertile. But experience has proved, that such soils, by not being replenished after long cropping, have become exhausted. Vegetable matter in its rotted or decomposed state constitutes the whole or nearly the whole food of plants. In the economy of nature nothing is lost. The process of vegetation and decay keep equal pace. The simple material elements, although essential to the growth of plants, serve but as canals to conduct, in a mysterious manner, the soluble or liquid vegetable food to the plant. Each kind of plant receives from the earth, water and air, the peculiar nutriment which its constitution requires. Soil is a compound of vegetable substance, and the simple elements of matter. Should the vegetable part be abstracted, vegetation would entirely cease. As our population increases we gradually (*but too slowly*) turn our attention to improvement in Agriculture, which, it must be confessed, is the great supporter of human life. It admits of no doubt, that the soil of New England, by being put in a high state of cultivation, is capable of supporting more than double her present population. This can be done only by devoting the requisite attention to the important art of making manure. This art very few seem to understand. But if understood it is certainly much neglected by nearly all the tillers of the ground. In travelling through the country, how few barn-yards or pig-yards do we find properly located? How few compost heaps do we see? How few barns have vaults constructed under the cattle's stall? But we often find the barn-yard on some elevated spot, so high and with a descent every way from it, that the most nutritious part of the manure, which the rains in the wet

season do not wash away, is dried up, or evaporated in the warm seasons. Farmers thus negligent, or so grossly ignorant, must live very economically; in order to live at all—they never can "go ahead." Every farmer ought to have a properly constructed vault under the cattle's stall, so that the liquid part of the manure may be retained. This is the most valuable part. Farmers, upon reflection, will be convinced that the liquid part only, or that which is soluble in water, is taken up in the mysterious process of vegetation, or is the *pabulum* of plants. The other parts serve only to render the soil more loose or porous. Experience as well as theory has convinced us, that one cord of manure from the vault is worth as much as a cord and an half taken from the yard or an open exposure.

It has been supposed by some in past times, that "rotted manure" is better than fresh stable manure, especially to "put in the hill" in planting. But it is certain that by laying a long time undergoing the fermenting, decomposing process in the heap, it loses half or a great portion of its nutriment. It is a great loss, as well as an unwise practice to suffer it to decompose, while subject to the action of heat and the atmosphere. Those who prefer to manure in the hole, will find that half the usual quantity of fresh manure, *thoroughly mixed in the soil*, would be equal to double the quantity of rotted manure.

To save the whole substance of manure, it should be ploughed under, or covered several inches in depth some other way, in its unfermented state. Considerable loss attends the practice of "harrowing it in," in the spring, where the green sward has been turned up the previous fall. But this cannot be avoided when long manure is applied. Could it be proved that harrowing in the manure would give a larger product than ploughing under, the first year, yet as ploughing under will more enrich the soil for crops in future years, the latter ought to have, as a general rule the decided preference. For several reasons, which will readily occur to farmers, it is a judicious practice to "break up" and plough deep, stiff, clayey, as well as some other soils in the fall.

After much reflection upon the subject, we are fully convinced, that the best method to enrich a farm is to make COMPOST MANURE. By the mixture of stable and mineral manures with the various kinds of vegetable substances within the farmers reach which can be decomposed, we can have not only a much larger quantity of manure, but the whole substance of the stable manure is thereby saved. Lime, gypsum, ashes, &c. acting as solvents, added to the compound, are found to be of great benefit. Compost thus made is better to spread and harrow in, in the spring, on land ploughed in the fall or at any other time, than fresh or long manure. Every farmer can find materials for the compost on his own farm, although some have advantages superior to others. A due regard to future profits will prompt him to deposit in his cattle and pig-yards or in heaps in the field all kinds of vegetable or other substances within his reach,

which will decompose. Much may be obtained from the shores of rivers, bays, or the sea; from the forest, such as leaves and the decayed substance of trees; from the scrapings of the roads and house-yards; but especially from the swamps, bogs, and lowest places of the farm. The turf and peat should not be neglected. The grasses and weeds, which grow in water or on dry land, will yield more food by being gathered, in their green state, into heaps to undergo fermentation. For this purpose in some places, sea weeds are drawn up by a well contrived machine into boats to be conveyed to the heaps. Most farmers can obtain an ample supply of the black, rich fresh mud or loam. Converting large quantities of such mud into compost, and thoroughly mixing it in the soil of the rising grounds, will ultimately render any farm fertile. Such mud is composed chiefly of decomposed vegetable matter, washed from the hills or conveyed by water courses to the swamps and bog-holes. It is much preferable to salt mud. But salt mud taken from the heads of creeks, &c. is better than such as is taken from the main shore. Salt mud must undergo a change and part with a portion of its saltiness, before it can be fit to nourishment to such plants or grasses as will not vegetate in salt marshes. That from the muscle beds is valuable. Oyster and clam shells pulverized, and perhaps all marine shells, lime being the chief ingredient, are highly useful spread upon high or sandy lands. But salt mud should remain in the compost heap, about a year previous to being applied to the soil. Of all kinds, the Bone manure, ground or pulverized, doubtless affords the greatest nutriment. This is well understood in Europe whither several cargoes of bones have been exported from the U. States. We are glad to learn that mills are constructed here to prepare bones for our own soil. Night soil is the next best manure, which no farmer ought to neglect to mix with a large portion of sand or earthy materials and convey to his fields.

The diligent husbandman, who uses his best efforts to fertilize his lands by procuring an abundant supply of compost or other manures, cannot fail, in the end, to have a rich reward for his labors. To enrich the exhausted soil of a large farm may require from six to ten years—but that length of time should be no discouragement to persevering efforts.

No situation in life is attended with a greater share of happiness and real independence, than that of the industrious farmer enjoying the luxuries and blessings of a farm in a high state of cultivation. On the other hand, miserable is the condition of the man who may labor hard upon a poor, exhausted and barren tract of land, and who is ignorant of, or neglects the means for its improvement.

It is also highly important that barn-yards should be properly excavated to prevent the richest portion of the manure from being washed away. And to preserve moisture in dry seasons, and also to water the cattle at all seasons, water should be conducted by pipes or otherwise to the yard.

Another method to promote vegetation is to mix coarse sand or gravel with a clay-soil, to render it porous, and prevent its baking hard like a brick in the warm drying seasons. On such a soil, a cart load of sand is worth as much as an equal quantity of manure. And clay, marl, or black mud, conveyed on to sandy land, and mixed in, is equally beneficial. The fact is well established, that the mixture of different soils of all kinds, promotes the vegetable growth.

In connection with this subject, it was our intention to make a few remarks going to show the utility of deep, as well as frequent ploughing, in order to derive the most advantage from manures, and obtain the largest products. But our suggestions are already extended beyond our prescribed limits. It is hoped, however, that in this enlightened age, every intelligent farmer gives the preference to a deep, rich, and mellow soil, as being most favorable to imbibe and retain moisture, and as affording more space for the roots of plants, often extending several feet from the stalk, and the minute and invisible fibres, projecting from the ends of the roots in quest of food. Some of the leading ideas now advanced, have doubtless, often before been communicated to the public. As our object is agricultural improvement by enforcing correct theories, no apology is offered for advocating old doctrines, which are founded in truth.

W. CLAGGETT.

Portsmouth, June 25.

THE SALT MINES AT NORWICH.

These mines attracted a good deal of attention, and a party of about eighty set off to visit them. According to previous arrangement, the gentlemen who were furnished by the President of the Geological Section with the necessary tickets, assembled at the railway station at a quarter before eight o'clock, but owing to some mismanagement, the train appropriated to the party did not start until within a quarter of nine. A little after ten, the train, after a run of thirty miles, came to a stop, and the rest of the journey, a distance of about four miles, was accomplished in vehicles which were in waiting for the party. On their arrival at the works, they were conveyed, in succession, to the bottom of the mine in a basket lowered by means of a windlass, four descending together, and then conducted through the various parts of the excavation. There are two beds of the rock-salt, the lower one being exclusively worked, owing to its superior quality. The floor of the mine is 336 feet below the surface, and the portion of the saline mass removed is about 40 feet in height and extends over an area of 30 statute acres. A great number of successive strata of clay, more or less indurated, occur between the upper stratum of salt and the surface, and the two saline deposits are separated by analogous formations, the portions of those next the salt being intersected with little veins of Sal gem, exhibiting a beautiful scarlet color, no doubt due to the presence of a small quantity of sesqui-chloride of iron. After having traversed the whole of the excavation, which was lit up in a most magnificent manner—several thousand candles having been employed for the purpose—the visitors were regaled within this subterranean palace with a very elegant dejeuner. We have seldom seen a company sit down in higher spirits, or to a better entertainment; and it is scarcely necessary to say, that when the health of the proprietors—particularly of Mr. Worthington, who had

conducted the party from Liverpool, and also through the mine, was given, it was drunk with the utmost enthusiasm. The entertainment being concluded, some fireworks were exhibited, which lighted up the excavation with various shades of colors, produced effects which it is no exaggeration to describe as at once grand and terrific. "God save the Queen," and, at the suggestion of Mr Porter, a psalm, having been sung immediately beneath the shaft, the whole party ascended, and returning by the same method of conveyance, reached the railroad station in Lime street, at five o'clock. While the party was below, Dr. Crook took occasion to make some geological remarks applicable to saliferous deposits, and drew attention to a peculiar appearance in several parts of the roof of the mine, from which he concluded that the salt originally solidified in globular masses, the crystallization proceeding from a centre. The temperature of the mine, which we should conjecture to be about 48°, was understood to be very equable throughout the whole year,—and not a particle of moisture was any where to be seen.—*Proceedings of British Association for the Advancement of Science.*

NECESSITY OF EDUCATION.

To every individual, education is important and valuable. It was once thought, and said, education makes rogues—observation has shown directly the contrary. We find in the State Prisons a large number that cannot read—many read very imperfectly—some read and write badly; none of them have ever employed the little they knew of letters to any purpose. There are very few who have a good education.

It is known that education promotes industry instead of idleness. Let the farmer be well educated, and his knowledge enables him to form the judgment of soils, and the best modes of cultivation and improvement. He labors himself, and enjoys the profits of his labors. He has, therefore, the greatest inducement to plan machinery to facilitate his labors, and to give care and attention to the means of making his farm productive. The farmer on the Continent of Europe, has labored for two thousand years, with the same ill-formed and inconvenient implements, always implying the hardest labor. He has not knowledge to invent machinery for himself. The learned regard not his toil. He enjoys a very small portion of the fruits of his labor, and therefore has not the stimulus to exertion. The farmer begins to enjoy the blessings of education. He cultivates his own soil. He has, therefore, improved almost every implement of husbandry. Labor to him is necessary—it is not degrading—it is honorable. To perform labor by machines, is a skillful application of knowledge to the practical purposes of life. Whoever has seen the shovel plough brought from Germany by the first emigrants—sometimes now found on the Mohawk River—and now in use in many parts of Germany, must have been struck with the inconvenient, ill-contrived machine, when compared to the common patent plough.

The simple invention of a horse-rake, saves three-fourths of the labor of gathering. The same may be said of the improved plough, scythe and threshing machine. A chemical knowledge of soil, manures, and stimulants, is of great importance to every farmer.

Knowledge awakens attention, and the reward of attention is success. The mechanic arts are to be improved in the same way. Knowledge instructs

the mechanic to facilitate his labors, and apply machinery to what was formerly accomplished only by the unarm'd hand. Every branch of the mechanic arts has been improving, aided by knowledge.

In every mechanic's shop we find a machine of late invention. It even requires enlightened minds to adopt improvements.

Chancellor Livingston, when in France, observed that all the inhabitants of the wine countries were stooped forward, forming a very great curve of the spine. He observed them hoeing the vines with a hoe, the handle of which was about two feet long. It accounted for the deformity. He sent to America for a parcel of hoes with long handles. They used them a few days, and then threw them away, and returned to their short handled hoes, and thus preserved their crooked backs, and entailed them on their posterity.

What a vast number of farmers absolutely refused to use plaster of Paris, although the success was seen in almost every field around them, covered with rich crops, while their own were barren wastes.

Some one painted a pail, and a very well-informed woman got her pail painted; but very great numbers refused, and still scoured with soap and sand, the wood and iron.

It is knowledge that gives a man an acquaintance with himself, his powers, his rights and interest. He learns to judge for himself, to respect himself. He is, therefore, unawed by the proud, nor is he the victim of the cunning and selfish. His knowledge and virtue are all the qualifications he needs as a voter. His knowledge informs him of his own interest and the public good. His virtue secures his honesty and independence. The evils of government no sooner reach him, than he not only feels them, but looks about for a remedy, consistent with the public peace.

There never was a well educated mob—if so, what expense, what effort is too great to obtain so desirable a good. The subject commends itself to every private, and every public man in the country.

The inmates of our prisons and poor-houses are generally ignorant, and among the ignorant, intemperance prevails to the most fearful extent.

The question may be asked,—will not a just, parental feeling accomplish this important object? Experience has proved that the work cannot safely be left to parents, and, therefore, government has undertaken to aid in the work. Parents have been found even to refuse the aid of the state. When the law was first passed to aid the school districts, many towns refused it. It required the power of government to establish the present valuable system. And we have reason to fear that the great end will never be attained until government enters heartily into the subject.

Xenophon gives an interesting account of the education of the Persian youth in his day. Much of it was mistaken, but the great design of educating the youth was good.

Sparta, one of the great republics, carried education among the free inhabitants, farther than any other people. It is true, the great principle on which that republic was founded, was false—because it assumed war to be the natural state of man, and educated her youth accordingly. But the effect of it was to preserve the state and form of government five hundred years.

The New England States, at an early period, entered heartily into the subject, and they enjoy

the advantages now, in possessing the best generally informed people of any country in the world. And they have furnished most of the states with a vast number of professional men, and teachers of common schools.

The state of New York has done something, and common school education has been extended to almost all the youth. Still the system is exceedingly imperfect, and capable of immense improvement.—*Herkimer Journal.*

THE FARMER'S GARDEN.

EVERY farmer should have a garden, for health, for pleasure, and for profit. For health, as nothing in the form of diet, contributes more to this blessing, than a variety of choice fruits and vegetables for his table; while the exercise and recreation which the cares and beauties of the garden excite, are highly promotive of health. For pleasure—and what can afford a more heart-felt pleasure to the eye, unalloyed with pain, than the various and ever changing beauties of a well-kept garden? and what a more rich and innocent enjoyment to the palate, than a succession of fruits and vegetables the product of our own culture and of our own soil. For profit—believing, as we verily do, that the labor judiciously bestowed in garden culture is amply repaid, in the subsistence it furnishes for the family. "It is incredible to those who have not had occasion to observe the fact," says Cobbett, "how large a part of the sustenance of a country laborer's family, in England, comes out of his little garden." And yet the culture of the English laborer's garden costs him virtually nothing. His occasional hours of leisure, with the aid afforded by the otherwise unproductive inmates of his family, suffices to complete the work. The rural scenery of England derives much of its interest from the beauty of the farmer's and cottager's gardens which every where abound; and many of the successful competitors for premiums, on fruits and flowers, at the horticultural shows which are there held in almost every town, are weavers and manufacturers, who cultivate their little patches of ground in the hours of exemption from professional labor. Indeed so prevalent is the taste for garden improvement and embellishment, that a man is judged by the character of his garden. "Poverty," says Cobbett, may "apologise for a dirty dress, or an unshaven face; men may be negligent of their persons; but the sentence of the whole nation is, that he who is a sloven in his garden, is a sloven indeed. The inside of a laborer's house, his habits, his qualities as a workman, and almost his morality, may be judged of from the appearance of his garden. If that be neglected, he is, nine times out of ten, a sluggard, a drunkard, or both." The great strife every where is to get wealth—and for what? To increase the enjoyments of life. A great many of the most substantial of these enjoyments are within the reach of most men—they lie at our door—IN THE GARDEN—but we too often reject or overlook them, because they are not "dear bought" and "far fetched."

Under our impression of the great advantages which are to be derived from the garden, to the body and mind—as a source of health, of pleasure and of profit, we intend, now that our sheet is enlarged, to devote more room for its improvement. We will shortly give a plan of a garden; and in the mean time, the scientific principles of gardening, of Prof. Rennie, which we are publishing, will

be found no less applicable to the farm than to the garden. Postponing to a future occasion, our remarks upon the soil, and laying out of a garden, we proceed to give some instruction for the management of gardens already located, more particularly adapted to the present season, barely remarking, that every man who would have a good garden, must, like the late Rev. Dr Dwight, be at least his own head-gardener—he must make himself so far acquainted with the principles and manipulations of the art, with the qualities of his soil, and the wants of his table, as to be able to superintend and direct his principal operations. He may obtain a good substitute, but he may be assured there are more than two blanks to a prize. And the task of qualifying one's self for this duty, is conducive alike to bodily health and mental gratification. It may become a passion, increasing with experience and with age; but it is a passion which bodes no ill to any one, but, which, on the contrary, is fraught with the best feelings of our nature.

The preparatory business in the garden, in the spring, is to rake together the haulm of last year's crop, and to burn it, as well for cleaning the surface, as to destroy the seeds of weeds with which the litter more or less abounds; to put the fences in good order; to take the manure to those parts where it is likely to be wanted; to procure and sharpen, if leisure permits, poles for beans, and sticks and brush for peas; to prune the fruit trees, if they must be pruned in the spring; to put the garden implements in order, and to procure a supply of good seeds. If a hot bed is to be employed, and we strongly recommend one, it should be prepared, if not already done, in the manner recommended in pages six, both in our second and third volumes. In these may be sown early and head lettuces, peppergrass, radishes, peppers, tomatoes, early cabbages, cellery, and seeds of many annual flowers. If cucumbers are designed to be raised under glass, they should have a separate frame, or be but little encumbered with other plants.

The seeds which should be first sown in the open ground, and the warmest border or part of the garden should be appropriated to them, are early peas, potatoes, turnip beet, spinach, sallads, radishes, early cabbage, celery, &c. The second course of sowing may embrace onions, beets, carrots, early corn and beans, sweet herbs and flower seeds. The third course will consist of the tenderer kinds, as Lima and other beans, sweet corn, cucumbers, melons, squashes, pumpkins, &c. The plants of the garden possess different degrees of hardiness, and require different temperatures to bring them forward. Some will germinate and grow at a temperature of 45° to 55°; and will not suffer from slight frost; while others will not grow unless the temperature is higher, and are liable to be injured by the slightest frost, or by cold damp weather. When corn put in the ground very early, shoots to the surface, it is deemed early enough to plant melons, cucumbers and other vines for a main crop. All roots, to be planted for seed, as turnip, beet, carrot, parsnip, onion, &c., should be put out as early as the condition of the ground will admit, where the soil has been well prepared. They should be put at sufficient distance from each other to permit their seed stocks to spread, and to enjoy the full benefit of light and air. No two kinds of the same family of plants should be put out for seed near each other, not even the turnip and cabbage, as the seed will thereby become adulterated. It is important in planting, for most crops, that

the ground should be well dug, or ploughed, to the depth of eight or ten inches, to which depth the roots of most plants run, and for the tap rooted plants, as beets, carrots, and parsnips, it were better to have the tith twelve to fourteen inches. The ground should be fresh turned or stirred when the seeds are put in, and either trod, on the lines where the seeds are to be deposited, before planting, or pressed upon them after they are covered with earth. Seeds should be planted no deeper than is required to keep them moist.

This is the season for transplanting. How often do we hear people regret, on seeing their neighbor's gardens abound with choice fruit, that they too had not planted in times past. The season for transplanting fruit trees is unavoidably limited to the season of defoliation, when the growth is dormant; and the excuse of men generally is, that they either had not time, or forgot, to put out trees when alone the work could be done. This is very much like the man who suffered his family to be drenched by every rain, because he could not patch his roof when it stormed, and because there was no need of doing it when the weather was fair. What short-sighted mortals, to undergo a life of privation, of many of the richest gifts of Providence, rather than incur the trifling outlay of expense and labor—of a few cents and a few hours—to secure those blessings for themselves and families? Mercenary considerations alone—the ruling passion—should prompt to the planting of fruit trees.

But in our zeal to commend the practice of planting, we must not forget to give some hints as to the method of doing it. A tree is like a plant of corn, or of any other farm crop; it will prosper and repay for labor, according to the soil in which it is placed, and the attention bestowed upon its culture. The soil must be good, to afford the necessary food for its sustenance and growth; it must be loose, that the roots may penetrate readily in search of food; it should be free from habitual wetness, as an excess of water will injure, if not destroy it. Like farm crops, too, it depends, for its development, and the maturation of its fruits, upon the unobstructed agency of light and air. Hence it should not be planted below its natural depth in the soil, nor shaded by other trees, nor encumbered by shrubs, weeds, or tall grass. Water is the medium by which food is transmitted from the soil, to the plant, and is required, therefore, to be always present in the soil to ensure the growth of plants. In transplanting, make your holes as deep and broad, not as the roots require when transplanted, but as they are likely to extend the first season after being transplanted, and fill this hole, as you put in the tree, with rich surface mould, or at all events the lower stratum, which the roots are destined to penetrate in search of food; tread the earth firmly around the roots, when they are covered, to bring it in complete contact with them, and to prevent the evaporation of moisture, which latter evil will be further prevented by spreading some coarse litter upon the surface about the stock of the tree. Two or three potatoes may be thrown in about the roots, before they are covered; and a bucket of water, thrown in when the hole is partially filled, will tend to bring the earth in contact with the roots, and supply needed moisture. The transplanting of evergreens should be delayed till the new growth has commenced, in this latitude the last of May.—*Albany Cultivator for April.*

From Silliman's Journal.

ON THE DRY ROT.

BY PHINEAS RAINEY, MIDDLETOWN, CONN.

(Continued.)

When I have known the period at which certain trees have been cut, and also their locality, I have afterwards, year after year, examined their stumps, and watched their decay, and have invariably found, that of those of them which were cut in the winter, the disease first made its appearance in the heart-wood, and continued its ravages until that was destroyed, and up to that period the albuminum was comparatively sound. And of those that were cut in the summer, the disease first made its appearance in the albuminum, which, in many cases, after a few years entirely disappeared, but the heart-wood remained sound and dry. And here let me observe, that in the examination of this description of timber, I have always found it sound and dry, which leads me to believe that this is owing to the peculiar state of the heart-wood at the time of the death of the tree, and therefore it is more impervious to water, which of itself, waiving every other consideration, would make it more durable.

Our woods afford many facts, which, if rightly examined, would go to show that the doctrine I have advanced is the true one. Trees may be found uprooted and lying prostrate, from which the albuminum has disappeared in consequence of dry rot, and yet the heart-wood remains sound; stumps of dry limbs are observed projecting from aged living trees, which from appearance have been in that situation for ages, and from which the albuminum has also disappeared, yet the heart-wood will be firm and sound; trees are seen standing erect, on the albuminum of which the dry rot seems to have exhausted all its power, and caused it also to disappear, but it had no power to act on the heart-wood; and by their dusky and ragged appearance such trees seem to have been in that situation for a great number of years, and thus it appears that time only was slowly decomposing their outer surfaces, for if examined, it will be found that they are sound and dry within, and much harder than the same kind of timber seasoned in any other way. Can there be any doubt as to the fact that these limbs and these trees received their death in the summer? Others also are found lying prostrate, with the heart-wood entirely destroyed by the disease, yet the albuminum is in a tolerable state of preservation; others present nothing but masses of decay, and in the bodies and limbs of others, holes will be perceived from which once projected healthy branches; and to one that is experienced in timber, these are sure signs that death has entered into their composition, however otherwise their appearance might indicate a healthy state. These trees and these limbs received their death wounds in the winter.

There are numerous facts in the most common transactions of life that will sustain me in my position. I believe that the general practice throughout the northern and middle states is to peel such trees as are to be manufactured into ship plank; by saving the bark, this probably makes the business more profitable than it would otherwise be.—It is invariably the case, that by the time the planks become thoroughly seasoned the albuminum becomes so injured by the dry rot as to be unfit to be used; and for my own part I never saw any timber of this sort where the heart-wood was af-

fectured at all, unless the tree had contracted the disease before its death. Now I appeal, for the truth of these assertions, to all the experienced ship-carpenters who are in the least acquainted with this kind of timber. The season of peeling is from the third week in May to the second week in June. It is not probable that all the timbers required for a seventy-four, or indeed any other public vessel, are cut in the compass of any one month, but that they commence perhaps in October, and continue the cutting into April, and sometimes into May, and in cases of great emergency, into June. Then, if I am right in my views, various periods must elapse before all the timbers will have been attacked by the disease; and when the planks are taken off from any one of them preparatory to their being repaired, do not the timbers present that appearance? Are there not those on which the dry rot has exhausted all its power and finished their destruction, and others which are less decayed, others not so much? Indeed, the disease can be traced until you find those which seem to defy and continue to defy its energy, even after the vessel has undergone repeated repairs, and these circumstances occur too, even after the timbers have been subjected to some artificial process to make them more durable.

The following is a case in point. In the North American Review, No. xcv. for April, 1837, pp. 343-44, in the article on the *Sylva Americana*, the following passage occurs. "The white oak was largely employed in the frame of our favorite frigate (the *Constitution*) which was built forty years ago. In the course of the very thorough repair to which this vessel was lately subjected, many of the white oak timbers of her frame were found in excellent condition; and it is stated on the best authority, that in several instances the timbers of this description were sound, while others by their sides, of the southern live oak, had decayed. Now the superiority of the live oak, in point of durability, over the oak of any other country, has never been doubted." Why did not all the white oak timber last forty years, if there had not been some variation of the season of cutting them? and so with the live oaks.

It is a well known fact, that the building of the *Constitution* commenced when we were on the eve of a maritime war with France, or it had already commenced, and therefore we may suppose that the completion of the ship was hurried; and that her frame did not all arrive from the south in time, so that they were compelled to employ the white oak in her construction; probably the season in which it was cut was not much regarded, and therefore some of her white oak timber lasted forty years.

I saw in one of the Reviews of the day a circumstance of this kind, although I cannot now give the reference. In a mine, I believe in one of the German states, the timbers made use of to support the roofs of the galleries, were in a few months destroyed by the dry rot, and this could not be obviated by every experiment that was tried, until they made use of the locust. The effect was accounted for in this way; the dry rot, it is true, destroyed the albuminum immediately; but the decayed albuminum answered for a coating to defend the heart-wood from its influence. If this be the fact, why did not the decayed albuminum of the other timber answer the same purpose? But however, if the histories of those locusts were reverted to, it would most probably be found that they were killed

some time in the summer; and it will also be found that if the decayed albuminum be not removed it will generate another disease, which in some respects resembles and is very often taken for the dry rot.

Numerous other instances can be brought to bear in this case. Farmers cut their rails in the summer, when the bark will peel, and they last from fifty to a hundred years. They account for the fact in this way; if they cut them in the winter, the bark will stick to the rails, and after a little while, the water gets under it and causes them to decay sooner. On the contrary, they cut their posts in the winter; probably this is done for the convenience of cutting holes in them at that season, and although their rails last so long, yet their posts begin to decay in about seven or eight years, according to the soil in which they are placed.—When from necessity they are obliged to cut a few posts in the summer, (with the expectation however that they will soon decay,) if they last thirty or forty years, (and there are instances of this kind,) they speak of it as a very extraordinary circumstance, but never inquire into the natural cause, nor alter their practice. There are other instances of the extraordinary longevity of timber; wooden abutments to bridges, pumps, piles, foundations of wharves, cofferdams, &c. a full notice of which would fill a volume, all go to show that there is a season in which to cut timber that will cause it to last for years beyond what it now lasts; and that there is a season in which to cut it, when it will not last over eight years, notwithstanding any artificial process through which the timber may pass.

Immersion in water was one process, that was thought good to make timber more durable, and which was practised by the British government for a great number of years, and followed by that of the United States, until it was exploded; and according to the English writers on the subject, the life of their oaks averaged only about nine years, and that of our own favorite live oaks about the same period. Salt is one of those substances that in the popular opinion is good to make timber more durable, and hence the room between the timbers of every new vessel built by the government, is filled with it. But notwithstanding this, they have to undergo repairs in their hulls in about eight or nine years. So it has been with every artificial process, and so it will be until nature is more consulted, and her dictates more regarded.

Nature no doubt was the preceptor of the ancients, and particularly the Romans, who, it is said, girdled their trees, and let them stand until they were seasoned. Is not this more in accordance with the dictates of nature, than to place timber under water, and let it lie there for eight or ten years, to have its tubular fibres swollen and distended to such a degree as to destroy its elasticity and its firmness, and thereby prepare it for a more rapid decay? And what was gained by that practice? Truly nothing; for, eight or ten years was its life, before immersion, and it is no more than eight or ten years, after its immersion; and in what consists the value of salt, which only cools the outside surface, and therefore keeps it sound, but within, the disease is raging with redoubled violence. The only question is, when *did* the ancients girdle their trees? Was it in the winter? If any other proof, is wanting, to show that they did not do it at that season, it may be found in the practice of the pioneers of our western hard wood forests: there, as I

have been informed, they used to girdle their trees in the winter, for the very purpose of having them rot and fall down, and thereby save the necessity of cutting them. I think therefore, that we may fairly conclude that the Romans girdled their trees in the summer; and further, that they let them stand until the dry rot developed itself in the albumen.

If the timbers in ancient buildings were examined closely, the season in which the trees were killed may be pretty correctly ascertained, for if cut in the summer, the powder-post will invariably be found on the albumen, and if that has disappeared, there will be always some appearance on the heart-wood, that will show that the disease has been there, but never within its surface, and the same is true as regards the dry rot. The result of the following experiments will prove these facts. Cut two saplings, (no matter how small, if there be any heart-wood in them,) one in June, and the other in December. Take one piece of a convenient length from each, and put them into the garret, and one from each and put them into the cellar. In about three years it will be perceived that the powder-post has appeared on the albumen of the one cut in June; and in the heart-wood of the one cut in December, of those in the garret; and that the dry rot has made its appearance on the albumen of the one cut in June, and in the heart-wood of the one cut in December, of those in the cellar. By these experiments it can also be seen, that the cause which produces dry rot, under other circumstances will produce powder-post.

Although it is my opinion that June is the best time to cut timber to make it last the longest, yet it is probable that there would not be much difference in its lasting, if it be cut in either of the summer months. But there is a period in which, if timber is cut, the dry rot, or under other circumstances the powder-post, will appear both in the heart-wood and the albumen, at the same time, although I have seen but few cases of it, and in those cases I had no knowledge of the time of the death of the trees; but I judge it is either late in the fall, or early in the spring, from the circumstance of the bark being closely attached to the albumen.

It would be satisfactory to know the exact period when the tree was killed, from which the block was taken that is now undergoing the severe ordeal of the fungus pit at Woolwich, England; and if that cannot be ascertained, whether the dry rot first made its appearance in the albumen or the heart-wood, of its fellow that was destroyed by it; and also to have a block taken from a perfectly healthy tree killed in June, with the albumen removed and the surface of the heart-wood left perfectly smooth, and without any seasoning put into the pit.

CULTURE OF TROPICAL PLANTS.

Having accidentally seen the manuscript of the following letter to the Hon. LEVI LINCOLN from a gentleman as well acquainted as any other in the country with every thing relating to Horticulture and Arboriculture, we have placed it in our columns as well for information to our readers on the matter which it treats of, as to show to them that the estimable writer has lost none of that zeal which has always distinguished him in the pursuit of objects likely to be useful or beneficial to his countrymen.
—National Intelligencer.

HAWTHORN COTTAGE,
Roxbury, April 17, 1839 }

MY DEAR SIR:—I am very much obliged to you for the report of the Agricultural Committee on the memorial of Dr PERRINE, in relation to the culture of tropical plants in Florida, which you were so kind as to send me. I have read it with the deepest interest, instruction, and pleasure; and so favorably do I think of his honorable and patriotic enterprise, that I most sincerely hope Congress will cheerfully and promptly grant his request, and aid him in the most liberal manner.

The introduction of a single plant, or seed, has, in all ages and nations, frequently produced the most important and valuable results. The mighty influence on the agricultural industry and the general prosperity of empires which the naturalization and culture of the cereal grains, the olive, vine, white mulberry, for the silkworm, the sugar cane, coffee plant, cotton, potato, rice, and tobacco, have produced, is well known; and I have no doubt that several of the plants which Dr Perrine has now growing at Cape Florida and Indian Key may speedily become staple articles of cultivation in several of the most southern States. Besides, I do not think so meanly of the capabilities of the soil of Florida as most people. I well remember that Louisiana was called a mere alligator swamp when first, so cheaply acquired. The single fact that East Florida is the *only portion* of the Union where many of the most precious tropical plants can be acclimated, will, at no very distant period, bring every acre of land into great demand for tillage. It will be drained, diked, embanked, and converted into various kinds of plantations.

What was Holland before its dikes and canals were constructed? What has made the cotton and sugar estates of Lower Louisiana so prolific, but the levees for restraining the overflowings of the Mississippi? What the rice fields of South Carolina and Georgia? Human genius and indomitable industry. Where there is a cheering prospect of reward, they will triumph over all natural physical difficulties. We know the knights of Malta made fertile gardens on the barren rocks of that island, so celebrated for their chivalric deeds, and as the site of Paul's shipwreck, by pounding up the loose and scattered stones which covered its bleak surface, and importing soil from Sicily to mix with their dust. The Mexicans had floating gardens on the lake Tezcuco, where their capital city was established. The Chinese have long resorted to the same means of rearing culinary and other plants, and not an inch of soil, even though situated amidst the precipitous cliffs of the mountains, is unutilized, so great is the demand for vegetable products by the thronged population of the Celestial Empire. The lemon and orange groves of Portugal and Sicily are established and maintained by an expensive and laborious system of artificial fountains and channels of irrigation. With us land is so abundant, in comparison with the population, that we have no just conception of its value, as estimated in those portions of the globe where the inhabitants are so numerous that a few roods are considered an estate so ample that the fortunate proprietor is accounted an independent man.

But, even in the vast extent of the United States, with the millions of acres still in a state of nature, how many thousands are now cultivated which, a few generations since, ay, in our day, were deemed worthless? In England, what extensive morasses have been reclaimed, and added to the domain of

agriculture, while the heath covered mountains of Wales and Scotland are rapidly being planted with magnificent forests, not for embellishment merely, but as inexhaustible sources of wealth. The old Duke of Athol planted on his estates in Perthshire 15,503 acres, which contained 27,431,600 young trees; and his successor set out 6,500 acres of poor mountain ground solely with larches. The land was not then worth over 22 cents rent per acre, and now, with the timber on it, is valued at 32,500,000 dollars. The citizens of this country have, here and there, selected the most fertile and eligible locations, and call most of the vast remainder of the land either refuse or worthless. Time, and the increase of population, will show that nearly the whole will become more valuable than even what is now deemed the most choice. The embankments in the vicinity of New Orleans will be extended on each bank of the Mississippi, from the Gulf of Mexico to the Falls of St. Anthony.

If but one of the most valuable of the two hundred plants introduced by Dr Perrine can be successfully cultivated, all Florida will be drained, and become luxuriant fields and gardens, and embellished by canals, rivers, bays, harbors, and beautiful lakes. It will be the Cuba of this nation.

I know your liberal disposition, and enlightened and enlarged views in relation to subjects connected with agriculture, and all the great branches of national industry, and am confident you will be disposed to do what is expedient on this occasion.

Dr Perrine, like most men of science and ardent patriotism, has devoted much time, and expended his resources, for a great purpose, sanguine in the beneficial results to the Republic, and the hope of future remuneration from his own practical exertions; and it is very desirable that he should not be left, as is too often the case, to lament his labors, and to find that others, hereafter, reap the fruits of his meritorious enterprise, without having endured any of the toils or expense of a first experiment. Congress must be to him as munificent as would have been Henry IV. and Napoleon, to render his indefatigable researches and intelligence useful and honorable to himself and the country.

With assurance of the highest respect and esteem, your obedient servant,

H. A. S. DEARBORN.

HON. LEVI LINCOLN.

PRESERVING MILK. — A foreign Journal states that some milk was lately exhibited in Liverpool from aboard a Swedish vessel, that was several months old, having made two voyages from Sweden to West Indies and back again, and remained perfectly sweet and fresh. The manner of preparing it is as follows. The bottles are made clean and sweet, and the milk is milked directly into them without the intervention of a pail. As fast as they are filled, they are closely corked, and the corks wired down as in bottling cider. The bottles are placed when filled in a boiler, a layer of straw and a layer of bottles until the boiler is full. Fill the boiler with cold water, kindle a fire and let it heat gradually; when it begins to boil, withdraw the fire, and let the bottles remain till cold. They must then be taken out, packed in hampers, with straw or sawdust, and stowed in the coolest part of the ship. The milk so exhibited was above eighteen months old, and was of excellent quality. The perpetual motion of the sea, in time improves milk as much as it does Madeira; at least such seemed the result in this case.—Gen. Farmer.

**NEW ENGLAND FARMER,
AND GARDENER'S JOURNAL.**

BOSTON, WEDNESDAY, JULY 11, 1838.

COMMENCEMENT OF VOL. XVII.

With the commencement of a new volume of the *N. E. Farmer* we should do ourselves much injustice if we refrained from a grateful acknowledgment of the kind and liberal patronage which this paper has experienced for a course of sixteen years; and if we did not express our determination to show ourselves deserving of this liberality; and as far as possible to elevate its character, and extend its usefulness.

When the *New England Farmer* was commenced, and for many succeeding years, it stood alone in New England, and we believe in the country, as an agricultural newspaper; and the most sanguine friends of agricultural improvement were somewhat doubtful of the practicability of sustaining it. The interest however, which its appearance excited, gradually and surely extended itself; and the spirit of inquiry and general ability with which it was edited, and the gentle and inoffensive good humor and pleasantry, which sparkled in its pages, gave it a powerful hold upon public patronage and good will, which it maintained until the death of its lamented editor. His eulogium is best pronounced in the universal respect and affection, with which his memory is cherished by all who knew him. The volumes published under his inspection; and many of the articles which flowed from his pen, contain a large measure of agricultural intelligence and instruction: have awakened throughout the community an attachment to the art, and a zeal for its improvement, which have been of immense service; and have rendered a very high benefit in elevating the character of the occupation of a husbandman, and the character of the husbandmen themselves; and in creating a general and sincere respect for agriculture throughout the community. No candid mind will deny its claims to having done thus much; and it is absolutely impossible to estimate the amount of good which it has thus actually effected. Since that time a host of other agricultural papers have entered as laborers into the field; and have brought to that noble service the most liberal and valuable contributions of wise experience, of practical skill, and enlightened inquiry. The field is now won, and agriculture has assumed that rank in the community to which its incalculable importance entitles it. We propose however to continue our efforts to maintain and advance these triumphs. We shall anxiously call to our aid the best talents that we can secure. We shall suffer no chance to escape us of enriching our pages, with whatever may be interesting and useful to the agricultural community. Without begrudging any lawful and honorable success to other agricultural publications in any part of our country, we cordially wish them all the patronage to which they will show that they have just claims. We look upon the great cause of an improved and enlightened husbandry as the great cause of human civilization and happiness. We respectfully, and we hope without offence, confidently ask the continued patronage of our agricultural friends and the agricultural community at large, promising our assiduous and devoted exertions to make the *New England Farmer* what it should be; and as far as possible to increase its usefulness.

The Commissioner of Agricultural Survey of the State will continue to lend us all the aid in his power, compatible with his public engagements; and from his extended examinations in every part of the State; and his wide correspondence throughout New England and the

United States, he will have it in his power to enrich the *Farmer* with many valuable facts and communications. We shall do what we can likewise to secure the contributions of other gentlemen interested in the great subject in various parts of the country; and we hope in various ways by original and valuable matter, we shall satisfy every reader interested in the subject that the value of his subscription before the close of the year will be returned to him more than five-fold.

It will be perceived that our printers have given us new type, which we trust will be acceptable to our subscribers. We shall soon forward bills to all who have not paid their last year's subscription with the hope that the amount will be forwarded without delay. We shall also do the same with those who have been more prompt leaving it with them to pay when most convenient, hoping however, that many of them will send the amount by the first good conveyance. Those who live at a distance may forward their dues by mail.

The index and title page for Vol. 16th, will be ready and sent out next week.

Boston, July, 1838.

MATERIALS AND SOURCES OF MANURE.

We spoke in our last communication of the construction of a receptacle for manure—a place of general deposit for every substance, which might go to increase the compost heap. The next inquiry is, where shall we obtain the means of forming this heap, from what sources shall collections be made; what shall we throw into it or upon it?

Every organized body, which is capable of being dissolved and reduced to its original elements, is by such solution converted into manure. There is in nature an uninterrupted circle of life and death, of production, solution, and reproduction. The process is going on perpetually; it has gone on ever since the creation; and, for aught we can see, must continue to go on as long as the present system of nature shall endure. Animals and vegetables are sustained by the solution and decay of other animals and vegetables; and the former, having accomplished their term, go to the support of another class; and so on in an endless succession, to be limited only at the pleasure of the Creator. The vegetable or animal having passed into a state of decay is then prepared to be taken up as food by other animals and vegetables; and it is humorously observed by some one, yet with hardly more humor than truth, that man with extreme meanness seeks to withhold his proper contributions from this general reciprocity of usefulness; and though more than any other animal he avails himself of the means of others, making every part of nature tributary to his wants, selecting his food with peculiar fastidiousness, where he will, and as he will, he then carefully and manly provides that his own body, though sustained always by the labors and contributions of others, should after he has done with it be buried so deeply in the earth, that its materials cannot be availed of for any further purposes of utility.

Every vegetable and animal substance of every kind is convertible into the food of plants; and therefore in a state of solution or decay is to be considered as manure. There is another class of manures, which are called mineral manures, some portions of which are essential in vegetation; first as promoting the solution and comminution of vegetable and animal substance so as to prepare it to be consumed by plants; and further to assist in a degree in the formation of the vegetable structure as lime is necessary to form the shell of an egg; but of these we shall speak at another time. The food of plants is resolvable into a simple substance by some de-

named vegetable extract, by others *gumme*; and this is found in all vegetable and animal substances; but it can be extracted and taken up by the living plants only when the animals or plants from which it is taken are in a state of solution or decay. Different vegetable and animal substances without doubt furnish this vegetable pabulum or food in different degrees and in various combinations; and different vegetables require it in different measures and forms. These are matters as yet very partially ascertained; and how far the human line can reach in sounding this profound depth cannot be conjectured. They are matters of scientific inquiry and philosophical investigation; and treasures of wisdom are in the course of being developed by the persevering labors of learned inquirers. But we leave them out of the question as we write only for plain farmers, whose experience and intelligent observation will in the main direct them right, and save them from any great mistakes. To them then the simple rules to be given in the case are, save every thing; waste nothing; and carry constantly to the heap every thing within your reach, which has answered its end and which is capable of being converted into manure.

Having prepared your place of deposit, as we said, in a saucer shape, and so formed the bottom that the fluids will be retained, overlay it with a bed of loam or of bog mud, which will absorb whatever liquid substances may pass down upon it.

The excrements of animals are ordinarily deemed of the highest value as containing the elements of vegetation in the most concentrated and active and soluble form. A farmer should save every thing of this sort as scrupulously as we would save gold dust. If he has sheep in a situation to be brought up at night without driving too far and without too much trouble they should be constantly yarded at night in places well littered with straw or refuse hay or leaves; and these when well saturated with their deposits should be carefully removed to the compost heap. If he has cattle, cows, oxen, or horses, they too excepting in some cases where the oxen have been in the yoke all day and you wish to give them their feed and repose in an open pasture by night, should be invariably tied in the barn at night over your manure vault, where their droppings both liquid and solid may be easily thrown or fall into this common receptacle. Or if your cattle for any reason should remain in an open yard, that yard should be well littered; and all the manure exposed to loss through the influence of the rain or sun, or air, should be as regularly as the day comes removed to the manure heap. Your hog-sties should be so formed and placed that their contents should be all saved likewise and frequently transferred to the general deposit. We know that some may boggle a little about this constant "removal of the deposits;" but they perhaps will not object to their being all placed in one great bank. Let your styes likewise be well littered; and abundant supplies of bog mud or, if nothing else is attainable, simple mould be thrown in. In the next place look after your poultry house and your pigeon house. The excrements of poultry constitute some of the most powerful manures that can be obtained. If you cannot induce them to make their roosts directly over your manure heap, then be sure that they make their roosts, where all their deposits may be saved. Next take care of your privy. Let this be so contrived by a swing door on the back side, and by having the building elevated and only a small excavation for the vault, that you can daily in summer and frequently at other times cover the contents with fresh mould, a pile of which ought always to be laid near at hand; and in this way the place will be prevented from becoming offensive, a

matter so highly important to health and comfort; and the contents can be easily and without inconvenience transferred to the common receptacle. Or else, which is by no means a bad plan, but in many cases highly eligible, let your privies be constructed in some corner of your barn or at the side of your barn, so that the deposits may go at once into the barn cellar. Next carefully save all your dish water, all your soap suds, all the emptyings of your chambers, all the water in which your hogs are killed; and indeed every thing of this sort; and let that go either by some tight drain directly into your manure cellar, or else regularly and scrupulously save it in tight barrels or tubs, and when these are full cause them to be carefully emptied upon your manure heap. Next go to the places in your pastures where your cattle are accustomed to collect either for shade or repose and carefully and frequently remove to your barn cellar all the deposits, which are accumulated here.—Then go into the roads and highways and daily collect every thing of this sort, which may be found, as much as you would go into the road to pick up money, if you had known that money had been dropped there. The amount which may be accumulated in this way you will find at the close of the season vastly to exceed your expectations; and most amply to compensate the trouble or expense, which it may occasion.

We shall reserve our further observations on this subject until another number. We do not profess to offer any thing new or to have any thing new to offer on this homely subject; but we may at least hope that some plain suggestions will at least put our farmers upon inquiry whether there are not sources of supply within their reach, which they may have hitherto partially overlooked; and whether the continual complaints which we hear every where of the want of manure and the difficulty of procuring it may not be in some measure attributable to their own fault or neglect.

MELANCHOLY.—The family of Mr Fernald of Dover N. H. were poisoned last week, by eating of the root of the water hemlock (*cicuta virosa*), which grew on the banks of the Piscataqua, mistaking it for sweet flag. One of the children, a boy aged 7 years, died in a short time after. Mrs Fernald and another of the children were violently attacked, but by the prompt aid of medicine, recovered.—*Concord Freeman*.

The Report of the Horticultural Exhibition on Saturday last, is in type, but is omitted for want of room; it shall appear in our next.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending July 8.

JULY, 1838.	7 A.M.	12 M.	5 P.M.	Wind.

Sunday,	8 70	82	72	S. E.

*Thursday was the warmest day we have had this year. The mercury was up to 99 in the shade, between 3 and 4 o'clock, P. M.

Massachusetts Horticultural Society.
The Rooms of the Massachusetts Horticultural Society, 23 Tremont Row, are open for the public every Saturday morning, from 10 till 12 o'clock.

The Fruits and Flowers are usually for sale.

BRIGHTON MARKET.—MONDAY, July 9, 1838.

Reported for the New England Farmer.

At Market 200 Beef Cattle, 1950 Sheep, 15 Cows and calves, and 220 Swine. 40 Beef Cattle and all the swine were reported last week. 120 Beef Cattle, and 200 Swine remain now unsold.

Prices.—*Beef Cattle*.—Dull, a few sales only effected, purchasers unwilling to pay the prices asked and the Drover refusing to submit to a reduction.—We quote first quality at \$7 75 a \$8 00. Second quality \$7 00 a \$7 50. Third quality, \$6 25 a \$6 75.

Cows and Calves.—Sales were noticed at \$25, \$30, \$32, \$35, and \$38.

Sheep.—Sales quick, lots were sold at \$2 33, \$2 50, \$2 67, \$2 85, and \$3 00.

Pigs.—"Dull." no lots were sold, and less than 20 were retailed, at about last week's prices. The demand for swine has very much abated—consequently prices must decline.

Error.—In our last weeks report for First quality Beef Cattle read \$3 instead 8 25 as reported.

SCYTHES AND RAKES.

Just received at the Agricultural Warehouse and Seed Store, a complete assortment of Garden and Field Tools, consisting in part of

- 100 dozen Hall's Rakes, superior.
 - 100 do. Wilder & Eddy's, dn.
 - 200 do. Common do.
 - 25 do. English Cast Steel Grass Scythes.
 - 10 do. do. do. Cradle do.
 - 10 do. do. do. Border do.
 - 100 do. Round Scythe Stones.
 - 100 do. Square do.
 - 100 do. Cast Steel Garden Hoes.
 - 100 pair Grass Shears.
 - 100 do. Pruning do.
 - 100 do. Fruit do.
 - 50 dozen Patent Sleep Shears.
 - 20 do. Pruning do.
 - 20 do. do. Saws.
 - 25 do. Budding Knives.
 - 25 do. Pruning do.
 - 20 do. Edging do.
 - 25 do. Breaking up Hoes.
 - 100 do. Garden do.
 - 50 do. Dutch do.
 - 20 do. Bill and Brier Hooks,
 - 10 do. Grass do.
 - 550 do. Garden Rakes,
 - 500 pair Chains, for tying up cattle,
 - 60 do. Trace Chains.
 - 25 dozen Halter do.
- ALSO—
- 300 dozen Patent Scythe Shafts, superior.
 - 100 do. Cast Steel and other Shovels,
 - 1000 do. Rifles, 500 do. Scythe Stones.
- June 27, 1837.

ALDERNEY STOCK FOR SALE.

For sale a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27

FOR SALE OR TO LET.

A pleasant and convenient house in complete repair situated on the Worcester Turnpike, 5 1-2 miles from Boston and 2 miles from Brighton market. The house contain contains 9 large rooms, and has a barn, chaise house and sheds attached. Also, with the same, 3 acres of mowing and tillage land and 1 1-2 acres wood land. An adjoining lot of 5 acres can be had, if desired. Three quarters of the purchase money can remain upon a mortgage. If not sold, the house will be let to a good tenant. Enquire of D. HOLBROOK No. 31 Court St. Boston, or on the premises. June 13, 1838.

SITUATION WANTED.

A Gardener, by a young man of practical knowledge and can be well recommended. A Situation West or South would be preferred. Address R. B. through the office of this paper.

GUNNY BAGS.

9000 Second Hand Gunny Bags, 600 Gunny Sacks, a cheap article for Hop Bagging. For Sale low by G. W. STEARNS, No. 10 Commercial Wharf. 1m June 27.

SPRING AND SUMMER.

BY CAROLINE ORNÉ.

Thy steps, fair Spring, have passed o'er the sod,
And grass springs up where thy light foot trod:
Bright buds peep forth, and their petals gay
Unfold in the warmth of the noontide ray,
While the glad bird plumes its radiant wing,
And its clear, wild notes through the woodland ring.

The squirrel has come from its hollow tree,
And runs 'long the wall full of frolic and glee;
Then darts to the ground, and peeping round sly,
Finds 'mong the autumn leaves, withered and dry,
The brown beechee nut that it loves right well,
Then sits and cunningly strips off the shell.

Thy breath is abroad in the fragrant breeze,
And the leaves expand on the waving trees:
Thy eye beams bright on the fisher's home,
That rises in sight of the blue wave's foam,
And blithe of heart he unfurls the sail,
And welcomes the bland, auspicious gale.

The heavens behold the glance of thy eye,
And smiling put on a mellow dye;
Changed is the storm for the genial shower,
All balmy with breath of the leaf and the flower,
And the rainbow dressed in its brilliant dyes,
Its smile of promise sends warm from the skies.

Thy steps, bright Summer, have passed o'er the vale,
And the high grass waves in the welcome gale;
The fragrant strawberry lifts up its head,
And blushing peeps forth from its verdant bed,
And where roses abroad their perfume fling,
The butterfly comes on its brilliant wing.

In busy throngs with their joyous hum,
Where the clover waves, the merry bees come,
Or nestle where over the garden bowers
The woodbine climbs with its fragrant flowers,—
Their nectar to sip in the early prime
Of the morning's fresh and dewy time.

Thou lingerest where torrents hoarsely rush,
And they change to the streamlet's soothing gush;
To the lake's serene, untroubled breast,
The lilies rise up from their cells of rest,
And gem it with stars as pure as are those,
That on the calm bosom of ether repose.

The glance of thy smile is bright on the wave,
Where the water fowl loves its plumage to lave.
On the fresh green marge, a child sits there,
Pulling flowers to wreath with her sunny hair,
Then into the wave looks slyly to see,
Her own rosy face full of laughter and glee:

The barns are all piled with fragrant hay,
And now thou preparest to hasten away,
Thou hast heard the wail of the Autumn breeze,
Caught the blush of fruit on the leading trees,
And hast seen through the amber husk appear,
The golden gleam of the ripening ear.

Farewell! for the grain is bound into sheaves,
The rustle is heard of withering leaves:
The fair-haired child on the margin green,
Of the clear, still lake no longer is seen,
And the bird that loved there its plumage to lave,
Has flown to some far-away sunnier wave.

When thy parting smile, bright Summer, grew dim,
Mate was the wood-bird's sweet vesper hymn,

Mourning and sad was thy farewell tone,
As lingering it swept through the forest loo;
Wild was its music upon the hill side,
Faint down the vale, its last echo died.

But look! A trim barque is nearing the land—
Children dance merrily on the smooth sand.
With a smile on her lip the mother stands by,
The tear drops of joy glistening bright in her eye.
O dearest to her is Autumn's bleak gale,
For it homeward waits her husband's white sail.

REWARDS OF INDUSTRY AND ECONOMY.

As it is a rational desire for farmers, in common with their fellow citizens following other pursuits, to make a comfortable living for themselves and their families, and to accumulate a reasonable fund for contingencies, and for giving their children, or others dependent upon them a start on the journey of life; I design to furnish some of the results of my own experience and observation on the means most likely to accomplish those desirable and meritorious objects. I started out in life a poor boy, destitute of property, being thrown on my own resources, as tens of thousands annually are in our country, and by *industry and economy*, with the *blessing of Providence* on my exertions, I have now advanced pretty well on towards the natural period of the termination of my earthly career; having always lived in comfort, and it looks likely that I shall be able to leave quite enough to those who may come after me, to promote their best interests.

Let young men set out in life with a firm reliance on the superintending providence of God in all the things of this world, and resolve to ply the hand of *industry* in whatever calling they may be engaged. Be prudent; pursue a rational economy; despise not *small gains*; and under the ordinary circumstances of life you will be prosperous, perhaps rich.

The prospects in life of more industrious young men are frustrated by the effort to get great gain quickly, than by any other cause whatever. Small accumulations, well husbanded, are the most certain and effectual in promoting comfort and wealth; the truth of this remark you cannot fail to see verified in every district of our country; but "those who seek after sudden riches fall into temptation and a snare."

I have often heard young men despise the idea of making but 100, 200 or 300 dollars a year, thinking it beneath their notice; and I have lived to see some such persons receive charity from the hands of the servants of their fathers. It is by no means an unusual circumstance in our country to see those who were "honed boys" to farmers, by industry and good conduct rise to opulence; at the same time that their master's sons, who were thought to be born to wealth, for want of those qualities, have ended their days in penury.

An experienced old gentleman, many years ago when I was young, gave me some very judicious hints on the subject of "small gains," and explained to me the manner in which they accumulated, and what the end would be, if followed up carefully; and if you have no objection, Mr Farmer's Cabinet, I will give you a table that is true to a figure, and which will show the wonder workings of money if it be let alone to accumulate; and I would have you observe that the same result will be produced, only in a much more extraordinary

degree, by adding each year, *not money*, but *ADDITIONAL FERTILITY* to the same amount to a farm.

One hundred dollars put to interest at 6 per cent, and an additional \$100 added to it each year successively, together with the interest accumulated for 10 years will amount to \$1318 07
An annuity of 100 in 20 years amts. to 3678 55
do do do 30 do 7905 81
do do do 40 do 15479 19
do do do 50 do 29033 59
do do do 60 do 53312 81
do do do 70 do 96793 21
do do do 80 do 174659 98
do do do 90 do 314107 51
do do do 100 do 538386 80

Only think of it! the poor despised 100 dollars a year! see the wonderful workings of it! it is almost incredible! I could scarcely believe it myself, if I was not positively certain the calculation was correct to a figure. Now is there a farm of 100 acres within 30 miles of Philadelphia, that by ordinary management would not produce 100 dollars per annum, clear; or that would not enable its owner to add 100 dollars worth of fertility to it annually? if there is not, then the above miracle almost, may be wrought out. Take courage young men, try it! do not desert your honorable calling for wild, uncertain speculation; try it stick to your calling, I say, and you will not repent of it. —*Farmer's Cabinet.*

The march of intellect is shown in small things as well as in great, and the grandeur of men's conceptions in the nineteenth century is symbolled forth by big words which are now so popular. Instead of schools, we have lyceums, seminaries, and academies. The boys do not play in the yard, they recreate themselves upon the *campus*. We do not now signify dissent, by saying "we don't think so;" "we repudiate the idea;" and a repeal is a rescission. A next door neighbor is a continuous individual, and so on to the great fatigue of the organs of articulation, and to the no little annoyance of those who know nothing of Greek and Latin, and seldom trouble themselves with dictionaries.

Nothing can stay the progress of refinement. The Baron of Bradwardine should be among us to talk of *subligaculi* when he spoke of slippers and brogans; for we observe that a man in New York sells to the thirsty a drink called "Salubrious Stomachic Effervescent Ginger Beverage." In former times, this liquid compound was known by the less euphonious and less imposing name of "Ginger Pop." The sable Gwynnecle who vends "Jam Spruce Beer" about the streets of Philadelphia, should now say "*heu jam satis*" to the lowly title of his commodity and invest it with greater sublimity. Although "jam" is well understood to be the superlative commendation, yet it is too brief to impress the mind with a vast idea. When cabbages are called *splendid*, and potatoes *magnificent*, it derogates from the dignity of beer to be no more than "jam." —*Penns 31*

AGRICULTURAL.

From the Horticultural Register.

FLOWERS, FRUITS, AND TREES.

BY H. A. S. DEARBORN.

MR BRECK—The season having been unusually favorable for vegetation, and especially since the 15th of May, the consequent verdant and magnificent appearance of the country, with the blandness and congeniality of the weather, have induced vast numbers of persons, to visit the many highly cultivated gardens in the environs of Boston, several of which have attracted universal attention, either from the great variety of ornamental plants they contain, or the beauty of some favorite kinds, that have been managed in the most skillful manner.

Mr Walker's exhibition of Tulips became the first chief point of attraction for nearly two weeks, and thousands were delighted, with the superb display, of that infinitely various and gorgeous family of flowers.

Other towns, it appears, have also enjoyed a like interesting spectacle; but a discrimination must be made between the merit due for quantity, and the resulting from the excellence of the varieties, and the perfection of their development. The enterprising gentlemen of Newburyport and Salem, are entitled to great credit, for the taste they have evinced, in the culture of elegant plants; but it is presumed they do not claim precedence, unless they had also as many kinds which were as rare and perfect in florescence, as those which Mr Walker presented; for the mere superiority in number, cannot be considered as giving pre-eminence, in any vegetable production, unless it is of some very peculiar or notoriously useful species.

To obtain bulbs of the best kinds of Tulips from Holland, Belgium, France, and England, is very difficult and expensive, as every person has experienced, who has undertaken to introduce any particular plant from foreign countries. The bulbs, generally sent to this country for sale, are the rejected of the large nurseries, as all the most choice and valuable kinds are carefully reserved for the European markets, where the amateur purchasers are numerous, and willing and able to pay the highest price, for the remarkable varieties. Even in our day the extravagant passion for Tulips has not entirely subsided, and from 500 to 1500 dollars have been given, within a few years, for a single bulb, while those disposed of, at our auction sales, do not average more than from five to fifteen cents, and often not so much. Some of Mr Walker's cost in London fifty dollars each, and many of them from ten to twenty.

I have cultivated the tulip during a number of years, and had five thousand in bloom at one time, three thousand of which were in a bed, and the remainder scattered in the borders of the avenues and garden walks; but as a show of flowers, it was, in all respects, inferior to that of Mr Walker's bed of only eight hundred, from the inferiority of the

kinds, small number of distinguished varieties, negligent mode of cultivation, and imperfect florescence.

To give this superb flower an opportunity of displaying all its charming attributes, the soil must be deeply trenched, and enriched by a peculiar compost of thoroughly decomposed barn-yard manure, river sand, and decayed leaves or other vegetable matter, while a screen is indispensable to protect the plants, from the cold, night air, the direct rays of the sun, and violent winds, when bursting into flower and during the period of their bloom. This Mr Walker provided, at an expense of several hundred dollars, in a neat and complete manner, in the form of a beautiful pavilion, which was covered with stout white cotton cloth, so arranged, as to be easily rolled up, and let down, by means of pulleys.

Tulips have been a favorite florist's flower for centuries, not only in Holland, but in England and other European nations; and as early as 1630, Parkinson, after enumerating one hundred and forty sorts, observes in his quaint manner, that "to tell of all the kinds which are the pride of delight, they are so many, as to pass my ability, and, as I believe, the skill of any other." He was a celebrated herbist and botanist, and acted in that capacity to James I, and Charles I. His book on gardening is the first which was published in Great Britain, worthy of consideration. It is entitled "Paradisus Insole Paradisus Terrestres; or a garden of all sorts of pleasant flowers, which our English ayre will admit to be nursed up; with a kitchen garden of all manner of herbes, roots and fruits for meate, and sause used with us; and an orchard of all sorts of fruit bearing trees and shrubbes, fit for our land, together with the right ordering, planting and preparing of them, and their use and virtues."

In Parkinson's time tulips were divided into *præcoces*, or early blowers, and *serotine*, or late blowers, with an intermediate class of *duplex medie*, doubtful or middle blowers, as they flowered between the two others. The early blowers, have short stems and the Duc Van Thiroul is almost the only variety in repute, among modern florists. The great number of distinguished and admired varieties are all produced from the late blowers, which having tall stems and much finer colors, engross nearly the whole attention of the cultivators of tulips. The modern mode of classing the late blowers by the Dutch florists is as follows.

Prime Baguets, from the French word *baguette*, a rod, or wand; they are very tall, with handsome cups and white bottoms, well broken with fine brown, and all from the same breeder.

Riguel's Baguets.—This variety is supposed to have received their distinctive appellation from some individual by the name of Riguel, who was eminent in this branch of floriculture. They are not quite so tall as the former, but have strong stems, and very large well formed cups, with white bottoms, handsomely broken with rich brown color, and all from the same breeder.

Incomparable Verports.—A particular kind of Bybloemens. Cups very perfect, cherry-red and rose color and white bottoms, well broken with shining brown. Some of these are from ten to twenty-five dollars a root.

Bybloemens, or next flowers, called by the French *Flamants*. They have white ground, or nearly so, and are beautifully broken, with shades of purple and a variety of colors. They are from different breeders.

Bizarres, from the French odd, or irregular. Ground yellow, from different breeders, and broken with a variety of colors.

Paroquets, or Parrot Tulips.—The edges of the petals are fringed, colors brilliant crimson and yellow, with shades of bright green; but still they are held in no sort of esteem among florists.

Double.—These are of various, brilliant red, yellow and mixed colors; but, like many other double flowers, are deemed monsters, and not appreciated by flower fanciers, although they have an elegant appearance, from their upright, tall, and firm stems, and crowns of large peony shaped flowers, and when scattered with the Parrot, among the small shrubs and other plants in the borders of avenues and walks, or planted out in separate beds, they have a pleasing effect.

In the catalogue of Mosan for 1820, there are six sorts of early tulips, four of Paroquets, twenty-two double, and upward of six hundred late kinds.

Breeders are such as have been procured from the seed, and consist of one color, which is red, purple, violet, gray, brown, black, yellow, or some other individual color, without any sort of variation. These are cultivated in a rather poor and dry soil, and become broken, or variegated, in from one to twenty years, and produce new varieties; but so uncertain is the prospect of a favorable result, that but few persons have been willing to make experiments, for after many years of patient and unremitting attention, there may not be one remarkable and choice variety, out of a thousand seedling bulbs. It is from this circumstance, that a new and superb tulip commands the high prices in Europe which have been named, and actually paid, within a few years.

When the Tulip has broken, the colors are unchangeable, and are perpetuated by offsets from the parent bulb.

The tulips which are deemed worthy of special attention, by amateurs, belong chiefly to the classes of Bizarres and Bybloemens; and the properties of a fine variegated late variety, according to the best modern florists, are as follows.

Petals of a graceful form, the three exterior ones larger at the base than those of the interior; colors delicate, yet conspicuous, from the manner in which the tints are displayed, whether spotted, striped, feathered, blotched, splashed, pencilled, mottled, flaked, or as the French more significantly term the breakings of this flower *panaches*; edges entire and rounded, or but slightly crenated, at the summit, and so symmetrically arranged, as to form a perfect cup-shaped corolla, with a round

bottom,—except in some anomalous and remarkable kinds, like that called the Mountain of Snow, whose petals are slightly acuminate, recurved, a little undulate, and the flower leaning to one side. Stem strong, upright, and nearly thirty inches high; radical foliage, long, broad, undulating, and of deep rich green. The ground color of the bottoms of cups should be clear white, or yellow; the centre of each petal should contain one or more bold blotches or stripes, intermixed with small portions of the original color, abruptly broken into many irregular obtuse points. The colors which are generally held in greatest estimation, in variegated striped sorts, are black, golden yellow, purple, violet, rose, and vermilion, each of which being varied in different ways; but such as are striped with three different colors, in a distinct and unmixed manner, with strong regular streaks, and but little or no tinge of the broader, are considered the most perfect.

An uncle of Mr Walker, who resides near Windsor Castle, is celebrated for his tulips and ranunculuses, having produced several magnificent varieties of the former and many of the latter from the seed. His exhibitions of those universally admired flowers have been so superb, that his garden has been annually visited by the sovereigns, nobility, and that numerous portion of the population of Great Britain who have a taste for ornamental plants. From him the nephew has received many of his superior roots.

Besides the commendable exertions of Mr Walker to present an interesting display of well cultivated and choice tulips, he has eminently succeeded in raising from imported plants and seed, numerous new varieties of the *Viola grandiflora*,—the most admirable of that large family of charming flowers. He has, in fact, made this large and brilliant Pansy, known to New England, by the extensive seminaries which he has established, and the multitude of plants which decorate his ground. He had seven hundred varieties in bloom at the time his tulips were in flower, and the corollas of some of them, were more than two inches in diameter. He also cultivates the ranunculus,—one of the most delicate, beautiful, and difficult of all herbaceous perennial plants, to bring into a full and perfect florescence. He has two beds, this season, containing over two thousand tubers, and one hundred and thirty kinds, which, if the weather should not be too hot, will present an exhibition of flowers as rare and interesting as that of his tulips.

To the above named plants and the Dahlia, Mr Walker has devoted his sole attention, leaving to others the vast field of floriculture, for the selection of their favorite flowers, and the distinction they have attained, or may acquire, from the intelligence, skill, and industry bestowed on their cultivation, and that complete success, which so amply rewards the ardent amateur.

The necessity of a division of attention to the several departments of ornamental and useful plants, is as obvious, as that of labor in the mechanical arts; and the advantages derived therefrom are as certain, as they are conspicuous and satisfactory.

Colonel Wilder is unrivalled, in this country, in the number, variety and successful cultivation of the Camellia, the Rhododendron, Azalea, and Rose, having over three hundred kinds of the first, and upwards of four hundred of the last named plants.

Mr Manning, of Salem, has the largest variety of pears, he having made that delicious fruit his principal object of culture, while the apple and

plum have claimed his next regard. Mr William Kenrick is well known for his extensive and well managed nursery of forest, fruit, and ornamental trees, shrubs, and herbaceous flowering plants; and for several years he has made most honorable efforts to introduce the *Morus Multicaulis* and other valuable species of the mulberry, for affording the best aliment to the silk worm. He has also the merit of establishing the first extensive nursery in New England, and has published a very interesting and useful work on fruit trees. He, with Mr Manning, first succeeded in obtaining Mr Van Mon's new kind of pears, and he has a collection of that kind of fruit trees, of great value, from the number of varieties.—(Concluded next week.)

REPORT

Submitted to the House of Representatives of the United States, on the culture of the Mulberry and Sugar-beet, by the Committee on Agriculture.

The Committee on Agriculture, who were instructed to inquire whether any, and, if any, what encouragement may be given to promote the culture of the mulberry and the sugar-beet, report :

That, in order to obtain satisfactory information of the present state and condition, as well as of the importance, of the culture of the mulberry and the sugar-beet, they issued a circular on the subject, shortly after it was committed to them, to which they have received numerous answers, giving much interesting and useful information; some of the most important of which the committee append to this report. The first question which naturally suggests itself is, whether the subject-matter is of such national importance as to merit the serious consideration of Congress; and in order to satisfy themselves on this point, the committee ascertained from public documents (the Treasury Department not furnishing an official statement, as requested) the amount of silk and sugar imported for the last five years, respectively, which is as follows, viz :

	Silk.	Sugar.
1832	\$9,147,812	\$2,933,688
1833	9,309,547	4,752,343
1834	(document imperfect)	5,537,829
1835	16,537,983	6,806,184
1836	25,033,200	12,514,551

This statement at once shows the immense sum which is annually paid by the people of this country to foreign countries for these two articles only; and, also, the very great importance of encouraging their culture among ourselves, if that be practicable: for whilst your committee are far from favoring what is termed the Chinese policy, and are equally averse to discussing, formally, at this time, any disputed questions of constitutional law or political economy, they would respectfully insist, that when the soil, climate, and other circumstances, will enable the people of this country to produce, by their own labor, on their own soil, any article which is extensively consumed amongst us, it is the duty of the government, as far as may be deemed constitutional, to facilitate, by all reasonable encouragement, the production of that article. This course has ever been pursued alike by our own nation, and by every enlightened nation on the globe. So far was the policy carried at an early day in Great Britain, that even the winding-sheet of the dead was required to be made of wool, by act of parliament; and to this day, notwithstanding the theories of her writers, and some of her statesmen, no article that can be extensively pro-

duced there but is adequately protected by government. It is true that this may, for a short time, add something to the price; but this will be much more than compensated by the introduction of a new article of industry, and its subsequent abundance and cheapness; and no nation can enjoy that desired state of lofty independence whose policy will not enable its citizens to produce such articles of prime necessity as are compatible with their habits and the soil and climate of the country, and which will render them, as well in peace as in war, secure from the fluctuations of trade and the policy of other nations. A government that is so bound up by constitutional provisions that it cannot act in a great national matter, but must stand the powerless victim of other nations, is such a political anomaly as no people would intentionally select for themselves. The universal sentiment would be, if it be too weak to protect the prime interests of the country, it is too worthless to be preserved. This subject commends itself to the people of this country with peculiar interest at this time, when, as will be seen by the following statement, the foreign grain-growers have not only taken possession of our market abroad, and thus greatly reduced our exports of grain, but have actually usurped our market at home, and thus must eventually compel the grain growing states, for the want of some exchangeable production, either to do without such necessary articles as are the subject of this report, or else to produce them themselves.

Bread-stuffs exported from the United States in

1832	\$6,199,863
1833	7,009,556
1834	5,677,341
1835	6,111,164
1836	4,799,151

Whenever a new enterprise is projected in this country, one argument is used which merits consideration, and that is this: that, on account of the cheapness of labor in Europe, the citizens here can never compete with the producers there. This objection is more specious than solid, and derives its importance from the want of a comprehensive view of the subject. That mere manual labor is cheaper in Europe than in this country, is unquestionable; but that the specific amount of the result of labor from a specific sum is greater there than here, is denied. In Europe the excessive taxes and other burdens imposed upon the producer are so much deducted from the price of labor; besides, the comparative amount produced by an ignorant people in a state of semi-vassalage, unnerved by their degradation, and uninfluenced by the many considerations that stimulate the citizens of a free country like ours, is vastly in favor of the latter; add to these the fact, that the use of machinery is much more extensive and powerful here than it is in the pauper-ridden governments of the old world; here, every inducement that can be suggested by enterprise and ambition, and wealth, is held out to encourage the invention and use of labor-saving and labor-doing machines; there, every discouragement presents itself: here, every successful invention enriches the country and meets with the kind feelings of the government and the people; there, an improvement in machinery, the invention of a horse rake, or the use of the cradle, throws thousands out of employment, greatly swells the pauper-list, and is greeted with mobs and rebellion. These reflections are amply supported by the history of the cotton manufacture in this country. Amongst the many interests which it is the duty of govern-

ment to encourage, none should be pre-eminent to those of agriculture, which, indeed, have been too long neglected, both by government and people. "Politicians," in the eloquent language of Mr Allen's New York report, "may speculate upon the influence which free institutions or a partisan administration may have upon the prosperity of a country; commercial men may extol the advantages of an extended foreign commerce; manufacturers may claim pre-eminence in conferring independence upon their country; and literature may arrogate the exclusive credit of rendering a community enlightened and polished; yet, after all, agriculture constitutes the broad base upon which the whole superstructure of society depends for support. If that languishes, either for want of the protection or patronage of the constituted authorities, or from the inattention and lack of intelligence in its rural population, the government becomes embarrassed, commerce crippled, and manufactures paralyzed." But agriculturists are arousing from their long slumber, and awakening to the true interests of themselves and their country; science and enterprise are pushing them to select whatever is best adapted to peculiar soils and climates, and will most benefit the cultivator and elevate his character and standing; and it is believed that the time is not distant when agriculture will take the first rank in character, as it is now in usefulness, and when young men of talents and education instead of engaging in some too-crowded profession, will devote their mental as well as physical energies to the cultivation of the soil, and find in that occupation the road to wealth, to honor, and to happiness.

Amongst the objects that may require the fostering care of government, the committee are of opinion that none are more deserving attention than those now under consideration. Many important advantages would arise from the extensive cultivation of the mulberry and sugar-beet in this country. It would introduce to the farmer new and valuable, and, as your committee believe, profitable productions; which, in rotation with other crops, would have a doubly beneficial effect on our agricultural interests. It would improve our lands, increase the amount of productive industry, and condense, improve, and enrich our population. It would be adding other branches to the home, the fire-side business of every family, and thus increase the pleasure as well as the prosperity of the domestic circle. Your committee cannot forbear to notice with approbation, on this occasion, the fact that Mr Lindsey, of Washington city, has frequently conferred with them on this subject, imparting his valuable information, enforced by the practical argument of his weaving a complete suit of domestic silk, cultivated and manufactured on his own premises. There is in this, as in every country, a large class of individuals, who, so far from adding any thing to the industry and wealth of the nation, are unable to support themselves, for want of suitable employment; such are indigent females and children, the aged and infirm, to whom may be added the long list of paupers in our poor-houses and asylums, and of prisoners in our work-houses and state penitentiaries. To this class, the cultivation of silk presents a most suitable and advantageous employment.

The manufacture of sugar from the beet, and of course the cultivation of the beet itself, for that purpose, is of but recent origin. It was first introduced into France in 1811, under the patronage

of the imperial government; but was, for many years considered of but little account: lately, however, the attention of the French has been called to the subject, and the production has greatly increased; so that last year it is stated to have amounted to 90,000,000 lbs. of sugar—being about one-half the quantity consumed in the kingdom. In this country, but little beet-sugar has as yet been produced; owing, as we believe, to a very great deficiency of definite practical intelligence on the subject. Messrs Ronaldson, Vaughan, and Shider, of Philadelphia, in connection with the Beet-sugar Society of Pennsylvania, have taken the lead in introducing into this country the cultivation of the sugar-beet, and have shown a most commendable zeal in obtaining and disseminating information on the subject. For this purpose they have been at the expense of sending to France Mr James Pedder, their agent, who, on his return, made a most able and interesting report to the society, which was published in August, 1835. Mr Edward Church, of Northampton, Massachusetts, has also placed his country under a heavy debt of gratitude, by translating from the works of Dabrunfaut, De Domballe, and others, and the preparation of a Manual on the cultivation and manufacture of beet-sugar, which he modestly styles a "Notice on the Beet-sugar." This manual was published in 1837, at Northampton, by J. H. Butler, Esq., and derives great value, not only from the research manifested by its author, but from his practical information on the subject, acquired by a residence of several years in the vicinity of Paris. This little work, together with Mr Pedder's report, embodying as they do nearly all the information we have on the subject, cannot be too highly commended to the attention of the American people.

The culture of silk was introduced into Europe as early as the sixth century, by two missionaries, who clandestinely conveyed from China, in a hollow cane, a sufficient quantity of the silk-worm eggs to commence the business in the vicinity of Constantinople; from whence it has spread through every part of Europe whose climate is adapted to the culture. England has been at great pains and expense to introduce the production of silk into the kingdom; but, finding the climate too moist, she now confines her efforts to the extensive manufacture of the raw silk imported from more congenial climes. Considerable efforts were made at an early period to introduce into this country so valuable an article of industry. Connecticut, New Jersey, Pennsylvania, Virginia, Georgia, and perhaps some other states, had made considerable progress prior to the revolution; but the trying scenes of that eventful period, so unpropitious to the success of any new enterprise, effectually prostrated this for many years; indeed, for a long time after the termination of that glorious contest, our country was so peculiarly situated with regard to the rest of the world—being not only the carriers, but the producers of grain and other articles of necessity for the belligerent powers of Europe—that few men felt inclined to abandon the production of what found a ready market and a high price for the purpose of testing any untried experiment in agriculture. There were, perhaps, some other reasons which induced the people of this country to neglect this subject for so long a period. The white Italian mulberry, till within a few years, was the only variety cultivated as food for the silk-worm, and this was unfit for use for several years; so that the cultivator was compelled to lose the use

of his capital and labor for some years, before he had any prospect of remuneration: add to this the extreme difficulty which, till very recently, attended the process of reeling, and the want of a market for cocoons, or even raw silk, and we have causes sufficient to satisfy any reasonable mind that the culture of silk was never abandoned in this country on account of the soil or climate, or any other supposed natural obstacle. The committee have the satisfaction to believe that these difficulties no longer exist: the world is at peace; each nation raises its own articles of necessity; the farmers of this country, so far from having a great market abroad for their grain and other produce, have really a competition at home; the cultivation of the white mulberry has been substituted by the *Morus multicaulis* and other varieties, which may be stripped of their foliage the same year that they are planted; and the dull, tedious method of reeling by hand, which required a regular apprenticeship to learn, and years to acquire facility in the use of, has given way to the new patent reel, by which a person (even a child) may learn in a few hours to reel, with great ease and expedition, a much more even thread than by the old process. It may also be added, that many silk weavers have established themselves in the country, and opened a good and permanent market for all the cocoons and raw silk that can be raised; they being now under the necessity of importing large quantities to keep their factories in operation.—(To be continued.)

CULTURE OF WHEAT IN THE TROPICS.—It is well known that the cultivation of wheat within the tropics has been deemed impracticable, unless at an elevation of from five to nine thousand feet; and that as a consequence the inhabitants of the West India Islands, and the adjacent main, are mostly dependent on the United States for their supply of wheat flour, while the great mass live on corn, 'Zea mays.' From some late experiments, however, it would seem that by selecting a proper variety of wheat, and a proper season for sowing, the difficulties attending the production of wheat on those islands is not insurmountable, and several cases have occurred within the last two years in which wheat sown at but a few feet above the level of the sea, has perfected a beautiful grain.

The wheat in these instances was sown in January, and was cut in April, having grown and ripened in the short space of ninety days. In the Journal of the Banaha Society for the Diffusion of Knowledge, is the following paragraph, giving notice of an example of productiveness which can be rarely paralleled in the history of the wheat plant.

"On the twelfth of March, Mr Lees stated, that he had been informed by Mr Storr, that each grain of the Victoria wheat which he had planted would be likely to produce 100 ears; counting only the very moderate number of 50 grains to each ear, this would be an increase of 5000 per cent, or five thousand bushels for one! Mr Storr intends, in the coming season, planting a quantity of this wheat, from which no doubt abundance of seed will be obtained."

ANECDOTE.—Does the previous question cut off every thing? inquired a member of the House of Representatives the other day.—'It does' was the reply. Then, said he, 'I shan't, the first chance, move it upon Mr Petrikim's piece.'—*Alexandria Gaz.*

BOOKS ON AGRICULTURE, FOR SCHOOL BOYS.

We have thought the cause of agricultural improvement would be greatly promoted by the publication of a series of elementary books on agriculture, designed for the use of the schoolboy. Why should not our children have facilities for the acquisition of knowledge applicable to this pursuit as well as on less useful ones? If education is designed to fit us to engage in the practical duties of life: why is it that the most important of all earthly subjects, and one which occupies the labors of a vast majority of our people, is not the leading object of the schoolboy's education? We have elementary books on every other subject; we have schools wherein are taught the rudiments of every science, schools of law, medicine, divinity, of fighting, dancing, and of every thing but of agriculture. There is something wrong in the national practice on this subject. We ought to give to the most important subjects the highest degree of attention—we must graduate various branches of education by the standard of their relative importance, and give to those having the nearest relation to our most important interests, the greatest share of favor. We ought to have the principles of husbandry taught in every common school and a chair of agriculture endowed in every college. And we think the first step to the introduction of this new branch of education is, to have the necessary elementary school books. We have many men in our country, eminently capable of compiling such works and adapting them precisely to the capacity of the schoolboy. And he who would prepare a set of works on agriculture for the use of schools, such as would give to the boys of the country destined for the pursuits of husbandry, a thorough knowledge of the principles and the outlines of the practice, of agriculture, would do more for the general good and for his own literary fame, than in any other walk of science or learning. Let it not be supposed that we decried other branches of science or learning. We are in favor of all; and especially those which contribute useful aids in the practical labors of life. We would render all subservient to man's use; and it is only in this view that they should be appreciated. But it is admitted on all hands, that agriculture is the most universal, the most dignified, the most congenial, virtuous and productive pursuit of mankind—the substratum of all other pursuits—the life and soul of commerce and manufactures—the mother of the arts and sciences—the basis of civilization; and we insist, it is not seeking too much when we seek to give to her own child, the husbandman, a higher grade of education. Whatever description of knowledge, relates nearly or remotely to the multifarious labors of the agriculturist, should be an object of his study, and constitute a portion of his exercises at the primary school and the college, and employ his reflections in all the riper years of after life. One of the most absurd and mischievous errors of the day, is that of the father, who gives to the son destined for a farmer an education inferior to that he bestows upon the one destined for a profession. The husbandman deserves a better education than a lawyer or a doctor; because his occupation requires the exercise of more knowledge; but it is too generally the case, that he is only allowed some snatched intervals between the crochets, to learn to read, write and cipher—and this a few weeks education enough for a farmer! O, what a degraded, miserable error is this—what a blot to the improvement and dignity of the class!

It ought, it must be banished, and the practice which results from it abolished, and a wiser and better one substituted. Now, however the remark may seem to ensure the general opinion and practice on this subject, and although we may be even ridiculed by many farmers themselves, for the apparent ultraism of the sentiment, we are bold to declare, nevertheless, that the farmer has need of a better education, and he actually more often requires the aid of more various branches of science in his ramified operations, than the member of any profession; and we sincerely believe, that if any discrimination should be made in the education of two sons, one destined for a farmer and the other for a profession, it should be in favor of the former. Let us not be misunderstood—the boy destined for a profession or trade should be thoroughly educated in all branches pertaining to his distinct calling; while the boy intended for a farmer should be thoroughly instructed in all the principles to which the intelligent and scientific agriculturist stands indebted for the successful result of his labors. We could easily show, that these principles are drawn from a wider range of sciences than are necessary to be consulted by one destined for any of the so-called learned professions; and consequently it would be shown that the husbandman needs a more extended education. A young man preparing for the bar is ready to enter upon his legal studies on attaining some smattering of Latin, (or it may be Greek;) and many do not even go thus far before taking up Blackstone. A short course of reading elementary works on the principles and practice of law, and the student enters on the practical field of his profession. The physician requires more preparation to qualify him for practice. He too, learns the dead languages, and studies the principles and practice of his art, but those principles involve a knowledge of various abstract sciences, and he is constrained to invoke the aid of anatomy, physiology, chemistry, mineralogy, botany, &c. before he enters upon the practice of his profession. We are speaking of those studies only as they relate to the professional qualifications of the student, and of course we are not to be understood as denying either the possession or the importance of other branches of learning to professional men. They, as well as agriculturists and others, in their social and political relations to community, are equally required to discharge the duties of citizens; and we hold that all classes should avail themselves of every accomplishment which learning or science can bestow, in aid of the performance of those high duties. But we need not stray comparisons or illustrations on the subject; our opinions may be presented at one view. We would give to every one, of whatever pursuit, precisely the education adapted to it—and it should be thorough and perfect in all its branches, or at least so far as any or all the branches related to the peculiar pursuit adopted by the student. It should thus qualify him for the intelligent prosecution of the labors of his life and ensure his complete success. It would render the farmer as illustrious, and certainly as useful, in his sphere, as the profoundest statesman or professor. But the subject is too interesting to be treated satisfactorily in the narrow limits to which we are circumscribed; and we mean to pursue it. In the meantime, we submit to the board of education, and to the commissioners of common schools, the propriety of early considering the importance of adopting a series of agricultural works, as text books in the school about to be put in oper-

ation under the excellent common school law of the state. They may do incalculable good to the children of Kentucky, which will flow to other generations, and they may render the system far more useful and effective, by seasonably directing their earnest attention to the subject.—Frankfort, Ky. Farmer.

THE COMING HARVEST.

Never was there the prospect of a richer fulfillment of the gracious promise made by the Almighty, when he set his bow in the heavens, and declared that thenceforth "seed time and harvest should not fail." From every section of the country, and more particularly from the principal agricultural districts, the accounts of the coming harvest are of the most cheering description; every where is the promise of an abundant reward for the labor of the husbandman. The continuance of warm weather and the abundance of rain has brought forward the fruits of the earth with unusual rapidity and perfection. The grass crop, which is partially cut and will be secured in the course of a week, is the heaviest that has been known for years. The pastures look nearly as well as the meadows have the two past years. Corn, wheat, and grain of all kinds look uncommonly well. Wheat, the great staple of the West, it is confidently anticipated, will be gathered in such abundance as will enable us to export instead of importing it. Not only is there the prospect of an abundant crop, but a large portion of the land has been devoted to its cultivation. The Spring wheat has succeeded admirably in latitudes where the season has been generally considered too short for this grain. Large quantities of this species have been sown in New England. On the Eastern shore of Maryland, and in Virginia, where the wheat crop has failed for successive years until the cultivation of it has been abandoned, the Spring wheat has been very successful and a great deal has been planted.

The Baltimore American says:—

"The Crops—the Harvest.—An all bountiful Providence has not only blessed our country with abundant crops, but also with the most favorable season for their ingathering. We never recollect to have witnessed a more genial period for the growth and final ripening of the crops than the last six or eight weeks have presented, or a more advantageous condition of the weather since the harvest has commenced. Each day's continuance of such weather as we have had for the eight or ten just past, secures to the country hundreds of thousands of bushels of wheat.

In Maryland the husbandmen are busy, and extraordinary wages are given to the best harvest hands, in order that the crops may be secured. As much as five to six dollars a day have been paid in some cases to first rate cradlers."

Respecting the wheat crop in Virginia, the Farmer's Register of June 25th says:—

"The present wheat crop throughout Virginia, and other adjacent states so far as we have heard, is the best in quantity and quality combined, that has grown for many years—if not the best that has ever been made. Some partial disasters, on particular farms, have been suffered, from chinch bug, hessian fly, or rust; but nothing worth naming as affecting the general crop of Virginia. A more considerable cause of diminution will be found in the circumstance that there is less surface now under wheat than a few years ago; as the repeated

losses and failures of wheat have caused almost every farmer to withdraw some portion of his fields (the part promising the least product,) from wheat culture, and substituting oats or rye. The crop is now so far advanced in lower Virginia, that it may be considered out of danger, except from continued wet weather during the time for harvest, by which cause we have known of one crop (in 1821) nearly lost, after it was ripe enough to be reaped. The weather now (June 25th) is very favorable.

Harvest was begun on some of the most highly improved marled land on James River on the 16th inst. with purple straw wheat—which was as early as what is called May wheat, elsewhere was ready for the scythe. There has been a predominance of cold weather for the time of year through the last 60 days or more, and the growth and ripening of wheat were every where more backward than usual."

The Charleston papers make remarks similarly encouraging of the crops in the northern part of South Carolina and Georgia.

A correspondent of the Journal of Commerce, writing from Ontario county, New York, estimates the wheat crop as the largest they have had in twenty years.

The New York Commercial Advertiser says: "During the course of a short ride on Long Island a day or two since, we had some opportunity to learn the prospects as to the crops in Queen's county this season. Never was there a fairer bidding for an abundant yield than there is at the present time. The wheat fields in particular are very fine. Rye and corn are also doing very well, though the latter has suffered in some instances from the ravages of the grub worm. The hay crop, which the farmers are now gathering in, will be very large."

In fact, the accounts from all parts of the country are but an echo of the same opinions. All unite in saying that there is every prospect to believe that a more abundant harvest will be gathered than has blessed the country for many years.—*Rhode Island Country Journal.*

DECOMPOSITION OR PUTREFACTION OF VEGETABLES.

All vegetables, when the principle of life has departed from them, begin spontaneously to be decomposed (to putrefy). The elements which enter into the composition of plants, when left entirely to the disposal of their chemical affinities, have a tendency so separate from each other, and form new compounds very different from those which compose the living plant. This is termed the "spontaneous decomposition" of vegetables. The substances formed by the new arrangement of the elements of the vegetable are aerial and colourless: hence the entire disappearance of the vegetable, as if it had been totally annihilated when life ceased to preserve its particles together in the vegetable form.

The compounds formed, when the vegetable dies and putrefaction goes on, are, carbonic acid, water, carbonic oxide, and carburetted hydrogen. The two former are the chief results of the decomposition; the two latter formed more sparingly, and principally when there is not a free supply of oxygen to the substance undergoing decomposition. The carbon and hydrogen of the plant have a constant tendency to unite with oxygen, and form carbonic acid and water. Now there is never present in the

vegetable a sufficient supply of oxygen to convert all the carbon into carbonic acid, and all the hydrogen into water; hence, if there be not a sufficient supply of oxygen to produce these compounds presented from external sources, as from the air, the two other matters are forced, one of which (carbonic oxide) requires a less quantity of carbon than the carbonic acid, while the other (carburetted hydrogen) requires no oxygen, consisting of carbon and hydrogen.

In vegetables which decay under water, carburetted hydrogen is abundantly formed; hence arises the gas which is found so plentiful in summer in stagnant waters containing quantities of putrefying vegetables.

The spontaneous decomposition of vegetables goes on most rapidly when they are exposed to the air, kept moist, and preserved at a degree of warmth higher than the usual temperature of the atmosphere. Putrefaction is retarded or almost prevented if the vegetable be dried, so that its own moisture is expelled, carefully excluded from air and moisture, and kept cold. The influence of heat in promoting the decay of vegetables depends upon the repulsive power it possesses, by which it disposes the various elements to assume the gaseous form. Animals and vegetables are frequently found in snow or ice, in a high state of preservation.

Such are the changes which go on in the dead plant. That mysterious agent, Life, is able by its peculiar power, to control and overcome the chemical attractions which tend to produce these changes, and retains these elements in that state of combination best adapted for the performance of their proper functions: at the moment however, in which life ceases to superintend the exercise of these functions, they cease and the chemical attractions, no longer restrained by the vital principle, obtain full sway. The carbon, oxygen, and hydrogen, formerly existing in the state of wood, bark, leaves, fruit, or seeds, obey the laws of chemistry, return to the state of carbonic acid, water or inflammable gas mix with the earth and atmosphere, afford nutriment to new plants, again form leaves, flowers, and all the beautiful and diversified organs of the vegetable creation—again wither and decay, and return to the soil to supply new generations, and continue the same series of unceasing revolutions.—*Chemistry of Nature.*

HINTS FOR JULY.

From a belief of its utility, confirmed by several years' practice, we earnestly recommend a trial, to those who have not adopted the practice, of curing their clover hay and such as abounds in clover, in grass cocks, instead of spreading and curing it in the old way. It will save labor, save hay, and add much to the value of that which is housed. As soon as the grass has become wilted in the swath, and the external moisture evaporated, and by all means before any of the leaves become dry and crumble, put the grass in grass cocks, as small at the base as possible, not to exceed a yard in diameter, and taper them off, by adding forkfuls, to the apex, which may be four to five feet from the ground. Leave them undisturbed at least 48 hours and until you are pretty certain of sun or a drying wind: then open the cocks, and if once turned, the curing will be complete in three or four hours, scarcely a leaf will be wasted, and the hay will be bright, fragrant, and will keep well.

Cut small grain before it becomes dead ripe, for the following reasons: 1. If omitted, bad weather

may intervene and delay the harvest too long. 2. Dead ripe grain wastes much in harvesting. 3. Early cut grain makes the best flour. 4. When any portion of the culm or straw has ripened, or become dry, there is no further supply of nourishment from the soil; and the grain then gets as much food from the cut as it could get from the standing straw. Hence, when the straw turns yellow under the ear, however green the rest part of it may be, the grain should be cut. And when the straw becomes badly affected with rust or mildew, the sooner it is cut the better.

Do not put the plough into your corn, if you have, as you may have for a trifle, a cultivator or horse-hoe. It severs the roots, which are the mouths of the plants, turns up and wastes the manure, which should always be applied to this crop, and deprives the plants of more than half their pasture. Hill your corn but slightly. Hilling renders it more liable to suffer from drought, and induces it to throw out a new set of roots, the old ones being in a manner useless, by being buried too deep, and beyond the reach of the influence of heat and air, the indispensable agents of nutrition and vegetable growth.—*Cultivator.*

WORKING DRESS FOR FARMERS.

Every person should be clad in a dress adapted to his occupation or calling: this indicates sound judgment and good taste, and enables a family to save a good many stray dollars in the course of a year. In our country, but little attention has been paid to this important matter, and much unnecessary expense is annually incurred for want of adopting a cheap and simple costume for a working dress, which we should not be afraid of having dirtied or injured by the business we are engaged in, and which can be quickly put on or off, as occasion may require. In France, where convenience and economy has been studied by the agriculturist, there is a particular dress worn, which contributes much to comfort, and has a very neat and pleasing appearance. It much resembles what is called the "hunting shirt" in this country, is made for summer wear of unbleached linen, comes half way down to the knees, has a breast pocket on each side with buttons, and an open slit in the seam on each side opposite the pantaloons pockets, to give ready access to them; the collar fastens with a hook and eye, and two buttons close the bosom slit. Around the waist is a belt either of the same material, or of leather buckled in front.

This dress, which in France is called 'Blouse,' is cheap, light, cool, convenient, tidy, good looking and tasty, and consequently every way adapted to the every day business of the farmer and gardener, and ought to be worn by men and boys when engaged in their daily work, to the exclusion of the inappropriate and inconvenient dresses with which many are attired.

Silk Ribbon in great perfection is manufactured by Messrs S. & T. Whitmarsh, at their Factory near South Street Bridge. The loom used was constructed by Mr P. Downing, of Enfield, and a more perfect and beautiful piece of machinery we have rarely seen. It is capable of weaving fourteen pieces of Ribbon of different widths at the same time, and it does weave them exquisitely. Some specimens which we have in our possession, the product of this machinery, are not surpassed by any Ribbon of foreign manufacture.—*Northampton Courier.*

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, JULY 18, 1838.

MANURES—CONTINUED.

We have spoken of some of the resources, which every farmer has upon his own premises for supplying himself with manure. We may be chargeable with some repetitions; but the importance of the subject must be our apology. We believe, and the conclusion is founded upon no small observation and experience, that almost every farmer has within his own reach the means of enriching his farm, of extending and improving his cultivation; and finally of carrying his cultivation to as high a pitch of productiveness, as the nature of his soil admits of. No farmer should be willing to stop short of this; and when this is made, as it should be, his great object of pursuit, and he is willing to devote to it all the attention and time and skill and labor, which men, who are determined to succeed, apply to other pursuits, success is equally certain. The great rule of accumulation in this case as in every other is, "Gather up the fragments that remain that nothing be lost."

We have spoken of a barn cellar; and of securing the contents of the stalls and the privy. The value of necessary manure or night soil is very partially appreciated among us. There is no manure more powerful. The farmers in the neighborhood of the cities are beginning to understand it. It is objected by many that its effects are transient. So is every thing else in this world—Nothing earthly or human lasts long. But we believe that in this matter the effects are much more durable than is generally admitted. Within a short time we have seen a field now in grass, which had a good dressing of it five years ago; and it tells of it in pretty loud tones to this day. The great objection to its use is in the difficulty of removing it. We have shown in a former number how in a private establishment this may be entirely obviated. The farmers in the neighborhood of the city, who remove the night soil from the city, are many of them, in the first disposition which they make of this article, sufficiently slovenly; and ought to be subjected to a more severe police; for by proper management all offensiveness might be avoided, and certainly no deposits near the highways or buildings ought to be in any case permitted; the heaps should be immediately covered with loam; and the carts and utensils as soon as emptied ought to be thoroughly washed with chloride of lime. The expense would be trifling. There is little doubt however that we shall soon have the French method of preparing the article introduced among us; a mode by which the crude substance, by the application of a prepared material to be found every where in abundance, and at small expense, and which, when applied constitutes about an eighth part of the composition and is in itself a valuable manure, becomes disinfected of all bad odor, and brought into such a dry and friable condition that it may be packed in barrels, and transported any distance; and used upon the land without inconvenience or offence. As yet no provision has been made for saving the liquid portions of this manure; but we know some individual cases in which this is saved with the greatest care, and to great advantage. In this instance a considerable pile of mould is collected under cover in a suitable place; and all the liquid from the house is daily and carefully poured upon it. The heap becomes thus thoroughly impregnated with its fertilizing qualities and forms a valuable manure for any purpose. We make no apology for stating so homely a subject in the plainest manner, to him who will think.

We have seen a good deal of false modesty and a fastidious affectation of delicacy in people, who, feeling that they are made of porcelain clay and not of common dirt, are very apt to be offended at the very word manure; but who in general are much like the sensitive and modest lady mentioned by Addison who swooned at meeting a man on a staircase, and poor thing was put to bed in three months afterwards. We consider every subject important, which essentially concerns health, and comfort, and wealth; and so far from being offended in treating of them, the spirit of true philosophy and piety will lead us to adore the wonderful and beneficent transformations, which are constantly going on around us.

The next great source of dependence of the farmer for manure should be his hog pen. Every careful farmer, if he will take pains to get the best breeds of swine, can afford to keep swine for the manure they will make. It is a general impression among farmers that pork can be fattened to advantage when its price in the market is as many cents as there are tens of cents in the price of corn; as for example when corn is fifty cents you can afford to fat pork at five cents a pound; when corn is a dollar or ten times ten cents, ten cents a pound for pork will be a saving price. We believe that this rule is rather matter of guess work than the result of any careful and exact experiments. Mankind are fond of generalising; and of leaping at conclusions without any careful weighing of premises; and almost any proverb or short rule in matters which are in their nature indefinite, will gain currency, if to the semblance of truth you will only add a certain quaintness of expression. In times of lawful money, and before dollars and cents came into fashion, the rule used to be, that pork must bring as many pence per lb as there were shillings in the price of a bushel of corn. This shows that this rule cannot be relied on with very great confidence. Our own experience has satisfied us after various careful trials that Indian corn is worth seventy cents a bushel to give to fattening swine, when pork will bring six cents per lb. in the market. But then we are not willing to give this as any certain rule. We only say that in cases, where we have kept an exact account this has been the result, and we usually calculate upon it; but then it is obvious how much the result may be affected by circumstances; by the breed of swine; by the age and condition of the subjects when put up; by the preparation of the food; by the mode of attendance; by the season of the year, and the temperature of the sty; by the number in the family which you feed, and their good temper and good manners to each other; and a variety of other circumstances. But we refer to this matter merely to say that with good management there is little risk of loss to the farmer in keeping swine; there is often a considerable gain; but even if there were a loss from the pork, there may be a great profit from the manure. Hog manure is in itself of the richest quality; swine are excellent fellows to work in a compost heap, and if you will not, like the Egyptian despots, compel them to make bricks without straw; but will give them an ample supply of the raw material, they will be sure to turn you out an abundance of the manufactured article of the very best quality.

Now hogs to do this must be properly accommodated, in spacious and well prepared compartments by themselves; and not suffered to run at large in the highway like many of our cosmopolites in the city, nor as we actually saw one a few days ago, brought into the parlor to lay down with the children on the floor. They should have comfortable, shaded, and well littered apartments for sleeping rooms. They should have a spacious, and remember, a well-paved yard to work in, if possible

made water tight. They should have access to water freely or it should be often conveyed to them. Then their sty should be kept well filled with loam, bog mud, leaves, straw, sea weed, scraps of leather, some saw dust, some spent tan, but these in small proportions, decayed vegetables, weeds, and every other substance, which you can find, which can be converted into manure, and which you have no other way to dispose of. Then again, if they grow lazy, and as the Virginia negro said, get to be gentlemen and will not work, shorten their allowance some what, and making holes with a crow-bar among the deposits of the sty bury here and there a handful of corn, and they will soon learn the art of minding; and will show you that they can find the corn though it were buried as deeply as the antients thought truth was in a well. In this way their labor will be turned to the best advantage. You will begin to get rid of your Jewish prejudices and feel some respect for this despised animal; and your corn fields and grass fields will soon show you in their favor a long column of credits. If in former times some of their kindred were deemed fit only for the possession of evil spirits, you will perceive no occasion for continuing and extending the malediction to the whole race; but you will regard them as well entitled to their place in the animal community and their share in the common good things of the earth; and if you can contrive any mode (and what is there in this age of improvement not to be hoped for) of softening their temper and improving their voices and mending their manners, you may at last admit them to the character of humble and useful friends. But we will give you breath. We have other topics here-after.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS

Saturday, July 7, 1838.

Grapes.—A basket of fine appearance from an unknown source.

Strawberries.—Methuen Castle from the Garden of Mr. J. L. F. Warren of Brighton.

Apricots.—From Col. Wilder from his garden, Dorchester.

For the Committee,

WILLIAM KENRICK, *Chairman*.

VEGETABLES.

Beets.—By Mr. S. Switzer, of Cambridgeport.

Lettuce.—By Mr. P. Hill, of Gorton.

Beans.—By James L. F. Warren, Brighton. The six week Bean.

For the Committee,

S. POND, *Chairman*.

EXHIBITION OF FLOWERS.

Roses. By Messrs T. Lee and S. N. Johnson.

*Dahlia*s. By Dr. J. C. Howard.

Seedling Geraniums. By Col. M. F. Wilder; those were the best specimens we have seen of Seedling Geraniums. Some of them deserve a name and a place in every good collection. We consider Mr. Donald, (Col. W's gardener), as being very successful, and his plants entitled to further notice when we shall have a suitable opportunity.

Bouquets. By Messrs W. Kenick; Hovey & Co.; Winslip; Howard; J. Hovey; Meller; and S. Walker. Among the specimens exhibited by Thomas Lee, Esq. of Brookline, we noticed several native plants of great beauty, viz. *Rhododendron in ximium*; *Cymbidium*?; *Mertensia glauca*, &c. &c.

In the Bouquets of Mr. W. Kenrick, we noticed the Ohio Lily, and a variety of the old White Lily with an irregular purple patch or tinge. As this last variety was particularly brought before us, we give it as our opinion that the pure whiteness of the lily is its great charm, and wherever you place a patch or spot upon it you destroy its beauty.

In our report of the 30th ult. we omitted to notice a specimen of *Liriodendron tulipifera*, presented by Dr. Aldin of Randolph, from the only native tree known to exist in the county of Norfolk. We shall call on Dr.

A, to know more about, and if convenient, to visit the tree, the first time we pass through Randolph.
For the Committee,
S. WALKER, Chairman.

Saturday, July 11, 1838.

FRUITS.

Grapes.—Dr John C. Howard from Woodland in Brookline, two fine bunches of Black Hamburg berries very large and high colored; also a fine large high colored Miller's Burgundy.

Gooseberries.—Mr John Hovey of Roxbury, two boxes very large and fine, White, oblong and productive.

Mr John G. Thurston of Lancaster, a large box of Gooseberries, very fine and apparently of the same kind.

Raspberries.—Mr James I. L. F. Warren, Red Antwerp Raspberries and White Antwerp do. good specimens.

Currants.—Mr James I. L. F. Warren, White Currants and Dutch Red do., and branches of the same, specimens good.

Cherries.—Two boxes fine specimens of Downer Cherry, by Mr Downer.

For the Committee,
WILLIAM KENRICK, Chairman.

FLOWERS.

Carnations.—From Messrs Johnson of Charlestown; Winslip of Brighton; and Meller of Roxbury.

Col. Wilder of Dorchester presented specimens of *Cactus speciosissimus*; *do. Jenkinsonia*; *Gloxinia speciosa* and *Combretum purpureum*.

Boquets.—From Messrs Howard, Hovey & Co. John Hovey, W. Meller, Winslip, and S. Walker.
From S. Walker Roxbury, *Aconitum variegatum*; and *Yucca filamentosa*.

For the Committee,
S. WALKER, Chairman.

BRIGHTON MARKET.—MONDAY, July 16, 1838.

Reported for the New England Farmer

At Market 200 Beef Cattle, 2200 Sheep, 20 Cows and calves, and 30 Swine. 60 Beef Cattle and all the swine have been before reported. 25 Beef Cattle remain unsold.

Prices.—Beef Cattle.—Prices have further declined—and we reduce our quotations First quality at \$7 50 a \$7 75. Second quality \$7 00 a \$7 25. Third quality, \$6 00 a \$6 50.

Cows and Calves.—Sales were effected at \$28, \$32 \$33, \$38, and \$45.

Sheep.—A few lots ordinary at \$1 50, \$1 75, and \$1 83; better qualities at \$2 00, 2 25, 2 50, 2 62, and \$ 1 00.

Swine.—A very few only were retained. No demand for lots.

NOTICE.

Massachusetts Horticultural Society's Rooms.

July 14, 1838.

The premiums for the best specimens of Carnations will be awarded on Saturday next, 21st inst. The specimens must be on the stands before 10 o'clock.

For the Committee,
S. WALKER, Chairman.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded Northernly exposure, week ending July 15.

AMERICAN FLOWER GARDEN COMPANION.

The American Flower Garden Companion, adapted to the Northern States.

By Edgar Sayers, Landscape and Ornamental Gardener. Published by JOSEPH BRECK & Co., and for sale at the Agricultural Warehouse and Seed Store, No. 51 and 52 North Market Street, Boston.

NEW ELEMENTARY WORK ON BOTANY.

Peter Parley's Botany; with descriptions of Trees, Shrubs and Plants; with a large number of fine engravings.

The publishers invite Teachers, and others interested in this subject, to examine this work, as they believe it will be found one of the most practically useful in use, being a complete manual of Botany for the adult and the pupil.

Parley's Cyclopaedia of Botany.—This work appears to be exactly what is wanted by young persons and in families. It not only contains the strictly scientific part of the subject, in an introduction and very full and complete genera of Plants, but it also contains a copious glossary of terms, and what is most important, a Dictionary of Plants of nearly 300 pages, containing familiar descriptions of all the most interesting trees, plants, and shrubs.—These are alphabetically arranged, with an English index, so that the reader may immediately turn to any plant he wishes to read about. The work is illustrated by over 200 engravings, and is sold very cheap.—
Boston Paper.

For sale at the New England Farmer Office, 51 & 52 North Market Street. JOSEPH BRECK & CO.

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds Garden and about 35 acres of land situated on Nonantum Hill, in Newton 5 1/2 miles from the city. The garden occupies nearly two acres is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

L. A. WHEELRIGHT.

July 16th.

SCYTHES AND RAKES.

Just received at the Agricultural Warehouse and Seed Store Store, a complete assortment of Garden and Field Tools, consisting in part of

- 100 dozen Hall's Rakes superior.
- 100 do. Wilder & Eddy's, do.
- 200 do. Common do.
- 25 do. English Cast Steel Grass Scythes.
- 10 do. do. do. Cradle do.
- 10 do. do. do. Border do.
- 100 do. Round Scythe Stones.
- 100 do. Square do.
- 100 do. Cast Steel Garden Hoers.
- 100 pair Grass Shears.
- 100 do. Pruning do.
- 100 do. Fruit do.
- 50 dozen Patent Sheep Shears.
- 20 do. Pruning do.
- 20 do. do. Saws.
- 25 do. Budding Knives.
- 25 do. Pruning do.
- 20 do. Edging do.
- 25 do. Breaking up Hoers.
- 100 do. Garden do.
- 50 do. Dutch do.
- 20 do. Bill and Brier Hooks,
- 10 do. Grass do.
- 50 do Garden Rakes,
- 500 pair Chains, for tying up cattle,
- 500 do. Trace Chains.
- 25 dozen Halter do.

—ALSO—

- 200 dozen Patent Scythe Smuthe, superior.
- 100 do. Cast Steel and other Sheavels,
- 1000 do. Rifles, 500 do. Scythe Stones.

June 27, 1837.

ALDERNEY STOCK FOR SALE.

For sale a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27

FOR SALE OR TO LET.

A pleasant and convenient house in complete repair situated on the Worcester Turnpike, 5 1/2 miles from Boston and 2 miles from Brighton market. The house contains 9 large rooms and has a barn, chaise house and sheds attached. Also, with the same, 3 acres of mowing and tillage land, and 1 1/2 acres wood land. An adjoining lot of 5 acres can be had, if desired. Three quarters of the purchase money can remain upon a mortgage. If not sold, the house will be let to a good tenant. Enquire of D. HOLBROOK No. 31 Court St. Boston, or on the premises. June 13, 1838.

SITUATION WANTED.

As Gardener, by a young man of practical knowledge and can be well recommended. A situation West or South would be preferred. Address R. B. through the office of this paper.

REVOLVING HORSE RAKE.

The Revolving Rake, which has been in general use in most parts of Pennsylvania and New Jersey, is found to be one of the most useful and labor saving machines now in use. One man and 1 horse will rake on an average, from fifteen to twenty acres per day, with ease, and do the work well, it not being necessary to stop the horse to unload. They are coming into very general use in all parts of the country, and will, no doubt, in a few years, supersede the use of the common hand rake. For sale at the New England Agricultural Warehouse and Seed Store, JOSEPH BRECK & CO.

GUNNY BAGS.

9000 Second Hand Gunny Bags, 500 Gunny Sacks, a cheap article for Hoag Bagging. For Sale low by G. W. STEARNS, No. 10 Commercial Wharf.

MISCELLANEOUS.

LINES TO POVERTY.

BY MRS SARAH WENTWORTH MORTON.

Oh Poverty! hard featured dame,
 Whence grow the terrors of thy name?
 'T is said that from thy serious eye,
 The laughing train of pleasures fly;
 That deep within thy mansion rude,
 Lurks the black fiend, ingratitude;
 That toil, and want, and shame are known,
 To make thy heartless hours thy own.
 'Till guilt, his phrenzied eye on fire,
 Bids the last vanished hope expire.
 Thus speaks the world—to manum true,
 While wrongs thy pleading worth pursue;
 To me—and I have seen thee, near,
 Though harsh thy withering look appear,
 Though stern the teachers of the poor,
 And hard the lesson, to endure,
 Yet many a virtue born of thee,
 Lives sundered from prosperity.
 Religion that on heaven relies,
 The moral of thy mind supplies.
 —Pity, with plaintive accent, kind
 And patience to her fate resigned,
 Are seen thy lowly eel to share,
 While temp'rance dwells an inmate there.
 Love joined by truth—no rival's eye
 Wakes to the wish of poverty,
 But all the best affections twine
 Round many a rustic home of thine,
 Close circling with the nuptial tie,
 Joys, which a monarch could not buy,
 Though boundless, and to praise unknown.
 Oft is the lusted life thy own:
 To thee the priests of God belong,
 And thine the Poet's deathless song;
 Thee, toiling science lives to claim,
 Thou lead'st his thorny step to fame!
 Creative genius feels thy power,
 Coeval with his natal hour;
 On him the rays of glory shine
 Too late—his parting breath is thine.

Let me thy simple g'ances meet,
 Near the green hamlet's calm retreat;
 Not where the city thronged with sin,
 Bids all the monster crimes begin.
 Thence will thy timid virtues fly,
 Scared by seduction's serpent eye.
 Their fate, each murdered hope to see
 While every suffering lives to thee.

Not that along the wintry shore
 The fisher plies the weary oar;
 Not that amid the sultry plain
 The peasant piles the labored grain,
 Wilt thou with frowning brow appear,
 To wring the grief-tortured tear.
 But when to wrongs thy sufferings lead,
 While shame and false reproach succeed;
 When genius, doomed with thee to mourn,
 Sees his unsheltered laurels torn;
 While ignorant malice rushing by,
 Quick glances with insidious eye;
 When all thy cultured virtues move
 Nor sense to feel, nor heart to love;
 While treachery under friendship's guise,
 Bids the pernicious humor rise,
 Still aiming with envenomed dart,
 To reach the life pulse of thy heart.
 Then Poverty, hard featured dame,
 We feel the miseries of thy claim,
 Would from thy close embraces fly,
 Or in their palsyng pressure die.

THE RAIL-ROAD STEAMER.

BY JAMES JOHNSON, M. D.

Were any of the ancients to rise from their tombs, and behold a steam-ship full of passengers, darting up the Thames, or a train of carriages, with a thousand people, flying along a rail-road at the rate of 30 miles an hour, they would be very apt to doubt the fact of their revisit to the same planet they had left—since a thousand years in the grave may probably seem no longer than a short siesta after dinner. Their surprise would not be much lessened, by the sign of a column of brilliant dame springing up from the middle of a street, or issuing from ten thousand metallic tubes, and turning the darkness of night into the glare day! If, while gazing at these phenomena, they saw a man, or even a monkey, descend from the clouds, suspended as the pendulum of a huge umbrella, they would no longer doubt that they had got into "another, if not a better world," than that of their birth and death!

But to return to the rail-road steamer. Without rudder or rein; without tug or tow-ropes; without chart or compass; without impulse from man, or traction from beast—this maximum of power in minimum of space—this magic automaton, darts forward, on iron pinion, like an arrow from a bow, along its destined course. Devised by science, but devoted to industry; harmless as the dove, if unopposed; but fatal as the thunderbolt, if obstructed in its career; this astonishing offspring of human invention; this giant in strength, though a dwarf in stature, drags along, and apparently without effort, whole cargoes of commerce; merchants and their merchandise, artisans and their arts, travellers and their traffic, tourists and their tours (some of them heavy enough)—in short, every thing that can be chained to the tail of this herculean velocipede!

The steam-carriage nearly annihilates distance between the inhabitants of a state, and thereby converts, as it were, a whole country into a city, securing all the good effects of combination and concentration, without the detrimental consequences of a crowded population. By the rail-road, Liverpool, Manchester, Birmingham and the Metropolis, are constituted contiguous cities, while wide and fertile tracts of country intervene! Thus, steam multiplies the products of human labor, by increasing their sale and diminishing their price. It will enable us to convert millions of acres from pasturage into cornfields, and consequently the provender of horses into food for man.

The whole transit of a rail-road steamer is a series of miracles, which, in former days, would have been attributed to angels or demons. At starting, the mighty automaton suddenly suppresses his torrent of hissing steam, and belches forth a deep and hollow cough, which is reit rated at shorter and shorter periods, like a huge animal panting for breath, as the engine, with its train, labors up the ascent from Foston square. These belchings more nearly resemble the pantings of a lion or tiger, than any other sound that I know of. With the slow motion, on any considerable ascent, the breathing of the animated machine appears to become more laborious, and the explosions more distinct, till at length the animal seems exhausted, and groans, as it were, under the tremendous effort. But the engine having mastered the difficulty, acquires velocity before it plunges into the dark abyss of the tunnel under Primrose-

hill. There the peal of thunder; the sudden immersion in Cimmerian darkness; the clash of reverberated sounds in confined space; the atmospheric chill that rushes over the frame; all combine to induce a momentary shudder, at the thought of some possible collision or catastrophe in this subterranean transit, which is increased rather than diminished by the gleams of dubious light that occasionally break in from above, or the sparks of fire that issue every instant from the chimney, rendering "darkness visible." On emerging from the gloomy and gelid covert, every thing appears of dazzling brightness, and we breathe with delight the pure atmosphere of heaven.

The moment the highest point of elevation on any part of the road is gained, and a descent commences, the engine, with its long train, starts off with augmenting velocity, dashing along like lightning, and with an uniform growl or roar, like a continuous discharge of distant artillery or thunder. The scene is now grand—I had almost said terrific. Although it may be a complete calm, the wind appears like a hurricane; and, while the train is flying along the raised embankments, as near Watford, it is impossible not to feel some sense of danger, or an apprehension that some unexpected impediment may hurl the whole cavalcade into the yawning gulf below.

The meetings of the trains flying in opposite directions [on double tracks] are scarcely less agitating to the nerves than the transits through the tunnels. The velocity of their course—the proximity, or apparent identity of the iron trajets along which these hissing meteors move, raise the involuntary but frightful thought of a possible collision, with all its horrible consequences. The period of suspense, however, is but momentary. An electrifying concussion, as it were, of sense, sight and sound takes place, and, in a few seconds, the object of terror is out of view behind.

But such Herculean labor cannot be carried on in so small a compass, without great exerture. The automaton thirsts; he knows the pangs of refreshment; utters a loud and piercing whistle, or note of preparation; slackens his pace; halts at the fountain, and ingurgitates a deluge of water, to quench his burning drought. In five minutes he is able to renew his gigantic task.

The steam shriek is a new phenomenon on the rail road, and a very startling one it is. By opening a small valve in the boiler, a volume of steam is driven, with tremendous force and velocity, through a narrow aperture, in imitation of a throat, causing a shrill shriek, unlike the voice of man, or of any known animal, but so loud as to be heard two miles off. It is a most unearthly yell, or scream, or whistle; which was compared by a distinguished poet, who sat by me, (Campbell,) to the cry of some monstrous animal while being gored to death. It forms an excellent alarm, to clear the road for the train, and apprise those at the stations, that the engine approaches. —To be continued.

MATERIALS FOR MANURE.

We have spoken of various sources and means of accumulation and manufacture in regard to manures; the barn cellar, the hog-stye, the privy, the compost heap, the wash tubs, the sink; in respect to all these matters we have made suggestions, which we hope will be taken in good part by the farmers; and which we are persuaded, if properly attended to, will result in accumulations of valuable manure little dreamt of, when the foundation of the heap was laid, and the first contributions brought to it. The sailors tell us of extensive islands, holding a large population and feasting them in plenty, and reefs stretching themselves for miles in the ocean, and columns of coral rising from the very depths of the sea to its surface, and if the sea could be for a time withdrawn, and their vast height and proportions disclosed to the eye they would be seen casting into the shade even the mighty pyramids of Egypt and the proudest trophies of human art and labor; and all these were the result of the combined and unintermitted toil of very small insects, laboring constantly at these erections by the gradual deposits of minute atoms. These mighty masses show what can be effected by persevering labor even with the most humble instruments and means. The termites or ants of Africa erect large cabins, which, spread out upon extensive plains, look like a vast military encampment. We see constantly upon our own pitch-pine plains, the heaps which the common pismires accumulate; and observe that all this is the product of single atoms brought by single individuals of these minute animals, thousands of whom we destroy at a single footstep. Every part of creation illustrates the extraordinary, immense, and triumphant results of persevering labor. Many of the largest fortunes that have ever been accumulated have arisen from minute savings and deposits.

We hope our illustrations of this homely subject will not be deemed too ambitious. We should be glad to make them as striking and memorable as possible; and we care little for the source whence they are drawn, provided only we can induce the farmers to gather every thing, and to save every thing, which comes in their way, by which the means of enriching their farms may be created or extended. We reiterate the great position that almost every farm, certainly where its products are consumed on the place, contains the means of maintaining and extending its fertility. Every traveller who visits China, reports the extraordinary condition of the Chinese cultivation; and concludes by stating that the most remarkable and particular attention is paid to the saving of manure. If gold dust, if coin itself were sprinkled in their streets, they could not be more careful in picking it up, and collecting it together, than they are in picking up and collecting whatever may go to the increase of their manure heap.

It is in this matter our farmers fail, perhaps more

than in any thing else connected with our agriculture; and this is a failure most essentially affecting their interests. If we would ever have an improved agriculture, a revolution in our habits must take place here; and when this is effected, and all the manure is provided and prepared, which we can provide and prepare, we have accomplished comparatively half the work. The getting of manure on a farm must be as much matter of study, care, and labor as the getting of crops from that farm.

We are of opinion that on every considerable farm there should be a man employed with a cart and horse or yoke of oxen, whose sole and exclusive business it should be, excepting in some extraordinary emergency, to collect the materials for manure; and to put them in the way of being manufactured. It is not enough for the farmer to say he will do this at his leisure; this shall be the business of old times; he will attend to this when nothing else presses upon him. It must be a specific, constant, principal object of study and labor. Remember again that every vegetable substance, and every animal substance is capable of being converted into a manure.

Now we will look out of the window where we are sitting and see what in a hasty glance comes within our sight, which ought to be saved. There is the garden, with an abundance of weeds and decayed vegetables; collect all them and let them go into the hogs' pen or the barn cellar. There is the pasture, where bramble bushes, sweet fern, Canada thistles, alder bushes, brakes, &c. abound. Gather them, and you will at the same time clean your pastures. There is the road lined for miles with all sorts of weeds and coarse grasses; get them. There is many a mud hole, which receives the washings of the streets, and where a great deal of valuable and rich manure has been collected; empty that. There is a large shade tree, where the cattle daily collect; and where their droppings are accumulated; collect these and put them into the common heap. There is many a rich spot by the side of the roads, which without any prejudice to your neighbor or the public you can plough up; take off the mould, and carry that likewise into your manure yard. There is the refuse of the shoe shop, scraps of leather, &c. collect them and lay them on your land to be ploughed in. There is a clay pit; occasionally get a load or two of that and throw into your barn yard. It will greatly improve the composition. Then you have a wood or grove at hand; collect the leaves from that and lay them in store for littering your cattle-stalls and your styes. But you have a bog meadow; here then is an abundant supply of the materials for enriching your fields. Collect this mud; it is full of the most enriching substances. They may be spread with great advantage upon your grass lands; but they are still better placed upon your compost heap.

We have seen an excellent arrangement on the part of two or three farmers for saving manure, and especially the liquid portions. They daily spread the back part of their cow stables with mould or sand, of which both in winter and summer they

keep a sufficient supply at hand under cover; and using this without covering, or covering it with litter, a great amount of the most valuable manure is saved.

We have grown out these hints, not thinking to treat the subject fully, or philosophically; but rather with a view to put other minds to considering what can be ought to be done. In new countries, where the accumulations of vegetable matter have been gathering for centuries, and have remained on the surface untouched, there is no occasion at present for the use of any manures. The soil is already full and needs rather to be exhausted than replenished. But it is not so with our old soils. We cannot get along without manure. The *guano*, the vegetable pabulum, must be supplied. We have, as Dr Dana says, the plates, but they require to be filled. We might sit down to a table covered with the richest porcelain or burnished and embossed gold; but if the dishes are empty, we should starve as certainly at such a table as at a naked board. Dr Dana is likewise of an opinion, in which Professor Hitchcock concurs that the earthy constituents of the soil are matters of comparatively little moment, provided always of course that they exist in combination and are sufficiently retentive of moisture. This, to recur to the former illustration, it is of little or no comparative importance what the plates are made of, or whether the table at which we sit down be plain deal, oaken, or mahogany; the main point is the food, which is placed upon it. This appears constantly. In our disdained and hard soil crops are occasionally produced, which vie with anything, which even the fertile alluvions of the West display. One hundred and thirty bushels of corn were raised upon an acre in Plymouth county. Forty bushels of rye, ninety-six bushels of oats, fifty-five bushels of wheat, one thousand bushels of carrots, more than nine hundred bushels of ruta бага, seven hundred bushels of potatoes, and more than four tons of hay have been raised upon an acre even in our granite soil. The incredulous may sneer at this; that does not at all affect the facts. It neither makes nor un-makes nor alters them. They are established by full and incontrovertible evidence. This however has been done by liberal cultivation, liberal manuring, applied with sound judgment; at proper times and in a proper form.

The collection of this manure and its application to the soil and crop is we admit laborious, and requires incessant care and diligence. In this respect the new countries have immense advantages over us; and when we compare our severe and expensive cultivation with their little expense and abundant returns we are often half disposed to pull up our boots and put on our hat and gloves. But then we come back to the great and established position, that agriculture in almost any part of New England having ordinary advantages, where conducted with skill, judgment, and frugality, affords an ample remuneration for all the toil and all the expense incurred; and when we recollect the multiplied social advantages which our community presents over

every new country, and take another deep draft of its invigorating mountain breezes, we throw aside our gloves and put on our frock again, and whistle to our team to go ahead.

[For the New England Farmer.]

Rochester, N. H. July 21, 1838.

MR BRECK—Nine or ten cows have died within a few weeks in my immediate neighborhood, and many more in other parts of the town, and thinking it possible that you or your correspondents may know the nature of the disease and the remedy for it, I will give you all the account I can of it. The disease appeared in this town two years ago, when several horses and cattle died. All the cattle on one farm died in the course of the summer and a few on the adjoining farms. Last summer it prevailed again on the same farm, and in its vicinity, and this week one cow died on the same farm. The past spring it appeared on a farm more than two miles distant from the place of its first appearance, and two oxen, one horse, and one calf, four or five months old, were lost. It also appeared in the month of June on another farm, two miles distant from either of the others, where eight or ten village cows were pastured, and five of them died within two weeks. The others have been taken from the pasture, some of them have been sick and recovered. It has also made its appearance lately in several distant parts of the town.

As nobody here is familiar with the diseases of cattle, I can give you no very definite symptoms of the disease. The animals usually die within twelve hours after it is perceived they are sick. Cows suddenly fail of giving milk, are seized with trembling or violent twichtings, and soon die. Oxen that work well all day are found dead the next morning; some live much longer. One was sick a week or more, with all the symptoms of the others, and got well. Several have been opened and all that can be discovered appears to be a disease of the *melt*. The melt is greatly enlarged and mortified, and it is supposed that the cattle are seized with a violent inflammation of the melt, which runs on to mortification, and produces death. Last year, a man who assisted in skinning a cow that died of this disease, had soon after a violent inflammation in his hand, which extended to his shoulder, producing severe suffering and considerable danger, but which finally subsided. This year similar effects have, in one instance, been produced.

If you or any of your correspondents can aid us in curing this disease, or in guarding against, you will greatly oblige me and others.

Respectfully yours,

A. S. HOWARD.

[Will some of our correspondents give their attention to Mr Howard's communication, and if the disease and its remedies are known, inform us that we may give it publicity in the Farmer? By so doing an important service will be rendered.

J. B.]

ADVANTAGES OF SCIENCE.

The British Farmers' Magazine abounds in communications urging the establishment of a national agricultural institution. Scotland is particularly referred to as affording a striking illustration of the utility of such associations. Forty years ago, says one of these writers, Scotch husbandry was far in-

ferior to that of England; but now, he says, it is manifestly superior. This is ascribed mainly to the influence of the Highland Agricultural Society, to the interest which the nobility and gentlemen of wealth have taken in diffusing agricultural science, and promoting agricultural improvement, and the establishment of museums for the exhibition of agricultural products, and models of agricultural implements.

Among these writers is a Mr Handley, who has addressed a very able letter to Earl Spencer, who seems to be regarded as the pioneer in this praiseworthy project. The following extracts from this letter will not fail to interest the reader.

"Science—by which it is to be understood, that knowledge which is founded upon the principles of nature, illustrated by demonstration—is the pilot that must steer us into those hitherto unexplored regions, where I am well convinced a mine of wealth is still in store for British agriculture. Chemistry, botany, entomology, mechanics, require but to be invited, to yield a harvest of valuable information to guide and to warn us.

"What has been the course adopted by our enterprising manufacturers? Had they been satisfied with the inventions which chance or the intelligence of their artisans might have discovered, in vain would they have struggled for the proud ascendancy which they now hold in the scale of the manufacturing world. How truly has it been said, that a Manchester manufacturer, who had been absent from England for the last seven years, would be ruined, if, on his return now, he endeavored with his former processes, to compete with the almost daily improvements of his indefatigable and intelligent rivals. How many thousand acres of land would the bleaching operations of Manchester alone require—what enormous capital would lie stretched for weeks unproductive on the sward—and how impossible would it have been to have completed the accumulated orders from foreign customers, had not chemistry furnished a cheap and rapid substitute?" * * * * *

The writer then adverts to the still disputed and unsettled questions, whether it is better to apply manure in a fermented or unfermented state? What are the principles upon which lime proves beneficial to lands? That nothing has been definitely settled upon the latter point, is evidenced by the fact, that "vast sums of money have been, not only uselessly expended, but much labor has been thrown away, in anticipation of beneficial results from the use of lime, which had the subject been better understood, might have been saved, but positive injury has resulted, which in thousands of acres has proved irredeemable." The same uncertainty is then pointed out in regard to the operation of gypsum, of salt; and also in many other interesting and important branches of agriculture, which can only be settled by chemical and philosophical research.

"Botany"—continues Mr H.—"by which I would be understood to mean, not that branch of the science which is confined to nomenclature and classification, but which treats of the structure, the economy, the properties, uses, and diseases of plants, a correct knowledge of which tends to increase their number, and improve their quality, offers to the farm not less valuable truths than it imparts to the garden. The important labors of Mr Knight, for instance, uniting as he does the ablest practice with the most profound science, and who has successfully cultivated the principles of the philosophy of vegetation, and thus improved the practice of horticul-

turf, are alone sufficient to stimulate the agriculturist to extend his inquiries into the same field of interesting and useful discovery.

"The diseases of plants, whether arising from a superabundance or deficiency of juice, from its impure qualities, or from external causes, though at various times treated of by practical and scientific writers, are as yet very imperfectly understood.

"Mildew, rust, smut, and a variety of diseases familiar to every farmer, continue prevalent, and baffle all attempts to guard successfully against them, notwithstanding the numerous nostrums quoted as infallible.

"How they are originated or propagated is still matter of doubt; yet this knowledge is essential to the cure. The preparation and choice of seed, the manures applied, their nature and quantity, and the culture of the soil, are probably all, more or less, intimately connected with their existence, and, if carefully and scientifically considered, might furnish the remedy.

"The rotation of crops and their comparative tendency to exhaust the soil on which they grow; their effects upon each other, in either furnishing or extracting the nutriment requisite for their successor; the theory of their excrementitious operation; the facilities they respectively afford to the propagation or destruction of noxious weeds; the still more important investigation as to the value of different plants and grasses as food: the most advantageous methods of cultivating them; their power to withstand seasons; the disposition of seed grown in southern latitudes to retain its propensity to early vegetation and maturity, though sown in the north; the benefits derivable from change of seed under all circumstances; the rules for selecting and improving new varieties, a subject so ably treated by Col. Le Coutier; and the habits, modes of growth, and peculiarities of weeds, which affect agriculture, and the most effective means of extirpating them; with many other similar subjects which it is unnecessary to enumerate, come within the legitimate range of the botanist's inquiries, and would render his co-operation invaluable to the agriculturist.

"Entomology, and that branch of Zoology which appertains to worms, furnishes another subject for scientific research, most interesting and important to agriculture.

"Lastly, I would refer to the benefits which would accrue to agriculture, were the *mechanism* of our implements more scientifically attended to. Mechanical men, possessed of talent competent to the production of the highest class of machinery, cannot be expected to draw upon their invention, unless, as in manufacture, they are stimulated to exertion by the assurance, that success in the improvement of old, or the invention of new machines, would ensure their reward, from premiums or general demand. Were such the case, it may be safely predicted, that the construction of even our simplest implements, which in fact constitute the mechanism of agriculture, would not be left to the contrivance of village smiths, but would command the attention of men whose intelligence would lead them to calculate the nature and amount of the various and frequently conflicting forces to be overcome, and whose mechanical skill would give to every implement its most effective shape.—*Cultivator*.

Our farmers have begun to cut their grass. There is an abundant crop, and but little stock to eat. Hay will consequently be cheap and stock high, during the coming fall and winter.—*Maine Far.*

OPINIONS OF THE ANCIENTS ON AGRICULTURE.

Moderns are in the habit of speaking very disrespectfully of the ancient methods of tilling the earth; and it must be confessed, that in many respects those modes were far inferior to modern ones. This inferiority must, in a great measure, however, be attributed to the defective nature of farming implements, and not to the prevalence of correct theoretical notions of most subjects of practical agriculture; and moderns need not be ashamed to gather wisdom from the works dedicated to the cultivation of the soil by Cato, Varro, and Columella, some of whom lived two hundred years before Christ. Incidental notices scattered through the Bible by the writers of both Testaments, throw much light on the farming practices of the ancients, and show that in some instances at least, they had crops rarely equalled in modern times. Isaac gathered a hundred fold from his sowing at Gerar; and according to the parable in Mark, good seed sown on good ground produced thirty, sixty or an hundred fold. Varro asserts, that a hundred fold was reaped in some of the most fertile districts of Spain and Northern Africa, and Pliny says, that from the latter place Augustus received a plant with nearly 400 stalks, all from a single grain.

The maxims relating to domestic economy and farm management, scattered through the writings of the men mentioned above, are such as are rarely exceeded in justness by any writer of the present day. "Always be sticking in a tree when ye have nothing else to do; it will be growing when ye are sleeping"—was the dying advice of the Highland laird to his son; and in Italy, where the oxen and horses for a large part of the year were fed with leaves and fruit, the planting of trees, such as the vine, fig, and olive, was a still more important matter. "Men should plant in their youth, and not build till their fields are planted;" is the direction of Pliny. "Build in such a manner that your villa (or farm establishment) may not be too small for your farm; nor your farm too small for your villa;" is the direction of Cato, and Palladius says, "the largeness of the house should be so estimated, that if any thing shall happen to destroy it, it may be rebuilt by one, or at most by two years rent or profits of the farm on which it is laced."

There are many moderns who would do well to profit by these hints in relation to building. Too many of our farmers forget the continual expense incurred by too extensive or unnecessary buildings, and deserve to feel the point of Cato's remark, that Lucullus had rendered himself liable to the chastisement of the censors, by building so largely "that fewer hands were required to plough his lands than sweep his house."

Oxen were mostly used in the husbandry of the ancients, though asses and mules were not uncommon. Horses were rarely employed in the labors of the field, their services being required for the army or the pleasures of the rich. It appears from Columella, that oxen, when laboring, had care taken of them, which should shame the abusers of this valuable animal in modern times. "It is thought proper, that oxen in ploughing, should be allowed to stop a little at the turning, and when they are stopped, the ploughman should put their yoke a little forward, that their necks may cool." He also gives directions about rubbing them down, cooling

their necks, lifting the skin where pressed by the yoke or harness, feeding and watering after labor, which shows that the use and value of the ox, as well as the best mode of treatment, was then well understood and practiced.

Among the ancients, ploughing was considered the most important operation of agriculture.—"What," says Cato, "is the best culture of land? Good Ploughing. What the next best? Ploughing in the ordinary way. What is the third? Laying on manure." The most deficient point in ancient agriculture, was that relating to manures; it neither seems to have been properly understood or valued.

The following remarks of Columella, might with propriety stand as introductory to the best modern works on systematic agriculture:

"Whoever would be perfect in this science, (agriculture), must be well acquainted with the qualities of soils and plants; must not be ignorant of the various climates, that he may know what is agreeable and what is repugnant to each; he must know exactly the succession of the seasons, and the nature of each, lest beginning his work with wind and showers just at hand, his labor shall be lost. He must be capable to observe exactly the present temper of the sky and seasons; for these are not always regular, nor in every year does the summer and winter bring the same kind of weather, nor is the spring always rainy and the autumn wet. To know these things before they happen, without a very good capacity, and the greatest care to acquire knowledge, is in my opinion, in the power of no man."—*Genesee Farmer.*

THE GREAT DANGER IN THE WEST.

Is, that the soil is so fertile, and so remote from the ultimate market for its produce, that there will not be sufficient inducements to industry, to ensure moral and physical health to its population. Where men can earn enough in two days to support them seven, they are too much inclined to spend the five in indolence, especially when the time comes, as come it may, that the many are sellers, and the few only buyers, of the products of the soil. And when a people are idle, from whatever cause, they readily, though often imperceptibly, slide into indulgences and habits which are the bane of individual and public virtue—unless their idle hours are appropriated to the improvement of the mind, and to the cultivation of a taste for rural embellishments, and the higher intellectual pleasures which emanate from literature and the science of agriculture. It requires far more philosophy and fortitude to resist the smiles of prosperity, than it does to bear the frowns of adversity. The latter is matter of necessity—while in the first we are left to exercise our own discretion. We have been led to these remarks, at this time, by the receipt of a letter from an esteemed friend in West Wisconsin, (Loway) an extract of which we subjoin.

"With us in the west," says our correspondent, "the lands are rich and productive, with but little labor. A bountiful Providence has bestowed upon us one of the most fertile and delightful regions of the earth. Yet what are the bounties of Providence when unemployed by the labor and science of man? The mind is fallow, and the 'Garden of God' lies barren and overrun with weeds, and the rose and lily are choked by brambles, unless the assiduity and skill of man are exerted in developing the riches and beauties of nature.

"Until the recent *heathful* check of the 'times,' the west was intoxicated with the fell spirit of speculation. Labor and industry were looked upon as too slow and tame a way of making money. The 'royal way' of making a fortune by speculation infested all classes; and, as a consequence, the main pillar and ornament of a state was almost entirely neglected.

"But it is to be hoped, that these times for sober reflection may correct the delusions of the day, and impress upon the minds of the community this fact, that *there is no accession to individual or national wealth, without the exercise of labor and skill*; and that that which feeds all, and which can employ all, is at once the most independent and honorable."

This mention of the mania of speculation calls to mind the facetious relation of a brother Yankee, who made the grand tour of the "Far West" in 1836. After describing the fertility and beauty of the country, in glowing terms, he added, after a pause—"but, the *inhabitants* will starve! their work is altogether of the *head*, and not of the *hands*—they are trying to live by speculation more than by labor. Why, if you accost even a farmer in those parts, before he returns your civilities, he draws from his breeches pocket a lithographic city, and asks you to take a few building lots, at half their value, and earnestly presses you to buy as a personal favor conferred on you."

We are heartily glad to learn by our friend's letter, that the times are mending beyond the Mississippi, and that the public attention is being turned to our parent art, and a strong evidence of the truth of his declaration came enclosed, in the form of a twenty dollar bill, being the subscription money for twentytwo copies of the *Cultivator*.—*The Cultivator.*

OPINIONS ABROAD ON AMERICAN AGRICULTURE.—In the first volume of the national work called "British Husbandry, at page 322, under the article Gypsum, and on the effects said to be produced in the United States by the use of the article, the writer says:

"Mr Parkinson, too, who resided a considerable time in the United States, and has written upon its farming, denies its effects, except upon particular crops; and as to the dung, in competition with which it was used, he says that the farm yard manure in that country is of little value; for it is ill managed, the straw weak, and the generality of the horned cattle so poor that their dung is light and worthless: to which he adds, that the common American farm carts contain no more than a large wheelbarrow."

Good!—and if he had only added, as he might when his hand was in, that it took three American cows to make a shadow, so thin are they; and that the young Jonathans lived on bean broth, so weak that the ten commandments might be read in the bowl at the depth of twenty feet, he would have established his fame as a second Munchausen, and gained an enviable rank among the cockney tourists of the present day.—*General Furner.*

A great sale of Durham cattle took place at Cincinnati on the 27th and 28th of June, at the farm of Maj. C. S. Clarkson. It was well attended, and the prices indicate a spirited competition. Total sales, \$26,867 50.

REPORT

Submitted to the House of Representatives of the United States, on the culture of the Mulberry and Sugar-beet, by the Committee on Agriculture.

(Concluded.)

Mr Miner, of Pennsylvania, had the honor of first bringing this subject before the house of representatives, by a resolution of December 29, 1825; by which the committee on agriculture were instructed to inquire whether the cultivation of the mulberry tree and the breeding of silk-worms, for the purpose of producing silk, be a subject worthy of legislative attention; and if they so thought, to obtain, as far as practicable, all requisite and proper information on the subject. On the 2d of May, 1826, Mr Van Rensselaer, chairman of the committee, made an interesting and able report on the subject, concluding with a resolution authorizing the secretary of the treasury to have prepared a manual on the growth and manufacture of silk; which resolution was adopted. And in February, 1828, the secretary transmitted to the house of representatives a Manual or Treatise (of rising two hundred pages) on the growth and manufacture of silk; which had been prepared, under his direction, with great care and labor. Six thousand extra copies of this valuable and highly useful document were ordered to be published for distribution. About the same time that Mr Rush reported his manual to the house of representatives, Mr James Mease transmitted to the speaker a treatise, of about a hundred pages, on the rearing of silk-worms, by Count Von Hazzzi, of Munich, who, having seen the resolution on the subject of the manual, prepared and sent the Treatise to the house; by whom it was ordered to be printed and distributed. These two essays contain much important practical information, and are well worthy a republication. In May, 1830, Mr Spencer, chairman of the committee on agriculture, to whom the subject had been referred, made a report embracing two interesting letters from P^{er} S. Duponceau, Esq., of Philadelphia, and "Essays on American Silk, by Messrs Peter S. Duponceau and John D'Homergue," of which six thousand copies were ordered to be printed for distribution. These documents are of an interesting character, and exhibit at once the valuable information of their authors, their patriotism and public spirit. This report proposed to grant to Mr D'Homergue the sum of \$40,000 for the establishment of a normal school of filature at Philadelphia, and the gratuitous instruction of sixty young men for two years in the various branches of reeling, manufacturing, and dying silk; and, during the time, Mr D'Homergue was to embrace every suitable opportunity to travel through the different States, and to give gratuitous instruction to farmers and others desirous of embarking in the silk business. This bill, though favorably received by Congress, was not acted on at that session, owing to the lateness of its being reported; and as a large portion of the next session was occupied with the trial of Judge Peck, this, with many other important measures, was left unfinished. In the mean time, however, Mr Duponceau, whose patriotic zeal on this subject is worthy of all praise, had established, at his own expense, in the city of Philadelphia, a filature of ten reels, and twenty women, under the direction of Mr D'Homergue; and, amongst the first fruits of his labor, had two flags of the United States made of American silk; the one of which was presented to the Legislature of Pennsylvania, and the other to the House of Rep-

resentatives, by whom it was received with great enthusiasm, and ordered to be displayed in their Hall, over the portrait of Lafayette. To prevent Mr D'Homergue from returning to France, Mr Spencer handed to Mr Duponceau a very flattering certificate, signed by eighty-nine members of Congress, approving of Mr D'Homergue's plan, and expressing their decided opinion that the bill would have met the approbation of the House of Representatives had time permitted its being called up. In January, 1832, Mr Root, from the Committee on Agriculture, reported the same bill and report which had been presented by Judge Spencer at the former Congress. On the 22d of May this bill was taken up, and discussed in Committee of the Whole, and reported to the House, when the discussion was renewed the next day with increased warmth; and, as Mr Duponceau supposes in his very interesting "*History of the Silk Bill*," owing to the tariff excitement of the time, and some other causes, the bill was defeated by a small majority. Thus perished the first important measure proposed by the nation to promote the production of silk in this country; a measure which the committee believe, with the lights then in existence, was wise, prudent, and important, but which the subsequent ingenuity and experience of our countrymen now render unnecessary; believing, as they do, that the recent improvements in reeling will do more in a few weeks than the establishment of many normal schools upon the old plan would do in many years. At the second session of the twenty-third Congress the subject was again referred to the Committee on Agriculture; and in February, 1835, Mr Beckee made a report, concluding with a resolution adverse to any protection or action, on constitutional grounds; and at the last Congress the subject was referred to the Committee on Manufactures; from which, in February, 1837, Mr Adams, the chairman, made a report, embracing a very interesting and valuable letter from Mr Judson, late a member of that committee. The statistical information, and present condition of the silk business in the different States, having been prepared with much labor, and being more extensive than your committee have been able to procure, they will annex the same, with other documents, to this report; observing, that within the last year the cultivation of the mulberry has been much more extended than in several preceding years, and the people and the Legislatures of several of the States have taken up the subject with increased spirit and vigor.

From all the information which the committee have been able to obtain, they are induced to believe that no country in the world is better adapted to the production of silk, or the sugar-beet, than most parts of the United States, whether we consider the soil, the climate, or the habits of the people. The mulberry will grow on high, stony, sandy, and comparatively barren land; and although the poverty of the soil may decrease the quantity of the foliage, it will improve the quality, and add fineness and beauty to the silk; whilst the climate is so varied, that although no part is too far north to destroy the mulberry or prevent the production of a single crop of silk-worms in a season, yet, in the southern parts of the Union from eight to ten crops may be raised. The worn-out tobacco lands of Virginia and North Carolina, and the impoverished soils of other old States, may be advantageously appropriated to the culture of the mulberry, and, as is confidently stated by gentlemen well qualified to judge, will yield a much larger annual

profit than is now usually derived from the best soils. The estimated profit per acre, both as to silk and beer-sugar, appears so various that your committee will leave the different individuals to speak for themselves in the documents annexed to this report; and they will also leave, with the same reference, the variety and mode of culture. The *Morus multicaulis* has, for some years, been considered the most valuable variety of mulberry; though the *Brusa*, recently introduced into this country from Turkey, is highly spoken of as of a superior quality. The large white six-week worm seems to be generally admitted to be preferable for the production of silk; and the white Silesian beet for sugar.

If, then, there are so many inducements for the production of these two important articles; if the market is large and yearly increasing, our soil and climate adapted to the culture, and the prospect of public benefit and private gain be good; why, it will be asked, may we not become a great silk-growing and sugar-making people? We can, and the committee believe in no distant time will, so become. It only requires that public attention should be called and kept to the subject; that our agriculturists be satisfied of a fair prospect of success; and that the Government should lend its aid to ensure the speedy and permanent success of the measure. The committee have considered the means by which Government might afford adequate encouragement to the production of silk and beet-sugar. One important means would be, for the House of Representatives to collect and disseminate valuable information on the subject; this the committee have endeavored to perform. Another plan has been suggested: for the Government to offer bounties for the production. But this mode might be subject to constitutional objections, and seems more proper to be adopted by the State Legislatures; and the business is not sufficiently advanced to authorize encouragement by imposts on silk or sugar imported. The committee have, therefore, as the best means of encouragement suggested to them, unanimously agreed to propose the following resolution:

Resolved by the Senate and House of Representatives of the United States in Congress assembled, That the President of the United States be, and he is hereby, authorized gratuitously to lease, for the cultivation of the mulberry or sugar-beet, for the term of ten years, any lot or land belonging to the United States, and not included in the unlocated or public lands.

From the Horticultural Register.

FLOWERS, FRUITS, AND TREES.

BY H. A. S. DEARBORN.

(Concluded.)

Mr Pond, of Cambridgeport, has become eminent for rearing large numbers of Plum trees of the most choice varieties, and also for his superior mode of raising asparagus.

The Messrs Winship of Brighton, have a vast nursery, a large green-house and forcing-house, in which are collected a greater number and variety of useful and ornamental trees and plants, than are to be found in any other like establishment north of Long Island. Their importations of European forest trees, and exotic shrubs, and herbaceous flowers, have been extensive, and contributed in an eminent degree, to extend a taste for rural embellishment in the eastern section of the Union. Their

collection of foreign new kinds of Roses, rivals that of Col. Wilder, as they have some 500 varieties. Peonies have also claimed their special attention, and they exhibit nearly 40 kinds.

Other highly commendable efforts have been made to multiply the fruits, culinary vegetables, and plants of all kinds, and especially by seeds. The establishments of Joseph Breck & Co., and of Hovey & Co., are well known, for they have so far kept pace with the rapidly increasing demand, and have so faithfully discharged their very responsible duties, in either raising or collecting the best varieties and of the most perfect quality, that they have merited and received the grateful acknowledgments of their numerous fellow citizens who "drive their team afield," or delight in the society, or the culture of the silent, yet eloquent, beautiful, useful, and ever interesting families of the vegetable realm.

As proprietors and editors of three of the most valuable agricultural and horticultural publications in this country, we are under the greatest obligations to them; and it is earnestly to be wished, that for all their diversified and indefatigable labors, they should receive that encouragement and reward, which will render their patriotic exertions annually more profitable to themselves, and useful to the public. In the diffusion of intelligence among the farmers and gardeners, and the extension of a taste for their honorable and important occupations, as well as for the improvement of the aspect of the country generally, by inducing a greater attention to all the branches of cultivation, those periodicals have already accomplished much, and if they receive that liberal patronage to which they are justly entitled, the beneficial results will be as universally conspicuous as they are desirable.

The new garden at Mount Washington, with its ranges of green and forcing houses, is becoming an object of great interest, and will soon rank among the first, which are now the most celebrated, as the intelligent and experienced Mr McCollough has fully shown that he is well qualified for the station he has assumed.

The Charlestown Vineyard, with its departments of other fruits, conservatories, graperies, and valuable, as well as ornamental plants, has given a well deserved reputation to the Messrs Mason, from the successful manner in which the whole of their spacious establishment is managed.

The valuable, new, and excellent varieties of the strawberry, with which our market is enriched, have rendered Mr William Mason of Charlestown, and Mr J. L. F. Warren of Brighton, celebrated for the zealous and successful exertions they have made to grow that delicious fruit. The Downton, Wilmot's, Keen's Seedling, Roseberry, Mulberry, Methven Castle, and other distinguished new kinds, are now abundant and maintain the high character which they had acquired in England.

Mr Town, of Snowhill street, in Boston, has a neat and well conducted green-house, which may be truly called a floral gem.

There is a humble little cottage garden on the Dorchester road, near Grove Hall, which reflects great credit on the unassuming and respectable old man, who carefully tills it with his own hands; and many a passer-by has stopped to admire his beautiful collection of choice varieties of pinks.—May he be made happy in his commendable efforts

to contribute to the happiness of others, is a blessing which every visitor must spontaneously bestow on the venerable Meller, and at the same time, attempt to enable him to realize the benediction, in the purchase of a single root, or a bouquet of flowers. How interesting and imposing is it to behold the aged calmly and studiously engaged in the culture of a garden of flowers. They appear to be appropriately occupied in a kind of religious rite, and as if actuated by a presentiment that their end was near, devoting their last moments in the preparation of the materials of a garland for the decoration of their own grave, and thus seeming to ask the grateful tribute of approbation, from a life industriously and reputedly passed, and now approaching its close, in the anticipation of that good name which all desire, and hope encourages us to believe may have been attained, and will be perpetuated when "we sleep in the narrow house of death."

There is very much wanted a large nursery of native forest trees, where they shall be raised in such quantities, as to be afforded to purchasers at as cheap a rate as they can import them from England and Scotland. So great is the demand, that not only our nursery-men, but many individuals, have recently imported vast numbers. Two gentlemen, one residing in Watertown, and the other in Salem, have received ten thousand each, this season, which cost only a few cents apiece. The quantities which might be sold, if furnished at even a liberal price, would be enormous; but the expense of obtaining trees from the forest, the mutilated manner in which they are taken up, and the consequent difficulty of making them flourish vigorously, deters those who would be glad to embellish their estates, or plant out woodlots, or groves for timber, from making the experiment.

The rapidity of the growth of seedling trees, reared in nurseries, compared with such as are selected from the forest, is well known to those who have attempted the culture of both kinds.

A pleasing illustration may be seen on the magnificent ground of Col. Th. H. Perkins, who imported about thirteen years since, 15,000 plants, which were not more than two feet high, and now they are large, healthy and beautiful trees.

Very respectfully,

Your obt. servant,

H. A. S. DEARBORN.

Hawthorn Cottage,

Roxbury, June 20, 1838.

TOADS.

MR HOLMES:—I have seen it recommended in some paper that we should cultivate the society of Toads, and domesticate them as much as possible.

To the minds of some this would appear ridiculous in the extreme. There is a very strong prejudice against those useful, innocent animals—they are looked upon as dronish and evil, by some; but not by those who know their usefulness.

I will venture to say that not one of your readers can nab a mouthful of any thing with half the dexterity that a toad can,—only give him a chance.

Should any one wish to see the thing done, take and lay before a toad any kind of a worm or bug that will stir, and if he does not go into "Davy Jones' Locker," in the way of a caution, then I am no judge.

Give them a good shelter, and not abuse them, and you can keep them in one place for years. There is one now in sight that has made his place

of residence some five or six years under the steps of my door; and if he does not look as fat and cheerful as any of Uncle Sam's office holders, then I am much mistaken.

As I had much rather see one toad in the garden than two dogs in the front door-way, I would recommend to every farmer who can, (and there are none who cannot), find time to hunt up a few dozens of them and put in his garden, and on his corn ground.

And do you ask where they are most likely to be found? Look into your old potato holes, and there you will find them imprisoned, if not relieved by some kind hand; perhaps for life,—not for debt or "opinion's sake," but probably for a *mis-jump before settling their accounts*. But a few days ago I released more than fifty in a very short time, and conveyed them to my corn ground, and I find that it was not only doing as I would be done by, under like circumstances, but I have the satisfaction of doing a deed of humanity.

E. G. B.

July 7, 1838.

[Maine Far.

DISEASE OF CORN.—"THE FRENCH."—There is a disease of corn, popularly called "*the French*," the cause and remedy of which, seem to have been satisfactorily discovered. The plants attacked by this disease, exhibit a yellowish feeble appearance, the blades are wilted, the stalks never attain the usual size and rarely mature any grain. Spots thus affected, are sometimes found in the fields embracing a hundred plants, where, the soil is as good as elsewhere. The injury is caused by the black ant depositing its larvæ in the joint just below the ground connecting the radical or root with the stock. From the punctures thus made, exudes the juice of the plant, which on its discharge forms into a jelly. An excellent remedy is found in the application of slaked lime or leached ashes to the hills when planting the seed, the alkaline or caustic effects of which serve to destroy the ants. We know a case, where, for several years, a colony of ants having destroyed almost every description of vegetation, the land was treated with decided success, the injury remedied, and a good crop obtained, by the application of leached ashes. The same farmer, also, in making an experiment on the value of the hydrate of lime applied to the hills of corn, had the satisfaction to find, not only that the growth of the plants was greatly stimulated, but that none of them were affected by "the French" as were others in the same field, to the hills of which no lime had been applied. These experiments seem to us decisive; and we invite attention to them the more confidently, as it is certain, that the proposed remedy, in its action as a stimulating manure, will increase the production of the plants to which it is applied, even beyond that of those not affected by the disease.—*Franklin Farmer*.

REGULATION OF STEAM BOATS.—The Senate on the 6th instant disagreed to the amendment of the House of Representatives to its bill for regulating the navigation of steam boats, by which it was proposed to inflict a fine of five thousand dollars on owners for any loss of life or lives by explosion of boilers, &c. and substituted for it a provision that, in all prosecutions at law for damages in such case, the fact of such explosion shall be considered *prima facie* evidence of wilful intent, &c. Thus amended, the bill has passed both Houses, and may be considered the law of the land.—*Maine Far.*

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, JULY 25, 1838.

INDIAN CORN.

SUCKERING, TOPPING STALKS, HARVESTING.

The inquiry is often made; whether it is best to take off the suckers from Indian Corn, or to allow them to remain. We have not at hand the means of referring to some facts in this case, which have been stated, and we can therefore only speak of them from memory, which after all may not prove entirely correct. The Rev. Dr. Linnan of Hatfield, Mass. some years since made a careful experiment, the result of which was to prove that it was best for the crop to remove the suckers. The crop or those parts of the field, from which the suckers were removed, proved larger than that on which they were suffered to remain; but the advantage was not deemed a sufficient compensation for the extra labor. In our own experience we have found certainly no injury to the crop from removing the suckers, those on which it was evident no ear was likely to be formed; and we have obtained from this source a considerable amount of valuable fodder. Where the growth is luxuriant however, and the field closely planted, there is risk, unless extraordinary care is used, of much being broken down and considerable injury being done to the standing crop. We have however the testimony of an experienced and most careful farmer in this case, who states that he has been in the habit of suckering his corn now for more than ten years. He takes off the suckers as soon as the tassels in his corn begins to show itself; and he says always with much advantage, the ears of corn so far as his experience goes in consequence of this operation being larger and better filled out. Going among his corn thus early, there is less danger of injury to the field. It is quite desirable that this matter should be fully tested by experiment; and we hope that any of our correspondents who are possessed of well authenticated facts in the case will be kind enough to communicate them. In the southern states the blades or leaves of the corn plant are always stripped for fodder for their horses, instead of hay of which comparatively little is raised. At what particular stage this is done we are not apprised; but it certainly should not be done too early, as the office of the leaves is highly important to the perfection of the fruit. The amount of fodder, afforded by a well cultivated acre of corn, is very considerable; in the opinion of most judicious farmers fully equal when well cured to a ton of the best English hay. Every pains therefore should be taken to secure it in the best possible manner.

In regard to topping the stalks of corn, the experiments of John Loran of Pennsylvania, and the Hon. Wm. Clark, of Northampton, and others, establish the point, that, if cut early, the crop of corn will be diminished many bushels to the acre. After the grain is perfectly formed and has become glazed the injury accruing from cutting them will be much less, but probably it will be something. We are satisfied that taking all things into consideration the best mode of harvesting is that, which is almost universally practised throughout New York and Vermont and many parts of New Hampshire; that of cutting up the whole plant at the bottom at a certain stage of its growth, and allowing it to finish its ripening in the shock. We have managed in this way repeatedly; and proceed from our own experience and trials of different modes to describe what we consider the best mode of performing it.

(To be continued.)

CURING CLOVER HAY.

There prevails with many farmers a strong prejudice against clover hay; and indeed in the condition in which it usually is found it is a very coarse miserable fodder, and hardly better than so much brush. Our Northern clover sown on richly manured land, and with the small quantity of seed commonly applied, makes a rough product; and, as the flowers and seeds are generally shaken off in the making, it contains little nutriment, and is scarcely fit for other purposes than litter. The southern clover is of smaller growth; and on that account makes a much better forage. Indeed clover hay, when well cured, is very much liked by cattle, whom we must allow to be pretty fair judges in the case of what is good for them; and no long feed, that can be given to cows, will make more or better milk. One of the best milk-men in the neighborhood of Boston speaks of it in the highest terms; and, in his mode of curing, prefers it to any other hay. Clover when mixed with other hay even in a small proportion injures the sale of the hay in market, for the reason only we believe that horses taken in at the livery stables, will eat more of it than of the Herd's grass, cut after it is dead ripe, and so coarse and hard that the mastication of even a small quantity is likely to employ all the time the poor tired horse has to spare from his sleep; and a rack full of it, like the show pickles and pound cake at taverns, is liable to stand by for some time and to serve many a guest. We consider clover hay, when well saved as some of the best hay which can be grown; highly palatable and containing an abundant nutriment; but its value greatly depends on the mode of curing.

Some farmers have cut it in the morning, and after a warm day have carried it in in the afternoon of the same day, and by a very liberal salting have saved it well. But the practice of other farmers is we believe a much preferable mode. We know several cases in which it has proved entirely satisfactory; and we shall proceed to describe it. They cut it in good weather, and when it is dry. They scarcely spread or stir it at all. At night of the day on which it is cut they put it into cocks of a good size, and then let it remain two or three days rain or shine. When well made in this way, which is easily determined by a practised hand, on a pleasant day in the morning they turn over the cocks and open them slightly, and then carry it in, giving it a very little sprinkling of salt. One great object is to avoid by much stirring the shaking off of the heads. Thus cured they regard it among the most valuable hay which they get. We have known the same plan pursued by one of the best farmers in western New York with all his hay crop. The Deerfield farmers of late years dry their hay in the sun much less than formerly, and they believe to their great benefit. In all cases however the most scrupulous care must be observed to rid the hay from all wetness of dew or rain.

THE SEASON AND CROPS.

The season, we believe, has not, within the memory of any man living, been surpassed for the fineness of its weather and the luxuriance of its vegetation. The sunshines and rains have come in such regular and beautiful succession; and the temperature has been so precisely what it seemed desirable that it should be that even habitual discontent has found no room for complaint; and the most fastidious imagination has not been able to say how matters should be improved. Hay is coming in abundantly; and the season has been as favorable as it ever was for securing it. Rye and wheat, and barley and oats, are looking extremely well. Potatoes promise profusion, and Indian corn, the best treasure of New

England, never presented a more healthy and brilliant appearance. There is really nothing to be done; but to shake our heads with sorrow, and cry; "it is too much trouble to gather all these good things." We shall never get through with harvesting and husking. O sad! our neighbors' crops are as good as ours. We have got too much, too much; prices must come down; prices will be low; the poor will have enough this time;" and other complaints as grateful and as benevolent, of which there is always in our community *quantum sufficit*.

VEGETABLE FIELD CROPS.

We have great pleasure in announcing the fact that excellent vegetables beyond what have hitherto been cultivated, such as ruta baga and sugar beet, are entering considerably as field crops into the cultivation of our farmers. Having once begun they are sure to keep on. This will lead to a most important revolution and improvement in our husbandry. It will increase to a great extent the power of the farmer to raise and keep live stock; it will greatly increase his manure heap, the material of agriculture, and enlarge his cultivation and the productiveness of his soil. It will lead to a much more careful and neat husbandry, which will prove in various respects a great gain. Its effects upon our dairy produce in quantity and quality will be most favorable. It is calculated by many observing farmers that three tons of sugar beets or of ruta baga are equal to one ton of the best of English Hay for neat cattle. We do not pretend to give a decided opinion on this subject. But we do know that twenty tons of Sugar Beet, of Ruta Baga, of Parsnips or of Carrots can be raised upon an acre; and in this way an amount of cattle feed equal to six tons of hay can be procured from an acre of cultivated land, what extensive advantages must the farmer derive from such husbandry.

POTATO BLOSSOMS.—Repeated experiments in England, it is confidently asserted, have demonstrated that the plucking off the blossoms of the potato before any balls are formed, have contributed very much to increase the produce. We have no personal knowledge of any facts in this matter, which would serve to determine it, and we do not pretend to understand the philosophy of it, even if it be true. But it is so often and confidently stated, and upon such respectable authority, that we hope some careful observers will make the experiment with exactness, and do us, or rather the agricultural public, the kindness to report the result.

TO CURE WOUNDS, BRUISES, SORES, SPRAINS, RING WORMS, &c.—Take two ounces of the Tincture of Hellebore, and put it into a junk or porter bottle, fill up the bottle with alcohol—the cost of all which is 50 cents—and a family should never be without it. Apply the mixture to the wounded part, by means of a linen cloth or rag, and which you may leave on the flesh—wet it frequently, and you will find it to have a most soothing and healing effect. Applied to wounds or sores on horses or cattle will effect a speedy cure. It has been known to cure the ring-worm, and fingers when so mashed as to endanger losing them.

Having personally experienced the good effects of the mixture, I consider it invaluable and recommend its use.

New York, July 17, 1838.

EXHIBITION OF FLOWERS.

"The fairest flowers of the season are our Carnations."

Saturday, July 21, 1838.

This was the day appointed for the exhibition of, and to award the premiums on Carnations. The competitors were Missis Winslop, Mason, Meller, and Johnson. A committee of three was appointed to examine the specimens and to award the prizes.

A fine specimen of *Asclepias tuberosa*, *Tukrous Scoul-*

low-curt, was presented by Dr E. Alden of Randolph. Mr S R Johnson of Charlestown exhibited some choice specimens of the *Punica granatum pleno*; and some fine Hollyhocks.

From the Messrs Winship of Brighton, *symphora variegata*, *Acer Nigundo*, very ornamental.

Bouquets by Messrs Carter, Hovey & Co. Jno. Hovey, Meller, and Walker.

For the Committee.

S. WALKER, *Chairman*.

The Committee on Carnations award to the Messrs Winship of Brighton, the prize of five dollars for the best display. To Mr Thomas Mason, of Charlestown, the prize of three dollars for the best six varieties. To Mr W. Meller, of Roxbury, the prize of three dollars for the best seedling.

J. W. RUSSELL, }
JOSEPH BRECK, } *Committee*.
WM. E. CARTER, }

EXHIBITION OF FRUITS.

By Jacob Tidd, Esq. Roxbury, several very large clusters of Black Hamburg? and white Chasselas Grapes.

By Ebenezer Breed, Esq. Charlestown, a beautiful cluster of French pears, grown under glass.

By Dr J. C. Howard, Woodland, Brookline, Black Hamburg (the berries very large.) Millers Burgundy and White Chasselas Grapes; red and white Antwerp raspberries and Dutch white currants.

By Mr John D. W. Williams, a quantity of Spitzenburg? apples, growth of 1837, very handsome and in a fine state of preservation; also two varieties of Gooseberries, and Dutch red and white currants.

By Mr Aaron D. Weld, West Roxbury, Dutch red and white currants, very fine specimens.

By Samuel Walker, Esq. Roxbury, Hovey's Globe Green, Gascon, Lancaster Lud Gooseberries, and branches loaded with fruit of the Red Seedling currants.

For the Committee.

E. M. RICHARDS, *Chairman*.

BRIGHTON MARKET.—MONDAY, July 23, 1838.

Reported for the New England Farmer.

At Market 165 Beef Cattle, 15 Cows and calves, 2300 Sheep, and 140 Swine.

Prices—Beef Cattle.—We quote to correspond with last week. First quality at \$7 50 a \$7 75. Second quality \$7 00 a \$7 25. Third quality, \$6 00 a \$6 50.

Cows and Calves.—We noticed sales at \$25, \$27 50, \$31, \$35 and \$45.

Sheep.—Prices a little reduced. We noticed sales at \$1 50, \$1 67, \$1 83, \$1 92 and \$2 00. Wetters at \$2 25, \$ 00, \$3 25 and \$3 50.

Swine.—No lots were sold to peddle. A lot of old prime quality, at 8 1-2; a few small pigs were retained at about the prices of the two last weeks.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Ten Hib Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham. ISAAC PARKER.

FOR SA. E.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

REVOLVING HORSE RAKE.

The Revolving Rake, which has been in general use in most parts of Pennsylvania and New Jersey, is found to be one of the most useful and labor saving machines now in use. One man and a horse will rake on an average, from fifteen to twenty acres per day, with ease, and do the work well, it not being necessary to stop the horse to unload. They are coming into very general use in all parts of the country, and will, in a few years, supersede the use of the common hand rake. For sale at the New England Agricultural Warehouse and Seed Store. JOSEPH BRECK & CO.

Massachusetts Horticultural Society.

The Rooms of the Massachusetts Horticultural Society, 23 Tremont Row, are open for the public every Saturday morning, from 10 till 12 o'clock.

NEW ELEMENTARY WORK ON BOTANY.

Peter Parley's Botany; with descriptions of Trees, Shrubs and Plants; with a large number of fine engravings.

The publishers invite Teachers, and others interested in this subject, to examine this work, as they believe it will be found one of the most practically useful in use, being a complete manual of Botany for the adult and the pupil.

Parley's Cyclopaedia of Botany.—This work appears to be exactly what is wanted by young persons and in families. It not only contains the strictly scientific part of the subject, in an introduction and very full and complete genera of Plants; but it also contains a copious glossary of terms, and what is most important, a Dictionary of Plants, of nearly 300 pages, containing familiar descriptions of all the most interesting trees, plants, and shrubs.—These are alphabetically arranged, with an English index, so that the reader may immediately turn to any plant he wishes to read about. The work is illustrated by over 200 engravings, and is sold very cheap.—*Boston Paper*.

For sale at the New England Farmer Office, 51 & 52 North Market Street. JOSEPH BRECK & CO.

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land situated on Nonantum Hill in Newton, 5 1-2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

L. A. WHEELRIGHT.

July 16th.

SCYTHES AND RAKES.

Just received at the Agricultural Warehouse and Seed Store, a complete assortment of Garden and Field Tools, consisting in part of the following:

- 100 dozen Hall's Rakes, superior.
- 100 do. Wilder & Eddy's, do.
- 20 do. Common do.
- 25 do. English Cast Steel Grass Scythes.
- 10 do. do. do. Cradle do.
- 10 do. do. do. Border do.
- 100 do. Round Scythe Stones.
- 100 do. Square do.
- 100 do. Cast Steel Garden Hoes.
- 100 pair Grass Shears.
- 100 do. Pruning do.
- 100 do. Fruit do.
- 50 dozen Patent Sheep Shears.
- 20 do. Pruning do.
- 20 do. do. Saws.
- 25 do. Badding Knives.
- 25 do. Pruning do.
- 20 do. Edging do.
- 25 do. Breaking up Hoes.
- 100 do. Garden do.
- 50 do. Dutch do.
- 20 do. Bill and Brier Hooks.
- 10 do. Grass do.
- 50 do. Garden Rakes.
- 500 pair Chains, for tying up cattle.
- 500 do. Trace Chains.
- 25 dozen Halter do.

—ALSO—

- 300 dozen Patent Scythe Smutths, superior.
 - 100 do. Cast Steel and other Shovels.
 - 1000 do. Riddles, 500 do. Scythe Stones.
- June 27, 1837.

ALDERNEY STOCK FOR SALE.

For sale a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27

FOR SALE OR TO LET.

A pleasant and convenient house in complete repair situated on the Worcester Turnpike, 5 1-2 miles from Boston and 2 miles from Brighton market. The house contains 9 large rooms and has a barn, chase house and sheds attached. Also, with the same, 3 acres of mowing and tillage land and 11-2 acres wood land. An adjoining lot of 5 acres can be had, if desired. Three quarters of the purchase money can remain upon a mortgage. If not sold, the house will be let to a good tenant. Enquire of D. HOLBROOK No. 51 Court St. Boston, or on the premises. June 13, 1838.

SITUATION WANTED.

As Gardener, by a young man of practical knowledge and can be well recommended. A situation West or South would be preferred. Address R. B. through the office of this paper.

AMERICAN FLOWER GARDEN COMPANION.

The American Flower Garden Companion, adapted to the Northern States. By Edward Savers, Landscape and Ornamental Gardener. Published by JOSEPH BRECK & Co., and for sale at the Agricultural Warehouse and Seed Store, No. 51 and 52 North Market Street, Boston.

GUNNY BAGS.

8000 Second Hand Gunny Bags, 500 Gunny Sacks, a cheap article for Hop Bagging. For Sale low by G. W. STEARNS, No. 10 Commercial Wharf.

MISCELLANEOUS.

THE HOME OF THE FARMER.

Still let me live among the hills,
The rocks, the trees, the flowers,
Where I have passed my earliest years,
My childhood's happiest hours.

How oft beneath an aged oak,
Near by my father's dwelling,
Have I reposed with kindred youth,
Some playful story telling.

The birds above would plume their wings,
And raise their happy voices;
Oh sure it is a pleasant place,
Where every thing rejoices.

Surrounded by the friends I love,
And freed from every letter;
I am an independent man,
And wish for nothing better.

My little children round me sport,
So blooming, bright, and healthy,
I often think that nature's gifts
Have made me very wealthy.

My wife is all that she should be,
Kind, gentle, prepossessing;
I'm sure if ever man was blest,
Mine is the greater blessing.

THE RAIL-ROAD STEAMER.

(Concluded from page 16.)

The railroad travelling possesses many peculiarities, as well as advantages, over the common modes of conveyance. The velocity with which the train moves through the air is very refreshing even in the hottest weather, where the run is for some miles. The vibratory, or rather oscillatory motion communicated to the human frame, is very different from the swinging and jolting motions of the stage coach, and is productive of more salutary effects. It equalizes the circulation, promotes digestion, tranquilizes the nerves (after the open country is gained,) and often causes sound sleep during the succeeding night, the exercise of this kind of travelling being unaccompanied by that lassitude, aching and fatigue, which, in weakly constitutions, prevents the nightly repose. The railroad bids fair to be a powerful remedial agent, in many ailments to which the metropolitan and civic inhabitants are subject.

To those who are curious, and not very timid, the open carriages are far preferable to the closed ones, especially in fine weather. In bad weather, and particularly at first, invalids may travel with more advantage under cover. I have no doubt, that to thousands and tens of thousands of valetudinarians in this overgrown Babylon, the run to Boxmoor, or Tring and back, twice or thrice a week, will prove a means of preserving health and prolonging life, more powerful than all the drugs in Apothecaries' Hall.

In fine, a man may travel from the pole to the equator—

"A Gadibus usque ad Gangem"—

without seeing any thing half so astonishing as the wonders of the railroad. The pangs of Etna, and the convulsions of the elements, excite feelings of horror and terror, without any thing of pride.—The magic—the miracles of the railroad, engender an exulting consciousness of superiority in the genius of man, more intense and conclusive than any effort of poet, painter, or philosopher.

The railroad journey, however, is not without its inconveniences, many of which may be prevented by a little ingenuity. The greatest is the dis-

charge of cinders, some of them ignited, from the chimney, which are not only disagreeable, but occasionally dangerous to the eyes of those in the open carriages. This might be prevented by an awning—a protection which is adopted on some railroads, and one that must ultimately be adopted on all. It is a protection from the elements of fire and water, which every company is bound to afford to the passengers, and is attended with trifling expense. Till then, glasses or a veil are necessary guards for the eyes.

The transits of the tunnels, in hot weather, causing a sudden vicissitude of temperature, to the extent of 20 degrees of the thermometer, or thereabouts, require some precaution on the part of sensitive invalids. A shawl, or large handkerchief, thrown over the head, is a sufficient protection, and those who do not take this measure, should keep their eyes shut, during the passage, since sparks and cinders are, unavoidably, thrown in closer showers over the passengers here than in the open space.

To speculate on the normal, physical, political and economical effects and consequences of railroads and steam navigation, when carried to their full extent, is beyond my province—perhaps beyond the bounds of human foresight. If the semi-civilized peasants of the remotest isles of the Hebrides, of Orkney, and of Shetland, can even now, transmit, in a few hours, the produce of their huts, their mountains, their moors, and their farm-yards, to the markets of Glasgow and Edinburgh, so as, in three or four days, to pay the annual rents of their tenements and wildernesses, what may we not expect from the extension and perfection of this facility of intercommunication? In days of yore, the imponderable products of the intellect travelled as slowly as the material merchandise of mankind. They will now be diffused, from the centre to the periphery—from the remotest outlines to the foci of society, with a rapidity little less than that of *thought* itself! The ultimate consequences cannot be appreciated at present; but we may safely conclude, that the benevolent author of our existence did not endow the mind of man with such extraordinary powers of invention, without the design of final advantage to his physical wants, his social relations, and his spiritual nature.—*Medico-Chirurgical Review.*

DR. BOWDITCH.

The character and life of the late lamented Nathaniel Bowditch presents such a striking and beautiful example of devoted and successful industry in the employment of time, in the husbanding of small portions and turning them all to some good account; and likewise of systematic attention and punctuality in business, that we gladly avail ourselves of an opportunity to transfer to our columns the following extracts from Judge White's Eulogy recently delivered in Salem. Such an example is far more powerful than many eloquent discourses.

After Dr Bowditch removed to Boston, as well as before, he was always up as early as sunrise, and long before it in winter. He had formerly been in the habit of walking before breakfast, but during nearly the whole period of his residence in Boston, he breakfasted immediately after rising. He always breakfasted alone, as none of the family were ready till long afterwards. He then applied himself to mathematics, getting from two and a half to three hours study before the time arrived

for going to his office. He then took a walk of about a mile or a mile and a half, with one of his sons, and was in State street at a few minutes after nine o'clock. There also he had his mathematical books beside him, and when not engaged with the business of his office, or with visitors or friends, he devoted himself to his studies. He frequently took a walk home in the forenoon for a few minutes, as he found his eyes strengthened and refreshed by being at intervals during the forenoon in the open air for a short time. Every day, a little before two o'clock, he balanced the cash account of the office, so that every transaction which had been completed was duly entered and examined, and the right balance of cash found to be in the bank before he went home. He then took the same walk again, usually with one of his friends, and dined about a quarter before three o'clock. After dinner he took a short nap or "siesta," as he called it, varying from fifteen minutes to an hour, sometimes even longer. He always awoke bright and prepared for recommencing his studies, which he pursued for about an hour and a half to two hours. The regular hours of business at his office ended at two o'clock; but he always, towards the close of the afternoon, went there again for a few minutes, to see if any thing needed his attention or explanation; and, toward the end of the year, he was frequently detained there a considerable time. He then took the same walk a third time, and returned to tea. During the evening he continued his studies, and from time to time joined in conversation with his family, or threw aside his books to devote himself to his visitors and friends. He always expected all the members of his household to return by ten o'clock; the house was then closed, and he usually retired between ten and eleven. During the summer, he was in the habit of taking a horse and chaise and riding eight or ten miles in the afternoon. There is no doubt that, taking the whole year together, he got as much as six, and perhaps as much as eight hours a day for his mathematics, besides the time devoted to his business and other pursuits.

In his habits of business, he was most exact and methodical. He made it a rule to do but one thing at a time, and hardly a day passed which did not witness the application and enforcement of this rule. He was very rapid and exact in all his calculations, computing interest, &c. and each one's business was, in succession, finished with the utmost despatch; so that it was wonderful how much he was able to accomplish. He disliked being obliged to leave any thing unfinished, and recommended as a motto, "end what you begin." Only the day before his death, having a week before he found himself too feeble to make an endorsement upon a promissory note of half the principal, and to look over and execute a deed of release of half the mortgaged premises, he sent to Mr Hale, the Secretary, to bring him the papers again, saying, "You know I never like to leave any thing unfinished." He made the endorsement and executed the release in question, only forty-seven hours before he died.

NEW ENGLAND FARMER AND GARDENER'S JOURNAL.

AN AGRICULTURAL EDUCATION FOR THE SONS OF LANDED PROPRIETORS.

[Our attention of late has been frequently called to the importance of the establishment of an Agricultural School for the education of farmers. We have had a number of applications from gentlemen wishing to obtain places for their sons, who having finished their collegiate course of studies, desire a situation where they may obtain a practical and scientific knowledge of farming. We find an article in the *Quarterly Journal of Agriculture* which we recommend to the notice of our readers; it contains some suggestions respecting the importance of "an agricultural education for the sons of landed proprietors" which although it may not be exactly suited to our country, yet contains some hints of importance. Will not some of our able correspondents take the subject into serious consideration and give us their views upon the expediency of an establishment of this kind for the benefit of the farming interest.

J. B.]

The ordinary education of the landed proprietors of this country is as complete as it can be effected by private tutelage and at public schools and universities. Accomplished in classical learning, literature, or the physical sciences, as each department of study may suit particular tastes, not a few of them have enhanced the literary and scientific character of the country, and some have even conferred lustre on it in the learned professions of medicine, law, or theology; and not to be outdone in the race of honorable distinction by their English competitors, many have participated in the academic honors of Oxford and Cambridge. Yet, strange to remark, anxious as landed proprietors certainly are to bestow a liberal education on their families, which is the best legacy they can leave to their younger sons, agriculture, which most materially affects the interests of themselves and their eldest sons, the very profession by which they are upheld in the high status of society they occupy, they almost entirely neglect, as if, after the acquirement of a superior education, a man should be ashamed of attending to the means of his subsistence. Is it not "passing strange," that any country gentleman should be unacquainted with farming, the very source of his livelihood, when all other classes of people, in learning their respective professions, whether learned or vulgar, serve apprenticeships and toil through life thereafter? It seems to be forgotten that landownership is a profession, that it is in the manner in which it is conducted, that the best interests of the country may be injured or promoted, and that it is a profession which requires as great capacity of mind to practice it aright as to conduct those large commercial and manufacturing establishments, whose importance is so much lauded. The comparison between them can in truth be pursued no farther; for, whilst commercialists conduct their business in person assiduously, land-

owners consign the guidance of their valuable estates to persons who, in too many instances, are ignorant of agriculture, and who, at any rate, cannot feel the same interest in their prosperity as the proprietors themselves. This allegation is made against landowners generally, though not indiscriminately sweeping; for we have the satisfaction of personally knowing landowners, members of the nobility as well as the gentry, who have made it a duty to acquire a knowledge of agriculture, and who, in consequence, manage their estates of themselves, or through competent factors, on the principles of the most approved practice. Those proprietors who entrust their estates to factors of known practical ability, adopt the best safeguard against the evils arising from their own want of knowledge.

There are many evils attending the neglect of farming by land owners. When called upon to take a share in the discussions or business of those interesting agricultural meetings which of late years have excited so much notice over the kingdom, the remarks or speeches of the land owners consist, with few exceptions, of apologies for not having attended sufficiently to agricultural subjects, and of excuses for want of practical knowledge; and, when it is their lot or ambition to become members of the legislature, how lamentable it is to find that, beyond every other class of representatives in Parliament, the landed interest know the least of what concerns themselves. They should know much more upon every subject connected with agriculture as an art, as being the most influential interest in the state, or the laws affecting the different branches of it, than mere tenants, whose education and means of observation must be comparatively limited. Yet the tenantry are frequently left to fight their own battles on public questions.

A greater evil exists in consigning the management of their valuable estates to the care of men who have perhaps acquired an intimacy with the quill, and the blandishments of their own tables, but who have neglected the guidance of the plough, and the unwearying attention required at the feeding-in board. Want of knowledge in proprietors may only personally affect themselves, but the appointment of incompetent factors cannot fail to affect the fortunes and happiness of numerous families. The nature of the legal profession, in which too many factors are brought up, predisposes their minds to carping at quibbles and litigiousness; which, whenever a farmer discovers, or thinks he discovers, in the factor, he withdraws his confidence from him, and places himself in a position of self-defence. Both are ever after prepared for dispute, and disputes inevitably ensue. And how can any other result be anticipated? How can a farmer hold "sweet converse" with a man who cannot understand his discourse, and it is only as a farmer that a tenant has occasion to converse with the factor at all? In these circumstances, when disputes do arise between the factor and the tenants, the proprietor, who is unwilling, or what is worse, and more likely to be the case, unable to

interfere, leaves their settlement to him who commenced them; and who, to gain his point over the tenant, persuades his master, by flattering his prejudices, to refrain from interference; and, in the end, contrives to place the proprietor in the most disagreeable position with his tenants. The probable result of this cunning policy is the degradation of the proprietor into a scape-goat for the sins of the factor. Or, stopping short of actual litigation, the factor may refer the settlement of the dispute to expensive arbitration. In either case, the weaker party, the tenants, are sure to be most injured, and, it may be, eventually ruined. The proprietor, instead of being the natural protector of his tenants, is thus converted into their oppressor.

By this train of argument, we do not maintain that factors should be ignorant of law, of business, or any other species of knowledge; but what we assert is, that they should be thoroughly versant in agriculture. Without that essential knowledge, we would not entrust a factor with the management of an estate, although he possessed the most amiable disposition. That knowledge, and no other imparts the faculty of looking at all agricultural matters in the right light. By it he will know what covenants of the lease are applicable to the peculiarities of every farm, or the circumstances of the tenant to whom it is let. No disputes will then arise about miscropping. He will easily discover whether the progressive or retrograde condition of the tenants arises from their own industry or negligence, or from circumstances connected with the state or situation of the farms themselves. He will regulate his conduct accordingly, by encouraging the industrious and skilful, reproving the indolent, or amending the unfavorable circumstances of the farms. Such a man's opinion will greatly influence that of the tenantry, and community of sentiment will produce mutual kindness of intercourse between them.

Every land owner, who resides in his mansion-house in the country, must have as much land in his own possession as to make what is familiarly termed a "home farm." Corn, hay, and straw will be required for the horses; green food throughout all the seasons must be provided for the dairy cows; fowls and dogs must be supported; butchers' meat must be regularly supplied in the best condition; and the whole domestic establishment must be maintained. To effect all this, two hundred acres of arable land, besides lawns and paddocks, are required. A manager for all this establishment must be procured. Another evil arises from the appointment of this functionary. He becomes proud in his new place, because he is in the service of a laird; overbearing, because he knows he is the only one acquainted with the management of land; important, because he finds himself purveyor for the whole establishment, and could starve the garrison at any time to a surrender; haughty, because disposing of a few unnecessary articles from the farm, he becomes the bearer, for a time, of a little loose cash. The temptations of his office become too strong for his virtue, he aggrandizes

himself and distributes hush-money liberally; at length his peccadillos are discovered, and he for ever after becomes unfit for a farm steward to any other proprietor or farmer.

When landlords have no knowledge of farming, their taste for the country usually declines. The sports of the field may detain them on their estates for the season, but are too rough and fatiguing to entice them to remain throughout the year. Without the excitement of field sports, their life is nothing but a monotonous scene, and the same society at length becomes irksome to them. They leave their demesnes with partial disgust, and wander about in foreign lands, or settle down somewhere far removed from their patrimonial inheritance. This we consider an evil; for we do not agree with Mr McCulloch, that it is of no importance to a country where the income derived from its land is spent. We are quite sure the small tradesmen of every class derive sensible benefits from the expenditure of the contiguous proprietors, and when the latter are absent, they soon feel that source of profit dried up. But, on the other hand, we do not bewail the absence of proprietors so lamentably as our Irish neighbors. Good farming proceeds, and laborers are employed, by the enterprising tenantry in their absence; and, in as far as regards the substantial improvement of the country, the claims of the landowners in the participation of the honor is little, compared with those of the tenantry.

Now the effects of all these evils, we venture to assert, may be most effectually remedied by the sons of landed proprietors, who will themselves become landowners, acquiring a thorough knowledge of farming in their youth, as a necessary branch of practical education, and the management of their estates will then be felt a desirable gratification, not a task. Proprietors would then be qualified to select and appoint competent factors,—to judge of the fulfilment of the factor's duty of impartial superintendence,—and to convince themselves, by personal observation, that their tenantry receive substantial justice and protection. They would then be competent to select farm-stewards to manage the home farm under their own directions, and to keep them in check by commanding them to render an account of their intrusions at the moment, and not at the protracted periods of terms. They would then discover there is not a more rational, pleasing, or interesting study than the science of agriculture, and its practical application, nor one which can be so well combined with those manly sports and amusements in which it is the pride of our country gentlemen to excel. They would then have no temptation to reside abroad, but would discover that a knowledge of the minutiae of farming creates a daily increasing interest in field operations, and the cultivation of stock. A personal acquaintance with their tenants would then open a wide field of human nature for their observation; and this ample field to glean from, in connexion with the facts acquired in their own practice, would supply them with cogent arguments and illustrations on all subjects connected with agriculture, whereby their sentiments would command respect in every public assembly.

Where is all this important knowledge to be acquired? It is to be acquired like every other species of knowledge, by observation; in the operations of nature, as displayed in the field of art. Is this question asked in a country, whose proud boast is to possess more enterprising, educated, and well

informed farmers, than perhaps any other country in the world? In all the best managed districts, where we mean the mixed husbandry is practised, or the culture of stock and crop are combined, there are farmers well qualified to impart instruction in their profession, as well as possessing such cultivated minds as to render them valuable companions. A two years' residence with an agreeable and intelligent farmer, who practises the raising of corn with the breeding and management of cattle and sheep, and putting the hand to every kind of work, could not fail to impart to young men of ordinary capacity, a competent knowledge of farming. Such a tuition we consider absolutely necessary for the eldest sons of our landed proprietors, who mean to reside in their own country, and enact the part of landowners; but it may be also profitably extended to those younger sons, who may turn their thoughts to the New World, as the surest means of success in any undertaking connected with the culture of the soil, or the rearing of the domesticated animals, in which they may embark. Their interests will be promoted by studying agriculture effectually, before they embark in their migratory undertakings. No proprietors' sons need be ashamed to receive instruction from, or sit down at the tables of, such men.

We are entitled to speak confidently on this subject; for the foundation of our practical knowledge of agriculture was laid by an intelligent farmer, and most agreeable companion, in perhaps the best country for farming in Scotland; and never since have we had cause to consider the time misspent. The facilities are evidently greater in Scotland than in any country we know, for young gentlemen acquiring a practical knowledge of agriculture, almost under the eye of their friends and relations.

Should these remarks attract the attention of those country gentlemen who may feel inclined to profit by them, we can furnish them with the names of some of the most eminent farmers who have been in the habit of taking pupils; and leave it to their own discretion to choose the most eligible situation.

But we think the system of tuition might be beneficially extended. Most farmers, we apprehend, are not quite competent to teach the science of agriculture in connexion with its practice. Suppose, then, an extensive farmer has a large house, capable of containing a number of pupils, not exceeding twenty. That number, we conceive, to be enough for successful and comfortable tuition. Let this house be subdivided into comfortable sleeping apartments, a large dining-room, a large drawing-room, and a large class-room, fitted up partly as a library, and useful, also, as a reading and writing apartment. Let a tutor of competent acquirements be appointed to take the immediate charge of the pupils, both within and without doors. He should be competent to teach the application of chemistry, although we are not so sanguine as most people of the utility of this science to agriculture. He should teach the application of the principles of mechanics, in order that the principle on which any implement operates may be comprehended—the application of the principles of hydraulics, that the principles of draining, embanking, and constructing reservoirs for water, may be easily understood. He should teach botany, to enable young farmers to distinguish soils by their natural vegetation; and particularly the physiology of plants, that the culture of plants of whatever kind may be in conformity with appropriate soil and situation. Also

geology, that the substrata or subsoils, on which soils rest, may obtain due regard. Meteorology should be studied, in order to be able to anticipate the changes of the weather. The anatomy and physiology of animals are also requisite for him to teach, that the good points of live stock may be duly appreciated. And, above all, he ought to be acquainted with the practice of agriculture; for, although the farmer himself will no doubt undertake to teach this department of the system, yet unless the tutor also understands it, he cannot so successfully demonstrate the application of science to the operations of practice. It may, at first, be difficult to find a tutor so amply qualified for the task; but as the practice of agriculture would most likely be the only department in which he would be deficient, he could, in the course of two years, acquire that knowledge as easily as any of the pupils.

With colloquial prelections and discussions in the house, at stated hours, so as not to interfere with the hours of labor in the fields, and with demonstrations in the fields, whilst the labor was in progress, a vast mass of useful information would, in a short time, be conveyed to, and acquired by, the pupils. It is presumed the pupils had already acquired, at school, or college, the elementary principles of all these sciences, besides mathematics. Such a house should be situate on a large farm of not less than six hundred acres, on which the mixed husbandry is practised; that is, the growing corn with the breeding and rearing of cattle and sheep.

The system might be extended still farther. It will scarcely be possible to find a sufficient number of large farms on which such establishments could be founded, or of intelligent farmers to conduct them; as the mixed system of husbandry cannot be successfully carried on, on a very small farm, or by small farmers. This difficulty might be obviated by the erection of a large house in a convenient village, in the neighborhood of which, intelligent farmers held farms. The tutor himself could engage the house, and draw the emoluments, and give premiums to the farmers, for permission to the pupils to inspect and witness all the operations.

We think such establishments would be conducted much more satisfactorily on private speculation, than under the guidance of any society, or public commission. Both the farmer and tutor would be stimulated by their own interests for their success, and competition would in time sharpen the stimulus still more keenly. Let any farmer, who has the requisite accommodation and qualification, begin the experiment with adequate appliances, and he will soon find customers. Like a coach or a steamboat starting on a new line of communication, his establishment will attract pupils; whereas, if he wait until the demand for such establishments rouse him into action, he may have to wait as long as the wagoner had for the assistance of Hercules.

CULTURE OF THE MULBERRY TREE AND THE TREATMENT OF SILKWORMS.

Not very many years have elapsed since the project of introducing the silkworm into this country was seriously taken up by several scientific persons; and the probability of its becoming eventually a source of wealth was warmly discussed. Gradually, however, the ardor of these projectors was found to cool, and the matter fell to the

ground; and was soon as little spoken of, as if an enterprise had been meditated which sensible men ought to disavow. Notwithstanding this implied reflection on the good sense of the supporters of the plan, a few gentlemen shortly after might be found scattered through England, who still cherished the conviction that the introduction of this insect was perfectly feasible. They planted mulberry trees and bred silkworms as an innocent source of amusement; and to this day they continue to occupy their spare time in trying experiments on a limited scale, on the best modes of bringing up their favorites; but if the project was eagerly received here, in Ireland it was hailed with enthusiasm as a certain mode of realizing a fortune. The ardent imagination of the Irish easily overleaped the barriers which inexperience or want of capital threw in the way; and for any one not to have implicit faith in the silkworm speculation, was looked on as a mark of meanness of spirit, or of total disregard to personal advancement. A joint-stock company was even proposed, and a vast number of names were marked down for shares; but when the day of paying the first instalment came round, the absentees were found to be so abundant, "that the company dissolved itself," as a wag afterwards remarked, "even before it was formed." The zeal of individuals was but little manifested in mulberry plantations or silkworm nurseries. One person only showed that he had been perfectly serious in his enthusiastic advocacy of the enterprise; he planted some thousands of the trees, and when we passed through some dozen or fifteen years ago, we saw the plantations in a most flourishing condition. The Earl of Kingston it was who had given this proof of his being serious in the silkworm project; and even to the last, we believe he spoke with every appearance of being thoroughly persuaded of the possibility of the plan. Both in this country and in Ireland, the great objection was that the climate was too severe for so delicate an insect as the silkworm. The slightest variations of cold and heat were known to affect it; and sudden changes were frequently found to cause its destruction; modern discoveries have proved this notion to be hastily assumed, and perfectly erroneous. The insect is now known to be capable, with proper management and due precaution, of supporting our climate; and it is with the intention of showing the truth of this important fact to our readers, that we have determined to lay before them some valuable information which has but lately come to light.

The source from which we derive this information, is a treatise by the Chinese themselves, which has been lately translated and given to the public in France. When we consider the acknowledged advancement of the Chinese in the arts and sciences, evidenced by their knowledge of printing—of the mariner's compass—of gunpowder, and many other curious discoveries, long before the inhabitants of Europe, it is a matter of wonder that their literature has not been more carefully studied, and the results of such studies made public. All that we have until lately known of the Chinese, and their habits, manners, customs, and knowledge, has come at first through the early missionaries, and next through the embassies sent over from this country. A third spring of information has now been opened; and we are not over sanguine, in predicting that a most important stream of curious knowledge will be found to flow from it. Should it be asked, how it happens that this particular

junction has had the merit of making public the contents of a Chinese work, we answer, that it is the same cause which, in the days of Ptolemy, caused the Roman parrots, when hungry, to salute their mistresses in the Greek words they had been taught, namely, self-interest, a most prolific source of research and invention. Thus it was that the work was translated.

The production of silk, at the present day, in France, amounts to a value of more than 60,000,000 francs a year; which is, however, quite insufficient for the consumption, as the foreign trade alone reaches 50,000,000 francs a year. Silk is one of the principal products of China: for not only is it used to a great extent in the fabrication of their clothes, but a vast quantity is exported in the raw state, as well as in the shape of fabricated articles. For forty centuries have they devoted their attention to study, in its minutest details, the rearing of the worm which furnishes them with this source of their national wealth; and as a natural consequence, this long experience, always stimulated by the sense of self-interest, has caused them to discover a crowd of attentions, of proceedings, and of practices, most likely to procure for them certain and advantageous produce.

The missionaries were at once struck with the importance of these practices to the European cultivator of the silkworm; and they determined to mark down some of their modes of treatment, for the benefit of their countrymen. Two treatises were drawn up, and afterwards published in France. One of them, by Father d'Entrecolles, gives the extract of an old Chinese work respecting the treatment of silkworms; and the other, composed by Father d'Incarville (or rather, from notes left by him,) describes the treatment given to three other species of worms, which the natives designate "wild silkworms," because their nature requires that they should be permitted to live at full liberty on the trees from whence they take their food. Some of the methods of treatment described by d'Entrecolles, were not long ago put in practice by M. Camille Beauvais, a large breeder of silkworms at Senart. He found them to be most serviceable, and most certain and faithful in their results; but above all, he found that the adoption of the Chinese treatment was of wonderful efficiency in preventing accidents, which before had dreadfully puzzled and annoyed him.

As the abridgment of a work is always incomplete in details, M. Beauvais thought that it would be important to have the original Chinese work translated. He applied to the Minister of Commerce on the subject, and laid before him the importance of the case. M. Passy was at the time minister; and he applied, in his turn, to M. Stanislas Julien, as the first Chinese scholar in France, or perhaps in Europe. He directed this eminent *savant* to undertake the task; and M. Martin (du Nord,) who succeeded to the Ministry of Commerce, made the work complete, by desiring M. Julien also to translate the Chinese work on the culture of the mulberry tree, which is always annexed to the work on the treatment of silkworms. M. Julien undertook this arduous task; and has just given to the public a translation of the two treatises, of rare precision and clearness. To this has been added, Father d'Incarville's treatise on the wild silkworms; and the whole has been published at the royal printing office. The French scientific men speak of the work as containing a vast quantity of useful details; and they declare that it will

be the means of greatly increasing the wealth of France. Without going the whole length of their sanguine anticipations, we can see that the information thus given is highly important, and that it may be of great value to this country as well as to France. One peculiarity of the work is, that the Chinese have followed no fixed plan; there is no succession of ideas in natural logical order in the Chinese writings. Down they put whatever thought occurs to them: satisfied, apparently, like the sybil of old, with having marked it down, but totally regardless of its fate afterwards. It might be a curious question to discuss the reason of this want of order; whether it arose from habit, or from some defect of organization: this, however, is beside our present purpose; we only desire to speak of the works before us. In considering them, it will not be found an easy task to place all in proper order. The little treatise by Father d'Entrecolles will be found of use as a sort of guide; but as it may not be practicable to obtain this work, we purpose culling from the translations some of the facts which strike us as useful and singular.

The silkworm, when it has just burst into life, is at first a little black caterpillar, about the length and thickness of an ant. In this state, its growth is so rapid, that after twentyfive or thirty days it has arrived at a size some hundreds of times more considerable. It then spins its cocoon, and is transformed into the chrysalid form; it emerges from thence a gay butterfly, engages in the work of generation, lays its eggs, and dies. The care of the Chinese follows the insect in all the phases of its short existence, without losing sight of it a single instant. The rapidity of its development as caterpillar, requires that it should several times get rid of its skin, and replace it by a larger covering. Every one of these changes constitutes a perilous crisis in the insect's existence; because it then remains without movement, and as if benumbed, during the period that nature urges on her handiwork.

It is easy to conceive, that the temperature, the food, and treatment, ought to be different for the insect when approaching its state of torpidity, from those which are most beneficial to it when in its time of health and vigor. The first and grand provision, therefore, for successfully rearing a season's insects, ought to be, to obtain a collection which, born at the same time, and under the same circumstances, shall be endowed with constitutions of like vigor, in order that the changes of their activity, of their torpidity, and of their final transformation, shall arrive simultaneously or nearly so. It is almost impossible to picture to one's self the multitude of cares which the Chinese devote to this fundamental condition. They commence their attention in the very choice of the butterflies destined to produce the eggs, rejecting such members of the two sexes as are born amongst the first or the last, and making use only of the intermediate ones; and even using their discretion in putting together, for the work of generation, those insects which their experience shows them are best suited to each other. Next the eggs become the objects of their solicitude. Here also they cast away the first and the last which are produced; and they pay great attention to having the batch equally distributed over the paper on which they contrive that the laying should take place. They thus avoid all heaping of the eggs, which would, when the hatching was concluded, place the insects in unequal circumstances; or if the eggs should, notwithstanding

ing their precautions, be heaped on each other, they reject the mass altogether as ineligible for their purpose. Afterwards, they preserve these eggs with a thousand precautions, causing them to undergo various washings and other preparations, before the moment when the insect is about to burst into life.

So great is their ability in managing the education (if we may so term it) of the silkworm, that they generally contrive that all the insects should come from the eggs in the same day. Here again they reject the precocious and the tardy ones, in order to retain and bring up only those of the middle class. Having procured the fulfilment of this principle of original simultaneity, they make every exertion to maintain all the phases attendant on the insect's existence. The cleverness of the Chinese is such, as to enable them to reduce the period of these changes, at most, to twenty-five, or even twenty-three days; whilst our unskillfulness obliges us to prolong the period to thirty or thirty-five days, to the serious detriment of the silk produced; for the Chinese have ascertained this important fact to be true, that the quantity of silk produced by the worm, is less in proportion to the length of time that it remains in the caterpillar form—the longer it remains, the less is the produce; and the rapidity of the reduction is enormous. To make this position clear, let us suppose that a number of worms, which have been developed in twenty-five days, have given twenty-five ounces of silk; if they remain, through any want of nourishment or necessary care, in the caterpillar state for twenty-eight days, the amount of silk produced will not be more than twenty ounces; and should they delay to the thirtieth day, not more than ten ounces will be given. This is not only a very curious fact, but of great importance in a commercial point of view, and well worthy our serious attention. The Chinese have been long aware of it; and hence they deem no care too great which will hasten the birth of the insect. We must also look with admiration on the minute and delicate attentions with which they regulate the insect throughout. They are particularly cautious never to detach the eggs from the papers on which they have been deposited, to place them in heaps, as is so unreasonably practised in France, but they leave them their separate station and their hold on the surface, both which are found to be favorable to a speedy hatching. They also take care never to handle, or even to touch with the end of a pair of pincers, the little worms when they are born, in order to place them on the mulberry leaves: they would fear to run the risk of tainting them. How different is the practice in Europe, where it is quite a matter of daily occurrence to detach the eggs from the paper and place them in heaps: afterwards they are tied up in linen and transported to a distance. May not this be the cause of those frequent mal-formations which appear in the European silk-nurseries, and which occasion such tremendous losses afterwards? a circumstance be it observed, never seen amongst the Chinese. Their practice is, to gently place on the leaves the papers on which the worms have come into existence, in order that they may of themselves descend and take their food; nor do they place within their reach entire leaves at first, but little morsels, cut very neatly and scattered through a small sieve, in order that they may be distributed uniformly and in proportion to the number and the age of the worms. The quantity given at each repast is ex-

ceedingly small; and the increase is made in the number of repasts, but never in the mass of food given at each. The practice, we may remark, is founded on just principles; and the proofs of its efficiency are seen every day in our farms in this country, where cattle are found to thrive best on small and frequent repasts; not only because such are most easy of digestion, but because the animals eat more eagerly, and with a better relish, their food, when fresh, than trampled on, or tainted by their breath, when given in large quantities.

It would be an endless task to follow the Chinese through all their minute details, the influence of which, however, must be exceedingly great on the silk produced. Their treatment of the cocoons—their proceedings with regard to their silk crop—and their mode of winding the thread, are exceedingly curious. Our limits will not permit us to delay much longer; we shall, therefore, only add an interesting fact or two before we close. The Chinese use two sorts of artificial food for their silkworms; one of these is the leaf of a tree called *tehe*, and a plant which bears the title of *Ouo-kin*: these are employed when the mulberry tree has not yet pushed forth its leaves, or when there is a scarcity of them. What these two productions are we have no means of ascertaining; that they are used throughout China for silkworms is certain, for mention is made of them in an old Chinese almanac, apparently intended for the working classes. The *tehe* tree is also noticed by d'Entrecolles, who describes it as a prickly tree, which grew on exposed and lofty situations, and had a fruit like pepper. In the work translated by M. Julien, a rude sketch is given of the tree; but so vague is the outline, that we are unable to assign it to any particular class. The same incertitude exists as to the *Ouo-kin*. Remusat identified it with the wild chicory; while in the *Anacnites Erotica* of Kempter, it is suggested that it resembles our lettuce; it surely will be worth while to try both plants, and judge by the manner in which the silkworms receive them. The Chinese also employ, in feeding the worms, mulberry leaves gathered towards the end of the preceding season; these they dry and reduce to powder; and having lightly sprinkled the fresh leaves, they scatter it gently over them. The worms are always found eager to feed on it; and one advantage of it, is that it can be used at all times. Rice is also found to answer. It is first husked and then boiled by steam; this is then ground, and the flour is given to the worms. A small sort of pea, after being first allowed to germinate a little, is also employed; and all these preparations are said to render the silk stronger and more abundant. All these expedients are favorable to the introduction of the silkworm into England, which the Chinese mode of treatment proves to be perfectly practicable.

The long experience of the Chinese has made them aware of the fact, that the artificial education of silkworms requires a succession of different temperatures, suited to the different changes of their existence; and that, at the same time, the air which they inhale ought to be constantly purified of their perspiration, their evacuation and the bed of leaves on which they are placed. To effect this, they have found it necessary to erect close buildings, where an artificial increase or diminution of heat can be given when required, and where fresh air is constantly admitted. They have also discovered that these transitions of temperature must be al-

most insensible; and all their skill and ingenuity are taxed to accomplish this desirable object.

The Chinese author enters into a most minute description of the structure, materials, and situation of a silkworm nursery. He gives an account of the mode of heating it; and at great length details the form and use of the different instruments and utensils required in the concern. We do not intend following him in these details, curious as they certainly are; we shall only mention one circumstance connected with the heating of the nursery, which will show to what extent their cares are given. In addition to their scientific modes of maintaining the exact temperature beneficial to the worms, they employ what they deem the best indicator of a proper equilibrium, and even superior to a thermometer—this is the woman who takes care of the worms, and who is called their *mother*. This personage is clad in a single thin vestment, in order that her sensibility to cold or heat may be constantly awakened. These women are considered persons of importance; and whether from organization or habit, can at once detect the slightest change of temperature.

It is owing to this judicious use of air and light (which we should have mentioned is particularly dwelt on,) that the Chinese are quite ignorant of those dreadful epidemics caused by mould, which in France makes its appearance on the bodies of the worms, in even the best regulated nurseries. In Italy also it is a matter of notoriety, that a vast quantity of worms perish every year from a similar disease: it is to be hoped, that from the present time the evil will be materially diminished. The best plan of a nursery yet tried in France, is one designed and erected by M. Darcey for M. Beauvais, of whom we have already spoken. This plan is considered, by some cultivators of silkworms, as most efficient; while others declare that it is little superior to a common workshop. The Chinese treatise shows that in many respects it is founded on wrong principles; and we may soon expect to hear that some modifications in its structure have taken place.

From what we have stated of the contents of the Chinese treatise, it may be seen that the cultivation of the silkworm is perfectly easy in this country. The difference of climate has been deemed by some scientific men as an insuperable bar; but this objection is taken away by the work, which establishes the fact, that the greatest produce of silk in China takes place in the central provinces, lying between 25 deg. and 35 deg. of north latitude. Thermometrical observations have also proved that the mean temperature of the northern and southern provinces of China differs but little from that of Provence in France, the winters being somewhat more severe, and the summers a little hotter. The work also shows, that the cultivation of the silk worm was carried on to an enormous extent in the most northern provinces of China, and we have no reason to suppose that the cultivation has been discontinued. Nor is it at all necessary that these silkworms should be reared in vast quantities or in large buildings; if this was necessary, how could the Chinese peasants pay their taxes, which are generally given in silk? The population of the country being exceedingly great, the land has been for ages divided into very small holdings; indeed, to this cause only can we attribute the declaration of Barrow and other travellers, that the appearance of the country is rather that of a vast collection of gardens, than that of an agricultural district. The

philosopher Meng-Tsu, who lived in the fourth century before the Christian era, says "that of the portion of land allotted to each family, it is sufficient to plant the twentieth part with mulberry trees, to enable the family to clothe themselves;" and since then, the tax imposed on each peasant's family is generally paid by a certain number of bushels of grain, a fixed quantity of silk stuffs, and some ounces of silk thread. This proves incontestably that each family rears worms to clothe themselves, as they cultivate the fields with their hands to feed themselves. Hence we may reasonably infer, that the methods prescribed in the Chinese treatise are equally applicable to private nurseries on a small scale; indeed, we might go much farther and say, that the great establishments are the exceptions, rather than the cottage of the husbandman; for as the work was drawn up for the general instruction of the nation, can we suppose that the writers had not in view the circumstances and condition of those for whom the work was intended? And as the vast majority of the inhabitants are of moderate means, ought we not to believe that the work was chiefly written for them, rather than for rich capitalists possessing large establishments?

We feel convinced that this branch of industry can easily be introduced into this country; and we do not deem the day far distant, when it will prove a source of wealth to thousands. Should our remarks lead to this desirable result, it will certainly be a source of great gratification to us; should we fail to excite public interest, we shall still have the consolation of thinking that we have faithfully discharged our duty.—*English publication.*

REMARKS ON PURCHASING A HORSE.

My neighbor Tyson, having occasion to purchase a horse for hard and immediate work, I advised him not to buy under five years of age. He yesterday took me to see a horse, for which he had partly agreed, warranted sound and five years old. On examining the mouth, I inquired of the owner if he would warrant him five years old? He answered, "he is coming five." "Yes," I replied, "and will be so, for nearly two years to come; the fact is, he is a three year old colt." This common trick reminds me of a butcher I once knew, who, when he had old beef for sale would spread his hand upon it, and declare it was under five, meaning it was under *four fingers* and a thumb.

Few persons, even amongst those to whom the knowledge ought to be indispensable, are acquainted with the mode of judging of the age of a horse by the teeth. As the lesson can be committed to memory in five minutes, I copy it from my memorandum book, asking for it an insertion in your valuable Cabinet.

How to form a judgment of the age of a horse by his teeth.

At two years old, the horse sheds the two middle teeth of the under jaw. At three years old, he sheds two other teeth, one on each side of those he shed the year before. At four years old, he sheds the two remaining, or corner teeth. At five years old, the two middle teeth are full, no longer hollow, as all the others are; and the teeth have penetrated the gums. At six years old, the four middle teeth are full, the corner teeth only remaining hollow: the tusks are sharp, with the sides fluted. At seven years old, the corner teeth are full, the tusks longer and thicker, and the horse is said to be *aged*.

Note. It is not meant that exactly at the periods above mentioned these changes take place in the horse; much depends upon his constitution; whether he be a late or early foal; also upon the manner in which he has been reared, as to food and shelter, &c. The corner tooth too, might remain a little hollow after the age of seven, but the appearance is still very unlike the mere shells, which they are, at the age of six. AN OLD FARMER.

[*Fur. Cabinet.*]

ON SMUT IN CORN, WHEAT, &c.

In *The Cultivateur* of last year, there is a curious article on "Smut in Corn," from the pen of M. Philippar, Professor of Agriculture in the Normal School of Versailles. He declares that smut is a "parasite plant, belonging to the mushroom tribe, of the genus *Uredo*." The article is neatly written, and does honor to the talents of the young professor. The opinion adopted and propagated by M. Philippar has been generally received as correct by the writers who have preceded him. The works of MM. Tillet and Tessier on this subject are well known to agriculturists in France. M. Benedict Prevost, and M. de Candolle, have also written on "Smut in Corn;" and they have all asserted that it was a kind of mushroom; this opinion is now controverted by M. Poiteau, who has lately written in opposition to the views of the above-named authors. He addresses himself particularly to M. Philippar; not because there was any thing to blame in that gentleman's work more than the other writers, but because, being the last who took pen in hand, he may be supposed to have illuminated the subject with the latest rays of science, and to have collected and detailed all that was known which had reference to his work.

M. Poiteau declares "Smut" to be "a local disease, contagious by touch, and *not* a parasite plant." His arguments for and against his opinion are given at great length. We shall, in a concise manner, bring them before our readers; and, first, his reasons for deciding against the "mushroom" theory. When Smut was first declared to be a plant, the labors of the microscope, applied to botany, were very imperfect; matters were declared to be *uredos*, *erines*, and *crisiphes*, which have since been discovered to be insects' nests, or tissular maladies to which the plant was subject. Hence it followed, that as microscopic botany became better known, these pretended plants gradually disappeared from the following editions of botanical works. Now these plants have been generally classed in the category as the Smut; and as these have been proved *not* to be of the mushroom race, so may Smut also. The opinions of some living agriculturists are cited by M. Poiteau, who considers Smut to be "an irritating humor, placed in the plant by the puncture of an insect, invisible on account of its smallness;" but he gives no proof that this can be the case; he only asserts that such is the opinion of men worthy of being listened to, from their experience and habits of observation. He brings forward the fact mentioned by Bose, who says, "a most remarkable thing is, that if the thick oil, which is taken from Smut by distilling it, by holding it over a hot fire, is placed in contact with sound corn, nearly a third of the ear will be affected with Smut." M. Poiteau maintains, that this is altogether inexplicable, unless Smut be contagious by touch; and even allowing this, it is no proof that the former opinions may still be well-founded. M. Poiteau says, that every experiment

tried by M. Philippar proves as much for the opinion that Smut is a disease, as that it is a parasite plant; but admitting this, M. Poiteau does not prove what he desires, namely, that his theory is correct. He also attacks M. Philippar's declaration, that Smut is propagated by seed; but we cannot find that he gives *proofs* that such is not the case. M. Poiteau very fairly cites against himself the *Memoire* of M. Benedict Prevost, at the Institute in 1806—in that paper he distinctly states, that he saw the Smut change its appearance and germinate. M. Poiteau asks, if that can be called germination which is nothing more than a change of form from round to oblong. "If," he goes on to say, "all changes which are seen in plants are taken for germination, every vegetable thing in nature should be deemed susceptible of germination." M. Poiteau gives M. Philippar great praise for his zeal and ability; but not the less insists that he is in error. We do not profess to give any opinion on the nature of Smut; we merely are anxious to lay before our readers the facts of the controversy. We must, however, declare, that we think M. Poiteau altogether fails to prove his position, that "Smut is a malady contagious by touch." He asserts boldly, and finds fault unhesitatingly; but he does not give *proofs*. We should much have preferred to see some hints given which might tend to remedy the evil. Smut does confessedly exist; and to be able to guard against its ravages would be a great blessing to the husbandman; but to enter into discussion as to the origin of the evil, without considering what are the best means of removing it, seems to us but of little practical utility. Any inquiry into the cause of Smut, or into its nature, can be profitable only inasmuch as we may, in our researches, discover the means of guarding against the devastation with which agriculture is so often cursed from it. If our neighbors, on the other side of the channel, would give us some hints bearing on this point, we should be more indebted to them than for their discussions on the origin of Smut. We conceive, however, that some good may arise from making known in this country what takes place respecting agricultural subjects in France; and for that reason have we referred to the above controversy. Perhaps, some of the experienced agriculturists of this country may be excited by it to give their view of the matter to the public. Should they do so, our article will not have been written in vain.—*Lond. Hort. Jour.*

BUTTER.

The business of making butter, for sale in the market, is a primary concern with a very large proportion of farmers who reside within a reasonable distance of towns or cities, and to obtain the best price for it, is, of course, an object of much importance in this money-making age of the world. Yet it is not a little surprising that, notwithstanding every body knows how to make butter, so small a proportion of what is taken to market commands the price of a first rate article. I think it may safely be said, that not one-fourth part of it can be assumed as first rate in quality, and, of course, much the larger part of it is sold at inferior prices. This, in many cases, must be ascribed to carelessness, inattention to neatness and cleanliness, and, perhaps, in many cases, to the impurities of the cellar or milk-house in which the milk or cream is kept. The atmosphere of the apartment where milk is kept, should be entirely pure and free from all contamination. No decaying vegetables, barrels of

fish, saurkraut, musty casks, or other articles which tend to render the air impure, ought to be permitted to remain in the same apartment with milk or cream. Fluids absorb the noxious vapors of the air in a remarkable degree. A pitcher of water being permitted to stand over night in a room where a segar has been smoked, in the morning will be found to be strongly impregnated with it.

It will be found to be impossible to make butter of good flavor, and of first rate quality, if the apartment in which the milk is set is not kept entirely free from all smell of what kind soever. It will receive a taint from foul air, of which it can never be divested, by any process whatever; therefore, if you desire to obtain the highest market price for your butter, keep your milk-houses and cellars as sweet and clean as your parlors, and let the exhibition of it in the market place be so perfectly neat and tidy as to attract the admiration of purchasers, and be sure never attempt to sell a pound of butter with a segar in your mouth.—*Far. Cabinet.*

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, AUGUST 1, 1838.

INDIAN CORN.

SUCKERING, TOPPING STALKS, HARVESTING.
(continued.)

When the corn throughout the field is completely glazed, so that from partial examination you cannot find an ear that is fit to be roasted and the kernels seem all to be touched, then proceed into the field with several hands to cut up the plants at the bottom. A sickle will answer for this purpose; or a knife made from the end of an old scythe attached to a short wooden handle. As the corn is cut keep it in your arms and do not allow it to be laid on the ground until sufficient is collected by yourself and those at work with you to form a good sized shock. Bring it next round a strong standing hill, or if necessary form a support for the shock by bringing the tops of two standing hills together; and around this support make your shock; bring the tops of the corn, which you have cut round it, and spread the bottoms widely for the free admission and circulation of the air; then with a band of rye straw tie the tops of all firmly together round those hills which are left standing. The corn must not be first tied in bundles as is frequently done, as in this case it is not likely to dry so well; and the ears frequently become mouldy, especially if damp weather follows; besides that when they are thus tied in small bundles the ears cannot be well reached in the husking and are liable to be missed, unless the bundle is untied, which is a great trouble. The hills which are left standing form a very useful support for the corn that is placed against them, and the shocks otherwise are liable to fall or be blown down. When the corn is sufficiently dry to be harvested proceed then to cut off the standing hill; the shock or stock then remains firmly bound by the band of straw at the top; and in this form is easily pitched upon the cart. When the corn is husked it is only for the husker to place the top of a shock or stock in his lap, and every ear is found at once and without difficulty. When this whole operation is well and properly performed we are satisfied that there is a considerable saving of labor in curing the fodder; that the whole fodder is saved in a much better condition; and that the grain itself becomes equally ripe, sound, and heavy, as if suffered to remain until it is "dead-

ripe" in the field. The fodder itself is more succulent and much better; and in truth, in respect to all parts of it, which are eatable, is as nutritious a food as can be given to live stock, either neat cattle, horses, or sheep.

In the event of the prospect of an early frost the crop in this way would often be saved, when otherwise it might be ruined; as there is no danger from frost after the corn has been cut and shocked twenty-four hours. Another advantage from this management is that it enables you to remove your corn much earlier from your field so as to have opportunity to prepare the ground for another crop, as where this is desirable the shocks of corn can be placed at the sides of the ploughed land. There is however an important suggestion to be made here. Where the shocks are placed at the sides of the field upon grass ground, there is danger that the grass will check the circulation of air under the shocks, and neither the grain nor the stalks will ripen well. The stalks too are liable to become mouldy at the bottom.

There is every prospect, let us be thankful to a kind Providence, of an abundant crop of corn the present season. The fields were never more luxuriant and beautiful. With the exception of some particular articles in particular situations, and what may at present be called fancy articles, such as beets for sugar and the silk cultivation, Indian Corn must be set down as the great crop for New England. We are fast departing to our very great injury from the good old fashions of Indian bread and Johnny cake. It is hoped we shall presently learn what is for our health and interest, and come back again. There is no more nutritious or healthy bread than that which is furnished by this rich gift of Heaven. Massachusetts alone can, and we have no hesitation in saying, ought to raise her three million bushels per year.

WHOLESAME DRINK FOR WARM WEATHER.—Take a two gallon stone jug and fill it with cold water. Put into this water a quart of oat meal; and shake it well. In half an hour it will furnish a pleasant, nutritious and excellent beverage. We know a farmer, who cuts ordinarily one hundred tons of hay. This is the only drink in the field for himself and his hands. He says he desires nothing better and he can find nothing more acceptable and useful to his laborers. Molasses and water and small beer are liable to be drunk in too large quantities and have a tendency to disorder the stomach. Cold water is excellent, but may be taken too cold and in too great quantities; and laborers in general want something different. Cider is inflammatory and irritating and stupefying. Ardent spirit is almost done with among respectable and decent people. Who wishes to be possessed of a devil?

For the New England Farmer.

MR. EDITOR—It has been a subject of surprise to me, for some time past, that with all the ingenuity for which the Yankees are so celebrated especially when a profit may be expected, no one has as yet in this part of the country (nor I believe in any part of the United States) ever introduced to our tables an article common in various parts of the world, viz: Capons. It may not be known to the great mass of your readers that in the West Indies and several parts of the old countries, a Capon is considered a great luxury and readily commands a much higher price than a chicken of the same age. They are apparently easily raised, grow to a large size, (say from 8 to 10 lbs.) and range together in flocks, never showing any disposition to fight each other. The writer sees no reason why they cannot be in-

troduced here, with profit to the raiser, and regrets his inability to furnish the information necessary to perform the required operation. The annexed from the Albany Cultivator of this month, is all that he can find anywhere on the subject, and as it does not go so fully into the "Modus Operandi," as could be desired, the writer is induced to request the insertion of this communication in your valuable journal, in the hope that it may meet the eye of some one of your intelligent correspondents, who will give through your columns, a full account, as to how this matter should be done, when the proper age, how the animal should be fed, &c. and thereby oblige at least one young farmer. NORFOLK, July, 1838.

CAPONS.—"To Capon Cocks make an incision with a sharp knife under the lowest rib; with your fingers lay hold of the parts to be extirpated, and cut them away with sharp scissors.

Put a stitch or two into the wound.—*Albany Cultivator for July, 1838.*

For the New England Farmer.

THE WAY TO MAKE GOOD BUTTER IN AUGUST.—Salt the milk before you strain it, at the rate of a heaped spoon of salt to a pail-full. Let it stand 24 or at most 36 hours. The first pan of milk you skim, put another heaped spoon of salt to the cream; add cream from day to day as you skim your milk. Churn three times a week or at least twice. Use a stone churn if you can conveniently obtain one. Set your churn in a pail of the coldest water, and change it as it grows warm by standing white you churn. Keep your cream in white earthen or a wooden bowl. It is injurious to health to use brown earthen ware for any thing salt or acid. These directions are for a small dairy of one or two cows.

A HORSEKEEPER.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, July 28, 1838.

Peaches.—Beautiful specimens by M. P. Wilder of this city, from his garden in Portland, raised under glass.

Gooseberries.—Jos. T. Buckingham, 2 boxes good. William Meller of Roxbury, 2 boxes, Jolly Printer, Champagne, &c. all of fine kinds.

George Newhall of Dorchester, 4 boxes of large and fine.

William Keurick, 3 boxes do.

Raspberries.—Dr. J. C. Howard from his garden at the Woodlands, Brookline; Franconia and White Antwerp; fine specimens.

Currants.—A. D. Williams from his garden in Roxbury, 4 boxes Dutch White and 4 boxes of Dutch Red, all of the finest quality.

William Meller, a box of Red and a box of White Dutch Currants, fine.

Honey.—Andrew P. Young, offered for exhibition a globular glass vessel, quite filled with pure honey, during 4 weeks from his yard in Hanover street and weighing 16 lbs.

For the Committee,

WILLIAM KENRICK, Chairman.

SINGULAR EVENT.—As two men were cradling wheat, near Milford, Del. during a thunder storm, a portion of the electric fluid struck the scythe of one, and glancing off, killed his companion.

BRIGHTON MARKET.—MONDAY, July 30, 1838.

Reported for the New England Farmer.

At Market 250 Beef Cattle, 100 Stores, 20 Cows and calves, 2050 Sheep, and 130 Swine. About 50 Swine were reported last week. 60 Beef Cattle remain unsold.

Prices — Beef Cattle.—Sales were dull and prices declined considerable. We quote, First quality \$7 25 a \$7 50. Second quality \$6 75 a \$7 00. Third quality, \$6 00 a \$6 25.

Stores—A very few sales only effected, purchasers refusing to pay the prices asked.

Cows and Calves.—Sales were noticed at \$24, \$25, \$32, \$35 and \$40.

Sheep.—Dull, and sales something less than last week for a like quality. Lots were taken at \$1 50, \$1 67, \$1 75, \$1 92 and \$2 12. Wethers at \$2 25, \$2 50, and \$2 75.

Swine.—We noticed the sale of one lot to peddle, but did not learn the price.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending July 29.

JULY, 1838.	7 A.M.	12, M.	5, P.M.	Wind.

Saturday,	28	70	92	84 S.
Sunday,	29	72	88	80 W.

FRUIT AND ORNAMENTAL TREES, MULBERRIES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honeyuckles; Pæonies, Dahlias and other Herbaceous Flowering Plants.

225,000 **MORTS MULTICAULIS** are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at fair prices, and varying with the size, and the quantity which may be desired. Also, Broussa and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to E. D. Breck, Commission Store, No. 132 Water Street, New York, M. S. Powell, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston. August 1, 1838. WILLIAM KENRICK.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham. ISAAC PARKER.

FOR SALE.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

REVOLVING HORSE RAKE.

The Revolving Rake, which has been in general use in most parts of Pennsylvania and New Jersey, is found to be one of the most useful and labor saving machines now in use. One man and his horse will rake on an average, from fifteen to twenty acres per day, with ease, and do the work well, it not being necessary to stop the horse to unload. They are coming into very general use in all parts of the country, and will, no doubt, in a few years, supersede the use of the common hand rake. For sale at the New England Agricultural Warehouse and Seed Store. JOSEPH BRECK & CO.

Massachusetts Horticultural Society.

The Rooms of the Massachusetts Horticultural Society, 23 Tremont Row, are open for the public every Saturday morning, from 10 till 12 o'clock.

NEW ELEMENTARY WORK ON BOTANY.

Peter Parley's Botany; with descriptions of Trees, Shrubs and Plants; with a large number of fine engravings.

The publishers invite Teachers, and others interested in this subject, to examine this work, as they believe it will be found one of the most practically useful in use, being a complete manual of Botany for the adult and the pupil.

Parley's Cyclopaedia of Botany.—This work appears to be exactly what is wanted by young persons and in families. It not only contains the strictly scientific part of the subject, in an introduction and very full and complete genera of Plants, but it also contains a copious glossary of terms, and what is most important, a Dictionary of Plants, of nearly 3000 pages, containing familiar descriptions of all the most interesting trees, plants, and shrubs.—These are alphabetically arranged, with an English index, so that the reader may immediately turn to any plant he wishes to read about. The work is illustrated by over 200 engravings, and is sold very cheap.—*Boston Paper.*

For sale at the New England Farmer Office, 51 & 52 North Market Street. JOSEPH BRECK & CO.

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land situated on Nonantum Hill, in Newton, 5 1-2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises. L. A. WHEELRIGHT.

July 16th.

SCYTHES AND RAKES.

Just received at the Agricultural Warehouse and Seed Store, a complete assortment of Garden and Field Tools, consisting in part of

- 100 dozen Hall's Rakes, superior.
- 100 do. Weather & Eddy's, do.
- 200 do. Common do.
- 25 do. English Cast Steel Grass Scythes.
- 10 do. do. do. Cradle do.
- 10 do. do. do. Border do.
- 100 do. Round Scythe Stones.
- 100 do. Square do.
- 100 do. Cast Steel Garden Hoos.
- 100 pair Grass Shears.
- 100 do. Pruning do.
- 100 do. Fruit do.
- 50 dozen Patent Sheep Shears.
- 20 do. Pruning do.
- 20 do. do. Saws.
- 25 do. Budding Knives.
- 25 do. Pruning do.
- 20 do. Edging do.
- 25 do. Breaking up Hees.
- 100 do. Garden do.
- 50 do. Dutch do.
- 20 do. Bill and Drier Hooks.
- 10 do. Grass do.
- 50 do. Garden Rakes.
- 500 pair Chains, for tying up cattle.
- 500 do. Trace Chains.
- 25 dozen Halter do.

—ALSO—

- 300 dozen Patent Scythe Smutths, superior.
- 100 do. Cast Steel and other Shovels.
- 1000 do. Rifles, 500 do. Scythe Stones.
- June 27, 1837.

ALDERNEY STOCK FOR SALE.

For sale a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27

FOR SALE OR TO LET.

A pleasant and convenient house in complete repair situated on the Worcester Turnpike, 5 1-2 miles from Boston and 2 miles from Brighton market. The house contain contains 9 large rooms, and has a barn, chaise house and sheds attached. Also, with the same, 3 acres of mowing and tillage land and 1 1-2 acres wood land. An adjoining lot of 5 acres can be had, if desired. Three quarters of the purchase money can remain upon a mortgage. If not sold, the house will be let to a good tenant. Enquire of D. HOLBROOK No. 51 Court St. Boston, or on the premises. June 13, 1838.

SITUATION WANTED.

As Gardener, by a young man of practical knowledge and can be well recommended. A Situation West or South would be preferred. Address R. B. through the office of this paper.

MISCELLANEOUS.

PUTTING A BOY TO SCHOOL.

The following sketch, drawn as it is to the life, we commend to our readers for its dry and sober humor.

Mr Squeers was standing in a box by one of the coffee-room fire-places, fitted with one such table as is usually seen in coffee-rooms, and two of extraordinary shapes and dimensions made to suit the angles of the partition. In a corner of the seat was a very small deal trunk, tied round with a scanty piece of cord; and on the trunk was perched—his lace-up half-boots and corduroy trowsers dangling in the air—a diminutive boy, with his shoulders drawn up to his ears, and his hands planted on his knees, who glanced timidly at the school-master from time to time with evident dread and apprehension.

'Half past three,' muttered Mr Squeers, turning from the window, and looking sulkily at the coffee-room clock. 'There will be nobody here to-day.'

Here the little boy on the top of the trunk gave a violent sneeze.

'Halloo, sir?' growled the school-master, turning round. 'What's that, Sir?'

'Nothing, please Sir,' replied the little boy.

'Nothing, Sir?' replied Mr Squeers.

'Please Sir, I sneezed,' rejoined the boy, trembling till the little trunk shook under him.

'Oh! sneezed, did you?' retorted Mr Squeers. 'Then what did you say—nothing, for, Sir?'

In default of a better answer to this question, the little boy screwed a couple of knuckles into each of his eyes and began to cry, wherefore, Mr Squeers knocked him off the trunk with a blow on one side of his face, and knocked him on again with a blow on the other.

'Wait till I get you down into Yorkshire, my young gentleman,' said Mr Squeers, 'and then I'll give you the rest. 'Will you hold that noise, Sir?'

'Ye—ye—yes,' sobbed the little boy, rubbing his face very hard with the Beggar's Petition in printed calico.

'Then do so at once, Sir,' said Squeers. 'Do you hear?'

'Mr Squeers,' said the waiter, looking in at this juncture; 'here's a gentleman asking for you at the bar.'

'Show the gentleman in, Richard,' replied Mr Squeers, in a soft voice. 'Put your handkerchief in your pocket, you little scoundrel, or I'll murder you when the gentleman goes.'

The school-master had scarcely uttered these words in a fierce whisper, when the stranger entered. Affecting not to see him, Mr Squeers feigned to be intent upon mending a pen, and offering benevolent advice to his youthful pupil.

'My dear child,' said Mr Squeers, 'all people have their trials. This early trial of yours that is fit to make your little heart burst, and your very eyes come out of your head with crying, what is it? Nothing; less than nothing. You are leaving your friends, but you will have a father in me, my dear, and a mother in Mrs Squeers. At the delightful village of Dotheboys, near Greta Bridge, in Yorkshire, where youth are boarded, clothed, booked, washed, furnished with pocket-money, provided with all necessaries—'

'It is the gentleman,' observed the stranger, stopping the school-master in the rehearsal of his advertisement. 'Mr Squeers, I believe, Sir?'

'The same, Sir,' said Mr Squeers, with an assumption of extreme surprise.

'I am in the oil and color way. My name is Snawley, Sir,' said the stranger.

Squeers inclined his head as much as to say, 'And a remarkable pretty name, too.'

The stranger continued. 'I have been thinking, Mr Squeers, of placing my two boys at your school.'

'It is not for me to say so, Sir,' replied Mr Squeers, 'but I don't think you could possibly do a better thing.'

'Hem!' said the other. 'Twenty pounds per annum, I believe, Mr Squeers?'

'Guineas,' rejoined the school-master, with a persuasive smile.

'Pounds for two, I think, Mr Squeers,' said Mr Snawley solemnly.

'I don't think it could be done, Sir,' replied Squeers, as if he had never considered the proposition before. 'Let me see; four fives is twenty, double that, and deduct the—well, a pound either way shall not stand betwixt us. You must recommend me to your connection, Sir, and make it up that way.'

'They are not great eaters,' said Mr Snawley. 'Oh! that doesn't matter at all,' replied Squeers.

'We don't consider the boys' appetites at our establishment.' This was strictly true; they did not.

'I should wish their morals to be particularly attended to,' said Mr Snawley.

'I am glad of that, Sir,' replied the school-master, drawing himself up. 'They have come to the right shop for morals, Sir.'

'You are a moral man yourself,' said Mr Snawley.

'I rather believe I am, Sir,' replied Squeers. 'I have the satisfaction to know you are, Sir,' said Mr Snawley. 'I asked one of your references, and he said you were pious.'

'Well, Sir, I hope I am a little in that way,' replied Squeers.

'I hope I am also,' rejoined the other. 'Could I say a few words with you in the next box?'

'By all means,' rejoined Squeers, with a grin. 'My dears, will you speak to your new playfellow a minute or two? That is one of my boys, Sir.—Belling his name is,—a Taunton boy that, Sir.'

'Is he indeed?' replied Mr Snawley, looking at the poor little urchin as if he were some extraordinary natural curiosity.

'He goes down with me to-morrow, Sir,' said Squeers. 'That's his luggage that he is sitting upon now. Each boy is required to bring, Sir, two suits of clothes, six shirts, six pair of stockings, two night-caps, two pocket-handkerchiefs, two pair of shoes, two hats, and a razor.'

'A razor?' exclaimed Mr Snawley, as they walked in the next box. 'What for?'

'To shave with,' replied Squeers, in a slow and measured tone.

There was not much in these three words, but there must have been something in the manner in which they were said, to attract attention, for the school-master and his companion looked steadily at each other for a few seconds, and then exchanged a very meaning smile.

'Up to what age do you keep boys at your school then?' he asked at length.

'Just as long as their friends make the quarterly payments to my agent in town, or until such time as they run away,' replied Squeers. 'Let us understand each other; I see we may safely do so. What are these boys;—natural children?'

'No,' rejoined Snawley, meeting the gaze of the school-master's one eye. 'They an't.'

'I thought they might be,' said Squeers coolly. 'We have a good many of them; that boy's one.'

'Him in the next box,' said Snawley.

Squeers nodded in the affirmative, and his companion took another peep at the boy on the trunk, and turning round again, looked as if he were quite disappointed to see him so much like other boys, and said he should hardly have thought it.

'He is,' cried Squeers. 'But about these boys of yours; you wanted to speak to me?'

'Yes,' replied Snawley. 'The fact is, I am not their father, Mr Squeers. I'm only their father-in-law.'

'Oh!' is that it? said the school-master. 'That explains it at once. I was wondering what the devil you were going to send them to Yorkshire for. Ha! ha! Oh, I understand now.'

'You see I have married the mother,' pursued Snawley; 'it's expensive keeping boys at home, and as she has a little money in her own right, I am afraid (women are so very foolish, Mr Squeers) that she might be led to squander it on them, which would be their ruin, you know.'

'I see' returned Squeers, throwing himself back in his chair, and waving his hand.

'And this,' returned Snawley, 'has made me anxious to put them to some school a good distance off, where there are no holidays—none of those ill-judged comings home twice a year that unsettle children's minds so—and where they may rough it a little—you comprehend?'

'The payments regular, and no questions asked, said Squeers, nodding his head.

'That's it, exactly,' rejoined the other. 'Morals strictly attended to, though.'

'Strictly,' said Squeers.

'Not too much writing home allowed, I suppose?' said the father-in-law, hesitating.

'None, except a circular at Christmas, to say that they never were so happy, and hope they may never be sent for,' rejoined Squeers.

'Nothing could be better,' said the father-in-law, rubbing his hands.

Names of well known physicians in different parts of the country.

Dr Graves,
Dr Coffin,
Dr Pilsbury,
Dr Physic,
Dr Toothaker,
Dr Slaughter,
Dr Kilham, pronounced Kill'em.

These titles are enough to frighten a hypochondriac out of life.

IMPROVED PROSPECTS OF GOLD MINING.—Various accounts have lately been published of an improved smelting process, discovered in Europe, by which not only a saving of expense, but a great increase in the amount of metal produced, is effected. If there is no mistake in these accounts, an important change is about to be effected in the productive-ness of the mines of this precious metal.

For the New England Farmer.

ARLEY'S CYCLOPEDIA OF BOTANY. Boston: Wells, Jordan & Co.

This is a handsome book of 400 pages, and illustrated by about 300 engravings. In several respects it possesses advantages over any other work we have seen on Botany. It is calculated at once to serve the purpose of the scientific student, and the uninitiated enquirer. The general principles of science are laid down in an extensive introduction, which will be found interesting to every reader. But the most original portion of the work, is the Dictionary of plants, containing, as we think, the most scientific and familiar descriptions of several hundred species of trees, shrubs and plants. These are generally brief, but many of them, relating to the productions of our own country, are particularly interesting. The descriptions are frequently spiced with queer extracts from old botanists, and frequent references to manners, customs and opinions, which relate to the vegetable kingdom. It is, on the whole, a work which we would be inclined to throw down the barriers of hard words, and knotty technicalities, which have hitherto surrounded the science of botany. If placed in the hands of a child, or a school, it will entice persons to read, and thus lead them on to a knowledge of the subject.

It ought to be in the library of every family, and of all our schools and academies. Botany is a study which easily sticks its roots into the human mind, and when once established, will not be so easily to grow. It is of all the sciences the most interesting, and in its tendency, is more than any other, fitted to impart pure moral influences. Nothing can better train the heart than the sweet companionship of flowers. The roaming over field and hill, and valley, in search of nature's most beautiful productions, is alike healthful to the body and to the soul. We are therefore interested to see many young botanists in this country as possible, and therefore commend this volume to all friends of mental improvement. We give an extract showing the descriptions referred to above.

LEX. Holly. 4-3. Calyx inferior, one-leaved-four-toothed, permanent; corolla wheel-shaped, four elliptical segments or petals, much larger than the calyx; filaments awl-shaped, shorter than the corolla; anthers small, two-lobed; germen globose; styles none; stigmas four, obtuse, persistent; berry globular, four celled, each cell one-celled; seeds oblong, pointed.

I. OPA'CA, American Holly: leaves ovate, acute, spiny, smooth, tough, shining, of a rich green above, lighter beneath; fascicles of flowers lax, peduncles compound; calyxes acute, smooth; fruit ovate; flowers numerous, scattered, small, greenish, white; June. A small tree, but one of the most interesting in the American forests. In favorable situations it grows to the height of forty feet, with a diameter of twelve or fifteen inches. The foliage is singular, and rarely equalled in the richness of its color. It is an evergreen, and on that account doubly interesting, as we have few that are not of

the cone-bearing species. Its flowers, which are scattered about the base of the older branches, are succeeded by red berries, which remain until late in the autumn.

This tree is not very abundant, but it is pretty generally disseminated, being found in all parts of the United States, excepting, perhaps, the northern parts of Maine, Vermont, and New Hampshire. The wood is fine-grained, heavy and compact; the albumen very white, from which it is sometimes called *White Holly*. It is used for the keys of piano fortes, and a variety of other purposes.

I. CANADENSIS, Canadian Holly; leaves oblong, acuminate, entire, or subserrated at the end; peduncles long, slender, axillary, one-flowered; flowers small, light green; corolla four-cleft, the segments acute, spreading; stemans long as the corolla; berries scarlet. Flowers in May; height six feet; grows in swamps.

I. CASSINE, Brown-leaved Dahoon: leaves alternate, distant, evergreen, lanceolate, attenuated both ways, serrated at the end. Flowers white; August; height twelve feet. This and another *I. vomitoria, South Sea Tea*, have bitter leaves, of which the Indians make a tea for an emetic. At a certain time of the year they visit the coast where these shrubs abound, and lighting their fires on the ground, boil a large quantity of the leaves, and drink about a pint each of the decoction, which in a short time induces a free and easy vomit. After pursuing this course, drinking and vomiting, for two or three days, they find themselves about right, and every one taking a large bundle of the branches, they return to their homes.

Italian Spring Wheat.—The crops of the Italian spring wheat now harvesting, are represented as very fine.—*Baltimore Chronicle*.

THEORY OF THE ACTION OF LIME ON SOILS, MANURE, &c.

The action of lime is threefold; each distinct. 1. It is a *Neutralizer*: 2. A *Decomposer*: 3. A *Converter*. 1. I have already alluded to some acid soils: free phosphoric acid, geic, acetic, and malic acids, also occasionally exist in a free state in soils. Here lime acts as a neutralizer. 2. Soils may contain abundant geates; particularly geate of alumina, the least of all demanded by plants. Long formed and sun-baked, they are scarcely acted on by rain or dew, and are almost useless. Here lime, by decomposing these metallic and earthy geates, forms a combination, which, in its nascent state, is readily dissolved. If the carbonate of lime acts better than the hydrate, it is because, following a well-known law, double decomposition is easier than single. If any acid geine exists in the soil, or any free acids, carbonic acid is then liberated; it acts on the geate of lime, supergeates result, and these are easily soluble.

3. The great use of lime is as a *converter*; turning solid and insoluble, nay, I go further, solid vegetable fibre, into soluble vegetable food. Here is the great puzzle, the point where our philosophy seems to leave us; giving us our choice, to refer this action to one of the numerous cases of mysterious '*catalytic*' change, with which we are becoming every day more and more familiar, or to explain the process by referring the whole to *saponification*. I use this word as conveying to you at once what I mean;—but I do not mean to say that the product of lime and vegetable matter is soap; but I cannot make myself more intelligible to a farmer than by saying, this lime makes compounds of vegetable matter, just as it makes soapy compounds of oil and fat. The action of lime on geine I take to be of the same nature, as its action on oils and fat. It is well established that animal and vegetable oils and fats are converted into acids by the action of alkalis, earths, oxides, and even by vegetable fibre itself. The general law is, that whenever a substance, capable of uniting with the acid of fat or oil, is placed in contact with fat or oil, it determines the production of acid. Now we have seen that alkali produces a similar change on geine; it develops acid properties. I go further, if alkali has converted vegetable oil and geine into acids, I see no reason why a similar action may not be produced by all those substances which act thus on oil. Hence lime, earths, and metallic oxides, convert geine into acid: as fast as this takes place, so fast it becomes soluble. Then too the long action of air on insoluble geine, rendering it soluble, is it not analogous to the action of air on oils? Both evolve in this case, vast volumes of carbonic acid, the oil becomes gelatinous and soluble in alkali; does not a similar change occur in geine? It is possible that during the action of lime on geine, a soluble substance may be produced, bearing the same relation to this process that glycerine does to saponification. These views you will see need to be followed out experimentally. If found tenable, the most signal benefit will result. We place ma-

nures on a new foundation, on which great practical results may be erected.

Practical application of the theory of the action of lime.

Taking the preceding principles as our guide, we may lay down a few general principles for the application of marls.

1. Enough ought to be applied to neutralize all the free acids in a soil; which may be known by its ceasing to produce acid plants, such as sorrel and pinc. Generally, however, the amount required for this purpose is small.

2. It will be serviceable to add enough to convert the earthy geates of a soil into geate of lime. The richer a soil is, the greater we may conclude is the quantity of geates which it contains.

3. It will be serviceable to add enough to convert all the insoluble geine and vegetable fibre in a soil into soluble geine. Hence the richer a soil is, and the more manure is added, the more marl will it bear with benefit. Indeed, *there appears to be no danger of adding too much marl, provided a sufficient quantity of manure be also added.* Ignorance of this principle, I apprehend, is the source of most of the failures that have occurred in the use of lime upon soils. Farmers have supposed that its action was like that of common manur, viz. to serve as direct nourishment to the plant; whereas it only *cooks the food*, if I may be allowed the expression, which exists in the soil, or is added along with the lime. In nearly all cases of over marling which I have read of, a fresh supply of manure has been found to be the remedy; which shows the truth of the above principle. Agriculturalists have spread marl alone, or with very little manure, upon land that has been worn out, that is, whose geine has been exhausted; and because such soils have not thereby been recruited, they have inferred that lime was injurious. Without acids, or geine, or geates, or vegetable fibre, to act upon, much excess of lime appears to operate injuriously, so as to diminish, instead of increasing the crop. They have also expected a sudden and surprising increase of fertility: whereas in some cases the chief benefit seems to consist in causing the land to produce for a greater number of years, by preventing the ultimate decomposition and escape of the organic matter. In general, however, it will add also to the yearly product: but those who employ marl or lime in any form, ought to moderate their expectations that they may not be disappointed, and to be satisfied if they can slowly and surely improve their lands, as they most assuredly can do, by this substance, provided they do not expect to accomplish it by the use of lime alone.—*Hitchcock's Examination of the Geology of Mass.*

From the New York Observer.

FLAX-SEED MEAL.

MR EDITOR.—I observe a communication in your paper of last week, on the subject of feeding cows on still-house slops. On the immorality of encouraging such a practice, your readers would probably so generally concur, that I need say nothing on that point; and the unhealthiness of the flesh of cows so fed, as an article of diet, or the inhumanity of condemning an animal to which we are so much indebted to such fare, need not be insisted on. My immediate object is, to direct the attention of your readers to a kind of feed for cows and other cattle, as healthful to them and profitable to the owner, as the slops are pernicious and waste-

ful. I allude to the flax-seed meal, after the oil has been expressed from it; the value of which, as a feed for cattle, appears to be but little known in this part of our country. The superiority of the cattle raised in those parts of the country where flax-seed mills are established, has long been a matter of notoriety; though few, excepting those residing in such localities, are aware that it is chiefly owing to the kind of feed supplied by them. I have been informed by a farmer of Pennsylvania, who has used the flax-seed meal for years, that, mixed with other feed, it is the best thing that can be given to cows for increasing the quantity and enriching the quality of their milk; and at the same time getting them into good condition for the butcher. He says that they will give, on an average, at least one third more milk than if fed on other food; and a little given to horses, also, very much improves their appearance, making their skin sleek and glossy. An experiment I have just made will, I think, justify me in endorsing his opinion. I have a cow which a few weeks since might well have claimed affinity to Pharaoh's lean kine, and she gave so little milk, that I began to consider her a "cumber of the ground." As no butcher would look at her, it occurred to me that I would try the flax-seed meal which had been so highly commended; and the effect exceeded by most sanguine hopes. Within the space of a few weeks, her milk has increased to nearly three times the quantity, whilst her flesh has increased so much and her general appearance has so much improved, that her former keeper did not know her when shown to him a few days since. I need only add, that she has been called one of the best looking cows in the neighborhood, and I have been offered a handsome advance upon her cost. Although living at some distance from the city, the meal I used was procured there; and your readers may be informed that there is an establishment there, which grinds as much, perhaps, as would supply all the milkmen of the city. I have been informed that it is so much prized as feed by the agriculturists of Europe, that it is exported from this country; while its value is comparatively unknown here. If so, you will doubtless render a service to the agricultural community by directing their attention to it. Yours, RUSTICUS.

P. S. The manner of feeding generally practised is, to give two or three quarts in the morning before the cows are turned out to pasture, and as much in the evening after their return, mixed with other feed. It may be given dry, but it is better for them and more tasteful, if put to soak in water for some hours previous. The common mode, I believe, is, to put that in water in the evening, which is intended for the morning, and then to put to soak that for the evening. Some cattle will at first reject it; but they almost invariably become so fond of it in a few days, that they prefer it to almost any other feed. If given in very large quantity, it is thought by some to impart an unpleasant flavor to the milk. I cannot say whether this is fancy or fact; but can testify that moderately given, it improves it. In large quantities it is said to be decidedly injurious to horses. I have not tried it upon hogs, but propose to do so.

[The bad effects here mentioned, are only such as result from over-feeding with any highly nutritious substance. We understand that the meal may be procured in any quantity along the Great West-

ern Canal, by over-bidding the farmers in that region,—which dairymen in this vicinity can well afford to do.—*Ed. Obs.*]

From the New York Observer.

Having read the communications which have appeared in the Observer by R. M. H. on "Milk Deries and Distilleries," I have felt both surprised and regret that the attention of our citizens has not before been called to so important a subject. Whatever concerns health and morals, should deeply interest us all, and I think, your correspondent has clearly shown, that both, to the extent the system complained of is patronised, will be sufferers by it.

But my object is, to state very briefly a few facts on the use of *impure milk*, corroborative of the views of R. M. H. as they occurred in my own family, with the hope that others may be benefited by my experience. A fine healthy child, aged about 2 months, was on account of his mother's health taken from her; and his diet, prepared by the direction of a physician, was cow's milk, and the precaution observed to use the milk of one dairy. But the health of the child presently began to fail, and in defiance of the most tender and assiduous care, continued to do so for many months. Medical skill did not avail to restore its health, or even to alleviate its sufferings; and at length its wasted and diseased condition destroyed all hope of rearing it. At this time a friend, conjecturing that the kind of milk on which the child was fed might have some influence on his health, desired the writer to ascertain its quality which he did not fail to do, and was grieved to learn that it was produced from distillery slush. On consulting a physician with the circumstance, the milk diet was continued, but by his advice was obtained from a dairy kept on natural food. This, he believes, was the means, in the hand of Providence, of saving the child's life. The advantages of the change were almost immediate. But though life was saved and health mended apace, disease was probably too firmly seated in the constitution to be ever entirely removed. He still lives, and may be spared many years; but his health, compared with that enjoyed by other children of the same family, is feeble. He is often sick, and through life will doubtless suffer from the consequences of a pernicious diet.

The writer of this article would not attach undue importance to a single fact, unsupported by other evidence. But subsequent observation convinces him that he did not misjudge in the case of his child. Other cases very similar have come to his knowledge, and he cannot doubt, that the same cause now destroying not only the health, but also the lives of great numbers of children in this city.

SENEX.

From the Farmer's Cabinet.

CONVERSATION BETWEEN TWO EMigrants.
GRANTS.

Sir,—Permit me to narrate a conversation which passed a few days ago between two emigrants from the old country. Although the subject might strictly come under the head of either agriculture or horticulture, yet as it embraces that of *menticulture* (if you will allow me to coin a term) which nearly allied to both; perhaps the lesson which teaches will procure for it a place in your interesting pages.

John D. "Do you know why I left the o-

country and came to this? I am sure I do not, for as well to do at home, and had plenty of work all that I wanted; to be sure, at first sight the wages that are given here appear higher than they are with us, but if you put *this and that together*, do not think there is much in favor of this coun-

George W. "I am sure you do not wish me to see you why you emigrated; but if you had gone to the English island of Jersey, perhaps you would have had the question put to you, as they sometimes do to emigrants, 'do you fly from justice or from your creditors?' I think it extremely unwise in sons coming to this country to pretend that they do all they could wish for at home; and have had, sometimes, to remind such of the Quack Doctors address, 'Gentlemen, you must not suppose that I came here for want—* * * I had enough that at home?' But to be serious, you and I came from the same parish in England where we were farming servants, and I wonder you should soon forget the hardships which we were driven every winter, when our masters used to turn their out-door servants, who were then compelled to labor upon the roads as *paupers*, dragging level carts like horses, and at wages which were not sufficient to keep body and soul together. I am open to have in my possession one of the printed papers issued by the *Guardians of the Poor* to the surveyor of the roads, which I will read to you; it states the rates of wages which he was to pay, and which you will have too much reason to know correct. The original paper is in the hands of the editor.

RATE OF WAGES TO BE PAID PER WEEK.

s. d.	
5	0
6	6
7	3
8	0
8	6
8	0
9	0

The number of children, in all cases, to be understood as of children who can earn nothing themselves, but are supported solely by their parents.

No boy to be employed on the Roads where the number of children does not exceed three.

No boy living with his parents to be employed on the Roads, who is under seventeen years of age.

Only one boy of a family to be employed, and his wages in no case to exceed the above mentioned.

The wages of the boy in all cases to be paid to the parents.

Where there are more than three children in the family, all beyond three will be taken in the House of Industry if the parents wish it.

Single men out of service to have 5 shillings per week only in those cases where they are not maintained by the parent.

And now let us put *this and that together*, as you proposed, and see if there is not some difference in favor of the wages in this country. I have hit upon a very simple plan of deciding this question;

it is to expend a man's wages for one week, and see what can be obtained for the same. I get a dollar and a quarter a day, and you do the same: to be sure we work hard for it, but that is no hardship as we are able—'tis a great mistake to suppose it is wrong to obtain one's bread by the sweat of one's brow, and so the magistrates think, for when they determine to punish a man most severely they send him to the Penitentiary and *keep him* without permitting him to work—well then, for \$7,50, a (week's wages,) may be bought

A new hat,	\$0 75
New pair of shoes,	1 00
New pair of trousers,	1 00
New umbrella,	0 75
25 lbs. of meat,	1 25
1 lb. of tobacco,	0 10
1 lb. of tea,	0 25
1 lb. of coffee,	0 13
3 lbs. of sugar,	0 21
New gown for wife,	0 56
An acre of free land,	1 50
	\$7 50

Now tell me, is there any other country in the world where this can be done? Why don't you speak?

I will leave you to lay out the wages for a week, such as we used to receive in the old country, for they are so small that I fear if I were to attempt to handle them, they would *slip through my fingers.*"

John D. was struck speechless, but when he recovers his senses he will be the better for the conversation so long as he lives.

I am, sir,

An Emigrant, and

YOUR SUBSCRIBER.

ACCOUNT CURRENT WITH A PIG.

MR HOLMES:—I write that farmers and pork raisers may learn whether it is profitable to go largely into the business in this State or not. I have to this end opened an account current with a pig, for which I gave on the first of October, at a month old,

\$1,50

Kept it until it was 16 months old, and then slaughtered it. 14 months of which time I kept it on raw and boiled potatoes—allowing it a peck a day; soon after weaning it did not need that amount, but it had milk or something as expensive; which results in his consuming, in the 14 months, 105 bushels,—at 20 cents the bushel, amounts to

21,00

The month on its dam, and 14 months on potatoes, as above, brings it to 15 months old; the other month (for it was not slaughtered until 16 months old,) I kept him on Barley meal, at 67 cents the bushel, and it eat a half peck per day,—which amounts, for the last month, to

2,40

Tax,

30

I charge nothing for attendance, risk, &c., being more than paid in offal and manure,

25,30

When slaughtered, it weighed three hundred pounds, which, at 8 cents the pound, brought me

\$24,00

Loss,

1,20

But if potatoes cost only ten cents per bushel, (which, in fact, is all they cost in raising,) then deduct from my charges against it

10,50

Making the profit \$14,70.

Twelve such would give a profit of \$176,40—a pretty item and plenty of manure.

Some may suppose the pig was not so expensive as I have made it—that it would not eat a peck of potatoes a day, &c. &c. If potatoes are worth more than I have put them at, pork should be too. I write, hoping to hear from others. No doubt September pigs are most profitable—they eat much less than earlier ones in winter; whereas early pigs eat, the first summer, what the later ones should have,—and on New Year's day, when the September pigs are 16 months old, there will be very little difference in their size, if the late ones are kept warm the first winter. Some have supposed an early spring pig on the whole most profitable to kill on the first of January following: respecting which, I hope some farmer will communicate his views through the *Maine Farmer*. PEN AND INK.

Maine Farmer.]

INFLUENCE OF THE MOON ON TIMBER.—A very intelligent gentleman, named Edmonstone, who was nearly 30 years engaged in cutting timber in Demarara and who made a number of observations on trees during that period, says that the moon's influence on trees is very great. So observable is this, that if a tree be cut down at full moon it will immediately split as if torn asunder by the influence of great external force. They are likewise attacked much earlier by the rot than if allowed to remain to another period of the moon's age. Trees, therefore, which are intended to be applied to durable purposes, are cut only during the first and last quarters of the moon, for the sap rises to the top of the tree at full moon, and falls in proportion to the moon's decrease.

Strong facts in regard to Horse Racing.—A writer in the Louisville city Gazette, thus tersely presents this matter:

"Races, it is said, improve the breed of horses. And what if they did, if they degrade the breed of men. But I doubt the truth of the position. Some few startling or stubborn races are on the other side. I never heard of races in Arabia, yet the best horses and the best blood in the world are there. The great racing stock of England and America came from the blood of the Godolphin Arabian. There are no races in New England, yet the New England horses in this country are worth from fifty to a hundred per cent. more than southern horses. The horses for the plough, dray, saddle, stage, coach, or gig, in New England, would bring under the hammer far higher prices in racing sections of the country, than their own horses. Racing only improves the breed of race horses. I was told in Virginia, by the stage drivers, that their best horses were brought from Vermont and New Hampshire, the Green Mountain horses are the best in the country for symmetry, strength, fleetness and endurance. Yet there is no racing in New England. Racing, then, is surely not essential to make good horses."

The operation of the new Banking law in New York, seems to be preparing the way for another blow-up, on a more extensive scale than has been known before. Fifty-Million Banks are talked of at every corner.—*Salem Gaz.*

TEMPLEMOYLE AGRICULTURAL SCHOOL.

The Agricultural Seminary of Templemoyle originated at a very numerous meeting of the North west of Ireland Farming Society at Londonderry, and it was at first intended that it should consist of two establishments, taking Mons. Fellenberg's Institution at Holfvyl in Switzerland in some degree as the model: the first to be a school affording instruction in every science and accomplishment aimed at by the children of the higher orders; the second for the education of the sons of respectable farmers and tradesmen, in the hope of disseminating the advantages of an improved system of farming with greater certainty, by combining the practice and theory of it in the instruction of those who were afterwards to make agriculture their pursuit. It was hoped that the extended scale of the institution would have allowed of a greater variety of masters and lecturers, and that the profit derived from the superior school would have contributed towards the maintenance of the secondary one; but a short experience convinced the subscribers that such a scheme was impracticable without much larger and more certain funds than they could rely on; they then gave their undivided attention to the agricultural seminary, which through their increasing exertion has attained such eminence as may justly entitle them to look forward with confidence to its increasing usefulness, and to its becoming a model for establishments of a similar nature in other parts of Ireland.

The school and farm of Templemoyle are situated about six miles from Londonderry; about a mile distant from the mail-coach road leading from Londonderry to Newtownavady. The house, placed on an eminence, commands an extensive and beautiful view over a rich and highly cultivated country, terminated by Lough Foyle. The base of the hill is occupied by a kitchen and ornamental garden, cultivated by the youths of the establishment, under an experienced gardener. The ground between the garden and house is laid out in beds in which all the different grasses, clovers, &c., are cultivated with the greatest care. The house is in the form of a ||—||, with range of farming offices behind, containing spacious, lofty and well ventilated school rooms, refectory, dormitories, apartments for the masters, matron, servants, &c.

Each pupil occupies a separate bed; the house can accommodate seventy-six, and the number of pupils amounts to sixty. They receive an excellent education in reading, writing, and arithmetic; book-keeping, mathematics, land-surveying, and geography. This department is managed by an excellent head master and assistant master, both resident in the house. The pupils are so classed that one half are receiving their education in the house, while the remainder are engaged in the cultivation of a farm of 130 Cunningham or 165 statute acres, in the management of which they are directed by the head farmer, an experienced and clever man, a native of Scotland, who has a skilful ploughman under him. The pupils who are employed one part of the day on the farm, are replaced by those in the school, so that the education always advances in and out of doors *pari passu*.

The pupils are thus instructed in all the practical parts of farming, and are also several times a week on the theory of agriculture. They are made acquainted with all the properties of different soils, the manures most applicable, and the crops best adapted to each; points in which most of our practical farmers displayed great ignorance.

They are also made acquainted with all the numerous varieties of cattle, and their qualities, such as early maturity in some breeds, hardihood in others, and have strongly impressed on them that one of the most essential points in farming, is to select the cattle and the crops best adapted to the situation, soil, &c.

The stables, harness-rooms, cow-houses, winter-feeding houses, piggeries, barn, tool-houses, are arranged in the best manner, and the pupils are required to keep them and their contents in the highest order. A respectable and intelligent matron has the superintendence of the dairy, cooking, and cleaning the house, and the charge of the domestic servants.

In sending a pupil to Templemoyle, it is necessary to have a nomination from one of the shareholders, or from a subscriber of 2l. annually. The annual payment for pupils is 10l. a year; and for this trifling sum they are found in board, lodging, and washing, and are educated so as to fit them for land-stewards, directing agents, practical farmers, surveyors, schoolmasters, or clerks.

From fifteen to seventeen is the age best suited for entrance at Templemoyle, as three years are quite sufficient to qualify a student possessed of ordinary talents and a knowledge of the rudiments of reading and writing, to occupy any of the above situations.

N. B.—Upwards of two hundred young men, natives of sixteen different counties in Ireland, have passed through or remain in the school. Of these between forty and fifty have been placed in different situations, such as land-stewards, agents, schoolmasters and clerks, or employed on the ordnance survey. Nearly one hundred are now conducting their own or their fathers' farms in a manner very superior to that of olden time; and the accounts of those who have been placed from the seminary are such as to gratify the gentlemen who have its interest at heart, and to convince them that the good seed sown is producing an ample and valuable harvest.

Templemoyle, Oct. 14, 1837.

[It gives us unqualified pleasure to lay before our readers the above gratifying account of an institution so eminently calculated to confer lasting benefits upon the country. We have been long strenuous advocates for the establishment of agricultural schools in all parts of Ireland, feeling assured that they would ultimately be the means of breaking down those absurd prejudices which have been hitherto the most insurmountable obstacles with which agricultural improvement had to contend.]—*Editors British Farmer's Magazine.*

NOTICE OF AN EXPERIMENTAL FARM IN FRANCE.—BY COL. LE COUTEUR.

It is situated in a beautiful and fertile country, well wooded and watered, but cultivated by the Breton farmers just as their fathers tilled it 200 years since. The college or experimental farm appears like a garden in a smiling wilderness, so far as culture goes. I rose at four in the morning, in order to witness the whole course of labor in this interesting institution.

There were from 80 to 90 students under the superintendence and tuition of a director, a professor of agriculture and agricultural chemistry, a veterinary surgeon, and an agricultural implement maker. At half past four they took a slight repast, and as the clock struck five, all were employed; some in

harnessing the horses and oxen, others in carting out and properly disposing the implements in field, others set to hoeing, others weeding, so ploughing, some hay making, in a word to all various labors of the season.

The school is divided into working parties ten; at the head of each is a steady young man of experience, called the 'decursion,' who directs the work of his party. In all difficult operations a regular farming laborer is at hand to perfect them; but such is the ardor and perseverance the youths, that they rarely allow any difficulty to arrest their progress. The duty of one 'decursion' ten, is to dress, litter and feed the cattle, wash as much regularly as a cavalry corps dress their horses; also to keep the farm-yard in order. They all, in turn, are made acquainted with every thing connected with a farm, whether in regard to horses, oxen, cows, pigs, or manures. These last are made and husbanded with the greatest care, mixtures being formed of sweepings, leaves, weeds that had not seeded, in alternate layers with stable manure.

The drainings of the stables and straw-yard, run into a tank, to be pumped out when required liquid manure, which is the best, most portable but least known in this country.

The learned professor M. Donku, who is an admirable practical farmer, as polite and communicative as he is learned, complained that he had no sufficient quantity of manure. I urged him to burn the underwood and decaying timber of the large adjacent forests, through which wide roads were cut, which would enable him to obtain an inexhaustible supply of ashes the best of all manures either for turnips and wheat; the cartage of ashes being easy, and the quantity required to dress the land not being great; in which he entirely coincided.

At nine all come into their studies, when they write remarks on the various operations of the morning. From eleven to twelve is the breakfast hour. From twelve to three is the time for recreation and study, which embraces for the first class questions of the following nature:—"His farm 600 acres, one eighth of which is always to be beet-root, is to be divided into the most eligible rotation of crops; show the most profitable courses and describe the nature and the chemical properties of the soil in each field, the proper manures to be applied to them, the quantity of seed required for the crop, its culture by previous ploughings, after-hoeing or weeding, and the cost and labor and the probable return."

The plans of farming given by some of the youths, would have done credit to an experienced farmer, and demonstrated clearly that though the theory alone in farming is an absurdity, the combination of the practice with scientific acquirement will soon operate great melioration in the agricultural world. From three till seven they prosecute their labor in the fields, being eight hours work in the day. They then come in for dinner. At eight the director receives the report, from every decursion, of the day's work of his party of ten. He then orders the work for the ensuing day, giving concise lecture on the subject when necessary to the culture of any unusual crop. A library of agricultural works is open to the students till bedtime, quarter past nine. * * * The crop that appeared to me to be most carefully cultivated, was beet-root in drills, which produced per acre about 750 pounds of sugar, selling at ten pence per lb. as fast as it could be manufactured.—*Cultivator.*

THE MORUS MULTICAULIS.

It is known to the public a considerable distance round Burlington, that large quantities of this most invaluable tree are now growing in the vicinity of this city. A larger quantity would have been raised the present year, but for the cold wet spell of weather which occurred at the planting season, causing numbers to rot in the ground; this was succeeded by a drought of three weeks duration, accompanied by intensely hot weather, producing effects decidedly more injurious to the young sprouts, than the cold damp which preceded it. From these causes the crop of trees is very far short of what was expected. The plants which survived these disasters, are now growing with a luxuriance of foliage that realizes to the mind by a single glance of the eye, the sterling value of the *Multicaulis* for the production of silk. It is true that different modes of planting, and a different course of cultivation, have produced different quantities as well as different qualities of trees, some having succeeded better than others. But from the stock of trees now growing, it is certain that the short supply will be more than compensated by the high prices they will command. There can be no doubt that trees will sell higher the coming fall and spring than they have ever done yet. The character of the *Multicaulis* is now well established in the middle states, from practical acquaintance with it, and it has lived uninjured, in the open fields of Burlington during the whole of the past winter. As its value becomes better known, the demand for it increases from all parts of the U. States. The high bounties on the production of silk which are given by the States of New Jersey and Pennsylvania, have been found sufficient to pay all the expense of producing the cocoons and of reeling the silk, making the whole produce clear profit. This fact, when added to that of an acre of ground planted with trees two years old, producing a net profit of \$300 to \$400 per annum, has stimulated the farmers in various sections of the middle states to embark largely in the business of planting trees for the sole purpose of raising silk.

From notices we have read in our exchange papers, of nurseries in various places, an impression appears to exist that all the trees now growing throughout the country are *for sale*. Nothing could be more contrary to the fact; and those persons who expect to make large purchases of trees this fall, will find themselves greatly mistaken. Some growers in our neighborhood could not be induced to sell at *any* reasonable price. We know one instance of a company which intended going into the business last spring, with a stock of 30,000 trees, being compelled to begin with about 5000 only, such was the impossibility of getting trees. Of all the trees now growing, probably but one third are raised for sale—full two thirds being grown to feed the worms. So far as the business has progressed in Burlington, it has answered every expectation that was formed of it. Very great profits have been realized from small lots of ground, and there is every prospect of our ancient city becoming the emporium of American silk.—*Burlington Gazette*.

PLUMS.

This delicious fruit has never been very plentiful in our market; not because it has not been esteemed as a luxury, nor because pains have not been taken to produce it. We presume that there

are few fruit gardens of any note in the vicinity of our city, which do not contain a number of the trees. But a certain insect, whose nature and habits seem now to be somewhat better known than formerly, has destroyed the fruit, soon after the flowering season. The operations of this insect are performed on the fruit, which soon after drops from the tree. The young brood then emerges from the fruit, and takes up its home in the ground, till another spring gives it life in another form, when it again ascends the tree, and commits its ravages on the fruit as before. A more detailed history of this pest of the Plum tree, and its operations, is to be found in W. Kenrick's Orchardist—a work, which every horticulturist ought to keep in his library.

But we began this article chiefly for the purpose of saying, in a very brief style, that the lovers of Plums may this year have a feast. Mr POND of Cambridge is the fortunate individual who has succeeded, in spite of the *Curculio* and the *Canker-worm*, in preserving the fruit upon the tree, till its arrival at maturity is undoubted. He will have at least thirty bushels. His trees are laden beyond any thing we have ever before seen, or could have believed without seeing. Some of them are supported by eight or ten props. Altogether they present a spectacle that is rich beyond description. They are of superior kinds, but chiefly of the *White Gage*.

Mr POND has also been quite successful in some other horticultural experiments. His giant *Asparagus*, and his superior *Rhubarb*, are already well-known and celebrated. A sight of his garden is good for eyes that take pleasure in beholding the luxuriant effects of skilful horticulture.—*Boston Courier*.

For the New England Farmer.

ON SUMMER TRANSPLANTING WHITE PINE.

MR. EDITOR:—I herewith forward you some account of transplanting of the White Pine (in the cemetery now forming at Worcester, Mass.) in the months of June and July, which perhaps may be useful and interesting to some of your readers and more especially to those who are desirous of planting Pine around their dwellings, &c. as ornamental trees.

The latter end of June, I removed several trees from 10 to 12 or 15 feet in height, and I have removed several on the same principle, and shall continue so to do perhaps for some time.

The process I follow is simply to cut around the tree with a spade at some distance in such a manner that the top surface can be taken up with the roots entire; holes are then dug larger than the circumference of the roots and soil taken with the tree; the tree is easily taken up with the soil adhering to it, especially if on a pasture or upon soil where there is a plenty of leaves, &c. to cover the roots; the tree is easily taken up with the earth by running a spade underneath the root, when it may be lifted into a wheelbarrow and conveyed to the hole and carefully planted, giving a plenty of water; if very dry weather succeed it will be proper to water occasionally, and by this process I have succeeded admirably, and believe others may do the same in planting the pine in summer. It will be best if possible to plant after a shower of rain, as the earth is better prepared then for the tree, &c.

I do not pretend to point this system out as *new*,

for I am well aware there are many persons acquainted with planting evergreens in this season, but I hope if it is practised which I have reason to believe it will be by many, it will be found to answer a good purpose in removing the Pine, Hemlock, Spruce, and many kinds of evergreens.

Yours,

E. SAYERS.

TO PREVENT THE RAVAGES OF RATS IN GRAIN.—How to prevent the ravages of rats in grain after it is housed, has been an enquiry of long standing. We can never exterminate them to such a degree as not to apprehend their incursions, for a horde of these troublesome visitors will often make their appearance when we least expect them. Instinct points the way to where that provision best suited to their nature is found most plentiful. We have often found when we went to trash, our oats cut and cleaned by them, and the straw rendered unfit for any purpose whatever, even the subservient one of litter.

But every evil has a cure; and I have found *common elder* to be a preventive, and have tested its properties as an anti-rat application. When the grain is to be packed away, I scatter a few of the young branches over every layer of bundles, being mindful to have them in greatest abundance on the edges of the pile. The drying of the twigs will give the grain an odor not relished by the vermin—which scent in no wise detracts from the quality of the straw for horses, as it makes no difference with them. I have tried it successfully, a number of years, in wheat, oats and corn.—*Huntington Gazette*.

EFFECTS OF INDUSTRY ON MICHIGAN SOIL.—

One of our citizens commenced ploughing on a tract of land which he had recently purchased, within two or three miles of this place, on the 16th of April, previous to which there had been no improvement upon it. He has now one hundred and twenty acres sowed and planted to crops, including the various kinds of grain, as wheat, oats, corn, millet and buckwheat, potatoes, ruta baga, &c. He intends to get off the crops in time to sow the whole to wheat this fall, and one hundred acres beside which he has yet to break up. A few more such men would very much relieve us from the withering effect we feel from the fact that so much of our valuable lands are owned by cold-hearted grasping, selfish speculators, who will not sell them to the farmers except at exorbitant prices.—*Grand River Times*.

The Richmond Enquirer has some particulars respecting a little insect called the Chinch Bug, which threatens some injury to the crops. A correspondent says—

"This formidable little insect is now threatening destruction to our growing crops of corn. Since the commencement of harvest, they are here seen by millions of millions marching in almost solid bodies to our oat and corn fields. Several fields of corn are already visited by them to an alarming extent, the stalk literally blackened from the ground to the 1st blade. What extent of mischief they will do none can say."

Three cargoes of new wheat, from North Carolina, have been sold at New York, two at \$1.60 and the other at 1.52. The quality is uncommonly fine. Sales of new wheat at Richmond, Va. have been made at \$1.20 a 1.25; at Fredericksburg, at \$1.10 to 1.25, delivered in store.

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, AUGUST 8, 1838.

HAYING AND HAY.

The haying season in the lower part of Massachusetts is now over; and in the western part of the state it is fast progressing towards a conclusion. On highly cultivated and new lands, or lands recently laid down to grass, the crops have been large; in other situations not so large, but about one third less than the last year. We hope some of our intelligent farmers have experimented upon the modes of making hay and other matters; and will give us the results of their observation.

First, as to the time of cutting the crop. In Massachusetts, Herds Grass or Timothy is the principal grass grown. What now is the best time for mowing this grass? The general answer given by the farmers is to cut this grass when it is in the flower; or when the blossom begins to fall. By some it is maintained, and this too upon high authority, that Herds Grass is most nutritious, when it has become completely ripe; and the seed is in that state that it would vegetate perfectly if planted. We deem it a matter of considerable importance to determine this point. In Sinclair's tables of the nutritive properties of different grasses, between Timothy cut in the flower or cut when perfectly ripe, the difference in favor of its perfect ripeness is very considerable; the precise difference we are at this moment without the means of ascertaining. We do not expect from our farmers a critical exactness; but we have no doubt that many of our experienced and intelligent farmers have made careful observations of this matter, and their opinions are what we want. Let the farmers, if they can, say then what trials they have made, or what they have observed in this matter. Some persons insist that the appetite of the cattle is the best criterion; and that what they like best must be best for them. We have not the same implicit confidence in the wisdom of this bench of judges, though so much given to sage reflection in their ruminating hours. It is certain that if left to them they would much prefer to eat Indian Corn for example in a green and half-formed state; but will any farmer say that corn in this condition would yield as much nutriment as when perfectly ripe? We have great respect for animal instinct; but we have much more respect for the reason and experience, and sound judgment, based upon careful observations, of intelligent men.

A second matter of important inquiry respects the curing of clover hay. Some years since an experiment was made by the Rev. Mr Packard of Marlboro'—and another by Samuel W. Pomeroy, Esq. then of Brighton, a gentleman possessed of one of the most observing and acute minds that are to be met with, of curing clover hay by salting it, the details of which experiments were given in the Massachusetts Agricultural Repository. In these cases the clover was cut in the morning and carried in the afternoon and when packed away abundantly salted. It is said that this hay came out green, fair, and in fine condition. But there is a prejudice against this mode from a notion, perhaps not without foundation, that the quantity of salt necessary to be employed in such cases destroys in some measure the nutritive properties of the hay.

Be this however as it may, another mode has been adopted to some extent in this and neighboring states; that of cutting the clover while dry or free from wetness, and after a few hours sun upon it without shaking or spreading it abroad much, putting it in a cock; al-

lowing it to remain until it becomes well made in the cock, and merely turning it over the day of its being carried in that the bottom of the cock may become dry; then taking it into the barn. We are not certain, that we have described this method intelligibly and properly; but we hope that some of the farmers, who have cured their clover hay in this mode will set us right both as to the mode and the results.

There are other points in regard to hay, which we wish could be determined. For example is hay injured by sweating in the mow or not? Many of the farmers on Connecticut river, who were in the habit of "making their hay a great deal," have altered their course and now get it in, in a much shorter time and in a comparatively green condition. They say much labor is saved and the hay spends better for their cattle. It does not come out so bright; the top of the mow will appear even discolored and injured; and it would scarcely pass for merchantable hay in Boston, but the starved cattle eat it better and thrive as well upon it; and therefore they consider it more succulent and nutritious, than if it was as thoroughly sun dried as possible. An experienced English farmer, upon whose authority we place some reliance, was accustomed to say that hay was always better to use his expression, for "sweating well in the mow." It will certainly not do to get hay into the barn with any wetness upon it from dew or rain; but with how much of the natural moisture or sap remaining in it, it may be safe to put it away, is the point on which we solicit information.

Another point of importance respects the spreading of hay. Should it be given in a long state, or should it be cut; and if cut should it be cut finely or coarsely. We have many facts on the matter of cutting all feed for stock; but we want more facts from the careful and observing. One of the Agents of the Eastern Stage Company, who had under his charge a large number of horses, said that he preferred to give them hay cut about four inches long rather than shorter. It compelled the horses he said to chew their feed, whereas when cut short, an inch or three quarters of an inch in length, mastication was imperfectly performed. Men in all such cases are seldom without a reason; but perhaps the true reason was that his machine was not adapted to cut his feed shorter than four inches in length.

Another matter which we wish could be ascertained relates to the shrinkage of hay. How much will a quantity of hay weighing one ton when put into the barn at haymaking, weigh in the month of March ensuing; or how soon does it arrive at a condition, where it may be expected to hold its own. We have generally heard it estimated at one fifth loss in that time. We have no facts in the case; but it is obviously a point of much importance in determining the farmers, who sell hay, and the persons, who buy hay, how the price should be made up; and at what rate they can afford to sell hay from the field compared with what they may expect to obtain for it in the spring.

Counterfeit two dollar bills of the State Bank, stereotyped old plate, signed E. A. Bourne, Prest. and Geo. Homer, Cash, are in circulation, well executed. The genuine bills have "Massachusetts" over the centre of the bill, the spurious have "Massachusetts" on the end of the bill, and not over the centre. By attention to this, they may be easily distinguished from the genuine.

The public are cautioned against receiving counterfeit \$50 of the U. S. Bank, new plate, which have been recently put in circulation.

Massachusetts Horticultural Society.

Saturday, July 21, 1838.

This meeting and several gentlemen were present at this meeting. The principal business before them related to the arrangement for the annual exhibition.

On motion of Mr Grosvenor, it was voted.—That the society have an exhibition of Fruits and Flowers, in the month of September following, between the 10th and 25th of the same, at such time and place, within the above limitation as a committee hereafter to be chosen, shall, considering the progress of the season, deem most expedient.

A general Committee of Arrangements was then chosen, viz:

Committee of Arrangements—Samuel Walker, Isaac P. Davis, Thomas Lee, Lemuel P. Grosvenor, Marshall P. Wilder, Ebenezer Putnam, E. Weston, Jr., Jacob Tidd, Beoj. V. French, Samuel Downer, David Haggerston, Wm. McLennan, Charles M. Hovey, M. P. Sawyer, Joseph Breck, J. E. Teschemacher, Cheever Newhall, Wm. Kenrick, Robert Treat Paine, Henry Sheaf, Samuel R. Johnson, S. Sweetser, Robert Manning, J. M. Ives, Dr J. C. Howard, P. B. Hovey, E. M. Richards, John A. Kenrick, Wm. E. Carter, J. L. L. F. Warren, J. W. Cowan, J. W. Russell, Jona. Winship.

On motion of Mr Grosvenor this committee was ordered to fill vacancies, and add to its number if found desirable—and the same was voted unanimously.

On motion of Mr Richards, a decorating committee was raised, with authority to add to their number. The gentlemen of this committee are the following.

Special Committee to decorate the Hall and take charge of the Fruits and Flowers—Samuel Walker, L. P. Grosvenor, Cel. M. P. Wilder, J. E. Teschemacher, Wm. Kenrick, E. M. Richards, S. R. Johnson, C. M. Hovey, D. Haggerston, W. C. Cowan, J. W. Russell, H. Sheaf, Mr McLennan.

EXHIBITION OF FRUITS.

Saturday, August 4, 1838.

Apples.—Good specimens of the following kinds from Mr E. M. Richards; Early Hardest, Curtis' Striped, William's Favorite.

Apricots.—Good specimens from Mr Wales of Dorchester.

From Mr Rundle, from his garden in Warren street, Apricots of good size and appearance.

From Mrs C. H. Jones, from her garden No. 14 Friend street, specimens of Apricots large and handsome.

Grapes.—Beautiful specimens of the following kinds were in exhibition by Dr J. C. Howard from Oakland in Brookline; Black Hamburg, Sweetwater, and Miller's Burgundy, all grown under glass. The berries of the latter very large for the kind, the fruit having been thinned while young and small.

Peaches.—The beautiful Peaches which were exhibited on Saturday, July 28, were from M. P. Sawyer, Esq. of this city, from his garden in Portland.

For the Committee,
WILLIAM KENRICK, Chairman.

EXHIBITION OF FLOWERS.

Notwithstanding the extreme heat of the weather and the want of rain, which together have almost burnt up vegetation, our friends decorated our tables with some fine bouquets and choice flowers.

J. C. Howard, Esq Woodlands, Brookline, exhibited a very splendid Bouquet. The specimens of the Dahlia in this collection were extra fine for the season. His gardener deserves great praise for the taste displayed in the arrangement of the various flowers, and for the general effect.

The Messrs Winship, of Brighton, presented two very large Bouquets, containing some choice and very pretty flowers. Our friend Story will permit us to state that these were, in our opinion, the best bouquets he has placed on our tables this season. They did him credit.

Mr S. R. Johnson of Charlestown, presented Roses and Carnations with other choice flowers. Mr Johnson's specimens are always clean and fine. He arranges his specimens with taste, and to great advantage. Feeling as we do, that as a cultivator, Mr Johnson has but few equals and no superior, we cannot let the present opportunity pass without saying that we at all times turn from his stand pleased and delighted.

Messrs Jno. Hovey of Roxbury, and Hovey & Co. of Boston, presented Bouquets.

Mr Jno. Hovey also presented a plant of Nerium carneum, plenum.

For the Committee,
S. WALKER, Chairman.

On Saturday, 23th ult. Mr Wm. E. Carter, of the Botanical Garden, Cambridge, presented a seedling *Philox*, (white) which we believe to be superior to any of our present varieties. We understand it is now under cultivation by Mr C. who we know can make the most of it.
S. W.

BRIGHTON MARKET.—MONDAY, August 6, 1838.

Reported for the New England Farmer.

At Market 310 Beef Cattle, 25 Cows and calves, 3520 Sheep, and 200 Swine.

Prices.—*Beef Cattle*.—First quality \$7 50. Second quality, \$7 00 a \$7 25. Third quality, \$6 00 a \$6 50.

Cows and Calves.—Sales were noticed at \$30, \$33, \$38, \$45 and \$58.

Sheep.—Dull. We noticed sales at \$1 50, \$1 75, \$1 87 1-2 and \$2 00, and one lot at \$2 83.

Swine.—Sales about the same as last week.

N. B. 20 Cattle remain unsold.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending August 5.

EMPLOYMENT WANTED.

A Gardener out of employment would be happy to attend to orders for hudding or gardening of any description. Apply at the New England Farmer Office.
August 8, 1838.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham.
ISAAC PARKER.

FOR SALE.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

Massachusetts Horticultural Society,

The Rooms of the Massachusetts Horticultural Society, 23 Tremont Row, are open for the public every Saturday morning, from 10 till 12 o'clock.

FRUIT AND ORNAMENTAL TREES, MULBERRIES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honey-suckles; Peonies, Dahlias and other Herbaceous Flowering Plants.

225,000

MORBUS MULTICAULIS are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussa, and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to E. D. BRECK, Commission Store, No. 132 Water Street, New York, M. S. PEWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near BOSTON.
August 1, 1838. WILLIAM KENRICK.

NEW ELEMENTARY WORK ON BOTANY.

Peter Parley's Botany; with descriptions of Trees, Shrubs and Plants; with a large number of fine engravings.

The publishers invite Teachers, and others interested in this subject, to examine this work, as they believe it will be found one of the most practically useful in use, being a complete manual of Botany for the adult and the pupil.

Parley's Cyclopaedia of Botany.—This work appears to be exactly what is wanted by young persons and in families. It not only contains the strictly scientific part of the subject, in an introduction and very full and complete genera of Plants, but it also contains a copious glossary of terms, and what is most important, a Dictionary of Plants, of nearly 300 pages, containing familiar descriptions of all the most interesting trees, plants, and shrubs.—These are alphabetically arranged, with an English index, so that the reader may immediately turn to any plant he wishes to read about. The work is illustrated by over 200 engravings, and is sold very cheap.—Boston Paper.

For sale at the New England Farmer Office, 51 & 52 North Market Street. JOSEPH BRECK & CO.

FOR SALE OR TO LET.

A pleasant and convenient house in complete repair situated on the Worcester Turnpike, 5 1-2 miles from Boston and 2 miles from Brighton market. The house contains 9 large rooms, and has a barn, chaise house and sheds attached. Also, with the same, 3 acres of mowing and tillage land and 1 1-2 acres wood land. An adjoining lot of 5 acres can be had, if desired. Three quarters of the purchase money can remain upon a mortgage. If not sold, the house will be let to a tenant at horse will. Enquire of D. HOLBROOK No. 51 Court St. Boston, or on the premises.
June 13, 1838.

REVOLVING HORSE RAKE.

The Revolving Rake, which has been in general use in most parts of Pennsylvania and New Jersey, is found to be one of the most useful and labor saving machines now in use. One man and horse will rake on an average, from fifteen to twenty acres per day, with ease, and do the work well, it not being necessary to stop the horse to unload. They are coming into very general use in all parts of the country, and will, no doubt, in a few years, supersede the use of the common hand rake. For sale at the New England Agricultural Warehouse and Seed Store. JOSEPH BRECK & CO.

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land, situated on Nonantum Hill, in Newton, 5 1-2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.
L. A. WHEELRIGHT.

July 16th.

ALDERNEY STOCK FOR SALE.

For sale, a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention.
June 27

SITUATION WANTED.

As Gardener, by a young man of practical knowledge and can be well recommended. A situation West or South would be preferred. Address R. B. through the office of this paper.

AMERICAN FLOWER GARDEN COMPANION.

The American Flower Garden Companion, adapted to the Northern States.
By Edward Sayers, Landscape and Ornamental Gardener. Published by JOSEPH BRECK & Co., and for sale at the Agricultural Warehouse and Seed Store, No. 51 and 52 North Market Street, Boston.

GUNNY BAGS.

9000 Second Hand Gunny Bags, 500 Gunny Sacks, a cheap article for Hop Bagging. For sale low by G. W. STEARNS, No. 10 Commercial Wharf. Im

MISCELLANEOUS.

STEAMBOAT LAW.

At the last session of congress, the following important act was passed, providing for the better security of the lives of passengers on board of vessels propelled in whole or in part by steam.

Be it enacted, &c. That it shall be the duty of all owners of steamboats, or vessels propelled in whole or in part by steam, on or before the first day of October, one thousand eight hundred and thirty-eight, to make a new enrolment of the same, under the existing laws of the United States, and take out from the collector or surveyor of the port, as the case may be, where such vessel is enrolled, a new license, under such conditions as are now imposed by law, and as shall be imposed by this act.

Sec. 2. *And be it further enacted,* That it shall not be lawful for the owner, master, or captain of any steamboat or vessel propelled in whole or in part by steam, to transport any goods, wares, and merchandise, or passengers, in or upon the bays, lakes, rivers, or other navigable waters of the United States, from and after the said first day of October, one thousand eight hundred and thirty-eight, without having first obtained, from the proper officer, a license under the existing laws, and without having complied with the conditions imposed by this act; and for each and every violation of this section, the owner or owners of said vessel shall forfeit and pay to the United States the sum of five hundred dollars, one half for the use of the informer; and for which sum or sums the steamboat or vessel so engaged shall be liable, and may be seized and proceeded against summarily, by way of libel, in any district court of the United States having jurisdiction of the offence.

Sec. 3. *And be it further enacted,* That it shall be the duty of the district judge of the United States, within whose district any ports of entry or delivery may be, on the navigable waters, bays, lakes, and rivers of the United States, upon the application of the master or owner of any steamboat or vessel propelled in whole or in part by steam, to appoint, from time to time, one or more persons skilled and competent to make inspections of such boats and vessels, and of the boilers and machinery employed in the same, who shall not be interested in the manufacture of steam engines, steamboat boilers, or other machinery belonging to steam vessels, whose duty it shall be to make such inspection when called upon for that purpose, and to give to the owner or master of such boat or vessel duplicate certificates of such inspection; such persons, before entering upon the duties enjoined by this act, shall make and subscribe an oath or affirmation before said district judge or other officer duly authorized to administer oaths, well, faithfully, and impartially to execute and perform the services herein required of them.

Sec. 4. *And be it further enacted,* That the person or persons who shall be called upon to inspect the hull of any steamboat or vessel, under the provisions of this act, shall, after a thorough examination of the same, give to the owner or master, as the case may be, a certificate, in which shall be stated the age of the said boat or vessel, when and where originally built, and the length of time the same has been running. And he or they shall also state whether, in his or their opinion, the said boat or vessel is sound, and in all respects seaworthy, and fit to be used for the transportation of freight or passengers; for which service, so performed upon

each and every boat or vessel, the inspectors shall be paid and allowed by said master or owner applying for such inspection, the sum of five dollars.

Sec. 5. *And be it further enacted,* That the person or persons who shall be called upon to inspect the boilers and machinery of any steamboat or vessel, under the provisions of this act, shall, after a thorough examination of the same, make a certificate, in which he or they shall state his or their opinion whether said boilers are sound and fit for use, together with the age of the boilers; and duplicates thereof shall be delivered to the owner or master of such vessel, one of which it shall be the duty of the said master and owner to deliver to the collector or surveyor of the port whenever he shall apply for a license, or for a renewal of a license; the other he shall cause to be posted up, and kept in some conspicuous part of said boat, for the information of the public; and, for each and every inspection so made, each of the said inspectors shall be paid by the said master or owner applying, the sum of five dollars.

Sec. 6. *And be it further enacted,* That it shall be the duty of the owners and masters of steamboats to cause the inspection provided under the fourth section of this act to be made at least once in every twelve months; and the examination required by the fifth section, at least once in every six months; and deliver to the collector or surveyor of the port where his boat or vessel has been enrolled or licensed, the certificate of such inspection; and, on a failure thereof, he or they shall forfeit the license granted to such boat or vessel, and be subject to the same penalty as though he had run said boat or vessel without having obtained such license, to be recovered in like manner. And it shall be the duty of the owners and masters of the steamboats licensed in pursuance of the provisions of this act to employ on board of their respective boats a competent number of experienced and skillful engineers, and, in case of neglect to do so, the said owners and masters shall be held responsible for all damages to the property or any passenger on board of any boat occasioned by an explosion of the boiler, or any derangement of the engine or machinery of any boat.

Sec. 7. *And be it further enacted,* That whenever the master of any boat or vessel, or the person or persons charged with navigating said boat or vessel, which is propelled in whole or in part by steam, shall stop the motion or headway of said boat or vessel, or when the said boat or vessel shall be stopped for the purpose of discharging or taking in a cargo, fuel or passengers, he or they shall open the safety-valve, so as to keep the steam down in said boiler as near as practicable to what it is when the said boat or vessel is under headway, under the penalty of two hundred dollars for each and every offence.

Sec. 8. *And be it further enacted,* That it shall be the duty of the owner and master of every steam vessel engaged in the transportation of freight or passengers, at sea or on the Lakes, Champlain, Ontario, Erie, Huron, Superior, and Michigan, the tonnage of which vessel shall not exceed two hundred tons, to provide and carry with the said boat or vessel, upon each and every voyage, two long-boats or yawls, each of which shall be competent to carry at least twenty persons; and where the tonnage of said vessel shall exceed two hundred tons, it shall be the duty of the owner and master to carry, and provide as aforesaid, not less than three long-boats or yawls, of the same

or larger dimensions; and for every failure in these particulars, the said master and owner shall forfeit and pay three hundred dollars.

Sec. 9. *And be it further enacted,* That it shall be the duty of the master and owner of every steam vessel employed on either of the lakes mentioned in the last section, or on the sea, to provide, as a part of the necessary furniture, a suction hose and fire engine and hose suitable to be worked on said boat in case of fire, and carry the same upon each and every voyage, in good order; and that iron rods or chains shall be employed and used in the navigation of all steamboats, instead of wheel or tiller ropes; and for a failure to do which, they, and each of them, shall forfeit and pay the sum of three hundred dollars.

Sec. 10. *And be it further enacted,* That it shall be the duty of the master and owner of every steamboat, running between sunset and sunrise, to carry one or more signal lights, that may be seen by other boats navigating the same waters, under the penalty of two hundred dollars.

Sec. 11. *And be it further enacted,* That the penalties imposed by this act may be sued for and recovered in the name of the United States, in the district or circuit court of such district or circuit where the offence shall have been committed, or forfeiture incurred, or in which the owner or master of said vessel may reside, one half to the use of the informer, and the other to the use of the United States; or the said penalty may be prosecuted for by indictment in either of the said courts.

Sec. 12. *And be it further enacted,* That every captain, engineer, pilot, or other person employed on board of any steamboat or vessel propelled in whole or in part by steam, by whose misconduct, negligence, or inattention to his or their respective duties, the life or lives of any person or persons on board said vessel may be destroyed, shall be deemed guilty of manslaughter, and upon conviction thereof by any circuit court in the United States, shall be sentenced to confinement at hard labor for a period not more than ten years.

Sec. 13. *And be it further enacted,* That in all suits and actions against proprietors of steamboats, for injuries arising to persons or property from the bursting of the boiler of any steamboat, or the collapse of a flue, or other injurious escape of steam, the fact of such bursting, collapse, or injurious escape of steam, shall be taken as full prima facie evidence, sufficient to charge the defendant or those in his employment, with negligence, until he shall show that no negligence has been committed by him or those in his employment.

Approved, July 7th, 1838.

CONVICTION OF STEAMBOAT CAPTAINS.—Six masters of steamboats have been convicted and fined at the Thames police office, for having illegally navigated their vessels at a greater speed than five miles an hour, between London bridge and Limestone reach.

AGRICULTURAL.

From the Maine Farmer.

ESSAYS ON THE GRAIN WORM.

It will be recollected that the Trustees of the Kennebec County Agricultural Society last year offered a premium for the best mode of destroying the Grain Worm, &c. Three essays only were handed in. We have recently received them from the hands of the Trustees, and have not learned what decision they have made in regard to them. We commence their publication, and doubt not that such facts as may be brought forward, will be interesting to farmers generally.

MR HOLMES:—In a former number of the Farmer, I made a few remarks on the Wheat Fly. Since that time I have found by observation that the grub that this fly originates from, is very different from what I then took it to be. I find that what I then took to be eggs, are grubs in a dormant state—inclosed in a tough shell or skin which they leave behind them when they undergo transformation. I also find that the greater part of those nits or grubs are deposited in the heads of the wheat at the time it is in its blossoming state; large numbers, however, are deposited at a later period.

These grubs can be distinctly seen in the heads of the wheat with a glass when they are not larger than the points of pins, and are of an orange color; their bodies appear in a moving posture—covered with small knobs. They are deposited in the heads of the wheat between the husk and the kernel, and appear to be deposited at various stages of the growth of the wheat—those that are deposited at the time that the wheat is in its blossoming state prevent the kernel filling out, and it remains in the same state that it is in when they are deposited. Those that are deposited at a little later stage of the growth of the wheat cause the kernel to be pinched, and very small; and so on through the various stages of its growth.

Those that are deposited about the time that the kernels begin to harden, do not injure it but very little; and as the wheat all becomes hard their ravages cease; and should the weather be dry, and not much dew, the grubs will remain in a dormant state, so long as they are kept dry; but should the weather be warm and damp, with heavy dews, they will undergo transformation, and take wing from the heads of the wheat, and will, I suppose, commence the work of destruction on all wheat that is in a green state that they may then have access to.

It does not appear that they eat the kernel or any part of the grain; but to all appearance they assist on the sap or juice of the wheat, and therefore entirely prevent its filling out after they are deposited in it.

I tried an experiment to demonstrate the certainty that those grubs would undergo transformation from the heads of the wheat. I took from a

piece of wheat a sufficient number of heads that contained large numbers of the grubs to fill a common flower box. These heads were in quite a green state. The box was filled with earth, and wet, quite wet. The straw was cut off about six inches below the heads; and with a wire set them into the wet earth quite down to the under part of the heads, to prevent them from drying up. The earth in the box was kept quite wet, and a covering of gauze was placed over the box to prevent the flies from escaping, should they take wing. The result was, that in the course of five weeks I found that the greater part of those grubs had taken wing and had escaped through the covering—in consequence of the flies being so very small when they first leave their shells, and the gauze being of rather a poor texture. Quite a number, however, were retained in the box, till they gained nearly or quite their full size. The fly is a very shy and sprightly insect,—not much larger than the grub that they originate from. The body and legs are changeable, tinged with a yellowish cast; the wings are also changeable, tinged with a hue similar to a rainbow.

These flies can be seen on the wheat at night in calm weather, as soon as the dew begins to fall, and in the morning as long as the dew remains on the wheat. In damp, cloudy weather, they can be seen during the whole day. They can also be seen on the wheat stubble, after the wheat is harvested.

These flies do not sting through the husk of the wheat, as many people imagine they do. I cannot discover any sting to them, any more than to the common house fly. There is a fly, the parent of what has heretofore been called the Wheat Worm, which stings quite through the husk of the wheat, and which causes a proper worm, that devours the kernel, in the husk. This worm can be seen in the wheat heads after it is ripe. The form of this fly is similar to the bot fly, which is so troublesome to horses. This fly, I should think, was not over one sixth part as large as the bot fly. They curl up their stings directly under the abdomen when they are on the wing, the same as the bot fly does. The ravages of this fly the last season was something more than it has been for some years past.

I find that the fly which has committed such depredations on the wheat crops, for the last two years, is the most singular insect that has ever come under my observation. I find that as soon as they can be seen on the wheat heads with a glass, they are living insects, and continue to increase in size till they gain their full growth,—and should the wheat heads continue, with sufficient moisture, and the weather should prove warm, it will cause them to undergo transformation and take wing from the head in a very short period of time after they have attained their full size. Should the wheat ripen off before they gain their full size, and the weather should prove to be dry, they will stop short of their full size, and go into a dormant state,—and I think will remain until moisture and warmth again comes

to them. They will then assume their moving posture and increase to their full size,—and should this process continue a sufficient length of time, it will in my opinion cause them to take wing at any season of the year.

I placed some of these grubs in a dry place in April last. I viewed some of them with the glass the first of September and found that the fly was in part formed, and was notable to escape from the shell for want of moisture,—they appeared to be so dry and thin that I thought they must be dead. I applied moisture and warmth to a number of them, and found, the third day after, that they were quite plump and lively, and in quite a forward state to take wing. How long they will live in this situation, I am not able to say: but I am quite certain that they never can escape from their shell unless moisture gets to them.

I am of the opinion that the greater part of the damage that these flies do to the wheat crop, is done in the night time, or between sun set and sun rise.

I found that the hot sun was very offensive to them; so much so, that they were not to be seen on the wheat in hot days. They appeared to be lodged on or near the ground; so that I am inclined to think that it would be almost impossible to dislodge them entirely from a large field of wheat, where they are very numerous,—unless they could be entirely exposed to the hot rays of the sun. This, I think, would prove very injurious to them, if it does not put a final stop to their ravages. On finding that the sun was so offensive to the flies, I tried an experiment on the grubs that they originate from. I applied moisture and warmth to a number of them, till they were in quite a forward state to take wing. I then exposed them to the hot rays of the sun, and they appeared to be qualmish, and in a few minutes would swell up and die; so that I found that the sun had a powerful effect on both the grubs and flies.

I have found, as far as my information has extended, that the ravages of the fly has been in this vicinity from one tenth part down to the total destruction of the crop. In some instances their depredations appeared to be more extensive in low places and on low lands, than on high lands, where there was more air and wind. My wheat crop, the past season, was injured about one-fourth part—taking the whole crop together. I perceived that the ravages of the fly were more confined to the edges of the pieces of wheat, than elsewhere; and more especially on the edges of those pieces that were sown nearest to where the wheat grew the year before. This, I suppose, is in consequence of the flies that originated from the grubs that were on the old wheat stubble. I noticed that the flies were most to be seen on the leeward sides of the pieces of wheat, and appeared to shift their position as often as the wind shifted. This, I think, will account for their doing more damage to the edges of the pieces of wheat, than they did elsewhere.

I observed that the heavy north winds that ye

had in August shelled out millions of these grubs on the ground, sometime before the wheat was fit to harvest. I observed also that large numbers fell out in harvesting the wheat, so that the ground then appeared to be seeded with a sufficient number of grubs to destroy the whole wheat crop, should they all remain in the ground and take wing. But according to the best observations I have been able to make on the subject, I have come to the conclusion that nature has done more, from the last of July to the first of October, to destroy these flies, than all that human art could devise. To corroborate this statement, I observed that by the middle of July these grubs began to take wing from the heads of the early sown wheat in large numbers; and about the time that the wheat was fit to harvest, I noticed in some fields large numbers of heads that were totally destroyed by the fly, and did not contain a single grub in them. These heads were full of the shells or skins of those grubs from which the flies had escaped. Some of these heads contained from one up to seven shells in each husk, throughout the whole head. I observed also that when these grubs fell out of the wheat in August, that the earth was quite moist, and remained so till after the wheat was harvested,—the weather being quite warm, with heavy dews, for some time,—these circumstances were very favorable for the grubs to take wing. This, together with the large number of flies that I observed after the wheat was harvested, led me to the belief that they had taken wing from the ground. Should this prove to be the case, I am inclined to think that their ravages will not be so extensive the next season as it has been the past season. In my opinion the grubs that took wing the past season will not injure the wheat crop the next season.

It will undoubtedly be recollected that a year ago last fall it was extremely dry, and remained so till the ground was frozen, and the snow fell on it. This, in my opinion, entirely prevented the grubs from taking wing. It will also be recollected that the last spring was very wet, and continued to be through the month of June. This, in my opinion, caused all the grubs that were in the ground, and all that were sown with the seed wheat to take wing; and at the very time that they could do the most injury to the wheat crop. These circumstances may account in part for the extensive ravages of the fly the past season.

I have observed that the fly has been more injurious to the bearded wheat, than they have been to the beardless wheat. I am somewhat at a loss to ascertain the real cause of this. It may be that the husk of the beardless wheat is more compact and snug than the bearded kinds are, so that the fly cannot, perhaps, penetrate it so easily as they can the bearded varieties. Some people think that the beardless wheat is inferior in quality to the bearded varieties, and think that is the only reason why the fly does not injure it as much. I have not had an opportunity to satisfy myself on this point—having always cultivated the bearded varieties in preference to the other, on account of its being earlier; and it is said to be less subject to blight.

I will here state another instance which has come under my observation. In the latter part of August, 1836, I sowed a small piece of winter wheat, which was winter-killed quite down to the ground, except a few small patches. In the spring following I sowed a piece of Malaga wheat, adjoining the winter wheat. That part of the winter wheat which was winter-killed sprung up late in the season, and

was in about the same state of forwardness that the spring wheat was in; so that both headed and was in bloom at one and the same time. The result was that the part of the winter wheat which was winter-killed, was totally destroyed; while the spring wheat that adjoined it was about one-fourth part destroyed by the fly.

Those patches of winter wheat that were not winter-killed, were not in the least injured by the fly—and the wheat was first rate. The kernel had begun to harden about the time that the other part of the piece and the spring wheat was in bloom. This I suppose was the only reason why it was injured by the fly.

The above instance seems to prove two things. First, that the fly cannot injure the wheat after the kernel begins to harden. Second, it proves to demonstration that the ravages of the fly are more extensive on the best varieties of wheat, when those varieties are within reach of them, than on the others.

To be continued.

From the Genesee Farmer.

CATTLE.—DEVONSHIRE.

While it may be affirmed with great truth, that the present beautiful and superior breed of Improved Short Horns are strictly artificial, and while some fears may be justly entertained lest the valuable qualities for which they are so distinguished, have not become so fully constitutional as to be beyond the possibility of lapse,—we here bring to the notice of the farmer, a breed of cattle, scarcely inferior in quality to the Short Horns, and of which no apprehensions can be entertained that the type of these distinguishing qualities are evanescent, and not durably incorporated in the constitution and race.

The north of Devon has long been celebrated for a beautiful breed of cattle, in activity of work, and aptitude to fatten, unrivalled. The place where they are found in the greatest perfection, is in the vicinity of Portlock and Biddleford, along the Bristol channel in the county of Devon. From the earliest records the breed has here remained the same, or if not quite as perfect in general as at the present moment, yet altered in no essential point until the last thirty years. No persevering successful attempts to improve the general character of British cattle were made until within some fifty or sixty years; and the Devonshire farmers were so well satisfied with their herds that they were about the last to dream that their beautiful red cattle could be improved, and they did not bestir themselves in earnest until the high prices and improved forms of the Collings Short Horns, convinced them that in estimating their advantages they were behind the age.

The most perfect specimens of the Devonshire cattle are found among the North Devons, and it is of these we shall speak. As the breed is of the middle horns, the horns should be neither too high or too low, those of the bull tapering to the points, not very thick at the base, and of a yellow or waxen color. The eye should be clear, bright and prominent, showing much of the white, and ought to have a circle of a variable color, but usually of a dark orange around it. The forehead should be flat, indented and small, for by the smallness of the forehead the purity of the blood is much estimated. The cheek should be small and the muzzle fine, and the nose should be of a clear yellow. The ox has a small head, singularly so relatively to the bulk

of the animal, yet it has a striking breadth of forehead. Its neck is well adapted to the yoke or the collar; the horns are small and fine; the forelegs are wide apart, looking like pillars to support a great weight. Angular bony projections are never found in a beast that carries much flesh and fat. A narrow chested animal can never be useful either for working or grazing.

The skin of the Devon of the pure breed, notwithstanding his curly hair, is very mellow, fine and elastic. Graziers know there is not a more important point than this. When the skin can be easily raised from the hips it shows that there is room to set fat below. The favorite color of the Devons is a blood red. The hair in some is curled, the curls running like ripples on water, and when dark giving a Mahogany appearance. If the hair is smooth it should be fine and glossy. Few of good blood have any white upon them, and the pure Devon is as uniformly red, as is the pure Short Horn red and white.

The comparative smallness of the Devon cow, is one of the most remarkable traits of their character. The bull is much smaller than the ox, and the cow proportionally smaller than either. This is considered somewhat of a disadvantage, as it is almost impossible to procure large and serviceable oxen, except from a roan cow. Owing to their peculiar build, however, the Devon cow is more roan than most other breeds of cattle of the same size, which in a great measure obviates the objection. The Devon cow is particularly distinguished for her full, round, clear eye, the gold colored circle around it, and the same color prevailing on the inside of the ear. The muzzle orange or yellow, but the rest of the face having nothing of black, or even of white about it.

The peculiar excellence of the Devonshire ox is a quickness of action in working, which few horses exceed, and no other cattle can equal. They have also a degree of docility and goodness of temper, and stoutness and honesty of work, to which many teams of horses cannot pretend. Mr Youatt who is great authority on the subject of cattle, thus describes their usual mode of treatment and aptitude to fatten.

The Devon steer is taken into work at about two years old; and they are worked until they are four to six; they are then grazed, or kept on hay, an ten or twelve months, and without any further trouble, they are fit for market. If the grass is good, no corn, or cake, or turnips are required for the first winter; but of course for a second winter these must be added. The grazier likes this breed best, at five years old, and they will usually, when taken from the plough, fetch as much money as six. Lord Somerville states, that after having been worked lightly on hill land for two years, at four years old they are brought into the heavy land—the vales, and used in hard work till six; and who deserves consideration is, an ox must be thus worked to attain his largest size. If he is kept idle until he is five or six, he will invariably be stunted in his growth. Mr Youatt, adds—In their disposition to fatten, very few cattle can rival them. They do not, indeed, attain the great weight of some breed but in a given time acquire more flesh and with less consumption of food, and their flesh is beautiful in its kind. It is of that mottled, marble character so pleasing to the eye, and to the taste.

As to the value of the Devon cow for the dairy and somewhat conflicting opinions are entertained in England. Mr Youatt says:

"For the dairy, the North Devon must be acknowledged to be inferior to several other breeds. The milk is good, and yields more than an average proportion of cream and butter; but it is deficient in quantity. There are those, however, and no mean judges, who deny this, and select the North Devons even for the dairy."

Perhaps one of the most valuable crosses that has yet been made, is the one described by the celebrated breeder, Mr Bolton, in a letter to the Farmer's Magazine.

"I have known many excellent beasts bred from improved Short Horn bulls and long horn cows; indeed I never knew one of these bulls put to any cow where the produce was not superior to the dam; but the cross which I advocate, and with which I am best acquainted, is that with the *Devon cow*. I have uniformly remarked that a cross here was attended with a proportionate improvement in size, quality of flesh, and aptitude to fatten. In every instance they have shown themselves superior milkers, and stand to the pail till within six or eight weeks of calving; and several instances have come under my knowledge, where they have never been dry since they first calved. So highly are they prized as milkers, that a friend of mine who hires out dairies, informs me, that the dairymen give him nearly 2*l.* per cow per year more for the half and three-fourth breeds, than they would for cows of any other breed."

Judging from the expressions of opinion given by cattle breeders in England, by the course of the agricultural periodicals of that country, and by the fact, that at the late Smithland cattle show, open to the whole Kingdom, the first prizes were taken by Devon cattle, we should imagine that since the demise of some of the most celebrated Short Horn breeders, such as Collings, Berry, and others, the Devons were treading close on the heels of the Short Horns in public estimation. The first premium was given at the late Smithfield fair, to a pure Devon, the property of Mr Coke of Holkham, and the second to a steer only 19 months old, of the improved Devon, or the Devon crossed with the Somersetshire breed. The ox weighed when dead, 1122 pounds; and the steer when dead, weighed 1332 pounds. The steer was a most remarkable one, and was owned by Mr Giblett.

The Devonshire breed of cattle have been more extensively introduced into the United States than any other breed of foreign cattle, and they form a large portion, in different grades, of the cattle of New England and the middle states. Some fine stock of this breed were sent from Mr Coke to Mr Patterson of Baltimore, and two oxen from this importation, raised and fattened by the Messrs. Hurlbut of Winchester, Connecticut, weighed when killed as follows:

First Ox.	Second Ox.
Carcass 1438	Carcass 1522
Hide 117	Hide 115
Tallow 175	Tallow 213
1730 lbs.	1856 lbs.

Mr Fisher of New York, addressed a letter to Mr Coke giving an account of these cattle, and received the following reply from that veteran agriculturist, which we insert as showing his opinion of the Devons.

HOLKHAM, April 21, 1831.

SIR,—I am this moment favored with your kind letter, and most flattering account of the Devon

oxen. It is a pleasing reflection to me, that I was the first person that introduced them into America, through my friend Mr Patterson. I thought them at that time, and I still more confirmed in my opinion now, that they are the most superior breed of cattle in the Island, if well selected. But I beg to be understood, when I speak of the Devonshire red cattle, it is in praise of the *North Devon cattle*, with yellow noses and indented foreheads, and yellow around their eyes, which mark their character beyond that of the South Devons, which have black noses, or intermixed with black. These I beg to be distinctly understood not to recommend as a superior breed of cattle. Be so kind as to express my acknowledgments to Mr Hurlbut, when you see him, and to assure him that I shall be at all times most happy to show him, or any of his American friends, should they come to England, every attention in my power, in the Agricultural line.

THO. WM. COKE.

PREVENTING CIDER FROM BECOMING SOUR.—There are several modes adopted by farmers, to prevent their cider from becoming sour. One is, the putting in of mustard seed—about a gill to the barrel. For some reason or other, this prevents the acetic fermentation, and the cider remains free from that sourness, or hardness, as it is sometimes called, which it otherwise would have. The different modes of refining cider, adopted by some who follow the business, depends undoubtedly on separating all unnecessary vegetable matter from the liquor, and checking the fermentation at the right time.

Farmers generally, have neither the time nor the skill to follow out all the operations required to do this; and hence the most of their cider becomes hard, by the next summer after it is made.

We have been informed that the addition of *Salt Petre*, in the proportion of one quarter of a pound to a barrel, would not only prevent the cider from becoming hard or sour, but even if added after it had changed, would restore it to a pleasant state again.

We cannot vouch for the truth of this from any experience which we had ourself with it, but can see no good reason why it should not succeed; nor can we discover any harm which it could do by any of the combinations which it would make with the cider, to which it may be added.—*Maine Farmer*.

THE HARVEST.—It is feared the corn crop will not be so good, unless rain should come to its aid in a few days. In this section of country corn is now suffering very much from the long continued dry, hot, weather; and we notice the same is said in other parts.

In Kentucky the crop is said to be very abundant, and it is thought wheat will be down to 50 cents per bushel.

The oats and grass crop will be more abundant than usual.

Our exchange papers from all quarters concur in saying that the harvest which has just been gathered is one of the best that our country has been blessed with for several years. After two weeks arduous toil in the hottest weather we have had for a number of years, the rich and waving mantles that a few days ago covered the fields of our farmers have been taken off by the sinewy arm of the reaper, but not without costing him much "sweat of the brow" and many palpitations of the heart. The prospects every where are of the most cheering kind. In Virginia, where the failures of crops have

been truly discouraging for several seasons in succession, the scene is described as quite *shock-ing*, and the most sanguine hopes of the farmer will be realized in his wheat crop. A contemporary says, "seldom have we seen before, so many showy monuments to the Author of all our "good and perfect gifts." Unlike several previous years, the "shocks" are not now like angels visits, few and far between, but stand in thick and profuse clusters,—blessings scattered all around.—*Zanesville (O.) Gazette*.

INDIAN WHEAT OR TARTARIAN BUCKWHEAT.—This is from Tartary or Siberia, via Germany. It is proposed where our buckwheat is killed by frost or heat, to substitute this. It is cultured in Pennsylvania, Vermont, and Western New York. It is heavier in the grain and more palatable than common buckwheat, and if properly milled, will give thirtyfive pounds of flour to the bushel. It does well on the poorest soil, and is not affected by the cold—does not require so much seed per acre, as it branches low and spreads much. It produces 30 or 40 bushels to the acre on ordinary land, and on good land is said to produce from 75 to 100. From 12 to 16 quarts of seed are sown to an acre, though many sow more, and the usual time of sowing is about the middle of June. The land should not be rich, and poor sandy soils that are not worth cultivating for other crops, are said to produce fair crops of this grain. It is used for various kinds of breadstuffs, as well as for feeding hogs, horses, cows, &c. It makes good bread when new, whether eaten warm or cold, having this advantage over common buckwheat, and it mixes well with other grains.—*New York Star*.

No avocation in life is more respectable and useful than that of the farmer. The time has gone by when "contempt is cast upon the husbandman." Agriculture, as a science, is becoming more important, and more honorable. It is the noblest for it is "the natural employment of man." The intelligent and independent farmer is ever respected; he holds an important and responsible place in society. Upon him devolve many duties: upon him rest many obligations. In him we look for examples in patriotism, virtue and intelligence. Living, not in the "hum of human cities," where he would be continually in the whirlpool of political and other excitement, he can examine questions of a moral, religious and political nature, with a cool head, a calm mind, and an unbiassed judgment. To him we look for correct opinion, and in him we should ever find a safe counsellor, and a correct adviser.

Our farmers should cultivate their minds and their hearts, as well as their fields. They can gain as rich rewards in the mental, as they can reap profitable harvests in the natural world. Without learning, a man cannot be a first rate farmer. Without intelligence he cannot discharge in proper manner, the duties of a citizen. Agriculture is a science that requires experience and study. Men must be educated to be farmers, as well as to be lawyers, or doctors. And there are thousands of young men who are in stores and offices, who should go into agricultural pursuits. It would be better for them, better for the country. And who would not rather be an independent farmer, than a small shop keeper, or a fourth rate lawyer or doctor? Who would not rather be first in a useful employment, than to be titman in one which the world calls honorable? Let young men seek for land, rather than for situations, "in the cotton trade and sugar-line."—*Buckeye Ploughboy*.

THE STRAWBERRY.

As the present month and the beginning of September, is the best season for making strawberry beds, some remarks as to varieties and the mode of culture may not be unacceptable.

The fruit of the strawberry is almost universally esteemed; and is prized as well for its delicious flavor, as for its tendency to promote health, and for its efficacy in mitigating or curing certain diseases. The berries are almost wholly soluble in the stomach, and neither there or elsewhere do they undergo the acetous fermentation. They dissolve the tartareous incrustations of the teeth. They promote perspiration. When used largely, they have given relief to those afflicted with the gout; and Hoffman states, that he has known consumptive people cured by them. The principal species and varieties are—

1. *Wood*, with oval serrated leaves; the fruit round and small, and white and green. Native of Britain.
2. *Scarlet*, with leaves like the preceding, roundish and scarlet colored. Native of North America. Varieties; early scarlet, Wilmot's late, common late, Wilmot's scarlet.
3. *Roseberry*. A Scotch seedling. The plants have few roundish leaves, larger fruit than the scarlet, and are very prolific. Continues bearing till August.
4. *Downton*. Fruit large, irregular and coxcomb-like; leaves large; plants hardy; and although prolific in England, has not proved so with us.—We have grown a berry that measured 5 3/4 inches.
5. *Carolina*, or *Bostock*.
6. *Musky* or *Hautboy*; with oval, rough, javelin edged leaves, the fruit large, of a pale red.
7. *Chili*; with large oval, thick hairy leaves and large flowers; the fruit large and very firm. A native of Chili.
8. *Keen's Imperial*, or *New Chili*; a large showy fruit, of great repute in England, but not so much esteemed here.
9. *Pine*; the leaves small and delicate. There are two sorts, the red and the white, or greenish-tinted, of the most rich flavored fruit. The Methven Castle belongs to this class. South America.
10. *Alpine*, or *prolific*, or *monthly*; commonly lasts from June to October; two sorts, white and red. The Alps.
11. *One leaved*; the pulp of the fruit pink colored. South America.

We received twelve kinds of select fruit from the London Horticultural Society in 1835; but continue to cultivate in our garden only the Methven and scarlet,—the latter coming in use ten or fourteen days before the former,—both abundantly prolific. Some of our beds are six years old, and they have produced as abundantly this as in any former year. We ascribe this continued productiveness to our pointing in horn shavings annually between the beds, and strewing upon the latter in autumn tan from the morocco leather factory. The Methven is in bearing about two weeks; we have had 47 berries that weighed a pound, many that measured over four, and one that measured five and one-quarter inches in diameter. Our practice is to clean the alleys and beds before the blossoms show, to leave the runners till the fruiting season is over, and after that to take off those that intrude upon the alleys, and to dung and dig these.

The strawberry multiplies rapidly by suckers or stolens, and may be transplanted as soon as the

leaves have grown at the joints, although the roots are but imperfectly formed. If planted out in this month, they will give a partial crop the next season, and will be in high perfection the second year.

Mr Keen, near London, who appropriates acres to the growth of this fruit, recommends that the pine be grown in a light loam, though no kind will grow better in a stiff one. The imperial and scarlets like a similar soil. The hautboys like a light soil. The wood strawberry is generally raised from seed, and the alpine always. The seed is best sown as soon as the fruit ripens; the plants to be set in fruit beds the spring following. Our own experience leads us to recommend, that the pines and scarlets be planted in a loose, rich, and pretty moist soil, our climate being dryer than that of Britain, and the strawberry demanding a great supply of moisture when fruiting.

The mode of planting is generally in beds containing two, three, or four rows, with alleys of two feet between them. The soil should be well dug and pulverized, and the situations open and exposed to the sun. The larger growing kinds may have intervals of two feet between the rows, and of 18 inches between the plants in the rows; the smaller growing kinds may be planted closer. Keen cuts the runners three times in a season—we cut them but once, and leave then the new plants that take root in the beds, mostly to grow. His culture may be the most perfect, but ours is attended with the least labor, the cost of which is there trivial to what it is here. Keen plants the pines and hautboys 2 feet by 18 inches apart, and the scarlets 20 by 18 inches. He found among the many different kinds of hautboys, one which had the male blossom on one plant and the female on another; and experience soon taught him, that to render them fruitful, it was necessary to mix the two kinds in his beds, in the proportion of one male to eight females. Mr Langworthy, of Cincinnati, and Mr Downing, of Newburgh, think that the male and female blossoms grow on different plants, in other kinds of strawberry; but our limited experience has not enabled us yet to confirm their opinions. The duration of most kinds with Mr Keen, is three years,—the wood strawberry and alpine, two years. The latter bears fruit the first year after sowing.

The general dependence, in the country, for the strawberry, has been upon those growing wild in the fields; but independent of the fact, that this fruit cannot grow where the farm is well managed, the extra trouble of gathering them in meadows, is more than equivalent to the labor of taking care of them in the garden.

With regard to manures for strawberry beds, such are to be preferred as are cool, and free from the seeds of weeds. Cow manure is preferable to that of horses. Bone dust and horn shavings are excellent, if not applied in too large quantity. A bushel and a half of either should go as far as a load of long dung. For top-dressing the beds in autumn there is nothing better than tan, that from the morocco leather factory being preferable. The tan smothers weeds, keeps the soil moist, the berries clean, and seems, withal, to afford the specific food of the plant. It is recommended to cover strawberry beds lightly with straw, in the spring, and burn it off, which destroys the seeds of weeds, &c. We have been cruelly censured for this recommendation, by one who unwittingly burnt piles of straw upon his beds, and consequently destroyed his plants.—*Cultivator*.

HINTS FOR THE PREVENTION OF DISORDERS IN HORSES.

Chiefly taken from Messrs Clarke and White's valuable Treatise on Horses.

STABLES.

Stables should be lofty, light, and airy, and should never contain more than six or eight horses. They are in general kept too close and hot.

Too much clothing also is usually put upon the horses, which thus become so tender, that they catch cold upon every slight exposure to a cool air.

The doors and windows of stables should be thrown open when the horses are out, but care must be taken that a cold current of air does not immediately blow upon them when in the stable, particularly if they are heated.

It is a bad practice to allow horses to stand upon litter in the day time, except they are unwell or fatigued.

FOOD.

The quantity and quality of a horse's food should invariably be regulated by the exercise and fatigue he has to undergo; high feeding, with proportionate work, produces half the disorders to which horses are subject.

Good hay is of much consequence to horses engaged in active exercises; but it should be given in small quantities during the day; and when owing to bad weather, the horses cannot be exercised, they should be stinted both in their hay and corn; and a bundle or two of clean wheat straw may be put before them. All grain given to horses, would be more nutritive if bruised in a mill and mixed occasionally with chopped straw. Carrots are a most wholesome food, and of all roots, rank next to corn in point of nourishment. They are particularly serviceable when a horse's wind is affected.

When horses are first taken from grass they should be gradually brought to a dry diet by giving them carrots, lucerne, bran mashes, &c. with their hay. After a few days a small quantity of oats may be given, and the feed increased by degrees till they come to their full allowance. They should likewise be put into a cool stable, and have plenty of walking exercise. If such precautions were attended to, a great saving might be made, both of physic, and the horse's constitution.

WATER.

Pond water, if it lie on a clay bottom and be sweet, agrees best with horses; hard water may be improved by throwing some chalk or clay into it, and exposing it in cisterns to the open air.

It is proper to let the water, intended for the horses, stand for some hours in pails in the stables before it is used.

Water should be offered to horses frequently; they would then never drink large quantities of it at a time, which is particularly hurtful to them when heated by exercise. It is a good and safe plan when travelling, &c. always to mix hot water enough with their cold to take off the chill.

EXERCISE.

A horse's exercise should be proportioned to his strength, manner of feeding, and the labor required of him. He ought, however, to have at least two hours of daily exercise.

Horses should not be ridden fast after having been newly fed and watered. A fat horse requires a long course of moderate exercise, before he can safely be put to trot, which is violent.

It should be a general rule to ride a horse slowly

at the beginning of a stage; afterwards increase the pace, and slacken it again a mile or two before the end of it, so as to bring him tolerably cool into the stable.

If horses come in very warm, they should be walked about gradually till cool, their feet should then be picked, and all dirt and gravel carefully washed out. In hot weather, washing their legs is proper, but they should always be well rubbed afterwards. In winter, cold water is injurious to the heels, and apt to bring on swelling and the grease.

Horses should on no account be permitted to stand uncovered in the stable, much less at the stable doors after being much heated, except the weather be very warm. Road horses should in the middle of a long stage have half a pail of water mixed with a little oatmeal; and on a journey, if no other corn but what is soft and new can be procured, oatmeal just moistened with water or some coarse bread, should be given in preference to such corn, which is extremely unwholesome. If a horse grow coarse, let him have some mashies of scalded bran or malt. If he have any difficulty in staling only, an ounce of nitre may be given in his food for a few nights.

Should he be seized with a violent fit of the gripes, let him be bled, back-raked, and have a glyster of three or four quarts of water gruel mixed with eight ounces of glauber or common salt.

The best instrument for giving a glyster is an ox bladder, that will hold two or three quarts, tied to the end of a wooden pipe about fourteen inches long, one inch and a half diameter where the bag is tied, and of a gradual taper to the extremity, where the thickness should suddenly increase, and be rounded off at the point, and made as smooth as possible. The hole through the pipe may be made sufficiently large to admit the end of a common funnel for pouring the liquor into the bag; no other force is requisite to throw it up, than the holding the bag a little higher than the level of the pipe. If in consequence of violent inflammation and pain, and opiates should be necessary, a table spoonful of laudanum may be given in a pint of water.

Should a horse be touched in his wind, be very careful that he has only moderate quantities of food and water at a time. Two spoonfuls of tar mixed with the yolk of an egg given in a morning fasting will be of great service to him when travelling. In hot dry weather, it is useful to stop horse's feet at night with a mixture of soft clay and cow dung, and to moisten them frequently with water.

FRUCTION.

The currying, brushing, and rubbing down horses is of great importance, not only to their coats, but also to their general health; when these operations are neglected, or slightly performed, an obstruction takes place in the pores of the skin producing mange, &c. and the hair instead of being smooth and shining, stares, and stands on end. Nothing tends so much to prevent grease and swelling of the legs, as frequent hard rubbing and carefully cleaning the heels.

TRIMMING.

The ears of horses are covered with a short down in the inside, mixed with larger hairs, to prevent cold air, rain, dust and flies from hurting the internal ear. The trimming therefore this part, is very prejudicial to the horse.

HINTS ON PRUNING FOREST TREES.

There were five competitors for the Highland Society's ten guinea premium, offered for the best essay on the pruning of forest trees,—a business which, to be sure, is not yet much practised among us; but as many of the principles which govern in the operation, apply in the pruning of fruit and ornamental trees, we shall state some of them. The essays are not published entire, but a digest of them is given by William Scott, one of the directors, who states, that on all the leading points, except as to the time of pruning, there is almost a perfect coincidence of opinion expressed in them all.

Is pruning beneficial? "Although pruning in ordinary cases does not ultimately increase the weight or bulk of wood, yet trees which are early and judiciously pruned, will be improved in quality, increased in their useful dimensions and ultimate value, and a great number can be grown on a given space."

2. *Thinning the plants,* as they advance in growth, is deemed indispensable.

4. *Pruning should be begun early,* and the directions for pruning, coming as they mostly do from professional nurserymen, are worth remembering:—"When trees in the plantation have produced three, or very thriving two years growth, pruning should be commenced. At this period the knife is the most suitable instrument, and the *top* is the principal part of the plant which requires attention. In order that only one shoot may be allowed to remain as a leader, the others next in size, if not very inferior, should be headed down, generally to about one half the length, and all the stout lateral branches of the tree headed in the same manner. No such branches need be cut close to the stem at the first, second, or third pruning." "All suckers or branches that spring from the roots, which tend to make the plant more like a bush than a tree, should be taken away."

4. *Error to be avoided.* The practice of cutting away the side branches to a certain height, at the first pruning, and afterwards to operate only on the under branches of the tree, is reprobated as tending to produce a small trunk, an irregular top, and side branches more vigorous than the leader. Under this management, in "exposed places, not one in a hundred ever becomes a large and valuable tree." "Such an excess of amputation destroys the health of the tree, by depriving it of the organs by which a sufficiency of sap is secured [elaborated] to be afterwards converted into wood."

5. The leading shoot should be preserved, and all others checked which have a tendency to compete with it, so as to divide the stem into forks or clefts.

6. "The writers agree in opinion," says Mr Scott, "that young trees should not be pruned at once close to the stem, but that the larger branches which it may be necessary to cut away, should be shortened first, and cut close afterwards." As deciduous trees give out an irregular tier of branches yearly, any branch should be shortened which is of greater length than the majority of those on the same tier; or, if the whole of them be too long, they must be shortened. By the concentration of the sap, which the shortening effects, a much greater quantity is thrown into the main stem," the leaves are much larger, the foliage healthier, and the tree shoots up much faster, and at the same time maintains a proportional circumference of stem.

The objects of the pruner should be "to give, in trees of advanced size, twice the length of the trunk to that of the top, in good soil; and in poor soil to leave the top as long as the trunk; and 2d. to have one inch in circumference to 15 feet of height; and if the circumference is proportionally greater, so much the better."

With regard to coniferous trees, as the silver fir, spruce, pines, &c. it is objected to their being pruned, *in any soil or situation.*

The opinions of the writers as to the best season of pruning are variant. One recommends April to June; another before the buds swell; another in autumn, &c. and Mr Scott, to reconcile the contradictory opinions, proposes to prune "a little before the buds begin to swell,—or a little after the leaves have expanded." We repeat—late in June.—*Cultivator.*

RECIPE FOR TAKING LIVES WITHOUT DESTROYING THE BEES.—Having always thought that there was great inhumanity in the old plan of *destroying* the bees, in order to take the honey, we determined to try the more humane plan practised by the French of robbing them of their sweets without depriving them of life, and we have put the plan twice into operation the present season with entire success. And as, besides the humanity of the process, it has economy to recommend it, we deem it our duty to lay the method before our readers, in the hope that we may be instrumental in saving many lives of those industrious workmen, and of securing their labors to their owners for numbers of years. The method, which is easy, is as follows:

In the dusk of the evening, when the bees are quietly lodged, place a tub near the hive, then turn the hive over with its bottom upwards into the tub, cover the hive with a clean one, which must be previously prepared by washing its inside with salt and water, and rubbing it with hickory leaves, thyme, or some other aromatic leaves or herbs. Having carefully adjusted the mouth of each hive to the other, so that no aperture remains between them, take a small stick and gently beat round the sides of the full hive for about 15 minutes, in which time the bees will leave their cells in the lower hive, ascend and adhere to the upper one. Then gently lift the new hive with all its little tenants, and place it on the stand from which the other hive was taken.

This should be done about midsummer, so as to allow the bees time to provide a new stock of honey for winter's use. If care be observed no danger need be apprehended.—*Baltimore Farmer.*

CORN.—The growth of corn for a propitious season has been so rapid, it is to be regretted that our farming friends have not planted larger quantities of this valuable grain. A friend at our elbow informs us that he measured corn, which had been in the ground but six weeks, and it had then grown a fraction over six feet. He also informs us that a gentleman measured a patch of corn, which had been planted fiftyseven days, and found it sixty inches in height. This is tolerably well for Penobscot, it does not come up to some planted by our friend Harlow of the Herald, which grew one foot in 48 hours!—*Bangor Mechanic.*

Sir Humphrey Davy says, that the refuse salt in Cornwall which contains some of the oil and *cruvia* of fish, has long been known as an admirable manure.

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, AUGUST 15, 1838.

THE SIZE OF FARMS.

The size of farms is often matter of conversation and of considerable diversity of opinion. The subject deserves a good deal of reflection; and the proper answer to the question, what size is to be preferred must depend on such a variety of circumstances that no general rule, applicable to all cases, can be laid down. For example, it is first to be determined what is the object of farming; is it a mere subsistence for yourself and family that you are seeking from the earth, or do you propose to pursue agriculture with a view to pecuniary profit, and accumulation, as any other commercial business or manufacturing or mechanical trade is pursued? Next what kind of farming is proposed to be pursued; is it tillage husbandry; or the keeping of a dairy, or a wool farm, or a grazing farm and the raising of live stock; or is it a sort of mixed husbandry, which comprehends a little of many things, and much of nothing. Or is it a market gardener's farm like those in the neighborhood of a city, where like the shop of a retail trader there must be a variety of little and great matters, suited to the season, the peculiar demand, or the caprice of the community. Then again the capital which can be commanded; and the facilities for procuring labor and manure, must be taken into the account before the size of the farm most eligible can be determined.

The size of farms in Massachusetts varies greatly from ten acres to five hundred; we mean cases where five hundred acres are held in one body, but we know no case in which any number of cases approaching this can be said to be used for agricultural purposes by one individual. In most instances where tracts exceeding one hundred acres are held, a large portion remains in forest; perhaps not even enclosed; and from which merely the fuel for the family is from year to year obtained. We know a few farmers in New England who mow from fifty to seventyfive acres in grass; and we know one extraordinary case, where fifty acres of wheat have been sown in a single season, and two hundred acres in all have been under cultivation at the same time. In general however the farms in New England average from seventy to one hundred acres; and it is not common on any farm to find more than twentyfive acres under tillage. The kind of farming pursued is altogether of a mixed character, combining a variety of crops and productions, with the exception of some few farms where wool or hay are the principal and almost exclusive objects.

If a man chooses to limit his agriculture to the mere supply of the wants of himself and family, with some little gradually accumulating balance in his favor at the close of the year; and will at the same time limit the wants of his family by rules of the strictest frugality, a few acres well managed will afford not only a comfortable subsistence, but ample means of reasonable luxury and kind hospitality. So many examples of this industrious and frugal management and simple independence have come within our own observation, that we have no hesitation in saying that a few acres well occupied and improved will sustain in plenty and comfort even comparatively numerous families. There are beautiful specimens of New England comfort which are scattered over our whole territory. They are cases where there is indeed nothing which may be called wealth and there is no poverty; there is food enough, clothing enough and fuel enough; there is no ambition of display; no harassing and

tormenting desire of accumulation; and no depressing, and allictive dread of want; there is a generous meal for the wandering and friendless beggar; there is a kind shelter for the respectable and way-worn traveller; and there is always a hearty welcome for the honored friend and guest. There is little labor and no anxiety. If one crop is cut off another succeeds. Some little improvement is made on the farm; some little comfort is yearly added in the house; and the stream of life flows calmly on to its close, without any violent agitations and disturbances other than those which are incidental to all human affairs. In such cases one hundred acres are equally sufficient with five hundred. The great object in such cases is to ascertain with how little labor and fatigue the common wants of the year can be supplied; and so long as this is accomplished the number of acres, which compose what is called the farm, is of no consideration, be it more or be it less.

But it is a different use when farming is pursued as matter of pecuniary profit; and here the only proper measure of the size of the farm is in the capacity and means of its owner to manage it to advantage. Farming cannot be pursued to advantage without the requisite skill, a skill founded upon intelligent observation and mature judgment; and that observation and judgment enlightened and improved by inquiry and practical experience. Farming cannot be pursued to advantage without exact, assiduous, and diligent personal superintendence. We know no position better established than the old adage,

"He that by the plough would thrive
Himself must either hold or drive."

Human machinery is of all other the most difficult to manage; the most easily disturbed and put out of place, and requiring, in order that it may go right, unremitted care and vigilance. Common laborers are liable to be ignorant, obstinate, conceited, or unfaithful, and think little of their employers' interest compared with their own ease and pleasure. They require constant direction and superintendence, and the master's eye is as important as the laborer's hands. Farming to be prosecuted to advantage requires capital. The farmer in every case must wait a year for his returns. Seed, manure, labor, all in advance, require capital; and then likewise he should not be compelled to sell at once immediately upon gathering the crops, in perhaps an unfavorable condition of the market, and when his necessities and not the value of the article must determine the price. It will be farther necessary to the farmer's success that he should be able to command what labor may be necessary to cultivate or to secure his crops seasonably and perfectly. Now if we suppose a case in which all these advantages are combined, where there is skill, industry, labor, capital in ample abundance, and where the farmer is determined to make agriculture as exclusively his business as the merchant or manufacturer make their trade or manufacture the object of their pursuit, then the size of the farm may be limited only by the capacity of the superintendent to take charge of it, and the amount of attention he is willing to devote to it. It is impossible in this case to say with any precision how many acres can be successfully managed, any more than we can determine, without an exact knowledge of all the circumstances of the case, how many ships a merchant may have under his charge, or how many spindles a manufacturer may superintend; this can only be safely determined by the particular circumstances of each case. We have few examples of such farming in New England. For the most part the small subdivisions of our territory forbid it; add to this the difficulty of procuring and managing labor, the want of capital or the unwillingness to invest capital in agri-

culture, and especially a prevalent opinion that agriculture among us can never be made profitable in a pecuniary view, and the universal disposition to try readier and quicker modes of pecuniary acquisition and gain, rather than wait for what in the best cases are considered its slow returns.

LONG ISLAND AGRICULTURE.

We have just met with an intelligent Long Island farmer, and we choose to fasten while it is fresh upon our minds the information he has given us.

He states that leached ashes are greatly used upon the Island both for wheat and rye; and are as important to the latter crop as to the former; that it is usually spread upon the land at the time of sowing the seed at the rate of 90 to 100 bushels per acre; and usually harrowed in; that their crops of rye vary much; of wheat the average is about 20 bushels; and are seldom subject to blight; that winter wheat succeeds much better with them than spring wheat; and that it is all essential to manure their land the same season when the wheat is sowed; and for this purpose stable manure is considered much the most valuable; and that this is applied as brought directly from the stable. Of lime they have made little or no use; but from experiments within his knowledge they are led to a strong belief of its utility. We are entire believers in its utility and advantages have been; but of its indispensableness in the production of wheat we are not so fully persuaded. He further stated that ashes were by no means sufficient without manure. This accords with the best doctrines of vegetable nutritions. They are not a manure properly so speaking. They are not the food of plants; but like lime in its various forms are a mere condiment or preparer of the vegetable food.

For the New England Farmer.

Newton, July 27, 1838.

MR. EDITOR—I am so much engaged in the various industrious duties that I cannot find time to read your useful journal, and had concluded to stop it; but in the last number I read "Materials for Manure." This single piece, induces me to pursue your very plan of making manure. I have adopted the same plan for more than a year. And yet, I am frequently told that I don't know how to farm it, yet I practise just as you lay it down. The reason is, that those who say I don't know, don't know themselves, and not one of them read your journal. The way I farm it is, I put practice and common sense together, and "go ahead." Please to give me credit for one year's subscription which is enclosed.

Yours,

A SUBSCRIBER.

P. S. I have cut this season, 50 tons of Hay, gathered 25 bushels of Wheat, 100 bushels of Rye; Corn and Potatoes look finely.

Massachusetts Horticultural Society.

EXHIBITION OF FLOWERS.

Saturday, August 11, 1838.

By Marshall P. Wilder Esq. of Grove Hall, Dorchester, by his gardener Mr J. Donald, two superb specimens of *Hibiscus fulgens*. These flowers were very large. They were much admired for their elegant shaped, pink colored cups. We hope Col. Wilder will favor us with other specimens of his new *Captown beauty*.

Bouquets.—By Messrs Hovey, Winslip, Sweetser, Howard, and Walker.

For the Committee,

S. WALKER, *Chairman*.

BRIGHTON MARKET.—MONDAY, August 13, 1838.

Reported for the New England Farmer.

At Market 300 Beef Cattle, 150 Stores, 20 Cows and calves, 2800 Sheep, and 40 Swine.

Prices—Beef Cattle.—Sales were quick and last weeks prices fully supported. We quote about the same, First quality \$7 50 Second quality, \$7 00 a \$7 25. Third quality, \$6 00 a \$6 75

Stores.—A sufficient number have not been sold to establish prices.

Cows and Calves.—Sales were made at \$25, \$31, \$35, \$42, \$45 and \$50.

Sheep.—Lots were taken at \$1 07, \$1 75, \$1 92, \$2 17, \$2 33, \$2 42 and \$2 75

Swine.—One small lot only was sold. Price not public.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending August 12.

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dome, situated in Rochester, N. H. six miles from the village of Dover and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quarries of the most desirable granite. Any persons desirous of purchasing may learn further particulars on application to JOSEPH BRECK & Co., No. 51 and 52 North Market Street, Boston. August 15, 1838.

MIDDLESEX AGRICULTURAL SOCIETY.

The Committee on Farms, Fruit, Mulberry, Forest Trees and Shrubs, will meet at the Middlesex Hotel in Concord, on Monday, the third day of September, next, at nine o'clock, A. M., and will then proceed to view such farms, &c. as have been entered for premiums.

NAHUM HENDY, Waltham,
JOHN H. LORING, Groton,
ELI RICE, Marlborough,
WM BUCKMINSTER, Framingham,
CYRUS WARREN, Concord,

} Committee.

All applications must be made to some one of said committee, or to the secretary of the society, on or before the above time.

TIMOTHY PRESCOTT, Secretary.

Concord, August 13, 1838.

NOTICE TO SUBSCRIBERS.

Subscribers can have the New England Farmer neatly bound for seventy-five cents per volume, by leaving them at this office. Aug. 15, 1838.

REVOLVING HORSE RAKE.

The Revolving Rake, which has been in general use in most parts of Pennsylvania and New Jersey, is found to be one of the most useful and labor saving machines now in use. One man and a horse will rake on an acre, from fifteen to twenty acres per day, with ease, and do the work well, it not being necessary to stop the horse to unload. They are coming into very general use in all parts of the country, and will, no doubt, in a few years, supersede the use of the common hand rake. For sale at the New England Agricultural Warehouse and Seed Store. JOSEPH BRECK & CO.

GUNNY BAGS.

9000 Second Hand Gunny Bags, 500 Gunny Sacks, a cheap article for Hop Bagging. For Sale low by G. W. STEARNS, No. 10 Commercial Wharf. 1m

WINTER WYE.

Just received at the New England Seed Store and Farmer Office, a few bushels of prime Winter Wye.

JOSEPH BRECK & CO.

Aug. 13, 1838.

FRUIT AND ORNAMENTAL TREES. MULBERRY TREES &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberry, Grape Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honeyuckles; Paeonies, Dahlias and other Herbaceous Flowering Plants.

225,000 MORUS MULTICAULIS are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussa and other varieties. Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. D. BRECK, Commission Store, No. 132 Water Street, New York, M. S. POWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston. August 1, 1834. WILLIAM KENRICK.

NEW ELEMENTARY WORK ON BOTANY.

Peter Parley's Botany, with descriptions of Trees, Shrubs and Plants: with a large number of fine engravings. The publishers invite Teachers, and others interested in this subject, to examine this work, as they believe it will be found one of the most practically useful in use, being a complete manual of Botany for the adult and the pupil.

Parley's Cyclopaedia of Botany.—This work appears to be exactly what is wanted by young persons and in Families. It not only contains the strictly scientific part of the subject, in an introduction and very full and complete genera of Plants, but it also contains a copious glossary of terms, and what is most important, a Dictionary of Plants, of nearly 300 pages, containing familiar descriptions of all the most interesting trees, plants, and shrubs.—These are alphabetically arranged, with an English index, so that the reader may immediately turn to any plant he wishes to read about. The work is illustrated by over 200 engravings, and is sold very cheap.—Boston Paper.

For sale at the New England Farmer Office, 51 & 52 North Market Street. JOSEPH BRECK & CO.

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land situated on Nonantum Hill, in Newton, 5 1/2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

L. A. WHEELRIGHT.

July 16th.

ALDERNEY STOCK FOR SALE.

For sale a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27

EMPLOYMENT WANTED.

A Gardener out of employment would be happy to attend to orders for hudding or gardening of any description. Apply at the New England Farmer Office. August 8, 1838.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Ten Hill Farm, Charleston. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham. ISAAC PARKER.

FOR SALE.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

Massachusetts Horticultural Society.

The Rooms of the Massachusetts Horticultural Society, 23 Tremont Row, are open for the public every Saturday morning, from 10 till 12 o'clock.

AMERICAN FLOWER GARDEN COMPANION.

The American Flower Garden Companion, adapted to the Northern States. By Edward Sayers, Landscape and Ornamental Gardener. Published by JOSEPH BRECK & Co., and for sale at the Agricultural Warehouse and Seed Store, No. 51 and 52 North Market Street, Boston.

SITUATION WANTED.

As Gardener, by a young man of practical knowledge and can be well recommended. A Situation West or South would be preferred. Address R. B. through the office of this paper.

THE CHILD AT PRAYER.

"T was summer's eve—the rosy light
Had faded from the sky,
And stars came twinkling pure and bright,
Through the blue arch on high,
And the western breezes softly stole,
To kiss the weeping dower,
And nature wore her sweetest smile,
To bless the twilight hour.

There sat within a curtained room,
A mother young and fair—
What voice comes softly through the gloom?
'Tis childhood's voice in prayer!
A cherub boy is kneeling now,
Beside that mother's knee—
She who had taught him when to bow
Before the Deity.

A father on the distant deep,
A sister slumbering near,
A babe upon the mother's breast,
And that kind mother dear:
For ev'ry living thing he loves,
His pray'r ascends to heaven,
And for himself he humbly asks
Each sin may be forgiven.

And in after years, when grief
Shall bow his spirit down,
And the world, the cold and bitter world,
Shall meet him with a frown—
And when allured from virtue's path
He treads a dangerous way—
Oh! he will turn to the blest hour
When he first knelt to pray.

And the kind hand which then was laid
Upon his silken hair—
And the soft voice which taught him first
His simple words of prayer—
Will come again with thrilling power
To still his passions wild,
And lure him back in that dark hour
As sinless as a child.

The prayer is o'er—the last fond kiss
By that kind mother given;
But rises not from scene like this?
That childish prayer to heaven?
It does, it does—an angel's wing
Has borne its tone with joy,
And the earnest blessing which it sought
Comes on the sleeping boy.

STATE OF MAINE.

LAND OFFICE.

Bangor, April 30, 1838. }

The twelfth section of "an act additional to promote the sale and settlement of the public lands," passed March 24, A. D. 1835, making it the duty of the Land Agent "to advertise the selling lands in market, once a year, for two months, in one paper in the city of Boston, one in Concord, N. H., and in one paper in each county in the State, describing the quality and situation of said land and the terms of sale," the Land Agent hereby gives public notice that Township number 4, in the fifth Range of Townships west from the east line of the State, has been lotted for settlers, and is now in the market for sale and settlement under the provisions of the following law passed at the last session of the Legislature. The price will be from fifty to seventy-five cents per acre, according to the quality and situation of the lots. The lots average 160 acres each. The soil in this township is good, being remarkably free from stones, and the land lying in moderate swells. The location of this township is favorable for settlement, as the Aroostook road passes within one mile of the western line of the township. There are between 40 and 50 settlers in the adjoining township No. 4 in the 6th Range, and a good saw mill and grist mill have recently been built there by Ira Fish, Esq. only one mile distant from this township.

Townships No. 3 in the 4th Range, No 7 in the 6th Range, and No. 8 in the 7th Range have been surveyed and lotted into mile sections. Lots of 160 acres will be run out from any of these sections to actual settlers, where the land is more suitable for farming than for timber. Townships Nos. 8, 10 and 12 in the 5th Range have been ordered to be surveyed, by the Surveyor General, forthwith, and will be open for settlers as soon as the lots can be run out. The Aroostook road passes directly through these townships and the soil is represented to be excellent for farming. The Aroostook road is laid out

and cut out from the military road leading from Bangor to Houlton, near Mattawamkeag Point to the Aroostook river, a distance of about 75 miles.

About \$17,000 will be expended this year, upon this road by the Land Agents of Maine and Massachusetts, and with the part already finished the road will be completed about one half of the distance. The whole distance will probably be completed next year. All the land on this road has been sold for about two thirds of the distance, and in several townships all the lots upon the road have been taken up by actual settlers. The remaining part of the land upon this road, owned by this State is now offered for sale to settlers. The price of lots in these townships under the condition of the new land law will be from fifty cents to one dollar per acre, according to their situation and quality. Should any company of settlers select any unsurveyed township in this part of the State on which they should wish to erect mills under the provisions of the new land law, the Surveyor General would proceed as soon as practicable in the survey of such township.

The settling duties required by law, are "that the purchaser of each lot shall clear in a proper manner, fifteen acres thereof, ten or more of which shall be well laid down to grass, and build a house thereon, within four years from the time of the purchase."

The board of Internal Improvement for this State have just ordered an exploration and survey of all the lands situated in the Aroostook country in reference to their settlement and agricultural capabilities. This survey will be commenced forthwith under the charge of Dr Eckzell Holmes, of Wintthrop. His report of the situation, quality and value of the public land in this part of the State may be expected in the course of the season, and will give all needful information, to those persons who may feel desirous of making a settlement upon them.

The following extracts from the second report of Dr. Jackson on the Geology of the public lands, made to the Legislature, and now in the hands of the printer for publication, show the value of these lands for cultivation. Speaking of the Aroostook country the Doctors says, "the average width of the alluvial region on the Aroostook river cannot be less than six or eight miles, and in some places it is much wider. It is a well wooded region and is the best settling land in the State, equaling in fertility the famed regions of the Western States, and capable even under a less genial climate, of producing crops of wheat and other grain, fully equal in abundance with any soils of which we have any records.

"We here found a yellow loam of a fine kind derived from the limestone rocks and luxuriant in its produce, and in some places covered to the depth of 4 or 5 inches by a black vegetable mould.

"This yellow loam is remarkable for the tall rank grass called blue joint, which skirts the margin of the river and from 4 to 5 feet high and extremely luxuriant. The forest trees are of a mixed growth, but the sugar maples are most abundant, and are of gigantic size. Elms, white birch, black and white ash also abound. The soft wood grows mostly on the low lands, while the uplands in the rear are densely crowded with hard wood trees, among which are scattered magnificent pines. In the course of two years, there will be a free communication between Bangor and the Aroostook and a great number of enterprising settlers will take up their residence in this fertile valley, and by farming, they will obtain an ample reward, and that region will become as it is destined by nature to be the granary of the north."

In another place Doctor Jackson says—"On the Aroostook it will be remarked, that very few if any hemlock trees exist, and the predominating growth is of a mixture of various hard wood trees, the sugar maple, ash and yellow birch abounding, while open scattering, some of the most lofty pine trees ever beheld. There are evident reasons why this should be the case, for the richest soils are always most crowded with a mixed growth, and the Aroostook soils are mostly of limestone alluvion, and are exceedingly rich and good settling lands remarkable for their heavy crops of wheat, rye and other grains, and are certainly richer as an agricultural district, than any other portion of Maine. The present population on this river is estimated between 400 and 500 persons, chiefly emigrants from Maine."

Towards the conclusion, Dr Jackson says: "the researches of the present season have brought to light many important resources in the public domain which were before unknown. Beds of iron ore of immense magnitude favorably situated for advantageous operations occur on the Aroostook, and all the marked characteristics of the regular coal formation exhibit themselves over a great belt of country from the Schoons to the Aroostook and St. John, and extend to the Temmiscouta lake near the

frontier of Canada. It will be at once perceived, that the country which we have explored is a most valuable territory, possessing every advantage required by settlers. Heavy timber offers a reward to the enterprising lumber dealer. A rich soil capable of producing an average crop of 20 bushels of wheat to the acre, and in some cases producing from 30 to 40 bushels, offers an ample reward to the husbandman. Inexhaustible supplies of limestone, valuable both for building materials and for agriculture, vast and inexhaustible mines of rich iron ore, and innumerable forests which will furnish an abundance of charcoal, required for the manufacture of the finest kind of iron and steel—the country presents every natural advantage that might be required to call forth the enterprise and industry of the farmer and manufacturer."

By an inspection of the map of Maine, it will be seen that there are nearly one hundred townships of land situate on the Aroostook river and its tributaries, one half of which belongs to the State of Maine and is now open for sale and settlement under the new land law. Considering the remarkable fertility of the soil in this region, and the high price of produce, and the ready market which it finds among the lumbering people on the Penobscot and St. John rivers, and the advantages of the road now making by Maine and Massachusetts into this region, it is believed that an uncommon opportunity is now offered to persons who may feel desirous of obtaining good farms at a low price.

The field notes of the surveys of all these townships are in the Land Office, open to the inspection of every person, and all information that may be received here, from time to time, from the progress of surveys, and the reports of Agents, will be cheerfully given to all inquirers, and every facility granted within the means of this office, to secure to individuals and companies, all the benefits and privileges intended by the Legislature, for actual settlers under the provisions of the following law.

ELIJAH L. HAMLIN,
Land Agent of Maine.

STATE OF MAINE.

In the year of our Lord one thousand eight hundred and thirty-eight. An act additional to promote the sale and settlement of the Public Lands.

SECTION 1. *Be it enacted by the Senate and House of Representatives in Legislature assembled,* That all lands lotted to settlers shall be sold to those only who will perform settling duties on the same as prescribed by law, the price to be fixed by the Land Agent, having reference to the field notes, not however at a less price than fifty cents per acre; three fourth parts of said price to be paid within three years from the time of said sale in labor to be laid out in making roads in such township where said lands so sold are situated, under the direction of the Land Agent; and the remaining fourth part to be paid in cash within four years from the time of said sale.

SEC. 2. *Be it further enacted,* That whenever twenty or a less number of individuals, shall each select a lot of one hundred and sixty acres of land in any township lotted for settlers, the same having no mill within its limits and shall give bonds satisfactory to the Land Agent, that they will within the term of three years from the time of said selection, erect in a proper and substantial manner a saw mill and grist mill, on such lot within said township, as shall be designated by the Board of Internal Improvement, the same shall be entitled to a deed of such lot; and each individual shall receive a deed from the Land Agent for his respective lot, without any further consideration, conditioned however, for the performance of the settling duties required by law.

SEC. 3. *Be it further enacted,* That from and after the passage of this act, all acts and parts of acts inconsistent with the provisions of this act, be and the same are hereby repealed.

In the House of Representatives, March 23, 1838.—This bill, having had three several readings passed to be enacted.

ELISHA H. ALLEN, Speaker.

In Senate, March 23, 1838. This bill having had two several readings, passed to be enacted.

N. S. LITTLEFIELD, President.

March 23, 1838. Approved.

EDWARD KENT,
Secretary of Office,

From the Maine Farmer.

ESSAYS ON THE GRAIN WORM.

NO. II.

DIXFIELD, DEC. 13, 1837.

Messrs Trustees of the Kennebec Co. Agricultural Society:—The following is submitted to your consideration, more from a hope of benefiting the community, than from any other consideration.

If the history of the insects called Grain Worms, is ever obtained, it will be gathered in detached fragments, as it is probable no one individual has at this time any very extensive knowledge of them. I have taken a great interest in relation to them from the time I first became acquainted with them; and have inquired into their history, as to the place where they were first discovered,—the length of time they have been known,—whether they have been known prior to their present visit, and how extensive a portion of the country they have spread over; but the information obtained, is quite vague and indefinite.

I have, however, a few facts that I might communicate. I have been informed by a gentleman who states that "he has resided in the north-westerly part of New York eight years, that the fly committed some depredations about the Lakes, six years last season; and he has since heard of it in the westerly part of New York, in Vermont, and along the St. Lawrence river, and that they still continue to do more or less injury upon the farms where they were first discovered in those places."

In 1832, they were in towns along the Connecticut river. In 1833, they were in Gilead, Bethel, and towns adjacent to the White Mountains. In 1834, they were very destructive in Bethel and Rumford, and made their appearance in Dixfield, Canton and Livernore, and also in towns along the Saco and Sandy rivers; and have since continued to progress in an easterly direction at about twenty or thirty miles a year.

From what I have learned, I suppose the fly to be a native of our own country, and has existed about the great Lakes, by depositing their eggs in some kind of wild grain that may have grown there; and agriculture has extended in that direction, until it reached them, and they have found in the heads of wheat, good receptacles for the deposit of their eggs; and from the facilities thus afforded for the propagation of their species, have spread till they have assumed their present formidable aspect; or they may be of foreign origin, and have been brought into the Canadas in foreign grain. I believe that this Worm is a native of cold climates. I am informed by an individual who has spent two seasons in the Upper Province, that they are very destructive to the crops; so much so, that the Catholic inhabitants besought their Priests to interpose their petitions in their behalf.

As relates to the history, the origin and spread of the Wheat fly, the few facts above, are all that I have learned.

The first appearance of the fly in the spring, though it may have wintered in the form of a grub, is about the time the wheat heads are making their appearance above the leaves. And here I will state, that there were apparently three kinds of flies upon my grain the last season—which were doubtless the male and female in different states of maturity. The female is larger than the black fly, very well known to those who visit our forests the latter part of June; its belly and exterior parts are of a yellowish color; its wings nearly the length of a musketee's, and nearly of the color. The male is somewhat smaller than the female, (which is the case with all the species of flies), and of a darker color,—feeds upon the grain, and especially upon rye, if there are any scattering heads among the wheat, or near by; and even on fields at a distance from the wheat field. I have never seen their eggs deposited in the ears of rye; but they prefer to feed upon the cleveland while growing—a hundred upon the same head. It requires about the same degree of heat, and length of time, to hatch them from their eggs or grubs, and bring them to a proper state to deposit their eggs, that it requires to vegetate wheat, and grow it to the blossom. The flies commence laying their eggs a short time before the blossoms appear, and the last season were actively engaged in depositing them from ten to twelve days. The egg, when first deposited, is so small as scarcely to be discovered without the aid of a magnifying glass,—is a little elliptical, and nearly of an orange color. It soon increases in length, and shows some signs of life,—and when disturbed, its motions are oscillatory. It is then a smooth grub, about three-sixteenths of an inch in length. I have seen them upon the top of full grown kernels; but they are generally by the side of them, and sometimes several with the same kernel. They either suck the nourishment from the kernel, or are poison to it. I have never discovered the least incision in the kernels. The kernel curves where they lay against it, and does not fill. If the grain stands till fully ripe, and the heads turn down, many of them drop out. After the grain is fully ripe, their ravages are over for that season; and after the grain is harvested, no further injury is sustained—except that the grain that is partially filled, shrinks more than that which is fully grown.

I took about a table spoonful of the grubs, and mixed them with soil from the wheat field, and have kept them there about two months. One half of them have been exposed to the weather the whole time; and upon examination they do not appear to have undergone any visible change. Another part of them was moistened and placed upon the roof of a building, spread thin in a pan, through one of our early cold nights, and frozen. I then mixed some wheat with the soil, and have kept them in the best situation to vegetate the grain. The grain came forward, and has grown finely; the grubs are also doing well. Some of them are 1-4 of an inch in length. Their external covering seems partially transparent. There is a dark spec

near one end; and, if I am not deceived, there is some appearance of wings inside the covering.—These results are very different from my expectations. Two years ago, I harvested my grain very damp, and it was heated in the mow. I thrashed two bushels, and winnowed it in the wind; and after it had lain in the pile an hour, the top of the pile was alive with worms or caterpillars, about 3-8 of an inch in length, with a row of bristles sticking up along their backs and from their sides, which I supposed were the weevils. I now give it as my opinion that their metamorphose is from the grub to a fly. One thing is certain, that they retain the grub form through the winter, and for two months in the spring.

I do not know that the fly deposits any eggs after dark; but from my observation, their most active time is between sun set and dark, and in cloudy weather.

To destroy this insect, or prevent its ravages, is truly of almost vital importance.

The application of lime, if applied at a suitable time, is doubtless of great utility; notwithstanding its general failure the last season. Some have supposed, that, as the grub is of animal substance, the alkali destroys it; but this is a mistake. The lime does not reach the grub, nor does the mixture after it becomes alkaline.

If the heads of wheat are white with lime, it does not prevent the fly from depositing its eggs, or destroy the eggs after they are deposited; and indeed it is impossible to destroy them after they are deposited, without destroying the grain.

The beneficial results from lime are in consequence of the particles of lime falling upon the wings of the flies and corroding their thin and extremely delicate texture, thereby rendering them useless, and the flies fall to the ground and perish.

These being the facts, it is evident that three things are necessary to the beneficial results of sowing lime.

1st. That the flies are present on the grain. 2d. That the lime be sowed before the flies deposit their eggs. 3d. That the air be filled with a fine mist that shall moisten the wings of the flies, so that the particles of lime may adhere to them.—When lime is applied under these circumstances it may be considered a sure remedy. (But this combination of circumstances seldom occurs.)—Hence the different effects of its application, and also the diversity of opinion. I would not, however, discourage its use. Ashes applied under similar circumstances, will be beneficial in proportion to their alkaline properties.

Early sown grain is most liable to be injured by the grain worm, unless it be very forward. The last season, grain sowed the last week or ten days of May, was not injured by them. All sown previous to that, in the vicinity of their ravages, was more or less damaged.

It is certain that their ravages have been greatest upon plains and interval lands; but I presume this difference results more from the forwardness of the grain than from any other cause. I believe

The opinion has been that this resulted from the agitation of the grain by wind. This must be a mistaken notion. My grain that was most injured by them, was almost as airy as the top of Mount Blanc, being situated where the air is in motion when it cannot be perceived on the hills around.

I have here I recommended to burn the chaff and straw of our wheat. This would do, if the fly did not deposit its eggs any where except in wheat, and all of them could be secured with the straw and chaff, and every farmer influenced to come into the measure. Late ploughing the stubble has also been recommended. This will effect nothing; unless the grubs are all shaken from the grain when cut,—and then it would be a doubtful experiment.

I have noticed that the fly when upon the grain will not move until a very near approach to it; and when disturbed, it invariably rises to fly to another head; which induced me to see if they might not be taken in netting. I therefore placed some thin cloth upon some sticks, and passed it over the grain—brushing it as it passed along,—and found it to succeed beyond my expectations; and from the success of this simple experiment, I have thought it important to recommend the following Machine, for the purpose of destroying them and preventing their ravages.

This machine is constructed as follows. 1st. Two wheels, 5 feet diameter, made as light as possible,—the folios 2 inches deep, and one inch thick on the concave; the convex surface reduced nearly to an edge.

2d. An axletree of light wood, 16 1-2 feet long, and two inches square.

3d. Two shives, 10 feet long, and 1 1-2 inch square diameter; tenoned into the axletree, four within each wheel; the opposite ends converging nearly or quite together—these are to guide and propel the car.

4th. Three slats, 2 1-2 feet long, 1-2 inch thick, and 2 inches wide—pass through the axletree at right angles with the shives, or perpendicular; and moveable, fastened with a thumb screw or key—one in the centre and one near each wheel.

5th. A rod, 1 inch square, upon the upper and lower ends of the slats—15 feet 6 inches long.

6th. Place two other rods upon the ends of some arms from the centre of the slats—the lower one above the thills—both equidistant from the two first rods, forming a half circle.

7th. Cover this frame with suitable cloth, so that it shall form something similar to half a bolting cloth, when upon the reel with both ends closed—the upper edge of the cloth ought to pass forward of the upper rod, and elevated a little by the support of wires from the rod—the thills will pass through the cloth.

8th. Place several good brimstone matches along the axletree. Light them up, and the machine is ready for operation.

The machine is to be pushed before the operator at a brisk walk. The lower rod should brush the grain about six inches from the top. As the machine passes over the grain, the breadths should lap a little; and it should be used as soon as the fly makes its appearance, between sunset and dark, for several nights in succession; not, however, till the heads of whe. appear above the leaves. It will be readily perceived that the width of the machine is not material. I have recommended 16 1-2 feet for depth of ch. It is probable that large grown

straw may require larger wheels; but I presume it will operate well if the lower rod is brought close to the axletree, and the axletree brushes the grain one foot from the tops—if the matches are situated a little above the axletree.

After having passed over the grain, the flies will be found, suffocated upon the canvass of the car.

Yours, &c.

LEONARD NORCROSS.

From the Farmer's Cabinet.

MANURE.

WHAT IS THE GREATEST QUANTITY OF MANURE TO BE OBTAINED FROM GIVEN MEANS?

MR EDITOR—There are in agriculture, as perhaps in every science, some leading propositions, calculated in a particular manner to arrest attention by their prominent importance. Such I hold that of a "Subscriber" in your May number—"What will an acre of land produce?" and also the question which heads this article.

Were it possible at once to afford a complete and palpable solution to these two propositions, what mind can calculate the vast increase of treasures that would instantly become accessible to humanity? As, then, we cannot inquire too strictly, or know too much regarding them, I propose, after recapitulating a few of the principal statements of a "Subscriber" concerning the latter question, to furnish my own experiments upon the former.

He informs us that a single acre of his land,* with abundant manuring and superior cultivation, was made to produce the sum of \$348,40 cents per annum, for five successive years, besides the vegetables used in a small family. He further states, in substance, as his present conviction, that the quantity of soil cultivated has nothing to do with the secret of gathering money out of it; that "this altogether depends on a judicious selection of soil, on the facility of obtaining manure, and on the proper application of it as food for plants," &c.;—that he found, by actual experiment, made upon a large scale, "that the profit of capital laid out in land produced an interest of only five per cent. per annum, the capital laid out in manure upon the same land produced twenty per cent."

Now, my own experience, as I shall presently show, abundantly confirms the probable accuracy of all these statements. Let us distinctly understand, then, that it is not the great quantity of land, but the abundance of manure upon a little, that is alone required to give wealth and independence; that the man who owns five or six acres, may (according to the above data,) with the aid of manure and good management, draw from \$1800 to \$2,000 from them each year, while he of a hundred acres may scarcely obtain half of it upon the common plan.

But where is the requisite manure to be obtained that shall so suddenly and surely enrich the farmer? In reply to this, I will simply give my own experience, and by it endeavor to convince the reflecting farmer what amount can, and in fact has been made from means incomparably more limited than is generally imagined possible.

Previous to 1829, I had followed in Philadelphia a sedentary occupation, which, by excessive application in it, had so enfeebled my constitution, that I was obliged to seek in the country for that measure of health which I might no longer hope for in

the city. So I bought, with my scanty savings, a small place of ten and a half acres, and moved upon it the same fall, of 1829.

Not being acquainted with farming, I hired a man to plough two and a half acres, and sow it in rye. The cost of seed and labor, in putting in, gathering, and threshing the said crop, was \$8 56 cents. The crop yielded five and a half bushels of very poor black rye, fit only for hay feed—say at forty cents per bushel, (as good rye was then selling at fifty and fifty-six cents per bushel,) was worth \$2 20 cents, and the nett loss sustained upon farming the ground was \$6 36 cents. The season was moderately good for grain, and the two and a half acres rather a favorable specimen of the rest of my land! I planted a potato patch the following spring, (1830,) of about the fourth of an acre, which I manured in the hills with one load of manure only, and the crop yielded but three and a half bushels!

Being a total stranger to the nature and character of soils, but having previously, from some cause, entertained the notion that land in general produced about twentyfive bushels of wheat, or forty bushels of corn, or four or five loads of hay to the acre, the conviction I had now received of the absolute worthlessness of my land fell upon me like the shock of a thunder-clap. Discouraged by the greatness of my disappointment, but not quite confounded, I determined that manure, in future, should be every thing to me, and stand in the stead of both land and crop. Being greatly improved in health, by the change of situation and exercise, I plied my avocation with increased diligence for the maintenance of my family, and made it the amusement of my leisure hours and leisure moments to collect from every corner, and pannel of fence, every thing that I imagined could furnish a vegetable nutrient, and placed it in the cow yard, so combined with the litter as to absorb and retain every thing of the putrescent character that might be deposited there. By such means I have gone on, every year increasing the quantity of my manure, to an extent that I believe has astonished most of my neighbors. The following is a sketch of the means I possessed, and the methods I took to obtain manure for the present year.

I commenced last summer by collecting into the outer part of my hog pen every thing of the weed kind I could find about the place, till I had a lay about twelve inches deep, which I covered with a layer of earth about five inches thick, continuing the process till the pen was filled to about two and a half feet deep. In the fall I littered my loose corncobs and the principal part of the buckwheat straw into the pen, interspersed with layers of earth in the same manner. The two stalls of my stables I served also the same, taking care to save therein all the chaff and refuse straw after thrashing. In these stalls I poured weekly, through the fall and winter, (for I had no cattle in them except in bad storms,) the soap-suds and such putrescent fluids that might be obtained, keeping the corners and outsides, and under the mangers carefully saturated.

As soon as my corn was gathered in the fall, I cut the stubs close to the ground, and wheeled them immediately, while yet heavy, into the barn-yard, where I packed them in every part of it, and also under the shed, being an area of ground about forty feet by twenty, and in a few days covered them also with a layer of earth, from a fence-row, close

* See Gen. Farmer, current Vol. p. 181.

by, to the depth of about eight or ten inches. Upon this earth I foddered my three cattle during the winter, occasionally depositing more earth upon the litter as it collected there.

Your readers will readily judge, that the object of all this preparation was not so much for the sake of saving the materials collected there as to obtain a manure, or rather *sponge*, if I may so call it, calculated to absorb and retain all the urine deposited in the yard during the winter. The compost masses, however, or layers, thus collected together, are not to be considered as manure prepared for the soil, but only as *materials* that require to be thoroughly *mixed*, in order to reduce them to a state fitted for a rapid and complete incorporation with the soil. Accordingly, with this view, I commenced late in April the operation of turning it, which, from its having become closely packed to the depth of twenty inches, with the stalks at the bottom, could only be done with the aid of a grubbing hoe, turning it in strips about a foot wide, reaching across the yard, and throwing the loosened manure back a sufficient space to allow a trench between, wide enough to work in. After removing the whole cover from the stalks, along a strip, as before mentioned, they were easily grubbed up, by first cutting them through all along the solid edge of the strip with the hoe, it being made pretty sharp for the purpose. In addition to this pile of yard manure, I have also emptied the contents of my hog pen and stables, extending the pile several feet, and lying upon the ground, when first loosened, more than two and a half feet deep. Of this manure I have used sixteen loads this spring, for truck and garden, and, judging from the size of the pile yet remaining, there cannot be less than sixty loads, which, being turned once more, I intend, to use for wheat next fall.

In this manner, from only three head of cattle, and the fattening of four hogs, I have made from seventy to eighty-two horse loads of manure, the highly fertilizing properties of which are abundantly attested by my own former experience. I will not say that it is stronger than the best barn-yard manure, but from its closer affinity to the nature of the soil, and its greater facility for being rapidly combined and incorporated, without loss by evaporation, I have no doubt it will be frequently found, upon trial, more effective and more durable.

In the process of turning manure, thus prepared, I hold it of the highest importance to mix well the earthy and vegetable parts together. Few persons are perhaps aware how rapidly the earth facilitates vegetable decomposition, and to what a surprising degree it absorbs the excess of fertilizing effluvia, which must otherwise be evaporated during the process of decomposition. This circumstance, I believe, taken in connexion with the careful economising of all animal excretions, constitutes chiefly the great secret (I might, perhaps, add *alleged* necromancy,) that has added already so much verdure to my previously exhausted soil, and been so profitable to me, and so surprising to my neighbors.

No farmer can imagine, that has not tried the experiment, what a prodigious quantity of rich, vegetable, and fibrous earth may be collected from corners and bye-places which lie out of the way of cultivation, and which, from their retired position, have perhaps, never so much as attracted his notice. All such refuse trash, and fibrous earths and weeds, by being conveyed to his barn-yard, at intervals, during the fall and winter, and judiciously combined

with its contents, will be converted into a rich, fertilizing, and durable manure, merely by absorbing and retaining that excess of putrescent fluids and effluvia, which is otherwise lost by filtration and evaporation; that is, by soaking away and drying up.

Pittstown, Salem Co. N. J., May 20th, 1838.

From Smith's Essay on the Honey-Bee.

LONGEVITY OF BEES.

"The several members of a hive have very different periods of existence. The general law among insects is, that both male and female shall perish soon after sexual union; a few days or weeks at furthest, according to the time, probably, that the female occupies in maturing and depositing her eggs. By retarding sexual union, the lives of some insects may be very much prolonged;—even ephemera have been kept alive by this means for seven or eight days. Annual plants, if prevented from seeding, may be rendered biennial. The ancients were very deficient in knowledge upon this subject. Virgil fixes the term of a bee's existence at seven years, having probably copied from Aristotle; though Aristotle says that bees who live to extreme old age, may reach to nine or ten years. Columella and Pliny have been supposed to regard their existence as extending to ten years; though the language of the former applies to the existence of the community, and not to individual bees; and provided the hive be never changed, nor the combs renewed, it is not likely that any one family should have its existence prolonged beyond that period; as the accumulation of silken pellicles with which the breeding cells are successively lined, would render them unfit for use in a very few years. In addition to the diminution of the cells by this succession of silken linings, they are also diminished further by the excrement of the larvæ, which is never cleaned out, but confined behind each lining; both together, therefore, soon render the cell unfit for use as brood cells. Mr Hunter found three of these layers deposited in a single season, and counted upwards in the cells of the old comb; which, upon an average of three a year, would correspond with the period fixed by the ancients; though this observation by no means proves that the hive upon which it was made, or any other, might not have had a much more protracted existence. Mr Espinasse tells us that he once took a hive which had stood fourteen years, having found it had become weak; it had, nevertheless, sent off a swarm the year previous. There is an instance or two on record, of one family having continued in the same hive for thirty years.

"One of these is mentioned by Reaumur, another by Moutet. Thorley speaks of a colony having occupied the same domicile for one hundred and ten years. The spot chosen was under the leads of the study of Ludovick Vives, in Oxford: the original swarm settled there in 1520, and kept possession till 1630. Query:—may not the bees, when the combs become very old, and the cells much diminished in size, remove them and construct fresh ones? To those who may wish for their own satisfaction to examine the linings of a brood cell, I would observe, that Mr Hunter's mode of proceeding was, to soak the cell in water, till the linings were swelled, when he had no difficulty in separating and counting them; he found them separate most readily at the bottom, on account of the inclosed excrement.

"To common observers it might appear, that the lives of the bees were coveal with the foundation of the colony, presuming upon all the young bees leaving the parent stock in swarms. But I have already stated that all swarms consist of a mixture of young and old bees; the difference between them is very distinguishable; those of the present year being brown, plump, and clothed with light hairs, whilst the old ones have red hairs, notched and ragged wings, and are paler and more shrunk in their bodies. The cases which I have related, and others of a similar kind, have led to the erroneous opinion that bees are a long lived race. But this, as Dr Evans has observed, is just as wise as if a stranger, contemplating a populous city, and personally unacquainted with its inhabitants, should, on paying it a second visit, many years afterwards, and finding it equally populous, imagine that it was peopled by the same individuals, not one of whom might then be alive. Such strangers are we to the honeyed hive; where, however quickly its generations may have passed away, the same face is presented to the beholder."

"The race and realm from age to age remain,
And time but lengthens, with new links, the chain."

"The usual term of the male's existence, is two or three months only: I say the usual term, for his life is always cut off by violence, when no peculiar circumstances arise to render his existence any longer useful. Such circumstances having arisen, (as has heretofore been observed,) he may be kept alive a much longer period, for a year at least, but how much longer has not as yet been ascertained. Messrs Kirby and Spence, in like manner, seem to think it not improbable, that when the workers (*females*) become too old to be useful to the community, they are either killed or expelled the society. Reaumur also throws out a hint to the same purpose. The length of a working bee's life has not yet been ascertained; but the general opinion is that it is short lived. Butler says that 'the bee is but little more than a year's bird'; and some think the period of their existence shorter still. 'The bees of the present year,' says Butler, 'will retain their vigor and youthful appearance till (Gemini) about the 21st of May in the following year, when they begin to decline, and from (Cancer to Leo) June 21st to August 21st, the ground in front of the apiary may be seen strewed with them, some dead, some dying, and a few alive, but incapable of rising again, and by (Libra) 23d September, scarcely an old bee will be left.'"

CURE FOR THE STING OF A WASP OR BEE.—A Liverpool paper states as follows:

A few days ago happening to be in the country, I witnessed the efficacy of the remedy for the sting of a wasp mentioned in one of our late papers. A little boy was stung severely and was in great torture, until an onion was applied to the part affected; when the cure was instantaneous. This important and simple remedy cannot be too generally known, and we pledge ourselves to the facts above stated.

SPRING WHEAT.—So far as we have heard at home and abroad, the experiments made with the spring wheat have proved successful, notwithstanding the cold and otherwise unfavorable weather at the time of sowing. In the neighborhood of this town as many bushels have been raised to the acre, as could reasonably have been expected on the same ground from the winter wheat.—Win. Repub.

From the Frankfort (Ky.) Farmer.

MANAGEMENT AND DISEASES OF HOGS.

To CHILTON ALLAN, President of the Kentucky State Agricultural Society.

I have seen in a late number of the Franklin Farmer, your circular address, calling upon the friends of improvement for essays upon a number of important subjects relating to the agricultural interests and pursuits of our state. Approving heartily the noble objects of the State Society, I read your address with great satisfaction; and I cannot but believe, that the action of the Society will bring about the most gratifying results in improving the science of agriculture, and hence the condition of the husbandmen; for I cannot doubt, that every one who desires improvement himself and who would derive useful information from others, will hold himself bound to contribute something to the general stock of knowledge. There are few intelligent farmers who do not know something unknown to others, and it is by an interchange of sentiment and opinion as well as of experience and practice, that the farmers of the country will be able to see and reject the errors of their husbandry and adopt those modes instead, which lead to improvement and success. In this view, I offer an humble tribute, which at least has the merit of a well meant design of benefitting others in some respects.

The commencement of our prosperity may be dated from the period when our agriculturists turned their attention to the raising of stock for export; and as the consumption and demand have increased in a ratio with the increase of population and wants of the people of the United States, the business has become a source of wealth to Kentucky. And no where has the improvement of stock been so great and so general, nor more zeal and perseverance manifested to procure the breeds of horses, asses, cattle, sheep and hogs. In enumerating these descriptions of stock, the last is not the least important in bringing wealth to the State, and should be looked to with a fostering care and attention.

Under this belief, I humbly submit to the public through you, the following observation on the management of hogs, with some remarks on some of their diseases.

In giving my views on these subjects, I deem it important to state some of the various ways of raising, feeding and fattening hogs in different sections of the country, which, according to circumstances, soil and climate will differ; and conclude with my views as to the best mode to be adopted by the farmers of Kentucky under her peculiar circumstances. In Europe and many parts of the United States, hogs are indispensably kept in pens or styes, and as the numbers raised are comparatively small, there is no great expense attending the manner of feeding them; indeed, this is the most economical, cheap and convenient method of fattening that could be adopted in any country where the number fed is small. In some of the New England States large buildings have been erected for raising and fattening hogs on an extensive scale, fed almost exclusively on vegetables produced on a few acres of land, which gives a profit of 50 per cent. more than any other way in which the products of the land could be disposed of. On this extensive scale, the business is unconnected with any other, having for its object, the raising and fattening of hogs alone, for it requires the most strict attention which daily habit and the

most scrutinizing observation, in time reduced to a perfect system, can give. It was ascertained to a fraction, what each hog would eat at a meal, which was measured out to him three times a day, the quantity according to age, allowing six of the same age to occupy a sty, which was regularly littered and cleaned out once a day. The amount of vegetables required per day, and the necessity of the different varieties coming on in due season, would require great attention. At the first view of the subject, we would conclude that a piggery conducted in like manner in Kentucky, would be equally profitable. But not so—there would be this difference:—The price of pork and lard in Boston is more than 50 per cent. higher than in Louisville; and the profit accruing from the superabundance of manure, which is worth from two to three dollars a load in the New England States, will amount to a large sum, which with us would be excluded from the estimate, as it will bring nothing here on sale, though useful to the land on which the hogs are fattened. In 200 hogs annually sold, these causes would produce a difference of perhaps three thousand dollars in favor of the New England piggery.

Say 200 hogs at 200 lbs. each, 40,000 lbs.	
pork at 10 cents in Boston,	\$4,000
For their manure,	1,000

	\$5,000
40,000 lbs. pork at Louisville at 5 cents,	2,000

Leaving a difference in favor of the New England piggery, \$3,000

In no way could an extensive piggery be made profitable to us but by being connected with a distillery. The expenses would then be much lessened; for it would require but a few vegetables or a little meal added to the slop of the distillery to make the swill highly nutritive. They might be put to graze in the summer and swill given them occasionally, and again put in the fall.

The manner of feeding and fattening hogs now generally adopted in this State, seems to me to be well calculated for our method of cultivation.—Taking into consideration the products and the great number of hogs fatted for other markets, together with the great number of beef cattle annually grazed and fed, the system is complete. In winter, they are amply supplied with food from the refused corn and pudding of the cattle—two or three hogs to each head of cattle finding thus abundant sustenance. In the spring, when the cattle are no longer fed, the hogs are put on the exuberant clover field, which was sown for the double purpose of enriching the land and supplying rich food for their cattle and hogs. In due time, when the clover becomes hard, and unfit for the hogs, it is given up to the earth, and they are removed to the rye fields there to fatten and complete another system of manuring, so admirably adapted to our lands and our wants. So soon as the rye field is consumed, the corn field is ready to receive them,* and in due time they are ready

* We presume our writer does not intend to be understood that the hogs are turned into the corn field; for though this practice may be adopted by some, the more general custom is to put them in a large pen adjoining, into which the corn is thrown. If the corn is not sufficiently ripe when the rye is consumed, old corn is fed to the hogs; and indeed, the feeders generally, we believe, prefer beginning to feed them on old corn after they are put up—introducing the new rather cautiously and gradually.—Ed. Franklin Farmer.

for market, leaving the fields and pastures richer than they were.

Although this arrangement is good for feeding and fattening, yet there are other important matters in relation to their raising and health, which in no wise should be neglected. Experience has taught me, that no matter how many pigs a sow has over six, they should be reduced to that number always retaining the large and healthy ones; for I can and will demonstrate that six pigs will make more pork at 12 or 18 months old, than eight would of the same litter—and eight will make more than ten. Give to the six the food which you would give the eight or ten, and you will find in the result, the truth of my statement proven. It is essential that pigs be kept fat a while sucking, and to have them so, six is a better number than eight or ten. At weaning time or when sixty days old, the time when the sows decline in milk, particular attention should be paid to the pigs, having them regularly fed either with corn or swill, for at this juncture, they are unaccustomed to root for themselves and will rapidly lose their flesh and their health, and their growth will be retarded, if left to shift for themselves. If they are kept fat during the fall, when provisions are plenty and cheap, they will keep thrifty and well through the winter, on very moderate feeding; but I prefer liberal feeding throughout. The food is by no means thrown away as you will have more pork and not any more corn consumed in the end.

Hogs should be kept free from diseases; particularly the disease of worms, which is very pernicious and a constant attendant on poor hogs. Liberal feeding at all times, is the best preventive; but when it is not in the crib, brimstone, spirits of turpentine, or tar mixed with their food will remedy the evil. All hogs are more or less subject to worms; but some are so overcharged, that their intestines are literally filled with them, and unless they are extirpated, it is throwing away corn to feed them, for in this condition it is almost impossible to fatten them; they will consume twice as much, as a hog will not troubled with them, as the nutritious juices are taken up by the worms, and their fetid excrement is all that is left as a miserable substitute for sustenance.

The most fatal disease of hogs is the swelled throat or quinsy. This too, is easily prevented. I have long been of the opinion that it proceeds from indigestion, caused by feeding on hard grasses or clover in their declining state; and my successful practice as a preventive for the last eight years is a strong confirmation. Yet it matters not concerning the cause, provided there is a remedy. The disease in the last stage, is highly inflammatory, but at no time infectious. It is an accumulation of matter formed between the glands of the jaw, which continues to inflame till the hog dies of suffocation. The disease may be cured before and after the matter begins to form; but as it may be more satisfactory to state my experience and knowledge on the subject, I will give an instance as coming under my observation, and conclude with my practice as a cure and preventive. In 1830, I discovered the disease among my hogs by the death of one of my fattest. As soon as possible, I had them removed from the clover field, and put in a spacious pen, where they were fed with as much corn as they would eat after it was glazed with tar and as much ashes put on as would adhere to the grains. They still continued to die till I lost to

the number of fifteen. This great number dying out of eighty, caused me to doubt the efficacy of the remedy or that the disease was too rapid for its effect. Shortly after, they were put up to fatten, which they did very readily, and I was left in doubts as to the effects of the medicine, until the day I butchered, when I found lumps of coagulated matter, in the jowls of many, about the size of a hazel nut or larger, without any signs of inflammation around them. I then came to the conclusion that they would have died had it not been for the remedy applied, and that the disease of those that died had advanced too far to be cured by any remedy. Observing that hogs kept in styres never had the quinsy, I attributed it to the wholesome quality of food they ate, and on the contrary, the cause of their having it out of styres, to the pernicious qualities of hard dry grasses. Since 1830, I have invariably given my hogs during the spring and summer months when grazing, slop or will once a week or oftener, consisting of kitchen slop with cooked vegetables of various kinds, apples, &c., with bran or a little meal, mashed to a paste, salted and cooled off by adding a quantity of water, and occasionally brimstone or saltpetre. Since the above date, my attention has been directed to the raising and fattening of hogs on the products of a small farm, and have never yet lost a hog by this disease nor in my recollection by any other. My opinion is still further supported as to the cause of the swelled throat, by its being less frequent since the practice lately adopted in putting the hogs to graze when the clover is young and tender, and taking them off when it is old and tough.

Every body knows that the young and old hogs should be kept apart in winter; and yet how shamefully this important matter is neglected by many. Young and old, great and small are crowded together, day and night, mashing and smothering; and yet many will look on with heedless regard at the great destruction of their young stock, without separating them. When young and old are fed together, the old will always get more than their share, thereby the young become poor and diseased, making little or no progress in growth.

The breed of hogs best calculated for our general purpose is yet to be ascertained. Within a few years, great exertions have been made, at considerable expense, to procure the best breeds, but whether any of them answer our expectations, I think very doubtful. The breeds imported here, were improvements made to suit the purposes of others under different circumstances, different soil and climate, different food and management, and under a different method of disposing of the pork; and according to our present mode of farming; thus differing from the methods abroad, whence these hogs have been brought, and our surplus pork being chiefly driven to the south, I think ultimately they will not do except in the event of the successful completion of the railroad from Lexington to Charleston. Then the smaller and earlier matured hogs, the Byfields, the Berkshires, the Bedford's, &c. will be more profitable than the larger breeds. But should this all-important improvement to the West, prove abortive, the hog that will be best calculated for our interests, is yet to be improved by some judicious cross from our present great variety of breeds. The fat varieties, as the Bedford, Berkshire, &c., from their early propensity to fatten, are best for family use and home consumption; but owing to their incapability to travel,

they must measurably give way to the longer legged hog, until the railroad from Lexington to Charleston is complete. **BIRD SMITH,**
Member Nj. State Ag. Society.

For the New England Farmer.

SOWING CORN BROADCAST—SUMMER SOILING, &c.

Ma Editor—By *summer soiling* European writers mean the cutting of green food for cattle and feeding it out without curing. And European writers frequently enlarge upon the advantages of this practice.

Some of the advantages of summer soiling are said to be the following:—The same ground will furnish food for cattle, in the proportion of from 3 to 5 by summer soiling; where but one would be kept without it.

The cattle kept in well shaded yards, or well ventilated stables will be guarded from the biting flies, and the scorching sun, and will feed in comparative comfort, and of course will thrive on a smaller amount of food. By summer soiling also the quantity of manure may be greatly increased, and may be used at any time and place which is desired. The keeper will find however, that it is somewhat more laborious to cut green food, and to place it in the mangers before the cattle, than it is to turn the cattle into the field and let them select and trample down for themselves. But in this country there seemed to be a difficulty in finding a succession of green crops for summer soiling through the season, particularly in the latter part of summer. To obviate this difficulty a gentleman of New London, Conn. sowed southern, long kernelled, or horse tooth corn. This corn come on after the first crops of grass were gone, and it come on too at a time when pastures were frequently dead or dried up. I have now been a number of years in the practice of sowing horse tooth corn, broadcast, for summer soiling, and the following experiment made two years ago, was attended with results very similar to the common results of experiments made in other years:—

EXPERIMENT.—On the 15th June 1836, about 16 square rods of ground which had been well manured, and well ploughed, were sown broadcast with horse tooth corn, at the rate of four bushels of seed to the acre. The seed was then lightly ploughed in with a small horse plough, after which the ground was harrowed and rolled.

On the 19th of August following we began to cut upon the crop of corn stalks which grew on the above described ground. The crop which grew from the 16 rods of ground before mentioned afforded forage for a horse from the 19th of August to the 8th of October, and also afforded the principal part of the food for a cow from the 5th September to the 8th of October. Making 50 days keeping for the horse and 33 days for the cow.

On the 5th of September when this corn was from 5 to 8 feet high, but had not eared or tasselled out, the produce of one square rod was cut up, and while green it weighed 375 lbs. This was at the rate 30 tons to the acre. This 375 lbs. which was cut from one square rod of grain was dried and on the 27th October 1836 it weighed 86 1-4 lbs. which is at the rate of 13,800 lbs. or 6 9-10 tons to the acre.

An acre of horse tooth corn, sowed in this way on good ground, would probably afford green forage for 30 cows a month, or for 8 horses the same length

of time. And we think such a crop of corn stalks, is far superior to any crop of guinea grass, or cow cabbage, which we could reasonably expect to grow in this country. It is proper to remark here however, that in order to make the horse active and strong for business a little provender is very useful.

While the horse was eating the corn stalks as before mentioned, he was allowed two quarts of shelled corn per day, and with this allowance he was more active and strong for business than when he had his two quarts of shelled corn, and as much good dry hay as he would eat. I may add, that though cows eat the green corn stalks voraciously for the first two or three days. If kept wholly on the green stalks they are apt to get cloyed, and afterwards not to eat as well. The stalks are not easily cured into good dry fodder.

The advantages of sowing the horse tooth corn, instead of some of the smaller sorts, are, the horse tooth corn being a taller kind makes a much greater amount of fodder.

It is a later kind, and therefore keeps green, and in a fit condition to be foddered out much larger, than the earlier sorts.

There is considerable difference in the sweetness of the stalks of different kinds of corn. And it might be worth the attention of Agricultural philosophers, to make experiments to decide, not only which kind of corn stalks, yields the greatest number of pounds to the acre, but also which yields the greatest amount of nourishment to the acre.

For those who are apt to be short for summer pasture, particularly in August and September, will not the cultivation of a patch of horse tooth corn, sown broadcast be found to be a matter of considerable practical importance?

Yours, respectfully,

ASA M. HOLT.

East Huddam, 15th August, 1836.

TUCK IN YOUR RUFFLE.—“We have a few nails to make,” said a blacksmith to his son as he came from school at 12 o'clock. Thomas tucked in his ruffle and took off his coat, and was a blacksmith till he earned his dinner, and eat it with a good relish. “Put out your ruffle, Thomas, it is school-time now,” said the father. This is the picture of the day; but it would answer just as well for a good many others. Thomas expected it; and was as happy with his ruffle tucked in, as his mates at their play.

It would be no bad notion, “in these hard times” for many a young man to *tuck in his ruffles*, and swing an axe, or hold a plough, or make a nail—for many a young man, whose expectation of riches from the gains of trade are sadly disappointed to earn a living in some calling which the world honors less but pays better—some humble occupation, which while it holds out no delusive hope of immense wealth by a single speculation, assures him of competent food and raiment.

We would here recommend Agriculture, in a special manner. Not such farming as consists in first running in debt for lands and mortgaging them back for payment; and then borrowing money to put up fine buildings, and then hiring men to carry on the farm. No! this is not the way.—But lay your own shoulder to the wheel—tuck in your ruffle, and earn your bread by the sweat of your brow. It will be the sweetest you ever ate.—*Franklin Farmer.*

**NEW ENGLAND FARMER,
AND GARDENER'S JOURNAL.**

BOSTON, WEDNESDAY, AUGUST 22, 1838.

THE SEASON.

In looking back upon the season thus far it would be difficult to say, how the weather could have been made better for the general productions of the earth. In some cases the drought has been severe; and farmers have begun to complain, for when was ever a time that some of them did not complain, that the corn ears would have no grain upon them, and the potato tops no bottoms. There are many persons, belonging to the family of the grumblers, a family which no man can number, who never were and never can be suited; who are always seeing spots upon the sun, which to their perverted vision are continually growing larger; and who are sure even in the clearest sky to predict a storm. We pity these people on their own account, because they never enjoy any thing; and they see poison at the bottom of the fullest and most sparkling cup; and we pity the community in which they are found, because to such a community they are always a miserable nuisance. Dr Franklin, in his ingenious and striking style, wrote an essay upon what he called, as well as we can remember, the Philosophical Leg, which illustrates some of the leading characteristics of different classes of mankind. He speaks of a man, who was unfortunate enough, or perhaps we should say fortunate enough, to have a lame or deformed leg, which he used to say always afforded him an infallible index to the characters of the persons with whom he associated. If meeting with an individual, he observed that the first thing which caught the attention of this individual was his deformity, and he perceived him in conversation frequently glancing at his lame leg, he thought him at least unkind and quite disposed to be censorious. If he met with another man, who immediately upon coming into his presence asked him what was the occasion of this deformity or injury; and if it did not inconvenience or pain him, he took him for a downright savage, whose temper inclined him to look only at the evils in the world, and to make others more unhappy by reminding them of their misfortunes. If next he met with another man who not only took no notice of his deformity, but was evidently at some pains to make it understood that he did not consider it, or that he was anxious that the sufferer himself should not be sensible to it or mortified or embarrassed by it, to such a man he at once gave his heart, as to a man of true benevolence and sound philosophy.

We hope this story so full of useful instruction will not be deemed unseasonable or misplaced; because it perfectly illustrates the dispositions and character of some persons in regard to the weather, the season, and every thing else. Nothing with them is just right; and defects or faults are the thing, which always first arrest their attention. The season is never as they would have it. As we have heard this very week, "the wheat looks well, but then it has some blighted ears;" or "I have observed that though the ear is long, and the straw large, yet it has not so many kernels in it as it sometimes has," or "the wheat is heavy and I shall get a good crop, but then I have observed it does not look of so dark a color as I like to see it." Now there is no suiting such people; and we almost believe, if an angel from Heaven should visit them in robes of light and glory, they would at once set about trying to find some shades upon them or some rent in them; or if they could not succeed in this, they would pretend that the fashion of these celestial garments was "not exactly" what they would have had them.

So it is with the beautiful, productive, and enchanting season, which is just passing over us. The drought has been in some places very severe, but it has not been universal, and there has been no where any suffering. If frequent rains had been intermixed with our hot suns, then rust and mildew would have blasted our wheat, which has now almost every where been gathered in excellent condition. As to our potato vines, which almost every where exhibit an extraordinary luxuriance of growth, having no bottoms to them, it will be time enough to make that discovery, when we come to dig them; and then again if our oat crop is small, as perhaps in many cases it seems to be, though by no means universally so, the corn crop promises every where to be extraordinarily abundant. The season as a whole, for general health and abundance of production, and the favorable opportunity of the early harvests, and the comfort of the weather, and the beauty and glory of the skies by night and by day, has never been surpassed; within the memory of few of us has it rarely been equalled. Two seasons of scarcity, and of the most unpropitious weather have just passed by; and yet throughout our whole land there has been no suffering for bread; if now then, in the midst of this abundance any man presumes to complain, what does he deserve but perpetual exile from a christian community; for "even the ass knoweth his owner, and the ox his master's crib."

TRIAL OF PLOUGHS AT HOBOKEN, N. Y.

The American Institute gave notice of their intention to have a trial of ploughs at Hoboken on the first day of August, with a view to test the advantages of their construction, their durability, their comparative cost, their comparative ease of draft, the manner in which their work is performed; and any other circumstances connected with them, which might be deemed important.

The competition was open to ploughs from all parts of the country, and the trial was had under the inspection of experienced and practical farmers. Eight ploughs only were entered, and the experiment was made under peculiarly unfavorable circumstances. The ground was fast locked by a severe drought. The time of year, the first of August, could hardly have been worse chosen; and the weather was intensely hot. Only two teams (one yoke of oxen and one pair of horses) were furnished for the occasion, which were to be used in succession, whereas each plough should have been separately furnished with team and ploughman, and the necessary preliminary arrangements for starting could not be made until some time after the hour appointed for the trial. For want of a suitable instrument likewise, the comparative power of draft required for each plough was matter not of certain test but of mere judgment. The committee under these circumstances felt great diffidence in coming to a decision; and having made it according to their best judgment could hardly repose in it with the confidence desired. Their report we shall publish after it is obtained from the Institute. We have pleasure in stating that the Howard plough from the N. E. Farmer office though tried under several disadvantages was much admired for the excellence of its construction and workmanship.—The plough of Mizer and Horton of Peckskill, N. Y. obtained the medal; and is an admirable instrument. We hope such a trial will be held another year and under circumstances more favorable. If made at a proper time of year and after reasonable and careful arrangements, it must be of great public utility; and the mechanical and agricultural community are already much in debt to the American Institute for their public spirited exertions.

The Virginia millers are buying up wheat at \$1 a bushel.

Massachusetts Horticultural Society.

EXHIBITION OF FLOWERS.

Saturday, August 18, 1838.

Dr J. C. Howard of Woodland, Brookline, exhibited several fine specimens of the Dahlia; among them we noticed Queen Adelaide, Brown's Desdemona, Royal William, Beauty of Cambridge, Ophelia, Cedo Nulli, and some other good varieties. Dr Howard also decorated our tables with one of his extra fine Bouquets.

There were other Flowers and Bouquets from Messrs Newhall, Hovey, Winship, and Walker, containing some choice flowers and as a whole, making a pretty good display for the season.

For the Committee,

S. WALKER, *Chairman.*

EXHIBITION OF FRUITS.

Pears—From Mr Aaron D. Weld, of West Roxbury, English Catharine, handsome specimens of the kind.

From Mr Downer, specimens of Dearborn's Seedling, Washington, and Queen Catharine.

Apples—From Mr Simon H. Mason of East Medway, Pond Apples, large, handsome variety of greening, not yet quite in eating; in flavor resembling R. I. greening so far as could be judged at this time.

From Mr Downer, Sopsavine, William's Favorite, very beautiful.

Mr Richards presented for exhibition the following kinds, comprising several of the finest varieties of Early Apples:—Early Harvest, Early Bow, Early Red Juncating, and Williams Early, also Sugar Loaf, Calville, and Spice Apples.

From Mr James Munroe of Cambridge, River Apple large, red, and now ripe, fine flavored and handsome.

Apricots—Handsome specimens from Mr Ezra Dyer. *Plums*—From Mr Downer, the Bingham, and Royal de Tours, both specimens large and very fine; also Damask or Danson.

From Mr Samuel Pond from his garden in Cambridgeport, Apricot Plum, fine specimens; Blue Mogul, so called, a large, oblong, blue Plum of fine appearance; Pond's seedling a noble fruit, large, blue and of delicious flavor. The tree is raised from offsets: Mr Pond has been eminently successful in the cultivation of the Plum, his trees produce this year by estimation from 25 to 30 bushels, the trees of several varieties being literally loaded with this valuable fruit.

Grapes—From Dr J. C. Howard, from his garden in the Woodlands, beautiful specimens of the White Chasselas, Black Hamburg, and the Meunier or Millers' Burgundy. With ordinary cultivation the berries of this last named variety are small, the clusters compact but of inferior size; but these specimens were of uncommon size, the berries large, the clusters of ample dimensions with large projecting shoulders.

Shepardia elagnoides—From Messrs Winship, some branches of the Shepardia or Buffalo berry, covered profusely with large and compact clusters of beautiful scarlet fruit. The fruit the size of the currant, is very grateful to the taste after being ameliorated by the frost. It is sometimes though improperly called the *American Olive*, but only from the resemblance of the leaf which is small, narrow, and woolly, having a silvery appearance. The tree is from the Rocky Mountains, therefore perfectly hardy. It is armed with strong thorns, hence it is believed it will become a most desirable plant for hedges. At Messrs Winship's it is cultivated along the highway, where innumerable droves of cattle pass, but no animal it is said has ever been known to browse it.

For the Committee,

WILLIAM KENRICK.

NOTICE.

The General Committee of Arrangements, are requested to meet at the rooms of the Massachusetts Horticultural Society, 23 Tremont Row, on Saturday, 1st September, at 10 o'clock, A. M.
The Special Committee are requested to meet as above, on Saturday, 1st September, at 11 o'clock, A. M. Per order,
SAMUEL WALKER, Chairman.

BRIGHTON MARKET.—MONDAY, August 20, 1838.
Reported for the New England Farmer.

At Market about 375 Beef Cattle, 300 Stores, 3,000 Sheep, and 725 Swine.

Prices—**Beef Cattle.**—We quote to correspond with last week, viz: First quality \$7 50 Second quality, \$7 00 a \$7 25. Third quality, \$6 00 a \$6 75

Stores—Less than half the number at market were sold. We quote the following prices, viz: Yearlings @ a 12. Two Year Old \$15 a 20. Three Year Old \$20 a 25.

Sheep.—Sales quick, lots were sold at \$1 75, 1 88, 2 10, 2 25, 2 42, 2 62, and 2 75.

Swine.—Several lots were sold to peddle at 7 1/4 a 7 1/2, more than half of which were Barrows— at retail from 8 to 10.

THERMOMETRICAL.

Reported for the New England Farmer.

REMEDY FOR CANKER WORMS.

The subscriber having obtained letters patent for his circular metallic trough and roof for preventing canker worms or other insects from ascending fruit or other trees, now offers his services to apply the same to any extent that may be wanted. They were put on to three orchards belonging to Jonathan Dennis in Portsmouth, R. I., in the autumn of 1837, and exterminated the canker worms so completely that some of the trees hung so full of apples as to render it necessary to prop them, although they have been eaten by the worms for a number of years previous, notwithstanding the application of tar. The public are invited to examine the orchards above referred to. The trough and roof is made of lead and bent to conform to the shape of the tree, and the ends soldered together and made enough larger than the tree to allow the trees to grow ten years before it will fill the space. The space between the trough and the tree is filled with hay, straw, seaweed, or any substance that is easily compressed by the growth of the tree; the trough is kept in its place by three nails driven into the tree below it; when the tree has grown so as to fill the space, the trough may be enlarged by putting in a short piece of lead to fill the troughs and more. A little cheap oil is sufficient to fill the troughs and fill them three times has been found to answer for one filling them; by stirring the oil once sometime after they are filled. Those who wish to have their trees fitted, would do well to make early application to the subscriber, postage paid. For sale, State, Town and County rights by
JONATHAN DENNIS, Patentee,
Portsmouth, R. I., August 22, 1837. 4w

FARM FOR SALE.

An excellent farm, near the centre of Framingham is offered for sale, on liberal terms. Inquire at this office.
Aug. 22, 1838. 3m

MIDDLESEX AGRICULTURAL SOCIETY.

The Committee on Farms, Fruit, Mallery, Forest Trees and Shrubs, will meet at the Middlesex Hotel in Concord, on Monday, the third day of September next, at nine o'clock, A. M., and will then proceed to view such farms, &c. as have been entered for premiums.

NAHUM HENDY, Waltham,
JOHN H. LORING, Groton,
ELI RICE, Marlborough,
WM BUCKWINSTER, Framingham,
CYRUS WARREN, Concord,
Committee.

All applications must be made to some one of said committee, or to the secretary of the society, on or before the above time.

TIMOTHY PRESCOTT, Secretary.

Concord, August 13, 1838.

FRUIT AND ORNAMENTAL TREES, MULBERRY, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Strawberries, Quinces, Gooseberries, Raspberries, Currants, Cherries, Grape Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Flowering Spikes; Paeonies, Dahlias and other Herbaceous Flowering Plants.

225,000 More **MULBERRIES** are now offered for sale; the trees genuine and will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussa and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to E. D. BACCK, Commission Store, No. 132 Water Street, New York, M. S. POWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston.
August 1, 1838. **WILLIAM KENRICK.**

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dame, situated in Rochester, N. H., six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quarries of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to **JOSEPH BRECK & Co.**, No. 51 and 52 North Market Street, Boston.
August 16, 1838.

NEW ELEMENTARY WORK ON BOTANY.

Peter Parley's Botany; with descriptions of Trees, Shrubs and Plants: with a large number of fine engravings. The publishers invite Teachers, and others interested in this subject, to examine this work, as they believe it will be found one of the most practically useful in use, being a complete manual of Botany for the adult and the pupil.
Parley's Cyclopaedia of Botany.—This work appears to be exactly what is wanted by young persons and in families. It not only contains the strictly scientific part of the subject, in an introduction and very full and complete genera of Plants, but it also contains a copious glossary of terms, and what is most important, a Dictionary of Plants, of nearly 300 pages, containing familiar descriptions of all the most interesting trees, plants, and shrubs. These are alphabetically arranged, with an English index. Thus the reader may immediately turn to any plant he wishes to read about. The work is illustrated by over 200 engravings, and is sold very cheap.—
Boston Paper.
For sale at the New England Farmer Office, 51 & 52 North Market Street. **JOSEPH BRECK & CO.**

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land situated on Nonantum Hill, in Newton, 5 1/2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

LOT WHEELRIGHT.

July 16th.

WINTER RYE.

Just received at the New England Seed Store and Farmer's Office, a few bushels of prime Winter Rye.
Aug. 13, 1838. **JOSEPH BRECK & CO.**

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Tea Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham. **ISAAC PARKER.**

FOR SALE.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

SITUATION WANTED.

As Gardener, by a young man of practical knowledge and can be well recommended. A S. situation West or South would be preferred. Address R. B. through the office of this paper.

THE CONFESSION.

There's somewhat on my breast father,

There's somewhat on my breast!

The lovely day I sigh for, father,

At night I cannot rest;

I cannot take my rest, father,

Though I would fain do so.

A weary weight oppresseth me—

This weary weight of wo!

'Tis not the lack of gold, father,

Nor lack of worldly gear;

My lands are broad and fair to see,

My friends are kind and dear;

My kin are real and true, father,

They mourn to see my grief.

But oh! 'tis not a kinsman's hand

Can give my heart relief!

'Tis not that Janet's false, father,

'Tis not that she's unkind;

Though busy flatterers swarm around

I know her constant mind.

'Tis not her coldness, father,

That chills my laboring breast—

It's that confounded cucumber

I've ate, and can't digest.

STATE OF MAINE.

LAND OFFICE,

Bangor, April 30, 1838. }

The twelfth section of "an act additional to promote the sale and settlement of the public lands," passed March 24, A. D. 1835, making it the duty of the Land Agent "to advertise the settling lands in market, once a year, for two months, in one paper in the city of Boston, one in Concord, N. H. and in one paper in each county in the State, describing the quality and situation of said land and the terms of sale," the Land Agent hereby gives public notice that Township number 4, in the fifth range of Townships west from the east line of the State, has been lotted for settlers, and is now in the market for sale and settlement under the provisions of the following law passed at the last session of the Legislature. The price will be from fifty to seventy-five cents per acre, according to the quality and situation of the lots. The lots average 160 acres each. The soil in this township is good, being remarkably free from stones, and the land lying in moderate swells. The location of this township is favorable for settlement, as the Aroostook road passes within one mile of the western line of the township. There are between 40 and 50 settlers in the adjoining township No. 4 in the 6th Range, and a good saw mill and grist mill have recently been built there by Ira Fish, Esq. only one mile distant from this township.

Townships No. 3 in the 4th Range, No. 7 in the 6th Range, and No. 8 in the 7th Range have been surveyed and lotted into mile sections. Lots of 160 acres will be run out from any of these sections to actual settlers, where the land is more suitable for farming than for timber. Townships Nos. 8, 10 and 12 in the 5th Range have been ordered to be surveyed, by the Surveyor General, forthwith, and will be open for settlers as soon as the lots can be run out. The Aroostook road passes directly through these townships and the soil is represented to be excellent for farming. The Aroostook road is laid out and cut from the military road leading from Bangor to Houlton, near Mattawakeag Point to the Aroostook river, a distance of about 75 miles.

About \$17,000 will be expended this year, upon this road by the Land Agents of Maine and Massachusetts, and with the part already finished the road will be completed about one half of the distance. The whole distance will probably be completed next year. All the land on this road has been sold for about two thirds of the distance, and in several townships all the lots upon the road have been taken up by actual settlers. The remaining part of the land upon this road, owned by this State is now offered for sale to settlers. The price of lots in these townships under the condition of the new land law will be from fifty cents to one dollar per acre, according to

their situation and quality. Should any company of settlers select any unsurveyed township in this part of the State on which they should wish to erect mills under the provisions of the new land law, the Surveyor General would proceed as soon as practicable in the survey of such township.

The settling duties required by law, are "that the purchaser of each lot shall clear in a proper manner, fifteen acres thereof, ten or more of which shall be well laid down to grass, and build a house thereon, within four years from the time of the purchase."

The board of Internal Improvement for this State have just ordered an exploration and survey of all the lands situated in the Aroostook country in reference to their settlement and agricultural capabilities. This survey will be commenced forthwith under the charge of Dr. Ezekiel Holmes, of Winthrop. His report of the situation, quality and value of the public land in this part of the State may be expected in the course of the season, and will give all needed information, to those persons who may feel desirous of making a settlement upon them.

The following extracts from the second report of Dr. Jackson on the Geology of the public lands, made to the Legislature, and now in the hands of the printer for publication, show the value of these lands for cultivation. Speaking of the Aroostook country the Doctor says, "the average width of the alluvial region on the Aroostook river cannot be less than six or eight miles, and in some places it is much wider. It is a well wooded region and is the best settling land in the State, equalling in fertility the favored regions of the Western States, and capable even under a less genial climate, of producing crops of wheat and other grain, fully equal in abundance with any soils of which we have any records.

"We here found a yellow loam of a fine kind derived from the limestone rocks and luxuriant in its produce, and in some places covered to the depth of 4 or 5 inches by a black vegetable mould.

This yellow loam is remarkable for the tall rank grass called blue joint, which skirts the margin of the river and from 4 to 5 feet high and extremely luxuriant. The forest trees are of a mixed growth, but the sugar maples are most abundant, and are of gigantic size. Elm, white birch, black and white ash also abound. The soft wood grows mostly on the low lands, while the uplands in the rear are densely crowded with hard wood trees, among which are scattered magnificent pines. In the course of two years, there will be a free communication between Bangor and the Aroostook and a great number of enterprising settlers will take up their residence in this fertile valley, and by farming, they will obtain an ample reward, and that region will become as it is destined by nature to be the granary of the north."

In another place Doctor Jackson says—"On the Aroostook it will be remarked, that very few if any hemlock trees exist, and the predominating growth is of a mixture of various hard wood trees, the sugar maple, ash and yellow birch abounding, while oak scattering, some of the most lofty pine trees ever beheld. There are evident reasons why this should be the case, for the richest soils are always most crowded with a mixed growth, and the Aroostook soils are mostly of limestone alluvion, and are exceedingly rich and good settling lands remarkable for their heavy crops of wheat, rye and other grains, and are certainly richer as an agricultural district, than any other portion of Maine. The present population on this river is estimated between 400 and 500 persons, chiefly emigrants from Maine."

Towards the conclusion, Dr. Jackson says: "the researchers of the present season have brought to light many important resources in the public domain which were before unknown. Beds of iron ore of immense magnitude favorably situated for advantageous operations occur on the Aroostook, and all the marked characteristics of the regular coal formation exhibit themselves over a great belt of country from the Schoodic to the Aroostook and St. John, and extend to the "Peninsular" lake near the frontier of Canada. It will be at once perceived, that the country which we have explored is a most valuable territory, possessing every advantage required by settlers. Heavy timber offers a reward to the enterprising lumber dealer. A rich soil capable of producing an average crop of 20 bushels of wheat to the acre, and in some cases producing from 30 to 40 bushels, offers an ample reward to the husbandman. Inexhaustible supplies of limestone, valuable both for building materials and for agriculture, vast and inexhaustible mines of rich iron ore, and interminable forests which will furnish an abundance of charcoal, required for the manufacture of the finest kind of iron and steel—the country presents every natural advantage that might be required to call forth the enterprise and industry of the farmer and manufacturer."

By an inspection of the map of Maine, it will be seen that there are nearly one hundred townships of land situated on the Aroostook river and its tributaries, one half of which belongs to the State of Maine and is now open for sale and settlement under the new land law. Considering the remarkable fertility of the soil in this region, and the high price of produce, and the ready market which it finds among the lumbering people on the Penobscot and St. John rivers, and the advantages of the road now making by Maine and Massachusetts into this region, it is believed that an uncommon opportunity is now offered to persons who may feel desirous of obtaining good farms at a low price.

The field notes of the surveys of all these townships are in the Land Office, open to the inspection of every person, and all information that may be received here, from time to time, from the progress of surveys, and the reports of Agents, will be cheerfully given to all inquirers, and every facility granted within the means of this office, to secure to individuals and companies, all the benefits and privileges intended by the Legislature, for actual settlers under the provisions of the following law.

ELIJAH L. HAMLIN,
Land Agent of Maine.

STATE OF MAINE.

In the year of our Lord one thousand eight hundred and thirty-eight. An act additional to promote the sale and settlement of the Public Lands.

SECTION 1. *Be it enacted by the Senate and House of Representatives in Legislature assembled.* That all lands lotted to settlers shall be sold to those only who will perform settling duties on the same as prescribed by law, the price to be fixed by the Land Agent, having reference to the field notes, not however at a less price than fifty cents per acre; three fourth parts of said price to be paid within three years from the time of said sale in labor to be laid out in making roads in such township where said lands so sold are situated, under the direction of the Land Agent; and the remaining fourth part to be paid in cash within four years from the time of said sale.

Sec. 2. *Be it further enacted.* That whenever twenty or a less number of individuals, shall each select a lot of one hundred and sixty acres of land in any township lotted for settlers, the same having no mill within its limit, and shall give bonds satisfactory to the Land Agent, that they will within the term of three years from the time of said selection, erect in a proper and substantial manner, a saw mill and grist mill, on such lot within said township, as shall be designated by the Board of Internal Improvement, the same shall be entitled to a deed of such mill; and each individual shall receive a deed from the Land Agent for his respective lot, without any further consideration, conditioned however, for the performance of the settling duties required by law.

Sec. 3. *Be it further enacted.* That from and after the passage of this act, all acts and parts of acts inconsistent with the provisions of this act, be and the same are hereby repealed.

In the House of Representatives, March 23, 1838—
This bill, having had three several readings passed to be enacted.

ELISHA H. ALLEN, Speaker.
In Senate, March 23, 1838. This bill, having had two several readings, passed to be enacted.

N. S. LITTLEFIELD, President.
March 23, 1838. Approved.

EDWARD KENT,
Secretary's Office,
Augusta, March 26, 1838. }

A true copy of the original on file.
Attest, SAM'L P. BENSON,
Secretary of State.

THE QUEEN BEE.

To the Editor of the New England Farmer.

Having read some of the various theories on the Honey Bee, and compared what I read with my own observation on the bees themselves, I have become satisfied, that notwithstanding so much has been written, very little is known of the government, police, or interior arrangements of the inmates of a bee hive.

Writers inform us that a "swarm of bees contains One Queen, Five Hundred drones and Nineteen Thousand Four Hundred and Ninety-nine neuters." Who knows any thing about this? Could we at pleasure examine the inside of an inhabited hive and closely watch the movements therein, we might form some opinions as to this army of neuters marshalled by a queen and drones, but human ingenuity can devise no way in which this can be done with any degree of exactness; we can only look around us and see how it is with other insects and animals who can be examined with impunity. Where throughout animated nature can we find a parallel? Does nature usually form neuters or are bees an exception?

But neuters are not my object in this communication. I am even so much of an infidel as to doubt the existence of a Queen Bee. My doubts are caused in part by the following circumstances. I have carefully examined several swarms of bees after suffocating them with fire and brimstone, without being able to find *her majesty* of "about eight lines and one half in length, her wings so short as scarcely to reach past the third ring and her color a deep yellow." The present season one of my hives swarmed and settled on the limb of a young apple tree near the ground. In a few minutes after, another hive swarmed and collected on the same limb nearer its end, leaving a space of about two inches between the swarms. The additional weight of the last swarm brought the limb so near that the wind swung it against the ground so as to accommodate the last comers. They began to gather up the limb nearer the first swarm and finally formed one cluster of bees, which I put into a flour barrel. They commenced working, and have now every appearance of prosperity. In this case where were the two queens who "are infused with the most deadly hatred and the most insatiable thirst for each other's life, which nothing but actual death can appease?" About sun set on the sixth of the present month I accidentally noticed a great stir amongst my bees, and on examination found a constant passing and repassing between an old hive and a late swarm from the same old hive, standing some eight or ten rods apart. The following morning at daylight the same intercourse was continued. The bees passed by thousands and both hives appeared alive with bees. Although very anxious to find out what they were about, yet as there was every appearance of perfect harmony in their proceedings, be they what they might, I left them to settle

their own business in their own way, and on my return after an absence of two days found that the old swarm had abandoned their hive to the bee moth and gone to reside with their children, having removed every particle of honey to their new habitation, leaving comb, bee bread, and moths in the old hive. Where were "the rival queens, who always lead the swarms, and cannot dwell in the same hive?"

In what age of the world the discovery was made, that a hive of bees contained but one female and that one *the ruler of the swarm*, is unknown, probably when a great taste for the marvellous was in fashion, and Huber and subsequent writers could adopt a plausible theory with much greater safety than to thrust their heads into a bee-hive and watch the bees for some days. J. B. T.

August 18, 1838.

NEW VARIETIES OF MULBERRY.

Extract from a letter from Wm. Prince and Sons of Flushing to C. S. Pool, Esq. relative to some new varieties of the Mulberry, dated August 8, 1838.

DEAR SIR—We now answer your queries relative to the new Hybrid varieties produced by an intermixture of the Multicaulis and Dandolo Mulberries. The leaves of the Hybrid Multicaulis, of which as we stated we have several varieties, are nearly as large as those of the original Multicaulis and some are quite so, and the worms feed on them with equal partiality. They are perfectly smooth and glossy and remarkably tender, being similar in this respect to their Chinese parent, and they are rather thicker and heavier. The joints are closer, the trees are profusely clad with foliage as that species and many consider them more so, and our opinion is that the weight of foliage is rather greater.

The silk is very beautiful and strong, assimilating in this respect to that from the Multicaulis. But the great advantage they possess is that of being far more hardy. We left above ten thousand young trees entirely exposed the last winter in a very bleak northern aspect, all of which were grown from layers the last summer and on which all the wood was formed after the 10th of June, which rendered it much less mature than is usual, but the result proved most propitious, as not one of the trees was injured. It may be also interesting to state that these varieties, almost incredible as it may seem, form roots from cuttings and layers with even greater rapidity than the Multicaulis itself. It will be highly gratifying to us, to have you and all other silk culturists call upon us and take a view of these trees, as you will then perceive at a single glance that their value is beyond all price, and that the great desideratum of variety of the Mulberry with an enormous burden of foliage, and possessing all the most desirable requisites for the silk culture is at length fully attained. The whole number we now have does not exceed 25 or 30,000 and there are none others in the Union as we have not up to the present period offered any for sale.

The *Morus expansa* has very large leaves next in size to the Multicaulis and its new seedling varieties. The leaves are much thicker and seem more succulent and nutritious than any other variety we have yet seen. They are perfectly smooth, and remarkably glossy, and greatly beloved by the worm. The silk is of superior strength and of the choicest quality. There is no variety that produces a greater weight of foliage than this, unless it be the new hybrid varieties of the Multicaulis, which in connexion with this will be sure to command the precedence wherever cultivated. This tree may be deemed the very hardiest of all the superior varieties of the Mulberry,—and in a nursery of about 17,000 trees which we left standing the last winter in an extremely cold and bleak location, not the smallest end of any shoot was injured.

Linnæan Garden and Nurseries, }
Flushing, near New York. }

From the Maine Farmer.

CURING GRAIN.

The following letter was for my publication, by CHARLES VAUGHAN, Esq. of this town. It contains valuable information on the subject of curing grain, which we would commend to the attentive perusal of our readers.

North Dixmont, July 31, 1838.

CHARLES VAUGHAN, Esq.—Dear Sir: Yours of the 25th inst. I have duly received, and shall with pleasure comply with your request, to give some account of my method of curing wheat.

And first—I will state that I cut my wheat when it is so green that the kernel can be easily nashed with the fingers—for these reasons: The grain can be bound and stooked much better, than when the straw is dry,—the straw is worth twice as much for fodder,—there is less waste in carting,—the flour is whiter—and there is no diminution of the crop, when managed in the following way.

Bind on the same day that you reap, as the straw should not dry in the "gavel." Bind with single bands, and those not full if the grain be tall. Bind sheaves for the caps, as you proceed in binding, out of the longest and straightest of the grain; bind them near the "butt," and very tight,—and if they are considerably larger than the others they will cover the stock better.

Set four pairs of sheaves firmly on the ground, bottoms apart, tops together, and one at each end—place your arms at one end of the row, extend the arms to the other, and gently press the tops of the whole towards the centre. Put on three caps—the middle one first,—in putting on the outside caps, drop them as low as the band of the end sheaf—then with a gentle pressure slide them up into their place, and tie them together. By this means the grain is covered deeper than by saddling them on at once.

The advantages of this mode of securing grain will be seen at once. It admits a free circulation of air among the sheaves. The caps are so near a perpendicular direction, that the water easily runs

off—and as the tops of the sheaves incline to the centre, they support each other, and will stand till the grain is thoroughly cured.

I am well satisfied with the ram. He has grown well, and is fat; his fleece weighed 5 1-4 lbs.

I have raised 26 lambs, of good quality for size and wool. At shearing time I weighed two of the best of them; one was just two months old and weighed 44 lbs.—the other was five days older, and weighed 46 lbs.

Just a month from that date my steelyards, which draw 60 lbs., would not swing him. By housing time he will probably be as large as the ram was when I bought him.

Yours truly,
HORACE WILDER.

(Published by Request.)

NEW SYSTEM OF EDUCATION.

In the last message from De Witt (Clinton to the Legislature of New York, he remarked, that with a proper system of education, and correct modes of teaching, all our children might become familiar with the physical sciences, botany, mineralogy, the various classes of animals, chemistry, natural philosophy, astronomy, the fundamental principles of agricultural and political economy, and with much in history and biography, without any additional expense of time or money for their instruction.—The soundness and truth of this remark has since been fully proved by the system of education in Prussia and other German States: as it has by schools for deaf mutes and the blind in this country.

The following facts also show that the same remark may be fully sustained as a plain deduction of reasoning:

1. Spelling books, in common use, contain from ten to fifteen thousand words. To learn the orthography of each word by the dint of memory, founded on the arrangement or relative position of the letters, must require as much time and effort as to learn the names, properties, and uses of ten plants, minerals, animals, or shells; or ten principles in chemistry, natural philosophy, astronomy, agriculture, or political economy; or the same number of facts in history or biography. Consequently while a child is committing to memory the words in a spelling book, he might learn a hundred thousand of the objects, principles, or facts above referred to.

2. The time, paper, ink and quills, ordinarily used by children in school, in *copy writing*, would be sufficient for writing the names, with brief descriptions of the same objects, principles, and facts.

3. The time spent in repeating lessons from reading books, if devoted to the reading and study of the Bible, works on science, history, &c. would be sufficient for examining with some care, and for some *critical reading*, of at least one author, on each of the subjects above mentioned.

4. The time usually spent in *memorizing* grammar lessons, would be sufficient for practical and critical exercises in descriptions and narrations, relating to the objects of nature and art, with scenery, operations, and events, witnessed by children during the period of their school days and years.

5. By this practical, rational, and consequently interesting course of exercises in spelling, writing, reading and grammar, it must be evident to every one, that children would become more familiarly

and thoroughly acquainted with these mechanical parts of education, than they could possibly be by a mere repetition of them for days, months and years, like so many parrots, without any knowledge of their meaning, sense, or use.

In proof of the correctness of the above statements, I beg leave to mention that I have had occasion to know many thousand children who have learnt the names, and something of the properties, of from twenty to thirty objects in one hour, many of whom had probably spent, not only days and weeks, but months, if not years, in learning the twentysix letters of the alphabet; and after all they probably did not obtain *one* distinct rational idea, from what was considered their instruction, though, it is true, they must have received many from their sports, and from their walks to and from school.

To secure the important objects specified by the distinguished statesman and philosopher above named, and now realized by the subjects of some absolute monarchs, the following provisions are desirable, perhaps essential:

1. Encouragement and aid to children in studying the volume of nature, with which all are delighted, and which they commence reading when they first open their eyes upon the light of heaven.

2. Assistance in collecting, arranging, and exchanging with others, specimens of minerals, plants, shells, drawings, mechanism, needlework, &c. &c. for the contents of FAMILY CABINETS.

3. The formation of "SCHOOL CABINETS" in all the seventy thousand schools in our country, and exchanges with each other in works of Nature and Art.

4. The early and daily use of slates for drawing objects of Nature and Art, such as the simple figures of geometry, viz: triangles, squares, hexagons, and circles; horses, dogs, birds, fishes, and insects; hatchets, knives, pitchers, shovels, ploughs, &c.

5. Writing words, or names of things, as dog, cat, hat, oak, rose, mica, lime, slate, &c., in connection with the things themselves, or pictures of them drawn by the children.

Following the pictures and names of objects, brief and familiar descriptions of them, first on slates, and then on paper, by lead pencils, followed by pens.

6. Simple instruments for visible illustrations, both in families and schools, viz: a globe, geometrical solids, levers, pulleys, screws, maps and other drawings or prints, &c. &c.

7. Frequent walks in the fields and gardens, over ledges or mountains, by rivulets or brooks, through markets, on wharves, in mechanics' shops, marble and granite yards, aided and encouraged by the presence and instruction of a teacher, parent, older brother or sister, or some other protector.

8. Small, simple and familiar books, describing the objects, principles or operations they have witnessed by their lessons in the book of Nature. With these some of the beautiful and interesting passages from the Bible, selected from the Gospels, the Psalms, Proverbs, or the historical sketches of the Old Testament, are peculiarly appropriate and delightful to children.

9. Larger and more systematic works on the sciences, arts, history, biography, and the Bible more fully, with abstracts, reflections, or drawings, of things and incidents, learnt from first elements of nature study.

10. Releasing children, principally or entirely, from the incongruous, unmeaning and irksome mas-

ses, found in spelling books, reading books and grammars, now consuming the greatest part of the precious time of children allotted to their education.

As a course of juvenile instruction, similar to that here pointed out, must commend itself to the common sense of every one, and as it is fully tried and corroborated by experiments, both in Europe and America, it is, at least, worthy of trial by every parent and teacher in our Republican nation.

I remain, as ever, sincerely yours,
J. HOLBROOK.

GEOLOGY OF MASSACHUSETTS.

We have made a few extracts from Professor Hitchcock's Geological Report, which will undoubtedly be read with much interest. We think this report is of much importance to the agriculturalist, as well as to the geologist, and shall from time to time give some extracts from it. J. B.

EXAMINATION FOR CALCAREOUS MATTER IN OUR SOILS.—A preliminary step of great importance in this analysis, consisted in an examination of the soils to ascertain whether they contain lime in the state of a carbonate;—that is, common limestone. And I conducted the process in the following manner. A small quantity of the soil was introduced into a watch glass, so placed that the light from a window would fall upon it. This soil was covered with water to a considerable depth. The soil was then stirred until all the light matter and every bubble of air had risen to the top. The impurity that floated on the surface was then removed by drawing over it a piece of bibulous paper, so that the water stood perfectly clear above the soil. Then a few drops of muriatic acid were added by a dropping tube, and the water was carefully watched to see if any bubbles rose through it, as they would have done if any carbonate were present. The minutest quantity of gas escaping, could in this manner be perceived. The result disclosed the remarkable fact, that *out of one hundred and twenty-five specimens of soils from all parts of the State, and several of them from limestone tracts, only seven of them exhibited any effervescence*; and even these, when analysed, yielded but a very small per cent of carbonate of lime, viz:

No. 31. Graywacke soil Watertown,	1.3 per cent.
— 51. Limestone soil, Sheffield,	0.8 "
— 52. Do. West Stockbridge,	3.2 "
— 78. Gneiss soil, Westminster,	3.0 "
— 80. Do. Fitchburg,	2.1 "
— 113. Sienite soil, Wrentham,	0.4 "
— 125. Greenstone soil, Deerfield,	2.0 "

Even in three of the above cases, Nos. 78, 80 and 125, I am strongly suspicious, that the calcareous matter might not have been natural to the soils. For, contrary to my usual custom, in these cases I took the specimens from small patches of cultivated ground near villages; and very likely these spots might have been manured with sea shells, or lime in some other form. Setting these aside, *only one in thirty of our soils contains any calcareous matter*. This is so different from the account given in the books of European soils, that it will doubtless be very surprising. For some of these contain more than 50 per cent of this substance; and nearly all of them a large per cent. But in our country the lack of calcareous matter is not confined to Massachusetts. In the able work of Edmund Ruffin, Esq. of Virginia, on calcareous manures, a similar statement is made respecting the

soils of that State, and of some of the Western States, even in limestone regions. I have, also, recently examined five of some of the richest soils of Ohio and Illinois, and although I find calcareous matter in all but one, yet the average quantity is not over two per cent. Hence I apprehend that we shall find a deficiency of carbonate of lime to be quite characteristic of a large part of the soils of this country. This could not always have been the case, especially in limestone regions, and hence we learn—that indeed agricultural chemists now generally admit—that in cultivated fields, calcareous matter is gradually changed or consumed: and hence too we learn, what is one of the great desiderata of the soils of Massachusetts.

NEW METHOD OF ANALYSING SOILS.—Without stopping to suggest any means for supplying the deficiencies which the preceding analyses have shown in our soils, I proceed to the development of a new method of analysis, which I very unexpectedly received from a distinguished chemical friend, and which he has allowed me to present in this Report, with its application to our soils. It is the invention of Dr Samuel L. Dana of Lowell; to whom, as will appear in the sequel, I am indebted for other important assistance in the way of analysis. In order to its being fully understood and appreciated, a few preliminary statements from myself, in addition to those by Mr Dana, will be necessary.

Till within a few years past, the state in which vegetable and animal matter exists in the soil, and the changes through which it passes, before being taken up by the roots of the plant, were almost entirely unknown to chemists. Long ago, however, Klaproth had discovered a peculiar substance in the elm tree, which he denominated *ulmin*. More recently it was found by Braconnet in starch, saw-dust, and sugar; and by the distinguished Swedish chemist, Berzelius, in all kinds of barks. Sprengel, and Polydore Boullay have ascertained, also, that it constitutes a leading principle in manures and soils. Hence they call it *Humine*; but Berzelius adopts the name of *Geine*. When wet, it is a gelatinous mass, which, on drying, becomes of a deep brown or almost black color, without taste or smell, and insoluble in water; and, therefore, in this state of being absorbed by the roots of plants. Yet after the action of alkalis upon it, it assumes the character of an acid, and unites with ammonia, potassa, lime, alumina, &c., and forms a class of bodies called *Geates*, most of which are soluble in water, and therefore capable of being taken up by plants. And it is in the state of *geates*, that this substance for the most part exists in the soil. I have thought it might at least gratify curiosity and perhaps be of some practical use, to add specimens of these forms of *geine* to the collection of soils. No. 227 is pure *geine*: No. 226 *geate* of potassa: No. 525 *geate* of lime: No. 225 *geate* of alumina.

It is but justice to say, that Dr Dana derived his knowledge of *geine* chiefly from his own researches, made with a view to improve the coloring processes in the Calico Printing Establishment, at Lowell: and his method of analysing soils is altogether original. The statements of Berzelius, indeed, though interesting in a theoretical point of view, afford a very little light to the practical agriculturist. Those of Mr Dana appear to me to be far more important in a scientific as well as practical point of view; although essentially coinciding with those European chemists, so far as they have

gone. His method of analysis, derived from his researches, I must say, after having made extensive application of it to our soils, is simple and elegant, and taken in connection with his preliminary remarks, it appears to me to be a most important contribution to agricultural chemistry, and promises much for the advancement of practical agriculture. I trust it will be favorably received by the government, and by all intelligent men, who take an interest in the subject. His preliminary remarks and rules I shall now present in his own language.

“By *geine*,” says he, “I mean all the decomposed organic matter of the soil. It results chiefly from vegetable decomposition: animal substances produce a similar compound containing azote. There may be undecomposed vegetable fibre so minutely divided as to pass through the sieve: (see first step in the rules for analysis) but as one object of this operation is to free the soil from vegetable fibre, the portion will be quite insoluble. It can effect only the amount of insoluble *geine*. When so minutely divided, it will probably pass into *geine* in a season's cultivation. *Geine* exists in two states: soluble and insoluble: soluble both in water and in alkali, in alcohol and acids. The immediate result of recent decomposition of vegetable fibre is abundantly soluble in water. It is what is called, Solution of Vegetable Extract. Air converts this soluble into *solid geine*, still partially soluble in water, wholly soluble in alkali. Insoluble *geine* is the result of the decomposition of solid *geine*; but this insoluble *geine*, by the long continued action of air and moisture, is again so altered as to become soluble. It is speedily converted by the action of lime into soluble *geine*. Soluble *geine* acts neither as acid nor alkali. It is converted into a substance having acid properties by the action of alkali, and in this state combines with earths, alkalies, and oxides, forming neutral salts, which may be termed *geates*. These all are more soluble in water than solid *geine*; especially when they are first formed. Their solubility in cold water is as follows: beginning with the easiest, magnesia—lime—manganese—peroxide of iron—(it does not unite with the protoxide of iron) alumina—baryta. The *geates* of the alkaline earths are decomposed by carbonated alkali. The *geates* of alumina and of metallic oxides are soluble in caustic or carbonated alkali without decomposition. The *geates* of the alkaline earths, by the action of the carbonic acid of the air, become *super-geates*, always more soluble than neutral salts. Soluble *geine*, therefore includes the watery solution—the solid extract caused by the action of air on the solution, and the combinations of this with alkalies, earths, and oxides. Insoluble *geine* includes all the other forms of this substance.”

“Soluble *geine* is the food of plants. Insoluble *geine* becomes food by air and moisture. Hence the reason and result of tillage. Hence the reason of employing pearlash to separate soluble and insoluble *geine* in analysis.”

“These are the facts. Will they not lead us to a rational account of the use of lime, clay, ashes and spent ley? Will they not account for the superiority of unfermented over fermented dung in some cases?”

To be continued.

One of the best forms of exercise for adults is gardening and light farming. Boys and girls require sports which are more active.—*Library of Health.*

LOCUSTS.—A writer in the Boston Daily Advertiser, from the southern part of the Commonwealth, says this is the year for the re-appearance of the seventeen year locusts, their last visitation in that quarter having been in 1821. These insects have a distinctly marked W on their backs. Shortly before their disappearance, many of the small twigs of the young oak appeared to be girdled and cut off, and hung suspended from the extremities; the leaves turn red, as when touched by the frost in autumn. On examination, these twigs appear to be sawed about two thirds off, and girdled, so that the circulation of sap being cut off, it soon dies, and probably falls to the ground in the course of the ensuing winter, by the action of wind, rain, and snow. The general belief is, that by a curious and remarkable instinct, the insect is led to deposit its eggs in some node upon these small twigs, and there thus partially to save them from the parent stalk, so that by their fall the eggs shall be borne gently and safely to the ground, into whose bosom they are in some form to be received and cherished, to re-appear in the form of the full grown locusts, after the lapse of seventeen years. The emblems presented by this beautiful and brilliant insect, rising from the earth, after being so long buried, full of life and activity, making the woods vocal with its shrill and animated song, is a beautiful one.—*Salem Gazette.*

SILK WORMS.—Before the worms are hatched, the eggs should be weighed, and the weight written on the back of the paper to which they are attached. When the silk worms are hatched, take care not to separate them from the paper. There are many persons who as soon as they see the worms hatch, detach them from the paper, with a small broom or quill; but these little beings, as delicate and slender as a hair, or a bit of silk, cannot support the wounds given them with the broom or quill. The Mulberry leaves must be cut into extremely fine shreds, and spread in an equal manner, upon a large sheet of paper. The side of the paper on which the worms are hatching, must be applied to that which is covered with bits of the mulberry leaves. The worms liking the smell of the mulberry leaves, descend themselves on the paper, destined to receive them.

Then the paper, on which the eggs were, must be newly weighed; the quantity of hatched worms will be known, and it can be calculated how many worms will be required to feed them. It is much better to have more leaves than are wanted for the number of silk worms to be raised. Then abundant nourishment will be had for the silk worms, and one will not be exposed to the misfortune caused by a scarcity of leaves.

There are many persons who do not make this calculation beforehand: but when the leaves are about failing, they find themselves reduced to the most painful extremities; they pawn or sell their effects to procure them. They have the grief of seeing their silk worms tormented by hunger; the hurdles are strewn with worms that languish and die. Thus by their want of forecast, they uselessly sacrifice the lives of a great number of these precious insects.—*Translated from the Chinese.*

TEMPERANCE IN THE SANDWICH ISLANDS.—The King of Oahu has suppressed all the grog shops except two, and placed them under severe restrictions.

From the Genesee Farmer.

WOODLANDS.

That the woodlands of our country have decreased, and are decreasing to a most alarming extent, no one can doubt; and when we remember the great quantity of wood annually required for fuel, fencing, and building, and see little or no effort made to supply the loss, we feel that the subject of planting trees for timber as well as for ornament, cannot be too earnestly pressed on the attention of the owner or cultivator of the soil. The great difficulty in any undertaking of this kind appears to lie in the time that will be required before any actual return can be realized from the capital required to be invested. Men should, however, remember that all their thoughts and their labors should not be for to-day, but that true greatness of mind takes in the future as well as the present; contemplates the wants of posterity as well our own; and if *money alone* is the object of exertion, finds by matter of fact calculation, that lands planted with timber will in thirty years pay a better interest, than the same amount expended in state stocks.

In any arrangements respecting woodlands, the first care of the farmer or land owner should be to save what he has, and place it in the best condition for increase. No matter what the kind of timber may be; experience shows that where woodlands are protected, young trees will rapidly spring up to supply the place of those taken away, and that either from seeds, or from suckers springing from the stump or the roots, the drain will be more than supplied so far as number is concerned.—Where lands left for wood are allowed to be a thoroughfare for cattle and sheep, the growth of young timber is impossible. The shoots are destroyed as soon as produced, and all the efforts of nature to supply the waste must be in vain.—When it is desirable to produce a thick growth of young timber in a grove or wood lot, let it be thoroughly enclosed, and there can be no doubt as to the result; in a few years thinning will be required instead of planting, and it should too be remembered that in this case, the timber grown is of the kinds adapted to the soil, stands where it is wanted, and can be multiplied to any desirable extent.

But in many cases it is requisite to plant new varieties, and where new woodlands are to be commenced, a knowledge of the kinds best adapted to the soil, or the purposes intended, whether fuel, or timber, should be obtained. In such cases recourse must be had to seeds, unless nurseries of forest trees are at hand, which can hardly be expected where planting to any considerable extent is to be performed. The seeds of forest trees have been divided into five varieties, the most of which require different soils, and different treatment in preparing and planting. 1st. *The farinaceous or nut seeds*; such as the oak, chestnut, beech, walnut, elm, maple, and basswood, sycamore and ash; with many shrubs, such as hazel, alder, &c. 2d. *Hard seeds*, or stones enclosed in pulpy fruit. Of this class are the cherry tree, pear, crab, thorn, mountain ash, and others. 3d. *Leguminous* or bean seeds, of which the Locust (yellow and honey) and the laburnum, are the only varieties of forest trees or shrubs. 4th. *Light seeds*, under which may be enumerated the poplar, smooth elm, and the tree willows. 5th. *The resinous seeds*, or those belonging to the spruce, pine, and fir trees.

In England, where for hundreds of years great attention has been paid to planting and growing timber, and where there are probably more artificial woodlands than in any other country of the same extent, it has been found by experiment that the fir, the beech and the birch, succeed best on sandy moor soils, incumbent on shale, or siliceous sand of great depth. The pine, larch, spruce and sycamore will succeed on an inferior sandy soil, incumbent on shale or coarse gravel. The sycamore will, however, flourish in almost any place not too cold, for its presence on our richest intervals proves that richness of soil is no obstruction to its growth. The oak, chestnut, whitewood, &c. grow rapidly on a soil light siliceous, if incumbent on a damp, clayey subsoil; but the soil that brings these trees to the highest state of perfection, is a clayey loam, incumbent on a clay subsoil. Some of the finest oaks and chestnuts in England are growing on a soil of which the analysis is as follows:—

Coarse gravel, partly calcareous,	40
Pine Sand,	190
Carbonate of lime,	16
Decomposing vegetable fibre,	14
Silex,	90
Alumina, or pure clay,	30
Vegetable extracts, oxides of iron, salts, &c.	20

400

The soil best adapted to the elm, maple, ash and horn-beam, is one damp, clayey, and incumbent on clay, or composed mostly of coarse siliceous gravel, silica, and alumine. The maple accommodates itself to a greater variety of soils than most other trees, and is found in western New York, on almost all kinds, excepting the most light and sandy, or those based on shallow covered calcareous rock.

By paying a little attention to the soils on which any kinds of timber are growing naturally the quality of the soil on which the planting of any desired variety of tree intended may be known at once; and if a soil is found on which most of our forest trees, such as the oak, chestnut, whitewood, basswood, white maple, walnut, black walnut, &c. are growing or have grown together, it will be found the best for almost any new variety of forest tree, as such soils are usually deep, and made up of ingredients suitable, in the main, for all. In general it may be remarked that where the soil is good for wheat, there the oak, chestnut, and tulip tree will flourish; where the soil is adapted to corn, there the sycamore, locust, the walnuts, and some of the elms will succeed; and that on all soils where spring grains are found the most profitable, the white elm, ash, maples, and the hardier evergreens will be the best. The pine, the locust, the maple, and the oak, require different soils, as the slightest observation of their natural growth will show; and though trees will make great efforts to accommodate themselves to any soil, yet where planting is to be performed, those the most suitable to the soil, and which will be of the most value in the particular location should always be preferred. The surest guide in such matters is to follow nature. Where it is desired to timber low lands, the cypress, black ash, swamp pines, and trees of this class, will be always available, according to circumstances.

In selecting as trees for cultivation in woodlands, a few which are valuable for fuel, timber, or mechanical purposes, our directions for the time of sowing seed must be mostly derived from Euro-

pean publications, as little attention has, as yet, been paid to this method of propagation in this country.

BASSWOOD, *Tilia Americana*. Seed to be sown in Autumn, in moist, light soil; but the usual mode of propagation is by layers. Basswood, like the chestnut, throws up abundance of suckers from the stump, and where woodlands are protected no other means of increase are required.

WALNUT, *Juglans*; including the common walnut, hickories, black walnut, butternut, and pignut. Preserve the nuts till the latter part of winter in their outer covering after which they may be sown. Slightly covered in the ground, and left to freeze through the winter, these nuts usually vegetate without difficulty. We have raised several hundred plants of the *Juglans cathartica* simply by allowing the nuts to lie in the grass where they fell from the tree, and transplanted them after one year's growth.

MAPLE, *Acer*.—The seeds should be preserved in dry sand till spring, and then sowed early; but should the soil be dry and free from the attacks of vermin, it is advantageous to sow as soon as the seeds are ripe. In this country transplanting from the forest will most probably be the easiest method of obtaining this beautiful and valuable tree, which deserves cultivation to a great extent.

LOCUST, *Glutischia* and *Robinia*.—The seeds of the locust were formerly among the most difficult and uncertain of vegetation, sometimes lying in the ground two years. But by gathering the seeds when ripe, preserving them till the spring, and then pouring boiling water upon them, and allowing them to remain till swelled, they will grow with certainty. The soil for a locust nursery should be warm and deep; and the tree itself will flourish best in a gravelly and moderately rich soil—cold, wet, clayey grounds are unfit for the locust. It is a tree of rapid growth, and the excellence of its timber is well known.

ASH, *Fraxinus*.—The time of sowing the seeds of the white or black ash, is in autumn, or as soon as ripe, and the plants will frequently appear the same season. If the seeds are kept over the winter, it should be in dry sand; and they should be sown as early as the ground can be prepared for their reception.

WHITEWOOD, *Liriodendron*, or tulip tree.—The seed must be sown in the spring, in a light soil. This tree grows quickly, has beautiful foliage, and fine flowers, and its wood for many purposes is ranked next to pine.

POPULAR, *Populus*.—All the varieties of poplar may be propagated by cuttings, suckers, or layers; the first mode is generally preferred. The poplars are of rapid growth but are unfit for fuel. Were it not for this fact, some of the varieties of the poplar would be the most valuable trees for woodlands that could be selected.

BIRCH, *Betula*.—The seed may be sown in autumn or spring, but must be kept in dry cool sand from the time it is ripe till sown. The black birch is the most valuable of our varieties, being of quick growth, excellent for fuel, and a valuable timber tree. Russian leather owes its durability, and its freedom from the attacks of insects, to an empyreumatic oil obtained by burning the bark of the birch tree in kilns constructed for that purpose.

OAK, *Quercus*.—Sow the acorns in November, or if kept till spring, lay them on a cool dry floor. We have this season seen hundreds of young oaks sprung from acorns that lay where they fell last

autumn. But two kinds of oaks are of much consequence as timber trees in our latitude, the white and the black, *quercus alba* und *quercus tinctoria*, and these may be grown in almost any soil, though they prefer a rich clay loam, with a clay subsoil.

BEECH Tree, *Fagus*.—Seeds to be sown in the fall; the only danger is to be apprehended from mice, as they sprout and grow with much certainty. The beech is good for fuel; and is highly prized where weight and solidity are required, particularly the wood of young and thrifty trees.

CHESTNUT, *Castanea*.—Seed to be sown early in the spring, in a rich, sandy loam; and it is in such a soil that this valuable tree attains its greatest perfection. It may, however, be grown in any soil where the roots can spread freely and are not subjected to stagnant moisture. Lands covered with chestnut timber, are very valuable, as they can be cut every twenty-five years for posts, rails, &c. and require no replanting, or care to secure a continued growth, except protection from cattle for a few of the first years of their growth.

PLANE Tree, *Platanus*. Sycamore or Buton Wood.—Seeds to be sown as soon as ripe in a moist shady situation; and the tree prefers moist loam, free from stagnant water. It is a tree of large growth, makes a fine ornamental tree, and is good for fuel.

ELM, *Ulmus*.—Seeds to be sown as soon as ripe, on a bed of fresh loamy earth, to be shaded from the midday sun until the plants appear to be well rooted. There are a number of varieties of elms growing in our forests, but the two most deserving of notice are the white elm, and the red elm. The red elm is the most valuable for timber of any of our varieties, but the white elm exceeds it in beauty and rapidity of growth. Michaux has pronounced the elm the most magnificent vegetable of the temperate zone; and the size they attain in our forests is astonishing.

CYPRRESS, *Cypressus*.—Seed to be sown in spring, in a warm situation, or in pots in light dry earth, to be kept in the cones till the period of sowing. The wood of the cyprress is very durable. Prof. Martin says 'the doors of St. Peters church, at Rome, were made of this wood, and lasted eleven hundred years? Worms rarely attack it. The common American cyprress attains the largest size in low, damp soil, though it will grow in those that are loose and sandy loam. In the swamps on the Mississippi below latitude 31 deg. it grows to the height of 120 feet, and is sometimes 40 feet in circumference near the ground.

Pine trees, are generally transplanted, or are allowed to spring up spontaneously; but where seeds are used, they should be sown immediately after being gathered as their vegetative power cannot be preserved for any considerable length of time after being taken from the cones. The seeds must be planted in fine light earth, and covered very lightly. The spruce, balsam fir, stone pine, and indeed all the resinous trees, or coniferous ones, require a similar treatment to succeed in the vegetation.

We have thus noticed a few only of the many trees that might be beneficially planted for the formation of woodlands; and the cultivation of some or all of them should be entered upon by the most of our farmers without delay, the selection being made with reference to the wants of the individual, whether for fuel, fencing, or timber, or all combined. Our roads, our avenues, the borders of our fields, should be planted with trees; every opening in our existing woodlands should be filled up with

one or more of the trees best adapted to the soil and the location; young trees where they spring up should be carefully preserved; and every reasonable exertion made to increase the quantity of our woodlands, and add to their value. Where beauty and utility are so closely combined as in the planting of trees, the farmer should engage in their propagation with alacrity; remembering that besides adding to the beauty of his farm, every tree he plants, and every acre of woodland he cultivates, is money at compound interest, a permanent income, the benefit of which will be realized by his children as well as by himself.

From the Village Record.

MARKS OF GOOD CATTLE.

MR SNYDER—As there is a disposition manifested by many persons to improve their stock of cattle, I have thought that a few observations upon the subject might be acceptable to some of your readers. In Indiana, the two principal objects in breeding cattle appear to be beef and milk. And as certain forms are found to possess particular qualities, I shall proceed to describe what are the proper forms, and what the desirable qualities generally connected with these forms; and in doing this, I shall avail myself of the experience and observations of others.

The head ought to be small and the muzzle fine, the countenance calm, the horns fine; the neck light, particularly where it joins the head; the breast wide, and projecting well before the legs; the shoulders moderately broad at top, and the points well in, so as to leave no hollows behind them when the animal is moderately fat; the girth behind the shoulders should be deep, so that if the carcass was cut across here, it would be an oval, blunt at both ends; the back straight, wide and flat; the ribs broad, and the space between them and the hips small, the flank full and heavy; the belly well kept in and not sinking much in the middle, the ribs globular, wide across, and on a level with the back; the twist should be wide, and the seam in the middle of it well filled; the thigh should be straight, tapering well down to the hock; the legs straight, short-jointed, clean, fine bowed, and standing wide apart; the tail broad towards the top, tapering down, and the smaller towards the bottom the better; the body long, and jointed well to the quarters before and behind; not barrel-shaped, for this does not allow sufficient depth, but a section of the body should be an oval blunt at both ends. Where the body is barrel-shaped, there will be a deficiency both before and behind where it joins the quarters.

I shall now proceed to state the particular advantages of the above described form. The reason why the head should be small and the muzzle fine, is that it facilitates birth; and as the head is composed mostly of bone, it shows fineness of bone, the advantages of which are that the animal possessing them will fatten upon half the food that coarse, big-boned, long jointed ones will require. Calmness of countenance, also, indicates a disposition to get fat—the restless and vicious never fatten kindly. The lightness of the neck is advantageous to the butcher, who will get less coarse meat in such. The wideness of the breast and deep girth give greater room for the lungs. A straight back shows strength, a weak animal being generally sway of hump-backed. Poor keeping will produce those deficiencies in a calf that was at first well formed. The straight back also denotes an apti-

tude to fatten kindly. Much depends upon the room the lungs have; no animal can be good whose lungs occupy a small space; and the lungs occupy all the space within the ribs, so it is of great importance that the space inside of them should be large—for this reason the ribs should be spread wide, and extend well back towards the hips. The full heavy flank in the cow is a most certain indication of a good milker, and the bull thus formed generally produces cows that milk well. The belly being nearly straight shows strength in the flates. Globular ribs hold much flesh, and it is much easier put on such than upon those that are sharp. Wide ribs give a broader loin and more capacity to the pelvis. From the hips to the rump long and straight with the back, the hind quarter that is thus formed will weigh very heavy, the wideness of the twist, and the filling up of the seam, gives the greater weight to the upper part of the thigh. Straight legs are stronger than crooked ones. Clean legs and small tail show fine bones. Shorts joints in the legs is also an excellent mark of an animal fattening easily, for every animal requires food to fatten it in proportion to the length of the leg. A short-legged animal with a large body will fatten upon less food than a long-legged one with a small body. When the brisket and twist are large, the legs will be wide apart, and it is important that both these be large.

I have said above that the head should be small; but I did not mean that a bull's head should look like any thing but a bull's head, for if it looks like a steer's or cow's, he will be uncertain in propagating his species. If the neck should be disproportionately long and slender, it denotes a weakly constitution. The body cannot well be too long whilst the legs keep wide apart, as a long body throws much weight in the carcass; but in very long bodies there is a tendency in the legs to get too close together, leaving the breast thin and reducing the twist. This I consider a serious misfortune.

In breeding it is of importance that where there is a deficiency in one, the other should be particularly good in that part, and the best should always be selected for breeders; rejecting every thing that is common. By always selecting the best and breeding from them alone, any stock may be very much improved, so that in a few generations they will hardly look as if they had sprung from such a stock.

I have frequently heard it asked what makes such cattle as I have described worth more than others equally large. There are many reasons; but I will confine myself to three. And first they come earlier to maturity, thus saving in those that are intended for beef two or three years' keeping. They carry more fat and flesh upon the most valuable parts. It is known to persons who are in the habit of buying beef of a butcher, that he makes a difference of four or five cents in a pound of meat taken from different parts of the same animal. Now it must be plain to every one, that those animals which carry their principal weight in those parts that command the highest price, must be worth the most, and of course he will give more for them. They fatten upon half the food that others require; of course they are worth more to the man who fattens them.

Wm. TRENOR.

Mrs Wirt, widow of the late Wm. Wirt, is about to publish a floral dictionary, with 58 engravings.

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, AUGUST 29, 1838.

DAIRY STOCK.

We are daily more and more convinced of the mistakes and folly of our farmers in regard to the management of our dairy and milking stock. If we are thought to recur too frequently to this topic, its great importance must be our apology. We can find cows in numbers of our own native stock which have produced for weeks in the best of the season twelve, and in some cases fifteen pounds of butter per week without being forced by extraordinary feed; and we have known of a dairy of twenty-nine cows having averaged in a season six hundred and thirty pounds of new milk cheese; and these too all of native stock. Now what stock will do better than this? and why need we look for any other if we will but do ourselves, and these beneficent animals even half justice?

We are perfectly convinced that for milking and dairy purposes we need not go out of the country to find as valuable a stock as can be brought into it. We have heretofore asked the owners of the Improved Durham Short Horn Stock to let us know by actual measurement for a length of time, a week, a month, a season, what their cows will produce. We now go further. Without the slightest prejudice against their stock, and with a grateful sense of the patriotism and public spirit, which has induced them to bring this stock at great expense into the country, we now challenge them to show the well authenticated and exact results of the trials of these improved animals. We, on our part, promise to meet them with time, place and person, with examples of the produce of our own native stock, and then we will compare them together; and we engage to go heartily for the best. The distinguished editor of the Cultivator considers the list of remarkable cows of native stock given in our Report on Essex as hardly deserving of notice, because they were only examples of individuals under a state of high feeding. Now we say with perfect respect to our distinguished friend, produce if you can from all the Improved Short Horns in the country as many and equal examples of productiveness; under any feeding you please to adopt; and then we are prepared with a longer and a brighter list than we have yet given. But until this is done, let us not be in a hurry to change what we have for a race, whose claims to superiority for dairy purposes yet remain to be established; which can only be procured at a considerable expense, and whose condition can be maintained only by extravagant keeping. For the luxuriant prairies and alluvions of Ohio, Kentucky, and the rich Western States, where size and early maturity are matters of the first importance, we are disposed to believe that this beautiful race of animals, the Improved Durham Short Horns, will prove an invaluable acquisition; but it is not so we believe, at least we want further light to be convinced that it is so, for the hard hills, the short pastures, and the long winters of New England, where butter and cheese are the great objects of the farmer. We do most earnestly wish that the owners of good cows of any breed would be more particular in ascertaining the products of their cows, that we may not be continually met with guesses, which are altogether capricious; and which take their complexion too often wholly from the private interest, or prejudice, or self-conceit, or vanity of the owner. Get a lactometer and measure your cream. Weigh your milk and observe the pounds and ounces. Measure your milk and let us know whether the vessel you use for this purpose be a beer or a wine quart. Try the whole milk of your cow for a

week, a fortnight, or a month, and see how much butter, how many pounds and how many ounces she will yield. This is the proper and the only proper trial and test of her merit.

USEFUL INVENTION.

We were much gratified a few days since in passing through Lee with the ingenious arrangement for obtaining or rather conveying water, adopted on the farm of Mr Cornelius Basset. His house and barn stand on a side hill, and it was not easy to procure water for his cattle. He has a small stream of a permanent character and of excellent water flowing at the bottom of the hill, 20 or it may be 30 rods from his barn yard. He has here placed a small water wheel in a cistern filled by the brook, which is constantly turned by the stream; and, through logs laid to the yard, by means of a forcing pump operated by this wheel the water is sent up to his barn yard and there flows in a constant supply. The whole is a miniature example of the Fairmount Water Works in Philadelphia; and the experiment succeeds to admiration. The expense is trifling as the diameter of the wheel is not more than four feet. The whole is enclosed in a wooden box, so as to be easily covered in winter, and secured from frost. The arrangement reflects honor upon his ingenuity, and his whole farming is a beautiful example of neat, industrious, and highly intelligent cultivation.

BUFFALO BERRY—OR SILVER LEAF SHEPARDIA.—In the planting of trees, has it never occurred to our friends who have small or large gardens in the rear of their houses, that a tree bearing fruit in the winter would be an acquisition? Such a tree can be had. Nature has placed ruminating animals in high latitudes, where for a large portion of the year vegetation generally is sealed to them. To remedy this deficiency, there are trees and plants which are accessible and nutritious in the winter season. Among these, one of the most beautiful and useful is the silver leaf Shepardia, which is indigenous to our Rocky Mountains. When in foliage, the tree is beautiful indeed. Its leaves on the upper side are of a deep green, and beneath are silver. As the winds lift them a beautiful effect is produced by the shifting colors; the light silver green glancing in relief against the darker olive. Something similar may be noticed in one of the trees in the Park, between the site of the old Bridewell and the Sessions Court. In the winter the fruit of the Shepardia comes to maturity. It is a red berry, growing in thick clusters. Slightly acid, it is very agreeable in taste, and capable of sustaining life, as many explorers and trappers have proved. It makes too, most capital conserves and jellies. The tree may be obtained of the Messrs Winship in Brighton, Mass. Now, or soon is the season for setting out, and transplanting trees, and whoever orders this, or any other, of the Messrs Winship, will be promptly answered, and faithfully.—*N. Y. Sun.*

Massachusetts Horticultural Society.

EXHIBITION OF VEGETABLES.

Saturday, August 18, 1838.

Mr Dana Parks of Roxbury, exhibited a fine large Autumnal Marrow Squash of the true sort weighing 37 1/2 lbs.

Mr Rogers of Watertown a basket of large late Lima Beans, extra fine. Also, without name, a basket of Tomatoes of unusually large size.

For the Committee,

SAMUEL POND, *Chairman.*

FLOWERS.

Saturday August 25, 1838.

By Thomas Lee, Esq. of Brookline, Hibiscus, Manihot, Portulaca pilosa, Gerardia flava, do. purpurea, a variety of Altheas, (one of which was new to us) and many other specimens of choice flowers.

By Dr J. C. Howard of Woodland, Brookline, a very fine Bouquet, and some specimens of the following varieties of the Dahlia, viz: Countess of Liverpool, Royal William, Beauty of Cambridge, Ophelia, &c.

Bouquets.—By Messrs Winship, Walker, Hovey & Co. and Jno. Hovey.

Dahlias.—By S. Walker, viz: Jackson's Rival Yellow King of Dahlias, Picta formosissima, Duchess of Buccleugh, and Belledonna.

For the Committee,

S. WALKER, *Chairman.*

FRUITS.

There was quite a display of Plums, and the exhibition was greatly indebted to Messrs Pond and Johnson for its attractions.

By Mr Pond, Smith's Orleans, Duane's Purple, Pond's Seedling, Green Gage or Reine Claude, Washington, White Gage, and Corse's Nota Bene *Plums*. William's Bon Chretien or Bartlett, Andrews, Juliette and Cushing *Pears*.

By Mr Johnson, Washington, Green Gage, and White Gage *Plums*.

By Thomas Lee, Esq., Early Ann *Peaches*; this variety has proved with him, hardy and productive for a number of years past.

Melons.—The Napoleon Melon—very fine appearance and most delicious flavor.

By Dr J. C. Howard, from his garden Woodland, Brookline, Nettle Cantaloupe, Melon de Roche de Carreir, or Queen's pocket, and Napoleon *Musk Melons*, the two latter new kinds, and Red Siberian *Crab Apples*.

By M. P. Sawyer, Esq. from his garden at Portland, two varieties of *Peaches* (grown under glass) of extraordinary size and beauty.

By S. Walker, Esq., *Plums*, and Green Chissel *Pears*.

By S. Downer, Esq., Washington, Frederic of Wurttemberg, (Capeumont) and Juliette *Pears*. William's Favorite *Apples*, very handsome.

From Mrs C. H. Jones garden, Friend street, Smith's Orleans *Plums*, very large and fine.

For the Committee,

E. M. RICHIARDS, *Chairman.*

VEGETABLES.

Tomatoes, or love apple, from J. L. L. F. Warren, Brighton.

A vegetable curiosity brought from Asia, by the Rev. Mr Malcolm, exhibited for a name by C. W. Green, Esq.

For the Committee,

SAMUEL POND, *Chairman.*

Mr Luman Bartlett of this town has reaped *sixty-nine* shocks of Flint Wheat from one acre and five rods of upland. The farm on which this was raised was formerly owned by Mr H. G. Bowers of this town, who, by intelligent and scientific experiments, put the soil in the best order. Mr B. is now cultivating one of the best farms in Illinois, and doubtless his taste and fondness for the pursuit will do much there to elevate and improve the noble calling of Agriculture.—*Northampton Cour.*

Connecticut River is lower than it was ever known to be before. The small factory streams that flow into it are nearly dried up.

NOTICE.

The General Committee of Arrangements, are requested to meet at the rooms of the Massachusetts Horticultural Society, 23 Tremont Row, on Saturday, 1st September, at 10 o'clock, A. M.

The Special Committee are requested to meet as above, on Saturday, 1st September, at 11 o'clock, A. M. Per order,
SAMUEL WALKER, *Chairman.*

VOL. XVII. NO. 8.

MARKET.—MONDAY, August 27, 1838.
Reported for the New England Farmer.

At Market about 475 Beef Cattle, 500 Stores, 5,000 eep, and 500 Swine.
A large number of Beef Cattle, several lots of Stores, eep and Swine unsold.

PRICE—Beef Cattle.—Several lots of cattle were ehashed on Saturday, at a higher price probably than as to day for a like quality. We reduce our quotations a trifle. First quality \$7 37 1-2 Second quality, 1 75 \$ 87 00. Third quality, \$5 50 a \$6 50

Stores.—Yearlings, \$9 a \$12. Two Year Old, \$15 a 00. Three Year Old, \$20 a \$25.

Sheep.—"Dull." Lots were sold at \$1 42, \$1 62, 88, \$2 00, \$2 25, and \$2 75.

Swine.—A lot of selected Old Barrows at 7, and a lot selected Barrow Shoats at a trifle over 8. A lot to ddle at 6 1-2 for Sows and 7 1-2 for Barrows: At re l from 7 to 9.

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more as he wanted, of the best kinds—consisting of the best selected varieties now in use, for cultivation, feeding rms, and making silk;—being acclimated to this country, adapted to either warm or cold climates, affording a e opportunity for companies or individuals to be supplied, in the most extensive collection of mulberry trees ever n in any village within the United States.

Autumn orders, the best approved for removal, and orders for seeds, I. B. Colt, Secretary of the Connecticut k Manufacturing Company, Hartford; Alonzo Wakeman, he office of the American Institute, No. 157 Broadway, Y.; Thomas Lloyd, Jr. No. 236 Fibert street, Philadela, Pa.; Luther L. Cox, Baltimore, Md.; B. Snider, & Savanah, Ga.; Bliss Jenkins, & Co. Mobile, Al.; James man, St. Louis, Mo.; Case and Judd, Columbus, O.; G. hard and Parley, N. Y.; and the publishers of this ad ments, or with the subscriber, in Northampton, Mass. Orders left with the above gentlemen will be promptly at tended to, and each will be furnished with samples of the age.

Several valuable farms may be had with or without Mulry Plantations.
D. STEBBINS.
Northampton, Aug 22, 1838.

REMEDY FOR CANKER WORMS.

The subscriber having obtained letters patent for his cir ar metallic trough and roof for preventing canker worms n insects from ascending fruit or other trees, now offers ervices to apply the same to any extent that may be nted. They were put on to three orchards belonging to rathan Dennis in Portsmouth, R. I., in the autumn of 7, and exterminated the canker worms so completely t some of the trees hang so full of apples as to render it easary to prop them, although they have been eaten by e canker worms, or any substance that is readily ap plication of tar. The public are invited to examine orchards above referred to. The trough and roof is ead of lead and bent to conform to the shape of the tree, the ends soldered together and made enough larger than e tree to allow the trees to grow ten years before it will e space. The space between the trough and the tree is ead with hay, straw, sawed, or any substance that is easily epressed by the growth of the tree; the trough is kept i place by three nails driven into the tree below it; when e tree has grown so as to fill the space, the trough may e argued by putting in a short piece so as to answer ten years e. A little cheap oil is sufficient to fill the troughs and ing them three times has been found to answer for one r, by stirring the oil once sometime after they are filled. Those who wish to have their trees treated, will be glad to eke early application to the subscriber, postage paid. For e, State, Town and County rights by
JONATHAN DENNIS, Patentee,
Portsmouth, R. I., August 22, 1837. 4w

MIDDLESEX AGRICULTURAL SOCIETY.

The Committee on Farms, Fruit, Mulberry, Forest Trees d Silks, will meet at the Middlesex Hotel, in Concord, on onday the third day of September next, at nine o'clock, M., and will then proceed to view such farms, &c. as have e entered for premiums.

NAHUM HENDY, Waltham,
JOHN H. LORING, Grotton,
ELI RICE, Marlborough,
WM BUCKMINSTER, Framingham,
CYRUS WARREN, Concord,
} Committee.

All applications must be made to some one of said com ittee, or to the secretary of the society, on or before the e next time.

TIMOTHY PRESCOTT, Secretary.
Concord, August 13, 1838.

FRUIT AND ORNAMENTAL TREES, MULBERRYES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honeysuckles; Paeonies, Dahlias and other Herbaceous Flowering Plants.

225,000 MORBS DORTHEALIS are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussa and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. B. BANGS, Commission Store, No. 132 Water Street, New York, M. S. PEWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston.
August 1, 1838. WILLIAM KENRICK.

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dame, situated in Rochester, N. H. six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quarries of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to JOSEPH BRECK & Co., No. 51 and 52 North Market Street, Boston.
August 15, 1838.

NEW ELEMENTARY WORK ON BOTANY.

Peter Parley's Botany; with descriptions of Trees, Shrubs and Plants; with a large number of fine engravings. The publishers invite Teachers, and others interested in this subject, to examine this work, as they believe it will be found one of the most practically useful in use, being a complete manual of Botany for the adult and the pupil.

Parley's Cyclopaedia of Botany.—This work appears to be exactly what is wanted by young persons and in families. It not only contains the strictly scientific part of the subject, in an introduction and very full and complete genera of Plants, but it also contains a copious glossary of terms, and what is most important, a Dictionary of Plants, of nearly 800 pages, containing familiar descriptions of all the most interesting trees, plants, and shrubs.—These are alphabetically arranged, with an English index, so that the reader may immediately turn to any plant he wishes to read about. The work is illustrated by over 200 engravings, and is sold very cheap.—*Boston Paper.*

For sale at the New England Farmer Office, 51 & 52 North Market Street. JOSEPH BRECK & CO.

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land situated on Nonantum Hill, in Newton, 5 1-2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

LOT WHEELRIGHT.

July 16th.

WINTER RYE.

Just received at the New England Seed Store and Farmer Office, a few bushels of prime Winter Rye.
JOSEPH BRECK & CO.
August 13, 1838.

FOR SALE.

A two years old Bull of the Cream top breed; from Mr Jaquette's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most luttler of any stock in this country. Inquire of the subscriber near the factories in Waltham. ISAAC PARKER.

FOR SALE.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

SITUATION WANTED.

As Gardener, by a young man of practical knowledge and can be well recommended. A Situation West or South would be preferred. Address R. B. through the office of this paper.

MISCELLANEOUS.

THE BIBLE.

Lamp of our feet! whereby we trace,
Our path when went to stray;
Stream from the fount of heavenly grace
Brook by the traveller's way!

Bread of our souls! whereon we feed,
True manna from on high!
Our ruddy and chart! wherein we read
Of realms beyond the sky!

Pillar of fire—through watches dark!
Or radiant cloud by day!
When waves would whelm our tossing bark—
Our anchor and our stay!

Pole-star of life's tempestuous deep!
Beacon! when doubts surround.
Compass! by which our course we keep!
Our deep-sea lead—to sound.

Riches in poverty! Our aid
In every needful hour!
Unshaken rock! the pilgrim's shade,
The soldier's fortress tower!

Our shield and buckler in the fight!
Victory's trump—our fan!
Comfort in grief! in weakness, might!
In sickness—Glead's lamb!

Childhood's preceptor! manhood's trust!
Old age's firm ally!
Our hope—when we go down to dust—
Of immortality!

Pure oracle of Truth Divine!
Unlike each fabled dream,
Given forth from Dolphin's mystic shrine,
Or grove of Academe!

Word of the ever-living God!
Will of His Glorious Son!
Without thee how could earth be trod,
Or heaven itself be won?

STATE OF MAINE.

LAND OFFICE,
Bangor, April 30, 1838. }

The twelfth section of "an act additional to promote the sale and settlement of the public lands," passed March 24, A. D. 1835, making it the duty of the Land Agent "to advertise the settling lands in market, once a year, for two months, in one paper in the city of Boston, one in Concord, N. H. and in one paper in each county in the State, describing the quality and situation of said land and the terms of sale," the Land Agent hereby gives public notice that Township number 4, in the fifth range of Townships west from the east line of the State, has been lotted for settlers, and is now in the market for sale and settlement under the provisions of the following law passed at the last session of the Legislature. The price will be from fifty to seventy-five cents per acre, according to the quality and situation of the lots. The lots average 160 acres each. The soil in this township is good, being remarkably free from stones, and the land lying in moderate swells. The location of this township is favorable for settlement, as the Aroostook road passes within one mile of the western line of the township. There are between 40 and 50 settlers in the adjoining township No. 4 in the 6th Range, and a good saw mill and grist mill have recently been built there by Ira Fish, Esq. only one mile distant from this township.

Townships No. 3 in the 4th Range, No 7 in the 6th Range, and No. 8 in the 7th Range have been surveyed and lotted into mile sections. Lots of 160 acres will be run out from any of these sections to actual settlers, where the land is more suitable for farming than for timber. Townships Nos. 8, 10 and 12 in the 5th Range have been ordered to be surveyed, by the Surveyor General, forthwith, and will be open for settlers as soon as the lots can be run out. The Aroostook road passes directly through these townships and the soil is represented to be excellent for farming. The Aroostook road is laid out and cut out from the military road leading from Bangor to Houlton, near Mattawaukeag Point to the Aroostook river, a distance of about 75 miles.

About \$17,000 will be expended this year, upon this road by the Land Agents of Maine and Massachusetts, and with the part already finished the road will be completed about one half of the distance. The whole dis-

tance will probably be completed next year. All the land on this road has been sold for about two thirds of the distance, and in several townships all the lots upon the road have been taken up by actual settlers. The remaining part of the land upon this road, owned by this State is now offered for sale to settlers. The price of lots in these townships under the condition of the new land law will be from fifty cents to one dollar per acre, according to their situation and quality. Should any company of settlers select any unsurveyed township in this part of the State on which they should wish to erect mills under the provisions of the new land law, the Surveyor General would proceed as soon as practicable in the survey of such township.

The settling duties required by law, are "that the purchaser of each lot shall clear in a proper manner, fifteen acres thereof, ten or more of which shall be well laid down to grass, and build a house thereon, within four years from the time of the purchase."

The board of Internal Improvement for this State have just ordered an exploration and survey of all the lands situated in the Aroostook county in reference to their settlement and agricultural capabilities. This survey will be commenced forthwith under the charge of Dr Ezekiel Holmes, of Winthrop. His report of the situation, quality and value of the public land in this part of the State may be expected in the course of the season, and will give all needful information, to those persons who may feel desirous of making a settlement upon them.

The following extracts from the second report of Dr. Jackson on the Geology of the public lands, made to the Legislature, and now in the hands of the printer for publication, show the value of these lands for cultivation. Speaking of the Aroostook country the Doctor says, "the average width of the alluvial region on the Aroostook river cannot be less than six or eight miles, and in some places it is much wider. It is a well wooded region and is the best settling land in the State, equalling in fertility the famed regions of the Western States, and capable even under a less genial climate, of producing crops of wheat and other grain, fully equal in abundance with any soils of which we have any records."

"We here found a yellow loam of a fine kind derived from the limestone rocks and luxuriant in its produce, and in some places covered to the depth of 4 or 5 inches by a black vegetable mould."

This yellow loam is remarkable for the tall rank grass called blue joint, which skirts the margin of the river and from 4 to 5 feet high and extremely luxuriant. The forest trees are of a mixed growth, but the sugar maples are most abundant, and are of gigantic size. Elms, white birch, black and white ash also abound. The soft wood grows mostly on the low lands, while the uplands in the rear are densely crowded with hard wood trees, among which are scattered magnificent pines. In the course of two years, there will be a free communication between Bangor and the Aroostook and a great number of enterprising settlers will take up their residence in this fertile valley, and by farming, they will obtain an ample reward, and that region will become as it is destined by nature to be the granary of the north."

In another place Doctor Jackson says—"On the Aroostook it will be remarked, that very few if any hemlock trees exist, and the predominant growth is of a mixture of various hard wood trees, the sugar maple, ash and yellow birch abounding, while oak scattering, some of the most lofty pine trees ever beheld. There are evident reasons why this should be the case, for the richest soils are always most crowded with a mixed growth, and the Aroostook soils are mostly of limestone alluvion, and are exceedingly rich and good settling lands remarkable for their heavy crops of wheat, rye and other grains, and are certainly richer as an agricultural district, than any other portion of Maine. The present population on this river is estimated between 400 and 500 persons, chiefly emigrants from Maine."

Towards the conclusion, Dr Jackson says: "the researches of the present season have brought to light many important resources in the public domain which were before unknown. Beds of iron ore of immense magnitude favorably situated for advantageous operations occur on the Aroostook, and all the marked characteristics of the regular coal formation exhibit themselves over a great belt of country from the Schoons to the Aroostook and St. John, and extend to the Tennessee lake near the frontier of Canada. It will be at once perceived, that the country which we have explored is a most valuable territory, possessing every advantage required by settlers. Heavy timber offers a reward to the enterprising lumber dealer. A rich soil capable of producing an average crop of 20 bushels of wheat to the acre, and in some cases producing from 30 to 40 bushels, offers an ample reward

to the husbandman. Inexhaustible supplies of limestone valuable both for building materials and for agriculture and inexhaustible mines of rich iron ore, amid terminable forests which will furnish an abundance of charcoal, required for the manufacture of the finest kind of iron and steel—the country presents every natural advantage that might be required to call forth the enterprise and industry of the farmer and manufacturer."

By an inspection of the map of Maine, it will be seen that there are nearly one hundred townships of land situated on the Aroostook river and its tributaries, one of which belongs to the State of Maine and is now open for sale and settlement under the new land law. Considering the remarkable fertility of the soil in this region and the high price of produce, and the ready market which it finds among the lumbering people on the Passoboscot and St. John rivers, and the advantages of a road now making by Maine and Massachusetts into that region, it is believed that an uncommon opportunity now offered to persons who may feel desirous of obtaining good farms at a low price.

The field notes of the surveys of all these townships are in the Land Office, open to the inspection of every person, and all information that may be received here from time to time, from the progress of surveys, and reports of Agents, will be cheerfully given to all inquirers, and every facility granted within the means of that office, to secure to individuals and companies, all the benefits and privileges intended by the Legislature, to actual settlers under the provisions of the following law.

ELIJAH L. HAMLIN,
Land Agent of Maine.

STATE OF MAINE.

In the year of our Lord one thousand eight hundred and thirty-eight. An act additional to promote the sale and settlement of the Public Lands.

SECTION 1. *Be it enacted by the Senate and House of Representatives in Legislature assembled, That all lands lotted to settlers shall be sold to those who only will perform settling duties on the same as prescribed by law, the price to be fixed by the Land Agent, having reference to the field notes, not however at a less price than five cents per acre; three fourth parts of said price to be paid within three years from the time of said sale in labor be laid out in making roads in such township where said lands so sold are situated, under the direction of the Land Agent; and the remaining fourth part to be paid in cash within four years from the time of said sale.*

SEC 2. *Be it further enacted, That whenever two or a less number of individuals, shall each select a lot one hundred and sixty acres of land in any township lotted for settlers, the same having no mill within its limits and shall give bonds satisfactory to the Land Agent, that they will within the term of three years from the time said selection, erect in a proper and substantial manner a saw mill and grist mill, on such lot within said township, as shall be designated by the Board of Internal Improvement, the same shall be entitled to a deed of said lot; and each individual shall receive a deed from the Land Agent for his respective lot, without any further consideration, conditioned however, for the performance of the settling duties required by law.*

SEC 3. *Be it further enacted, That from and after the passage of this act, all acts and parts of acts inconsistent with the provisions of this act, be and the same be hereby repealed.*

In the House of Representatives, March 23, 1838. This bill, having had three several readings passed and enacted. ELISHA H. ALLEN, Speaker. In Senate, March 23, 1838. This bill having had two several readings, passed to be enacted.

N. S. LITTLEFIELD, President.
March 23, 1838. Approved.

EDWARD KENT,
Secretary's Office,
Augusta, March 26, 1838. }

A true copy of the original on file.
Attest, SAM'L P. BENSON,
Secretary of State.

THE NEW ENGLAND FARMER.

Is published every Wednesday Evening, at \$3 per annum payable at the end of the year—but those who pay within sixty days from the time of subscribing are entitled to a deduction of 50 cents.

AGRICULTURE IN MAINE.

The capabilities and resources of Maine as an agricultural country have been much underrated, not only by strangers but by a great majority of its own inhabitants. It has been looked upon as a place fit only for lumbering, fishing and speculation, and it was supposed, generally, that she must be dependent upon the fertile fields and prairies of the West for a supply of bread stuffs to support her population while engaged in these vocations. Maine has been thrown upon her true resources of wealth in consequence of the great depression in the commercial world, the failure in part of its trade, and the reaction of the speculations, which so intoxicated many of her own citizens as well as of the neighboring States. Aided by the liberal patronage of the State, and encouraged by the splendid success of two successive seasons, it remains no longer a matter of doubt, but a certainty, that Maine can, not only raise her own bread stuffs, but soon have a surplus for exportation. We have recently returned from an excursion in Maine, New Brunswick and Nova Scotia, of four weeks, having travelled five hundred miles in the former place in various directions, giving us an opportunity to visit many farms and to fall in company with many intelligent men, who are largely engaged in agricultural pursuits, and from what we have seen and heard, have come to the conclusion that we were possessed of the spirit of emigration, we would look eastward, rather than turn our faces to the "far West." Some portions of the State are equal in fertility to any part of our country which will be seen by the facts which are given below. There are large tracts of it for sale, yet untouched by the woodman's axe, which may be purchased for \$1.50 to \$2.50 per acre, a short distance from navigable streams, and in one of the most healthy climates in the world.

It appears that the grain worm, so injurious to the wheat crop has not crossed the Penobscot; but between that river and the Kennebec we found it had been somewhat injurious in many places. Immense quantities of wheat are raised this year, exceeding by far the amount raised last season, although it is said not to be quite so plump and heavy; but the quantity sowed was much larger.

Mr S. C. Clark, of Springfield, gave us the following statement of the quantity of produce raised upon his farm last season, viz:

1100 bushels of wheat on 31 1-2 acres from 31 1-2 bushels sown.

589 bushels of wheat and oats mixed; two fifths of which was wheat on about 13 acres, from 13 1-2 bushels sown.

86 1-2 bushels of rye from 2 bushels sown on short of two acres of land.

1500 bushels of potatoes on six acres.

160 " ruta baga on one fourth an acre.

7 " white beans.

50 tons hay on forty acres.

400 lbs. maple sugar.

12 bushels beets and carrots beside what were used in the family.

The land was taken from the stump, or was in a wilderness state eight years since. Mr Clark also stated that the poorest man in the town, who by the way, is deaf and dumb, raised eighty bushels of wheat. This town is about sixty miles from Bangor, near the military road from that place to Houlton, and was "from the stump," about the same time Mr Clark commenced his operations.

The Hon. Ira Fisk, of Lincoln, informed us that he raised last year in township No. 4, adjoining Springfield, 1200 bushels of wheat, at the rate of 30 to 35 bushels per acre: 500 bushels of oats, 60 bushels to the acre: 1900 bushels potatoes, 700 of which were raised on 1 3-4 acres without manure: 1100 bushels ruta baga, at the rate of 400 bushels per acre, and 85 tons of hay at the rate of 1 1-4 tons per acre. The produce of his farm was sold on the place to timber-men at the following prices. Wheat \$1.50 per bushel: oats 42 to 50 cents per bushel: hay \$15 per ton: potatoes, 33 cents per bushel. The price this year will probably be somewhat reduced. The cost of clearing wild land, viz. cutting, burning, rolling the logs and sowing the seed, is estimated from 12 to \$15 per acre: at these prices it is generally taken on contract. The average crop is estimated from 25 to 30 bushels of wheat to the acre in this section of the country; and crops of 35 bushels and even more not unfrequently, which will pay the cost of the land, clearing and harvesting, and leave a handsome profit. The land on the seacoast is generally much inferior to many tracts back in the country; but the advantages that are, or may be derived from the muscle beds and other maritime manure will make up the deficiency so far as the raising of potatoes, hay, oats and barley are concerned. As to wheat, the seacoast is not so favorable for its production.

A farm in Ellsworth, on which are 90 acres of mowing, produced this season by estimation 140 tons of hay. It has been mowed fifteen years in succession, and the hay sold, no stock of any consequence having been kept upon it, and has not deteriorated. Its productiveness has been retained by suffering the after crop to remain on the ground, and by an annual dressing of muscle manure. It was remarked that the shells were somewhat in the way of the scythe, but a heavy roller passed over it in the spring would remedy that evil. A muscle bed attached to a farm is a valuable appendage not often appreciated as it should be.

Indian corn is not much cultivated east of the Penobscot, and in comparison with other grain, very little between that river and the Kennebec. This species of grain is an uncertain crop, and even where favored with the best season, does not give so profitable a return as wheat. We noticed many fields which looked well and to all appearances out of the way of frost, the last week in August. Hay has come in bountifully throughout the State, and the prospect for potatoes is generally good, and we see no reason why Maine should not thank God and take courage.

J. B.

GREEN'S STRAW CUTTER.

Our ingenious countryman, Mr Green, has received a high compliment, in the encomium which has been passed upon his machine by the Highland Agricultural Society of Scotland. A description of this machine was sent from Canada to the secretary, by Mr Ferguson, who pronounced it "the easiest and the most effective cutter he ever met with—a real first rate machine." The communication was laid before the committee on machinery, who, after making a machine according to the description, and sufficiently testing it, reported that they found it "to bear out all that was reported of it by Mr Ferguson;" that "it is now ascertained, that it will cut *three times more* than the best of the common sort, and with *less force*;" and that "one person driving the machine will cut with ease five hundred weight of hay or straw in an hour." This is a high, but deserved commendation. The notice, with a cut of this machine, is published in the society's papers for June.—*Cultivator*.

Green's Straw Cutter, may be had at the office of the New England Farmer. In the next number we shall have an engraving of the machine. How-ever high the commendation of the H. A. S. of Scotland may, it is not overrated.—*Pub. N. E. Farmer*.

STEEPING SEED WHEAT.

We have two communications from Mr J. Hathaway, persisting in his notion, that the germinating power of Italian wheat is destroyed by steeping it a few hours in brine; though Mr H. admits, that his results might in some measure have been produced by the grain having been passed through a smut machine. On the other hand, Mr Hathaway's neighbor, B. P. Johnson writes us, that he soaked the seed for six acres, in a pickle as strong as he could make it, to which he added saltpetre, for fourteen hours, and that he never has known wheat come finer and better. In another case his wheat was soaked twentyfour hours, in brine that would bear an egg—and afterwards remained in a barrel ten or twelve days, was then sown, and gave a product of twentyfour bushels to the acre. We have other notices to the same effect, which it is hardly necessary to detail, as we feel a perfect confidence, from the ten, nay, hundreds of thousands of trials that have successfully been made, that steeping seed grain in brine, and liming it, does not destroy its vegetating principle. Yet there is one other case we may quote, which, if there were doubts remaining, would seem to set the matter at rest. Mr Medary, editor of the Ohio Farmer, steeped the Italian wheat *eightyfour hours*, in a warm temperature, in a pickle so strongly saturated with salt as to coat the grain—and yet *every seed grew*. In another instance, the seed remained in the liquid, or brine, *three weeks*; and of this, too, every seed appeared to grow.

While on this subject of steeps, we will detail a fact communicated to us by Mr. B. V. French, of Brintree, Mass. He steeped seed corn in a solu-

tion of saltpetre, and planted some of it upon dry, and some upon wet ground; not more than a tenth of the latter grew, while seed not soaked, planted upon wet ground, came well. The steeped seed planted upon dry ground, came up almost without a failure. We leave to naturalists the solution of the questions, why Mr French's soaked corn, planted in wet ground, and Mr Hathaway's brined wheat, did not grow. They seem both to be exceptions to a general law.—*Cultivator*.

THE REVOLVING HORSE RAKE IN ENGLAND.

Newly Introduced American Hay Rake.—A new hay rake of American invention has been introduced into this country, and promises to be of material benefit to the farmer during the hay-making season. The implement has a light beam or stock, nine feet in length, to which are attached rows of teeth, both before and behind. It is drawn over the sward by a horse; and as soon as the interstices between the teeth are filled, the workman in attendance moves a handle, which turns the rake right over, and presents the side which has hitherto been empty. In this manner the hay is deposited in little heaps throughout the field, and the principle advantages of the implement are, that it vastly economizes labor in a very busy season, and at the same time sweeps the field with the greatest nicety.

Thus it is that the inventions of civilized countries may benefit each other; and though occasional importations are made, still they are not to the extent that is desirable. Prejudice may have something to do with this. We may fancy that we have arrived at the highest point of perfection in the invention and manufacture of all sorts of tools and implements: if so, the sooner such notions are discarded the better it will be for ourselves. 'Tis true that America is only a newly civilized country, but for all that she can boast of her intelligent farmers. The able papers of Mr Ruffin, which appeared some time ago in the *British Farmer's Magazine*, and the address of Dr Beekman, in our present number, need no comment. Our farmers will perceive that the sound sentiments embodied therein are worthy of the oldest of civilized nations: they show an intimate acquaintance with the subjects of which they treat, and their writers will be regarded with the veneration that ever follows the memories of talented men. If, however we would have agriculture advance in the same ratio as manufactures, we must take similar measures to effect it. We must banish prejudice, and avail ourselves of the foreign aid that may be had for seeking, and by thus increasing our resources, we shall simplify the operations on the farm, and secure increased produce.—*British Farmer's Magazine*.

(Selected for the New England Farmer.)

HOGS.

SECTION 1. "Hogs are most extraordinary animals; but, though in many respects rather disagreeable, they are of very considerable importance to the community at large, and to the farmers in particular. There is no animal affords so much human sustenance in flesh, in proportion to the time in which it is raised: and in no instance has Nature shown her economy more than in this race, the stomachs seeming to be intended as a receptacle for many things that other creatures refuse, and

which, but for them, would be entirely wasted; for they industriously gather up, and greedily devour, what would otherwise be trodden under foot—the refuse of the fields, the gardens, the barns, and the scullery."

THE BOAR.—"In describing the boar, I mean to give the form, and every good property a hog ought to possess. Beginning at the head—the mouth should be small; the snout, or nose end, fine; the fore part of the face, from the nose to the crown, rather short, thin, and straight; the eyes quick, and shining like that of a ferret; the ears short and thin, sharp at the end, turning up, standing near together, and put forwards so as nearly to meet at the ends; the crown, or forehead, should be narrow and the cheeks full; the upper part of the neck very full, so as when fat, to be nearly as broad at the top as the shoulders and back, viz. from the ears to the shoulders, that part where the head is cut off, being nearly as round as the body; the shoulders should be very broad above, and continue of that regular breadth all along the back to the tail; the tail should stand low down; the back from the neck to the top above where the tail is set on should be straight, and the tail fixed in such a manner as for the upper part of it to be invisible when fat; the ribs well extended, and rather rounding, but not required to be so much so as some other animals; from the part where the tail stands, down to the carmel, between the thighs, what is called the twist, should be very much cloven; the thighs very thick, both inside and out; the belly part, when fat, should nearly touch the ground, from the hind legs to the fore, and continuing to the chops; the shoulders should be well extended, so as to form a complete, deep, round side, from head to tail; the tail small and short, with little hair; the bone of the legs rather small in proportion to the size; the leg, from the carmel to the ground, short; the fore legs the same; the hoofs short and round, to tread very straight on all the legs; the hair long, fine, and thin, having few bristles, or if none the better; if the hair shed along the back, like a long-wooled sheep, it is a recommendation; and the skin, or rind, should be thin, without any being loose or superfluous."

SECTION 2. "The mouth being small, will prevent its taking in much food at once, and the animal is therefore more likely to masticate it properly; a fine snout indicates fine symmetry in other parts; the crown being formed narrow, with a quick eye, looking smart, is almost a certain indication of quick aptitude to fatten; the ears short, and sharp, hair long and thin, without bristles—if a pig have these properties, let the other shape be what they may, he is sure to be a good feeder. A hog that has short, mossy hair, thickly set, generally has a thick, coarse skin, loose and wrinkled, which is one of the worst faults a pig can possess. There is little waste or offal about hogs; therefore, a large long ear, hanging down on each side of the head, with long, large legs, &c., would not be so great a fault in them as in other animals, if they were not a certain indication of hard thrivers, and that they will on a certainty cost more feeding than they are worth. I have remarked that the upper part of the neck should be thick, which is one of the very best properties in regard to being well covered with flesh, and that of a good quality; for when a hog in a store state is thick on the upper part of the neck, that sort of flesh, which is lean, or rather in a fattening state, is sure to continue all along the back, on both sides the chine, inside and out, ma-

king very heavy griskins, and prime roasting parts when killed as pork pigs; and if kept to the age of bacon hogs, (which ought not to be less than two years, as there is not the requisite solidity in the fat or flesh of young pigs,) that sort of flesh naturally descends to the shoulders, and along the fat parts of the sides, producing the bacon flitches agreeable layers of lean in every part, and by being so mixed or layered, the fat will be rendered more firm, not so soft and greasy. Hogs that are not so properly made are, some of them, all fat, and in every stage, either as pork or bacon, they have no more flavor than hogs-lard."

SECTION 3. Hogs are of various kinds, therefore the choice of the sort should be regulated by the treatment they are to receive. I shall describe the several species that have fallen under my observation."

"The *Berkshire* pigs are distinguishable by their color and shape. Their color is a spotted white, and some are sandy, with small black spots regularly all over them; a few are entirely sandy. The hair is long, and thinly set, but much curled, looking very rough, and the real true breed feathered, having long hair growing round the outward edge, which looks rather unseemly, but is found not to be an imperfection. The hair indicates a coarseness, as if the skins were thick, but they are quite the reverse; the best sort, although very large, being remarkably thin in the rind, and equally fine in the flesh; they are, with very few, if any exception, better known by their hair than any other appearance, and the best of these pigs have no bristles; indeed, so remarkable are they in that respect, that those I took into America received the name of Parkinson's no bristle pigs. The Americans were so partial to this breed that I sold sucking pigs weighing 20 to 32 lbs. each, at 20 dollars a sow, and 25 dollars a boar. I knew a pig, of this breed, killed at the age of 15 months, which weighed 574 lbs.* When choice is made of even the best kinds, they require very attentive nursing, and good support when sucking the sow. The sow should be well kept, in a clean warm dry sty, well littered with clean dry straw, changed once a week at least; every place should be made thoroughly clean, even the bottom must be swept, and the trough they are fed in washed daily. The young pigs should be learnt to eat as soon as possible,

* Along with the sheep, Mr Barney brought a hog, two years old last fall, of General Ridgely's Parkinson stock, which weighed:

Nett weight,	751
Leaf fat,	88

American Farmer Vol. 5th p. 40.

The following is an extract of a letter from the Hon. Oliver Fisk (see *New England Farmer Vol. 3, page 222*.) He says—"I have obtained the following account of the introduction of this breed of swine from the Hon. T. Pickering. He saw them first on a farm of General Ridgely, at Hampton, 14 miles from Philadelphia. General Ridgely, informed him that they were brought to this country, as a present to General Washington, from the Duke of Bedford, (hence, the name, by which they are now known,) who committed them to the care of an English farmer by the name of Parkinson. This man took a farm in the neighborhood of Baltimore; but instead of sending the swine to Gen. Washington, Parkinson sold them. General Ridgely esteemed them very highly, and sent Col. Pickering a pair of them, in a vessel bound to Salem. Mr John Reed of Roxbury obtained the breed from Col. Pickering's stock; from Mr Reed I obtained the offspring from separate litters, and transferred them to Worcester, where by avoiding the breeding directly in and in, I have preserved them without their degenerating."

and never suffered to remain with the sow longer than from seven to eight weeks."

"The *Susser* pig is another very good kind, distinguished by being black and white but not spotted; frequently black at both ends, and white in the middle. These pigs are of smaller size, but very handsome in their form: the skin, or rind, is superior to that of most other kinds; the hair very thinly set, fine and long; their general size, when full grown, is about 280 lbs. They are quick growers, and with proper care attain perfection more early than any other breed."

"The *Suffolk* white pig stands high, is narrow in the back, and the forehead is rather broad; the ears stand pretty well; the hair is short with many bristles. The weight when full grown is about 260 lbs."

"The *Lincolnshire* white pigs are distinguished as being of superior form to all others, except the Berkshire. Their ears are neither long nor short, stand rather near together, pointing forwards; are sharp at the extremity, rather flat, and turn up a little at the ends. They are of very fair size and can be made to weigh over 400 lbs. when full grown."

"*Cheshire* pigs are distinguishable by their gigantic size: in color they are black and white, blue and white, and some all white. Their heads are large, with very long ears hanging down on both sides of the face, so that they can scarcely see their way; they are from head to tail remarkably long, as is the tail likewise; very narrow according to their size, and many have an elevated or curved back; they are very flat on the sides and deep, with large bones, long legs and much loose skin."—*Parkinson on Live Stock.*

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Sept. 1, 1838.

From Hon. E. Vose of Dorchester, Melons of the Greenflesh variety, viz. Persian, Minorea and Cantaloupe. (The contributor very politely placed this fruit upon the Committee's table for the proof of its quality: upon dissection it was found to be of very delicious flavor, finely ripened and of the genuine varieties.)

From Joshua Gardner, Esq. of Dorchester. Fine River Apples.

From Mr J. Wiggins of Portsmouth, a beautiful summer apple (name unknown.)

A fine Apple from Manchester, Virginia, gathered by a traveller.

From Capt. John De Wolf, Brighton, a basket of Julian Pears, very fine.

From Mr John B. Barstow, Hanover. A basket of Summer Pippin, apparently a fine fruit, but having been too long kept the flavor was lost.

From Sam'l Walker, Esq. Roxbury, a dish of fine Plums, variety, Bolmar's Washington, Princes White Gage and Italian Damask.

From Sam'l R. Johnson, Esq. Charlestown. Three baskets magnificent Plums, two of Bolmar's Washington and one of Green Gage; also, a branch from the tree very full and of large size fruit.

From Robert Manning, Esq. Salem, was received a large basket containing the following Pears. Variety, Summer Frankreal, Red Juneating, Harel or Hessel, and Dearborn's Seedling. Apples, variety, White Astracan, Nonsuch, (English,) and Putnam's Harvey. Plums, variety, Dana, Byfield, and Red Canada, (the latter planted for stock) it

was unfortunate that the liberal contribution was not received till at the close of the exhibition, as it contained many very valuable and handsome specimens.

From Mr Pond of Cambridgeport. His usual large and handsome display of *Plums* for which he is so much distinguished; his varieties were, Smith's Orleans, Duane's Purple, Bingham, Green Gage, White Gage, Corses Field Marshal and Bolmar's Washington.

From Hon. John Lowell, a specimen of Cuba Tomato, very beautiful, they were distributed for the seed, agreeable to the wish of the contributor, as expressed in the following letter received by the Committee.

For the Committee of Fruits and Vegetables.

JAMES L. L. F. WARREN.

Roxbury, Sept. 1, 1838.

To the Committee of the H. Society for Vegetables.

GENTS.—I send you the Tomatoes of Cuba, which are much preferred by the Spaniards to those we raise. Indeed, for a preserve for the desert, they are much more beautiful. I was fearful, they would not ripen in our climate; but I found they were eight days earlier than our own raised near them in the open ground.

I thought some cultivators might like to try them, and therefore send some ripe ones. They are abundant bearers.

I am very respectfully, your ob't servant.

JOHN LOWELL.

FLOWERS.

Dahlias.—By Messrs Hovey & Co., a fine specimen of variety, Mrs Rushton. The form, color and size of this variety are good; it will rank among the *number ones*.

By S. Walker, varieties, Jackson's Rival Yellow, King of Dahlias, Dutchess of Buccleugh, Dennisii, Widnall's Perfection and Lady Ann.

Bouquets.—By Dr J. C. Howard, Woodlands, Brookline; Messrs Winship, Brighton; Messrs Hovey & Co., of Cambridgeport; Mr John Hovey, and S. Walker of Roxbury. For the Committee S. WALKER, *Chairman*.

The Committee of Arrangements at their meeting this day, voted that the annual exhibition shall take place on *Wednesday, Thursday and Friday*, 19th, 20th and 21st days of the present month.

The *Special Committee to decorate the Hall and to take care of the fruits and flowers*, viz.: Messrs L. P. Grosvenor, M. P. Wilder, J. E. Teschemacher, Wm. Kenrick, E. M. Richards, J. R. Johnson, C. M. Hovey, D. Haggerston, W. H. Cowan, J. W. Russell, H. Sheafe, Alexander McLennan, J. Breck and J. L. L. F. Warren, will meet at the room of the Society on Saturday morning 8th and 15th inst. at 11 o'clock.

Per order,

J. WALKER, *Chairman*.

From the Albany Cultivator.

INDUSTRY vs. INDOLENCE.

J. BUEL, Esq.—Sir—Industry produces a stream that flows slowly on to elevate the inquiring mind, which forms a sure foundation and great barrier against every vice. It is a granary to the mind, where every virtue will be stored: it lends a sweet tincture to every action, which is gratefully cherished.

The man who has no occupation must be quite unhappy; toil is the price of sleep and appetite, of

health and enjoyment. How nobly every order is displayed! The very necessity which overcomes our natural sloth is a blessing. Every briar and thorn which is strewn in our path; every annoying insect which appears to surround us, by divine mercy, could not have been spared.

We are happier with the sterility which we can overcome, by our united exertion, than we could have been by spontaneous bounty, and unbounded profusion.

No way can the body and mind be so morally and effectually improved, as by the toil that fatigues them. That toil receives its manifold rewards daily, by the pleasure it bestows. The enjoyments are so varied and peculiar, that no wealth can purchase them, no honor can win them, no indolence can taste them.

Many people imagine themselves in pleasures, provided they are neither in business nor study. Nothing like it; they leave not one trace of their laborious and intellectual exertion behind them, no more than if they were asleep.

By contracting habits from laziness they frequent only those places where they are free from all those restraints, attractions and demands, which do justly surround them.

This sinks the indolent into contemptible obscurity all the days of his life. He only lives to die in a thousand errors, and rather adopt the prejudices of others than give himself the trouble of acquiring true knowledge, which tends to form correct opinions of his own.

Idleness leaves a man in the lowest state; his pleasures are all sensual, no wants are sought after but those of appetite. The man of industrious habits is looking forward, with a degree of superiority, to more noble and higher attainments in intellectual enterprise. He discovers that the happiness of individuals and security of society are formed by the industrious habits which elevate the mind, and is carried forward in search of something more excellent, and obtains a proper degree of superiority over the common senses of life by learning to feel himself capable of higher aims and nobler enjoyments. That which abstracts the thoughts from sensual gratifications, and exerts us to look for happiness within ourselves, will surely advance, in a measure, the dignity of our nature: therefore all good pursuits reward themselves; one truth constantly presents another to view, and while our store of knowledge and enjoyments are constantly increasing, kind nature can never be exhausted.

Industry, properly applied, will most assuredly advance our prosperity: the advantages of which are two-fold; it will, in a measure, be estimated by the pecuniary profit produced, but more by the superior tone of industry and economy which the possessor unconsciously acquires.

That which the industrious has obtained by his own proper and well directed exertion at once causes him to feel raised in the scale of being, and endows him with the capacity of enlarging the stock of his possessions.

When property is accumulated by the industrious peasantry, it never fails to produce impressions on their minds, very lasting and unavoided. In such instances it renders them more industrious. They also strive to better educate their children, that they may be better fitted for some good and useful attainment and station in life.

S. W. JEWETT.

Weybridge, N. Aug. 8, 1838.

From the Genesee Farmer.

WEEDS.

The astonishing increase of weeds,—and by this name we mean all noxious plants that infest soils, especially cultivated ones,—such as the thistle, redroot, charlic, Johnswort, daisy, and a multitude of others with which our farmers are but too well acquainted, would seem to demand that more attention should be paid to the best methods of exterminating them, or at least preventing their increase, before the cultivation of our richest fields becomes impossible or unprofitable.

Many weeds spread rapidly by the root, as the thistle, Johnswort, &c.; others are propagated only by seeds, as the redroot and charlic: but, as there is scarce a plant that cannot be propagated by the seeds, and those first named it is evident spread extensively that way as well as by the roots, it is clear the preventing the formation and ripening of seed should be the first object with the farmer, to prevent their being scattered by sowing, or by the spreading of manures, the second thing to be aimed at.

Farmers who allow the weeds named, or indeed any others, to ripen and distribute their seed unmolested, are preparing a rich harvest of losses in the actual value of their farms, and of toil and trouble in their management; and those who sow, or allow to be sown on their farms, seed of any kind containing these pestiferous germs—we say nothing here of those who knowingly dispose of them, as the conscience of a man who would spread his neighbor's fields with the thistle, steincroot, or charlic must be proof against all ordinary appeals to a moral sense—must we think entirely overlook the fearful consequences, if not to themselves, to their posterity. There are many farms within our knowledge the profits of which are already most materially lessened from the operation of these causes, and the evil instead of diminishing is yearly increasing.

In the cultivation of grain, to which so much of our country is, and must be devoted, the farmer is exposed to this increasing evil in at least three different ways to which the owner of a grazing farm is not liable; first from ploughing in seed scattered by the winds or the birds; second, from that mixed with the grain or grass seeds sown by him; and thirdly, from that carried from the yard in manures and spread upon the soil; and it is unquestionably owing to this last cause that we witness such a rapid spread of some of these weeds on cultivated land. The foul stuff grown with the hay or grain, principally the latter, ripens its seeds in the field, is carted to the stack or the barn, fed out or threshed out and thrown into the yard, the seeds lie unhurt in the manure preparing for vegetation until carted upon the ploughed fields for fallow or spring crops, and ready to spring with vigor the moment they come in contact with the earth. The weeds may in a great measure be prevented by proper precautions from ripening their seeds in the fields; the grain or grass seeds sown may be, and should be, thoroughly cleaned or never put into the earth; but if the bad seeds get into the manure, there is scarcely a possibility that they will not spread as far, and into as many fields, as the manure is carried.

We are the advocates of the application of long manure, unless some pressing reason forbids. It clearly affords greater nourishment to crops than if allowed to ferment and rot above the surface, and,

therefore, where circumstances admit should always be ploughed under, to undergo the process of decomposition. But we are also prepared to forego part of these advantages, if they cannot be secured, (and where foul stuff has been grown in the hay or straw that constitutes the principal part of long manure, we are confident they cannot,) without running the great risk, or encountering the absolute certainty of stocking our fields with the justly dreaded weeds. In this case the gain from the unrotted manure, is far more than counterbalanced by the loss on the crop occasioned by the presence of the weeds; to say nothing of the more serious injury resulting from their, obtaining a foothold in our fields yet free from them, an injury which half a dozen ordinary crops would hardly compensate. It, therefore, seems plain that a method that shall destroy the seeds in the dung, before it shall be applied to the soil must eventually be preferable to one that leaves them free to vegetate, even should some part of its efficiency be lost in the process.

This destruction of all seeds in manure can be effected by the great heat produced in dung by fermentation, when that process is conducted under circumstances favorable to its development; and to do this it is only necessary that the decomposition of the manure should be carried on in the piles. It is well known that the degree of heat produced in an ordinary hot bed, in which the manure is not disturbed, would become destructive to all vegetation were the seeds planted upon it while the fermentation was most active, or the heat not mitigated, and that it actually is so to all seeds that are in the manure when placed in the bed. So certain is this effect, that some have deemed it cheaper in the end, to be at the expense of constructing hot beds, for the sake of the manure, rather than to use common barnyard manure with its infinity of seeds on the garden. All manure ferments in decomposition, and consequently heats more or less; but it is only when made into piles, that the heat is sufficient to destroy the vitality of the seeds it may contain. If, therefore, farmers would adopt the practice generally of heaping their manure either in the yard, or the field, and allowing the heat to rise and remain sufficiently long to destroy the seeds of weeds, &c., that might be in it, they would be certain of being freed from one of the most prominent causes of the propagation of worthless plants. If the heaps were formed of alternate layers of vegetable mould, or swamp mud, and manure, the mould or mud would absorb much of the fertilizing gases that without such precautions will escape during the fermentation, and the whole mass be rendered more valuable than without such mixture.

It is true the system here recommended would add something at first to the labor necessary on the farm; but when the work required for keeping down weeds in the field, or the garden, or separating foul seeds from grain, is taken into consideration, a very great saving in labor would undoubtedly be effected, independent of the pleasure in working a farm, and the additional value given to a farm, free from the nuisances to which we have alluded. The only precaution that would seem necessary in this preparation of manure would be to occasionally examine the heap of dung or compost, and if the heat was like to be so great as to injure the mass to open it to the air a little; and if on the contrary the fermentation should not be brisk enough to add a little water to the pile, or what

would be still better, from the yard as that always contains a large quantity of salts in solution, and would prove an effective as well as valuable agent in the process. Our farms are too valuable to be surrendered to the dominion of these weeds without an effort to check or destroy them. The weeding system as practised in England to keep their grain and farms clean cannot be adopted here where labor is so high; but we can endeavor to prevent these weeds going to seed, and we can prevent their extension in the manure by destroying their germination; and there is no one who knows the loss they would occasion, but will admit the object is at least worth an effort.

TO DESTROY THE GRAIN FLY.

A gentleman has just communicated to us a method of destroying the grain fly which will cost but a very little, and which he thinks will not only be effectual in saving a crop of grain, but if generally practised by farmers, will rid the country, in a great measure, of this enemy. He observes that he was lately examining a piece of wheat and was surprised in finding only now and then a grain worm in the hull, as they were generally very plenty; he inquired of the farmer the cause, who told him that he had destroyed the flies by carrying pitchwood torches through his grain, commencing in the evening as soon as it began to grow dark, and as early in the season as the flies made their appearance, and continuing the operation till the flies were all destroyed or had fled, which was about six or seven nights. As he passed through the grain, he carried a pole that struck against the tops of the grain, which caused them to fly up into the fire, as is the general practice, with insects, when they were either destroyed, or disabled by having their wings burnt off so as to prevent their doing mischief. This farmer said he was induced to try this method as his neighbor last year saved his grain in this manner, while others in the vicinity had theirs greatly injured by the grain worm.

A cheap apparatus can be made for destroying flies in this manner, by which the business can be done with great expedition. Take two long, light poles, and commencing two or three feet from the butt ends, cut them away so as to bring the butt nearly to a point, then splice them together, lapping about as far as they are cut away, and fasten them with nails. In this manner a great length of pole may be had with but little weight, as it is to be carried by the middle. One pole may be used, but it will not be on so good a principle for lightness. We will give another method of making this part of the apparatus, as it may be more convenient for fixing the fires. Take a very long piece of board, straight on one edge, four or five inches wide in the middle, with the other edge cut away straight from the centre to about one inch in width at the ends; let the straight edge of this board be up, and nail on to it another piece, lying flat wise, of the same length, three or four inches wide in the middle, and about one and a half inch wide at the ends. This will be light and strong.

These boards or poles are to be carried so as to strike the tops of the grain and start the flies, and the fires should be a little above the boards so as not to burn the grain. When pitchwood can be had it will be good for fires; pieces can be fitted to small holes bored into the poles or boards; they should be of sufficient length to bring the fire above the wheat. Where pitchwood cannot conveniently

be obtained, tar, which is very cheap, may be fixed with tow so as to burn long, and if the light be not bright enough, spirits of turpentine may be added. The lights should be within two or three feet of each other. A thin piece of board might be elevated ten or twelve inches above the flat piece, before named, and on this might be fastened light vessels for the tar. By proper care in fixing poles or boards, a breadth could be taken through a piece of grain of twenty or thirty feet.

These suggestions as to an apparatus for destroying this great pest of the farmer may be of advantage to some; others may fix a better contrivance. We regret that we did not hear of this method earlier, that it might have been tried when the flies first made their appearance. Though the season in which the flies usually do mischief may be passed, yet farmers may judge, in a measure, of the utility of this method by carrying lights through their wheat as soon as it is dark, as there may be some flies remaining. We think that it appears reasonable that the grain fly may be destroyed as here recommended, and the experiments that have been made, so far as we have heard, have been successful. The vast amount of grain destroyed by these insects, should induce every farmer in the country to exert himself to discover a remedy against their ravages, and every method recommended that has any reason to support it, should be fairly tested; and those who make experiments should communicate the result to the public that others may benefit from their experience.—*lb.*

GEOLOGY OF MASSACHUSETTS.

BY PROFESSOR HITCHCOCK.

NEW METHOD OF ANALYSING SOILS.—Continued.

Dr Dana's remarks in answer to these inquiries I shall omit for the present, and quote the remainder of his remarks preliminary to his rules for analysis. If any sentences seem to be somewhat repetitions of those already quoted, it is sufficient to say, that they were communicated at different times, in private letters in answer to inquiries which I had made, that I might be sure not to mistake his meaning. On a subject so new, some repetitions are not undesirable.

"Geine forms the basis of all the nourishing parts of all vegetable manures. The relations of soils to heat and moisture depend chiefly on geine. It is in fact, under its three states of 'vegetable extract, geine, and carbonaceous mould,' the principle which gives fertility to soils long after the action of common manures has ceased. In these three states it is essentially the same. The experiments of Saussure have long ago proved that air and moisture convert insoluble into soluble geine. Of all the problems to be solved by agricultural chemistry, none is of so great practical importance as the determination of the quantity of soluble and insoluble geine in soils. This is a question of much higher importance than the nature and proportions of the earthy constituents and soluble salts of soils. It lies at the foundation of all successful cultivation. Its importance has been not so much overlooked as undervalued. Hence, on this point the least light has been collected from the labors of Davy and Chaptal. It needs but a glance at any analysis of soils, published in the books, to see that fertility depends not on the proportion of the earthy ingredients. Among the few facts, best established in chemical agriculture, are these: that a soil, whose earthy part is composed

wholly, or chiefly, of one earth; or any soil, with excess of salts, is always barren: and that plants grow equally well in all soils, destitute of geine, up to the period of fructification,—failing of geine, the fruit fails, the plants die. Earths, and salts, and geine, constitute, then, all that is essential; and soils will be fertile, in proportion as the last is mixed with the first. The earths are the plates, the salts the seasoning, the geine the food of plants. The salts can be varied but very little in their proportions, without injury. The earths admit of wide variety in their nature and proportions. I would resolve all into '*granitic sand*;' by which I mean the finely divided, almost impalpable mixture of the detritus of granite, gneiss, mica slate, sienite, and argillite; the last, giving by analysis, a compound very similar to the former. When we look at the analysis of vegetables, we find these inorganic principles constant constituents—silica, lime, magnesia, oxide of iron, potash, soda, and sulphuric and phosphoric acids. Hence these will be found constituents of all soils. The phosphats have been overlooked from the known difficulty of detecting phosphoric acid. Phosphate of lime is so easily soluble when combined with mucilage or gelatine, that it is among the first principles of soils exhausted. Doubtless the good effects, the lasting effects, of bone manure, depend more on the phosphat of lime, than on its animal portion. Though the same plants growing in different soils are found to yield variable quantities of the *salts* and earthy compounds; yet I believe that accurate analysis will show, that similar parts of the same species, at the same age, always contain the inorganic principles above named, when grown in soils arising from the natural decomposition of granite rocks. These inorganic substances will be found not only in constant quantity, but always in definite proportion to the vegetable portion of each plant. The effect of cultivation may depend, therefore, much more on the introduction of *salts* than has been generally supposed. The *salts* introduce new breeds. So long as the salts and earths exist in the soil, so long will they form voltaic batteries with the roots of growing plants; by which, the '*granitic sand*' is decomposed and the nascent earths, in this state readily soluble, are taken up by the absorbents of the roots, always a living, never a mechanical operation. Hence so long as the soil is *granitic*, using the term as above defined, so long is it as good as on the day of its deposition; *salts* and *geine* may vary, and must be modified by cultivation. The universal diffusion of granitic diluvium will always afford enough of the earthy ingredients. The fertile character of soils, I presume, will not be found dependent on any particular rock formation on which it reposes. Modified they may be, to a certain extent, by peculiar formations; but all our granitic rocks afford, when decomposed, all those inorganic principles which plants demand. This is so true, that on this point the farmer already knows all that chemistry can teach him. Clay and sand, every one knows: a soil too sandy, too clayey, may be modified by mixture, but the best possible mixture does not give fertility. That depends on salts and geine. If these views are correct, the few properties of geine which I have mentioned, will lead us at once to a simple and accurate mode of analysing soils,—a mode, which determines at once the value of a soil, from its quantity of soluble and insoluble vegetable nutriment,—a mode, requiring no array of apparatus, nor delicate experimental tact,—one, which the country gentleman

may apply with very great accuracy; and, with a little modification, perfectly within the reach of any man who can drive a team or hold a plough."

To be continued.

THE CROPS.—GRASSHOPPERS.—THE DROUTH.

Columbus, August 1, 1838.

We are cheered from every quarter with information of the abundant harvests which have been made this year in all parts of the country. The wheat harvest has been particularly fine and abundant; and husbandmen in all the wheat growing states, have been blessed with unusual plenty.—The hay harvests have also been good, and if the yield of clover and timothy and other grasses has not been as great this season as has been known, the weather has been of the finest for making and scouring the crops. The oat crop where it has been gathered is of excellent quality and yield, but we have noticed many fields of late and unripe oats much damaged by grasshoppers. Corn, which in the early part of the season, was backward and unpromising, is now looking unusually fine, and gives promise of great plenty.

The heat and dryness of June and July, seem to have been peculiarly favorable to all the insect tribes. We find our meadows and fields swarming with innumerable hosts of grasshoppers and other insects, which are doing much damage. Oats, as before observed, are suffering much from this cause, and even corn has been attacked by them. We are beginning too to feel the want of rain very much, it being now several weeks since we have had even a shower. We trust, however, that these causes will operate only as slight drawbacks to a season of unusual plenty and rejoicing.—*Ohio Farmer.*

To the Editor of the New England Farmer.

RESPECTED SIR—Enclosed in a package is a sample of seed corn taken from the field on the 18th inst. to all appearance fully ripe, being just ninety days from the time it was planted, which was 14th to 22d May. The original seed was what is generally termed the small size Canada corn which I began to plant about four years ago, occasionally mixing some of a little different and larger sort in some part of the field, and selecting the earliest and largest for planting the ensuing year, a bushel was gathered and ground at the mill 22d of this month, being 25 days earlier than I was able to obtain any from the same field fit for grinding the last year. The land on which it grew is rather high, inclining to a sandy appearance, formerly used for a pasture. Should the above be worth accepting you will please distribute to any who may wish to try the same, or more if wanted.

Yours, most respectfully, &c.

JOHN S. CHAMPNEY.

Abington, August 24, 1838.

GREAT CROP OF OATS.—It will be seen by a communication in this paper, that our correspondent, *A Livingston Co. Farmer*, raised the last year nine hundred bushels of oats on nine acres of land. The land had been many years under the plough, and without manure. The Genesee Flatts have, we believe, produced the largest wheat crop on record, (68 43-60ths bushels per acre), and we shall be glad to hear where a greater crop of oats than the one here recorded has been raised.—*Gen. Farmer.*

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, SEPTEMBER 5, 1838.

ON EXPERIMENTAL AGRICULTURE.

What is called experimental farming has been always matter of derision and ridicule with a certain portion of the community, who have not sense enough to form a just judgment on any important subject; nor public spirit enough to conceive of any effort or enterprise the sole object of which is general utility; nor industry enough to attempt any good themselves; nor honor enough to do justice to any man's intelligence, patriotism, or disinterestedness. Whenever therefore any individual steps out of the beaten track with a view to render a public service or make a useful discovery, if he indulges, in their view, the idle and vain conception that any thing more is to be learnt than what is already known, or that he can penetrate further into the mysterious depths of knowledge than their short line has reached, he is at once assailed with opprobrium and sneers; if he succeeds they will immediately attempt to rob him of the honor of the discovery or in some way to tarnish its lustre; and if he fails, as in most cases from the very nature of things a failure is to be expected, they will then sing songs of triumph over him; and inflated with their own self-complacency they will wrap themselves the more closely in their own ignorance and pride.

It is painful and vexatious to encounter these sharp points in human nature; but the mind, which is conscious of right purposes, and bent upon the pursuit and diffusion of truth, should regard such meanness only with the indifference and contempt, which it deserves. Philo-sophy in its literal signification means the love of wisdom; the knowledge of truth is the only foundation of wisdom; and the first and great dictate of all philosophy to every man is, seek the truth; in relation to every thing make it your great aim and study to find out what is true.

All the practical and useful arts are founded upon facts. Agriculture is pre-eminently so. All true science in agriculture is the process of induction; consists in inferences drawn from well ascertained and established facts. Theories in this case, however elaborate and fine spun, are of little, or of no value excepting as the application or proof of them may lead to the eliciting and multiplying of facts, which themselves will lead to important practical rules. As the great orator of antiquity said in regard to the importance of action to the public speaker, so we say of the importance of facts to the farmer. If he would excel in his art, if he would extend the knowledge of his art, if he would advance its power and productions, let him remember that *facts, facts, facts*, must be the great object of his inquiry.

To a gentleman then who has the means and the opportunity of pursuing a course of experimental agriculture, and who at the same time has the carefulness and the intelligence and the disposition to make these experiments fairly and fully, and patience and acuteness and impartiality to note the results; and at the same time the courage and manliness to publish them whether successful or unsuccessful, whether they make for or against himself, the highest meed of praise is due; and he is every where to be recognised as the benefactor of the community and as the true friend of humanity. We have known several such men. They are among us. We are justly proud of them. A fear of wounding their delicate sense of propriety and that modesty which has induced them to keep themselves out of sight in all their attempts to serve the public welfare and the great cause of agricultural improvement, prevents the communication of their names

They are well known however and justly appreciated. They have been blessed with ample fortunes; and they cheerfully give their money, their time, and their talents to the improvement of agricultural skill and knowledge; to the advancement of this great art, which lies at the foundation of national wealth, and of social comfort and improvement.

Now experiments are so valuable in agriculture that we do not fear to be thought by the intelligent too inopportune in continually urging them upon the farmers. It does not require a large farm or a great capital to make experiments which might prove highly instructive and useful. The smallest farmer may make on his premises experiments from which the greatest benefits may flow to the whole community; and in respect to some of the most important experiments yet to be made in agriculture, on which the solution of great questions in relation to crops, seeds, manures, modes of planting and cultivation, modes of harvesting, saving, and use, a farm of ten acres or even less may be as sufficient as a farm of a hundred or a thousand acres. Indeed an intelligent farmer upon reflection will perceive at once that every agricultural operation, which he performs, is in itself an experiment. In preparing, manuring, and sowing his fields with any crop and in any season he is making an agricultural experiment; and if he will carefully observe and note every step in the process of cultivation, and the progress of vegetable growth, the facts which he observes may prove highly useful and may elicit some most valuable truths. The discovery of the sublime and universal law of gravitation, on which all astronomical calculations are founded; and which regulates and binds together the infinite universe, is said to have sprung from observing an apple falling from a tree.

But experiments to be useful and instructive, require peculiar habits of observation and inquiry, in which many men, otherwise intelligent, are deficient. A large part of mankind seem to be travelling through the world with their eyes shut; and may almost be said to see nothing, while others see so imperfectly, that little or no reliance is to be placed upon their observations; while others from a difficulty of conveying their ideas, or a vivid imagination, which leads to too much embellishment, are incapable of making a just representation of any thing, which comes under their notice.

Much discredit has been brought upon what is called experimental agriculture from circumstances, which ought to be avoided, or should be more considered. In making an experiment, the first point of importance is to attend to all the circumstances, in the case by which the result can possibly be affected. In the application of plaster for example, we want to know the quantity, the condition of the plaster, the mode of its application; for example, whether applied on the surface, under the surface, or top of the plant, at the roots of the plant, alone, or mixed; with ashes, if so, crude or spent ashes; or with manure, and if so what kind of manure; what the kind of soil; what the condition of the soil, wet or dry; what the season of the year; what the state of the weather; what the condition of the plant to which applied; what the kind of plant; what the effects observed; much or little; immediate or late; what the character of the effect; increasing the growth of stalk; increasing the amount of grain; forwarding or delaying the ripening; cost of plaster; quantity used; expense of its application; and other inquiries which will at once suggest themselves. Then again we wish to know whether the experiment has or has not been repeated; and if so, whether the same or different effects have resulted; and we wish to know, whether the effects represented to have resulted from its application have been tested by leaving a part of the field and crop in the same circumstances, to

which plaster was not applied, and with which the plaster part might be directly and fairly compared.

An enterprising farmer took us into his wheat field this season to show the powerful and beneficial effects of lime, which he had spread upon it, and wished us to compare his wheat with a neighbor's field near at hand. But now what were the circumstances of the experiment, and how far were they conclusive? Here was a magnificent growth of Italian Wheat; this could not be denied; and the field of his neighbor was clearly much inferior to it; but this did not decide the efficacy of the lime. Was his field manured the previous year; yes, abundantly with barn manure; was the lime applied alone? no, mixed well with wood ashes; was there any part of the field, which was not so dressed? no, it was all served alike; was his neighbor's field manured for the present or the preceding crop? not known; was the same quantity and the same kind of wheat sowed by his neighbor as himself? the same kind, but judged only half the quantity to the acre. We pursued the inquiry no farther. The experiment though deemed so decisive in fact proved nothing; and the important questions whether the superiority of the product to that of his neighbor was owing to the manuring of the previous crop, or to the lime, or to the ashes with which the lime was mixed, or to the greater quantity of seed, were entirely unsettled. We give this example by way of illustrating the subject.

Another matter which has brought much discredit upon what is called experimental agriculture is in the suddenness and rapidity and confidence, with which persons come to their conclusions. They make a trial, with a view perhaps to decide a point, which has puzzled experienced cultivators for years, and a single experiment decides them. The result is immediately and confidently given to the public and a general rule of practice deduced. Under such circumstances intelligent minds often become disgusted; modest minds are deterred from presenting the results of their experiments either from a fear of ridicule or of being brow beaten by the more confident; and the credulous and inexperienced are led to practices, which result in disappointment; and too often bring the whole matter of agricultural experiments into discredit and disgrace. It should not be so.

A CURIOSITY.—We have been shown a cucumber which is really a great curiosity. It is a complete and excellent representation of a Parrot with the exception of the legs and tail. The head is perfect—the back, the eyes, the ears, being minutely preserved. The head too is thrown to one side in the somewhat 'quizzical' manner in which that bird is wont to observe you while speaking to you. The color of the vegetable very nearly resembles the plumage of the bird; and, indeed so nearly does it appear like it that many persons have really taken it for the carcass of the true bird, when seen at a short distance. This vegetable is now hanging up in the bar-room of the Franklin House.—*Columbia Pa. Spy.*

POWER OF ELECTRICITY.—A salad of mustard or water cress may be produced in a few minutes by the assistance of electricity. The process is to immerse the seed for a few days previously, in diluted oxymuriatic acid, then sow it in a very light soil, letting it be covered with a metallic cover, and then bring it in contact with an electrical machine. By the agent employed in this process, eggs, which require from nineteen to twenty days application of animal heat to hatch them—may be hatched in a few hours. Rain water, apparently free from any noxious animalcula, in an hour may be rendered full of living insects!—*Mer. Journal.*

BRIGHTON MARKET.—MONDAY, Sept 3, 1838.
 Reported for the New England Farmer.
 At Market 525 Beef Cattle, 480 Stores, 3,300 Sheep, and 750 Swine.
Prices.—Beef Cattle.—We quote to correspond with last week. First quality \$7 37 1-2 Second quality, \$6 50 a \$7 00. Third quality, \$5 50 a \$6 50
Stores—Yearlings, \$5 50 a \$6 50. Two Year Old, \$16 a \$24. Three Year Old, \$22 a \$30.
Sheep—Lots were sold at \$1 42, \$1 62, \$1 88, \$2 00, \$2 25, \$2 37, and \$2 35.
Swine.—Lots to peddle were sold at 6, 6 1-4 and 6 1-2 for sows, and 7, 7 1-4 and 7 1-2 for barrows. One entire lot to close, at 6 1-4. At retail, 7 1-2 and 8 a 8 1-2.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northernly exposure, week ending September 2.

August, 1838.	7 A.M.	12 M.	6 P.M.	Wind.
Monday,	27	55	78	E.

Wednesday,	29	50	78	E.
Thursday,	30	52	70	N. E.
Friday,	31	56	78	N. W.
Saturday, SEPT. 1	62	76	70	W.
Sunday,	2	58	70	N. E.

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more as may be wanted, of the most approved kinds—consisting of the best selected varieties now in use, for cultivation, feeding worms, and making silk;—being acclimated to this country, and adapted to either warm or cold climates, affording a rare opportunity for companies or individuals to be supplied from the most extensive collection of mulberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and orders will be received of B. Colt, Secretary of the Connecticut Silk Manufacturing Company, Hartford; Alonzo Wakeman, at the office of the American Institute, No. 187 Broadway, N. Y.; Thomas Lloyd, Jr. No. 236 Filbert street, Philadelphia, Pa.; Luther I. Cox, Baltimore, Md.; B. Snider, & Co. Savannah, Ga.; Bliss Jenkins, & Co. Mobile, Al.; James G. Lyman, St. Louis, Mo.; Case and Judd, Columbus, O.; C. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass.

Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Mulberry Plantations.
 Apply at the office of
 Northampton, Aug 22, 1838.

D. STEBBINS.

REMEDY FOR CANKER WORMS.

The subscriber having obtained letters patent for his circular metallic trough and roof for preventing canker worms or other insects from ascending fruit or other trees, now offers his services to apply the same to any extent that may be wanted. They were put on to three orchards belonging to Jonathan Dennis in Portsmouth, R. I., in the autumn of 1837, and exterminated the canker worms so completely that some of the trees hang so full of apples as to render it necessary to prop them, although they have been eaten by the worms for a number of years previous, notwithstanding the application of tar. The public are invited to examine the orchards above referred to. The trough and roof is made of lead and bent to conform to the shape of the tree, and the ends soldered together and made enough larger than the tree to allow the trees to grow ten years before it will fill the space. The space between the trough and the tree is filled with hay, straw, seaweed, or any substance that can easily be compressed by the growth of the tree, the trough is kept in place by three nails driven into the tree below it; when the tree has grown so as to fill the space, the trough may be enlarged by putting in a short piece so as to answer ten years more. A little cheap oil is sufficient to fill the troughs and filling them three times has been found to answer for one year, by stirring the oil once sometime after they are filled. Those who wish to have their trees fitted, would do well to make early application to the subscriber, postage paid. For sale, State, Town and County rights by
 JONATHAN DENNIS, Patentee,
 Portsmouth, R. I., August 22, 1837.

FOR SALE.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

MIDDLESEX AGRICULTURAL SOCIETY.

The Committee on Farms, Fruit, Mulberry, Forest Trees and Shrubs, will meet at the Middlesex Hotel in Concord, on Monday, the third day of September next, at nine o'clock, A. M., and will then proceed to view such farms, &c. as have been entered for premiums.

NAHUM HENDY, Waltham,
 JOHN H. LORING, Groton,
 ELLI RICE, Marlborough,
 WM BUCKMINSTER, Framingham,
 CYRUS WARREN, Concord, } Committee.

All applications must be made to some one of said committee, or to the secretary of the society, on or before the above time.

TIMOTHY PRESCOTT, Secretary.

FRUIT AND ORNAMENTAL TREES, MULBERRIES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces, Goosecherries, Raspberries, Currants, Strawberries, Grapes, Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honeysuckles; Paeonies, Dahlias and other Herbaceous Flowering Plants.

225,000 MORUS MULTICAULIS is now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussa and other varieties.
 Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. D. BRECK, Commission Store, No. 132 Water Street, New York, M. S. POWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston.
 August 1, 1838. WILLIAM KENRICK.

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dame, situated in Rochester, N. H. six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barn and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quantities of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to JOSEPH BRECK & Co., No. 51 and 52 North Market Street, Boston.
 August 15, 1838.

NEW ELEMENTARY WORK ON BOTANY.

Peter Parley's Botany; with descriptions of Trees, Shrubs and Plants; with a large number of fine engravings. The publishers invite Teachers, and others interested in this subject, to examine this work, as they believe it will be found one of the most practically useful in use, being a complete manual of Botany for the adult and the pupil.

Parley's Cyclopaedia of Botany.—This work appears to be exactly what is wanted by young persons and in families. It not only contains the strictly scientific part of the subject, in an introduction and very full and complete genera of Plants, but it also contains a copious glossary of terms, and what is most important, a Dictionary of Plants, of nearly 300 pages, containing familiar descriptions of all the most interesting trees, plants, and shrubs.—These are alphabetically arranged, with an English index, so that the reader may immediately turn to any plant he wishes to read about. The work is illustrated by over 200 engravings, and is sold very cheap.—
 Boston Paper.

For sale at the New England Farmer Office, 51 & 52 North Market Street. JOSEPH BRECK & CO.

WINTER RYE.

Just received at the New England Seed Store and Farmer Office, a few bushels of Prime Winter Rye.
 JOSEPH BRECK & CO.

Aug. 13, 1838.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham. ISAAC PARKER.

WANTED TO HIRE

A single Man, who is capable of taking care of a small Farm. Inquire of JOSEPH BRECK & CO. Sept. 5.

MISCELLANEOUS.

SIR ASTLEY COOPER.

In Pettigrew's Medical Portrait Gallery, part V. lately published in London, are the following amusing anecdotes of the celebrated Surgeon, Sir Astley Cooper:

"He received, perhaps, the largest fee ever given at one time for an operation. It was upon an old gentleman named Hyatt, who was a resident in the West Indies, and, when arrived at the age of seventy, being afflicted with stone in the bladder, determined on going to England, to undergo an operation for its removal. He selected Sir Astley for the occasion. It was performed with his accustomed ability: and upon visiting him one day when able to quit his bed, he observed to his surgeon that he had *fe'd* his physician, but that he had not yet remunerated his surgeon. He desired to know the amount of his debt; and Sir Astley stated "two hundred guineas!" "Pooh, pooh!" exclaimed the old gentleman, "I shan't give you two hundred guineas—there—that is what I shall give you," taking off his night cap and tossing it to Sir Astley. "Thank you, sir," said Sir Astley, "any thing from you is acceptable," and he put the cap into his pocket. Upon examination it was found to contain a check for one thousand guineas!"

"One other anecdote must be related as singularly illustrative of character. Mr Steer consulted Sir Astley at his own residence, and having received his advice, departed without giving the usual fee, Sir A. took no notice of this, but gave his assistance to him cheerfully, under a feeling, that he was a gentleman who had seen better days, and was now in indifferent circumstances. Shortly after, however, Sir A. received a note, acquainting him that in going into the Stock Exchange, he found he had some omnium, which he had not disposed of, and that he had taken the liberty to put £3000 of it in his name; and finding that it had soon after risen he took the further liberty of selling it for him, and now sent the difference, which was £63,10.

Sir Astley's annual amount of fees, far exceeds that of any member of the profession. In one year he received no less a sum than £21,000, and for many years from 15,000 upwards. His patients have comprised all classes of society, and his attention was equally bestowed on the wealthy and the indigent.

INSTINCT OF ANIMALS.

The following is from a new work on Natural History, published in England:

A lady residing in Glasgow, had a handsome cat sent to her from Edinburgh; it was conveyed to her in a close basket, and in a carriage. She was carefully watched for two months, but having produced a pair of young ones at the end of that time, she was left at her own discretion, which she very soon employed in disappearing with both kittens. The lady at Glasgow wrote to her friend in Edinburgh, deploring her loss, and the cat was supposed to have formed some new attachment, with as little reflection as men and women sometimes do. About a fortnight, however, after her disappearance at Glasgow, her well known *meow*, was heard at the street door of her old mistress, and there she was, with both her kittens; they in the best state, but she very thin. It is clear that she could carry only

one kitten a time. The distance from Glasgow to Edinburgh is forty miles, so that if she brought one kitten part of the way, and then went back for the other, and thus conveyed them alternately, she must have travelled one hundred and twenty miles at least. Her prudence must likewise have suggested the necessity of journeying in the night, with many other precautions for the safety of her young.

We extract the following very excellent article from the Peoria (Illinois) Register.

'*Croix vs. Alcohol.*—Col. B. has one of the best farms on the Illinois river. About one hundred acres of it are now covered with waving corn.—When it first came up in the spring, the crows seemed determined on its entire destruction. When one was killed it seemed as though a dozen came to its funeral. And though the sharp crack of the rifle often drove them away, they always returned with its echo.

The colonel at length became weary of throwing grass, and resolved on trying the virtue of stones. He sent to the druggist for a gallon of alcohol, in which he soaked a few quarts of corn and scattered it over his field. The *black-legs* came and partook with their usual relish: and as usual they were pretty well *corned*; and such a cooing and cackling—such a strutting and staggering! The scene was like—but I will make no invidious comparison—yet it was very much like—

When the boys attempted to catch them, they were not a little amused at their staggering gait, and their zigzag course through the air. At length they gained the edge of the woods, and there being joined by a new recruit, which happened to be sober, they united at the top of their voices in haw, law, hawing and shouting either the praises or the curses of alcohol. It was difficult to tell which, as they rattled away without rhyme or reason, so very much like—

But the Colonel saved his corn. As soon as they became sober, they set their faces steadfastly against alcohol. Not another kernel would they touch in his field, lest it should contain the accursed thing, while they went and pulled up the corn of his neighbors. To return like a dog to his vomit—like a washed sow to the mire—like—not they. They have too much respect for their character—black as they are—again to be found drunk."

VELOCITY.—The planet Venus one of the nearest and most brilliant of the celestial bodies, and about the same size as the earth, is found to move through the spaces of the firmament at the rate of seventy-six thousand miles an hour; and the planet Mercury, with a velocity no less than one hundred and fifty thousand miles an hour—a motion two hundred times swifter than a cannon ball. These velocities will appear more astonishing, if we consider the magnitude of the bodies which are thus impelled, and the immense forces which are required to carry them along in their courses.—*Wonders of the Heavens.*

A ROUND BILL.—Tom presented his bill to his neighbor Joe, for services rendered. The latter looked it over and expressed much surprise at the amount. "Why, Tom, it strikes me that you have made out a pretty round bill here, eh?" "I am sensible it is a round one," quoth Tom, "and I have come for the purpose of getting it *squared*."

Taken from the celebrated Dr. Kirtledge's Book.

Liniment, or Salve for the Rheumatism.—Linen seed oil and Neatsfoot oil pint each—Red and White Lead one pound each, Gum Camphor and Gum Myrrh two ounces each, Rosin and Beeswax four ounces each—the Beeswax and Rosin to be put into the oils, and then heated until they are dissolved—the Camphor and Gum Myrrh to be made fine and then put into the oils—then add the white and red Lead.

A Salve for Sores and Wounds.—2 oz. Turpentine, 4 oz. Beeswax, 1-2 do. Baberry Tallow, 1 drachm spirits Turpentine.

4 oz. Turpentine, 1-2 do. Olive Oil, 1 drachm spirits Turpentine, a small piece Baberry Tallow a small piece Mutton Tallow, 1-2 oz. Verdigris powdered fine—for healing and cleansing ulcerated sores and removing proud flesh.

Bone Ointment.—Green Tobacco, Millelet, Nightshade, Hemp Mallows, Yellow dock roots, Yellow Lilly roots, Garlics, Henbane, Green Elder, Heartsease, Johnswort, Camomile, Comfrey roots, Plain-tain, all to be green—simmer the herbs in equal quantities in hogs lard twenty-four hours often stirring the herbs, then add one third part fresh butter, then simmer it twelve hours after the butter is added,—then strain the ointment fit for use—this ointment ought to be made in June or July—the herbs and roots must be pounded before they are put into the lard to simmer.

Nerve Ointment.—One pint Neatsfoot oil, 1-2 pint good Rum or Brandy, 1 gill oil of Turpentine, 1-2 oz. Rattle Snakes oil, 1 gill Beef gaul, simmer the whole together 8 or 10 minutes when it will be for use.

A Syrup for Coughs and Colds.—Two quarts of Burdock root, 4 oz. Elccampare root, 1-2 lb. Spikenard, 2 table spoons full white pine Turpentine, 6 oz. honey, 1 pint of water, spirits 4th proof 1 pint, put all in an earthen pot, cover it with dough, then put it in an oven during the night, then strain it, squeeze the root well in the strainer, then this will be fit for use.

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land, situated on Nonantum Hill, in Newton, 5 1-2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

LOT WHEELRIGHT.

July 16th.

ALDERNEY STOCK FOR SALE.

For sale, a full blooded Bull, 3 years old the first of July next—the Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27

FARM FOR SALE.

An excellent farm, near the centre of Framingham is offered for sale, on liberal terms. Inquire at this office. Aug. 22, 1833. 3m

AGRICULTURAL.

From the Maine Farmer.

ESSAYS ON THE GRAIN WORM.

NO. III.

WINTHROP, JAN. 1, 1837.

Messrs Trustees of the Kennebec Co. Agricultural Society:—GENTLEMEN: The recent appearance of the Grain Worm, among us, and the short time allotted for persons to hand in the observations which they may have made for the consideration of the Trustees, do not permit the exhibition of so many well established facts upon the subject as it is desirable should be upon one of such great importance to the community.

The GRAIN WORM is the product of a slim or slender and delicately formed fly. This fly lodges its egg in the husk, or rather between the valves of the wheat when in blossom. This egg hatches into a small yellowish worm or maggot. This worm attaches itself to the growing kernel, and sucks from it all the milk or pulp, and prevents its growth. A shrivelled and worthless grain is the consequence.

After it has arrived to maturity, it forms a crystal in the place where it has lived, from which it is dislodged, either by the ordinary process of thrashing, or by the ripening and shelling out of the grain. It is not certain that it invariably remains in the husks of the wheat to form the crystal. On the ninth of August last, there was a warm rain, and it was observed that immense numbers of these worms were crawling out of the wheat, and apparently seeking shelter somewhere else. But it has not been certainly ascertained whether they actually went down into the ground to put themselves into the preparatory condition for a change into the fly.

Yet it is certain that immense quantities of them were in the wheat during the last harvest, and covered the thrashing floors, being blown out with the chaff.

It has not yet been ascertained what length of time the insect remains in the crystal state. There is little doubt, however, that it continues in the dormant state during the winter, and even through the spring, until near the time when the wheat is in blossom. It is at this time that the fly is first seen. It is soon after this that the worm is seen, and the crystal has been observed in the chaff late in the fall, and it is contrary to all the laws of nature as applying to most insects which undergo these three transformations, to come into the fly state during or at the beginning of our winters.

The insect in question, has received the name of weevil. This is incorrect, and leads many to wrong opinions in regard to its nature. The weevil is an insect which infests some countries, and is exceedingly mischievous among grain after it is put into the bin, by eating into the dry grain, and devouring the farinaceous parts. But the Grain Worm does all its mischief while the grain is in

the milk state, and as its get through this stage, or grub state, by the time the grain is ripe, and becomes dormant previous to changing to the perfect state, it can do no damage to the grain after it becomes hard.

That there is a particular time when the fly does and must deposit the egg that produces the worm, is certain. This is corroborated by observation, and the fact that late sown grain was not injured by them, while the early sown was. After the warm rain above mentioned, on the 9th of August, when so many of them left the heads, no new heads were injured, or no new depredations were committed by them.

Many have supposed this insect to be identical with the small worm that is found in the heads of clover, and is seen spinning down from lofts or mows where clover has been stowed away. The cold seasons having retarded the blossoming of the clover, the worms have taken the wheat as a substitute. However, this may be, we are certain that the grain worm, or clover worm, if clover worm it be, is not alone in its multiplication.

The cut worm has become more numerous of late, as also the white headed worm and grasshoppers. The cause of this must be sought for in the state of the weather or seasons. Ever since the winter of 1830 and '31, the ground has been long covered with snow. Even our January thaws have not much reduced the covering of snow upon the ground, so that the ground has remained in one state, or has not often thawed and frozen during the winter, and the worms or grubs not disturbed. When there shall come a winter in which the ground shall be often thawed and frozen, so that the germ, or whatever produces the fly, shall be disturbed, it will very probably diminish their numbers very much. Warm weather, it is well known, is most congenial to insects; yet they do not increase in exact ratio to the warmth of climate.—Why not? Because the winters being more open or freezing and thawing, more frequently kills them.

The present increase of the grain worm must be a multiplication of them, for I hold that there has been no new creation since the first six days, and if so the causes above mentioned must have brought it about. Having multiplied they must spread in a corresponding ratio to previous numbers in such situations as are congenial to them.

We first heard of them several years ago in Vermont State, and they have travelled North and East, ever since. Thus it seems, their first increase was where the ground was covered early in the fall and late in the spring, and exactly where, according to my theory, they ought to have begun. As far as I can learn, they are not much known on the sea board, where the snow does not lay on long or but a short time in the winter.

In regard to remedying the evils of this insect, it must be pretty much or wholly, on the preventive plan. I think that lime or ashes, put upon the soil in sufficient quantities to make it disagreeable

to the worm, must be a good mode of preventing its increase.

From the fact that late sown grain has wholly escaped, it must be evident, that sowing late so as to bring the time of blossoming beyond the time of the fly's hatching, will prevent the mischief.

Sowing also, on high or elevated, and airy situations, where the breezes will agitate the grain, will also prevent their operations in a great degree.

Respectfully Yours, ELIJAH WOOD.

GREEN CORN PUDDING.—This is one of the few "delicacies of the season," which are peculiar to our townsfolk. It has been a favorite dish, from time immemorial—a knowledge of its composition and manufacture having been originally derived from the tawny natives among whom our ancestors squatted down two hundred years ago. Visitors to this place during the corn season, are often regaled, of course, with this sort of fare—the memory of the flavor of which abideth with them long after their departure hence. For this reason, much anxious researches among city housewives, for a correct prescription in the premises, has been known to have occurred. "My dear lady Adams, can you inform me how those Nantucket barbarians contrive to concoct their corn-puddings?"—"Pray, Mrs Clay, or Miss Van Buren, tell me the *modus operandi* of the corn-pudding miracle! I am longing for another taste of that most savory compound, so deliciously fabricated by those unsophisticated females out there in that Island of Wotchukollit." And there is no end also to the epistles on this subject which are annually poured in upon us during dog-days, evidently from the very fairest of correspondents—all imposing upon us the sweetly grateful obligation of sending them, respectively, a code of directions.

That we might be enabled to fulfil our whole duty towards every applicant at the same moment, we have procured from a sympathising friend the annexed recipe, which may be relied on as the real Simon-pure—the primitive, orthodox, corn-pudding cannon.—*q. c. d.*

Rules for making, cooking, and eating Corn Pudding.—Gather ye come in ye milke, when neither too young nor too ripe. Shell, cut, or scrape ye corn from ye cob, and pound it fine in a big mortar, with a heavy pessle. To ye come of foure dozen ears, add one pint of milke, and half a pounce of sugar—the whole to be mixt together, and baked about two houres, till ye crust shall shewe a darke browne complexyon. It is to be eaten with fresh butter laide thereon—to which some adde a sprinklyng of pepper. The addition of eggs doth not helpe ye puddynge. Boyled come puddyns are softer, but not so goode.—*Nantucket Inquirer.*

The different species of trefoil always contract their leaves at the approach of a storm; hence these plants have been termed the Husbandman's Barometer.

From the Library of Useful Knowledge, Farmers Series.

FLEMISH HUSBANDRY.

The poor sandy heaths, which have been converted into productive farms, evince the indefatigable industry and perseverance of the Flemings.— They seem to want nothing but a space to work upon; whatever be the quality or texture of the soil, in time they will make it produce something. The sand in the Campine can be compared to nothing but the sands on the sea shore, which they probably were originally. It is highly interesting to follow, step by step, the progress of improvement. Here you see a cottage and rude cow-shed erected on a spot of the most unpromising aspect. The loose white sand blown into irregular mounds is only kept together by the roots of the heath: a small spot only is levelled and surrounded by a ditch; part of this is covered with young broom, part is planted with potatoes, and perhaps a small patch of diminutive clover may show itself; but there is a heap of dung and compost forming. The urine of the cow is collected in a small tank, or perhaps in a cask sunk in the earth; and this is the nucleus from which, in a few years, a little farm will spread around.

In another spot more extensive improvements are going on; a wealthy proprietor or lessee is trenching and levelling the surface, sowing broom-seed, and planting young fir trees, which are to be cut down in a few years. In another, the process has gone on further, the firs or the broom are already cut down: a vein of loam has been found, and is dug out to be spread over the sandy surface: the earth with liquid manure is preparing the surface for the reception of seed, or the same, diluted with water, is poured over the young blade just appearing above ground. The soil is created, and, if the cost and labor were reckoned, is paid for at a dear rate; but perseverance insures success, and there are few instances of improvements being abandoned, after they are fairly begun, unless they were undertaken on too large a scale; but then the land is soon divided into smaller portions, and improvements go on from different centres, and with more certainty.

We are here describing the labor of bringing a soil absolutely barren into a state of cultivation; but in most of the districts which have been originally waste and covered with heath, and which are now fertilized, a less ungrateful soil was found. Deep trenching and levelling at once presented a surface which required only to be manured to produce rye, flax, and potatoes. This is what we should call a moderately good sand, in which a small portion of clay and oxide of iron produces a certain degree of compactness, so as at least to retain moisture: under this kind of sand a stratum of loam is usually found at the depth of two or three feet, and almost invariably between the sand and the loam, an indurated crust of earth cemented by carbonate of iron, which is well known to all improvers of poor sands by the name of the *iron pan*; this pan must be broken up and the loam under it mixed with the sandy surface, before any cultivation can succeed; and in this operation the Flemings are very dexterous. The instrument they use is a light wooden trenching spade, the end of the blade only being shod with iron: the handle of this spade is about two feet long, the blade from twelve to fifteen inches. A light pick-axe is used to break the pan where it appears. A ditch is dug with the trenching spade, two or three feet wide, and as

deep as the trenching is intended, generally two feet, or at least twenty inches; this ditch is filled with the earth which is taken in long thin slices from the edge of the solid side of the ditch. Every slice is distributed carefully, so as to mix the whole, and keep the best soil at top, and likewise to fill up hollows and level eminences. If there is more than can conveniently be spread level, little heaps are made of the superfluous earth, which are afterwards carried, in an ingenious manner, to fill up more distant hollows, by means of horses and an instrument which is called a *mollebart*. Wherever there is a pan it is carefully broken, and the loam, which is always found under it, is mixed with the sand dug out. Draining is seldom required here, except that which is effected by making deep ditches to carry off the superfluous rain water, which, in a country almost as level as a lake, is no great difficulty. A canal near at hand is, however, an essential condition of extensive improvement, to bring manure, and carry off the produce of the land, as well as to be an outlet for the water in the ditches. When Count Chaptal traversed a barren part of Flanders, accompanying the Emperor Napoleon, the latter expressed his surprise, at a meeting of the Council of the Department, that so great a tract of land remained uncultivated in so industrious a nation. The answer was, "If your majesty will order a canal to be made through this district, we pledge ourselves that in five years it will be all converted into fertile fields. The canal was ordered to be made without delay, and in less time than they promised not an unproductive spot remained.—(See Chaptal, 'Chimie Appliquee à l'Agriculture,' vol. i. p. 347.)—One great cause of the agricultural prosperity of Flanders is the ready transportation of manure and produce by canals. But to return to the newly trenched land. If there is no manure at hand, the only thing that can be sown on poor sand, at first, is broom; this grows in the most barren soils; in three years it is fit to cut, and produces some return in favots for the bakers and brick-makers. The leaves which have fallen have somewhat enriched the soil, and the fibres of the roots have given a certain degree of compactness. It may now be ploughed and sown with buckwheat, or even with rye without manure. By the time this is reaped some manure may have been collected, and a regular course of cropping may begin.—As soon as clover and potatoes enable the farmer to keep cows and make manure, the improvement goes on rapidly; in a few years the soil undergoes a complete change: it becomes mellow and retentive of moisture, and enriched by the vegetable matter afforded by the decomposition of the roots of clover and other plants. It is surprising that so few sheep should be kept on these new farms.— Sheep folden would do good by their tread, as well as their manure, but the management and feeding of sheep is a part of husbandry in which the Flemings, with very few exceptions, are decidedly as much behind our light land farmers, as they are before us in the feeding of their cows, and preparation and economy of manure.

If about twenty small cart-loads of dung can be brought on each acre of the newly trenched ground, the progress is much more rapid. Potatoes are then the first crop, and generally give a good return.— The same quantity of dung is required for the next crop, which is rye, in which clover is sown in the succeeding spring; and a small portion is sown with carrots, of which they have a white sort, which is very productive and large in good ground, and

which, even in this poor soil, gives a tolerable supply of food to the cows in winter. Should the clover fail, which sometimes happens, the ground is ploughed in spring and sown with oats and clover again. But if the clover comes up well amongst the rye stubble, it is cut twice, after having been dressed with Dutch ashes early in spring. It is mostly consumed in the green state. The clover-ley is manured with ten cartloads of dung to the acre, and rye sown again, but not clover. After the rye comes buckwheat without any manure; then potatoes again, manured as at first, and the same rotation of crops follows. It is found that the poor land gradually improves at each rotation from the quantity of dung used; and, as this is essential, it will be easily seen that without water carriage the improvement could not go on; for the necessary quantity of dung could never be brought to the ground by land carriage through the deep sandy roads, which are mere tracks.

For want of sufficient manure, broom-seed is sometimes sown with the rye after the clover. The rye is heaped and the broom continues in the ground two years longer. It is then cut for fuel. The green tops are sometimes used for litter for the cows, and thus converted into manure. It is also occasionally ploughed in, when young and green, to enrich the land. Oats, clover, and broom are occasionally sown together. The oats are reaped the first year; the clover and young broom tops the next, and the broom cut in the third. This is a curious practice, and its advantage appears rather problematical. All these various methods of bringing poor sands into cultivation show that no device is omitted, which ingenuity can suggest, to supply the want of manure.

After the land has been gradually brought into a good state, and is cultivated in a regular manner, there appears much less difference between the soils which have been originally good, and those which have been made so by labor and industry. At least the crops in both appear more nearly alike at harvest, than is the case in soils of different qualities in other countries. This is a great proof of the excellency of the Flemish system; for it shows that the land is in a constant state of improvement, and that the deficiency of the soil is compensated by greater attention to tillage and manuring; especially the latter. The maxim of the Flemish farmer is, that "without manure there is no corn—without cattle there is no manure—and without green crops and roots cattle cannot be kept." Every farmer calculates how much manure he requires for his land every year. If it can be bought at a reasonable rate, he never grudges the outlay. If it cannot be purchased, it must be made on the farm. A portion of land must be devoted to feed stock, which will make sufficient manure for the remainder: for he thinks it better to keep half the farm only in productive crops well manured, than double the amount of acres sown on badly prepared land. Hence also he does not reckon what the value would be of the food given to the cattle, if sold in the market, but how much labor it costs him to raise it, and what will be the increase of his crops from the manure collected. The land is never allowed to be idle, so long as the season will permit any thing to grow. If it is not stirred by the plough and harrows to clear it of weeds, some useful crop or other is growing in it. Hence the practice of sowing different seeds amongst growing crops, such as clover or carrots among corn or flax; and those which grow rapidly between the reaping of

one crop and the sowing of another, such as spurrey or turnips, immediately after the rye is cut, to be taken off before wheat sowing. These crops seem sometimes scarcely worth the labor of ploughing and sowing; but the ploughing is useful to the next crop, so that the seed and sowing are the only expense; and while a useful crop is growing, weeds are kept down. These are the general principles of Flemish husbandry.

The collection and application of manure is the great secret of Flemish husbandry. Upon their poor light soils nothing could be raised without an abundance of manure. It is consequently, an object of minute attention to the Flemish farmer to collect as much as possible, and to apply it in the most advantageous manner. For this purpose the dung of the different domestic animals is generally kept separate, especially that of cows, from that of horses; the former being thought better for dry sandy soils, the latter for colder loams and clays. They look upon pigs' dung as being cold and inferior, adopting in this respect the opinion of the ancients. We think differently; but this may be easily accounted for. The Flemish store pigs are fed in the most miserable manner, and are merely kept alive on weeds taken from the fields, or by very scanty grazing in rough pastures. We need not be surprised, therefore, that their dung is poor. The cows are better fed, and their dung is consequently richer. Cow dung is thought to last longer in the soil, and its effects on the second crop are more conspicuous than that of horse dung, which stimulates more and is sooner effete. Sheep, which are so important to the light-land farmer in England and Scotland, for their manure, are not kept in sufficient quantities in Flanders, nor well enough fed to do much good to the land. They are commonly housed every night, and driven about in the day to gain a scanty subsistence along the roads and sides of fields. The manure collected in the sheep-fold is carried out on the land, and its effects are duly appreciated. A flock is occasionally folded on a clover ley before it is ploughed up, but never on turnips, which are always given to the cows. This is owing to the small extent of the farms, which do not allow of a considerable flock of sheep being kept by any one farmer; but a flock is made up of different lots of sheep belonging to several proprietors, and put under the care of a common shepherd, or it is sometimes the property of the shepherd, who occupies no land, but lets out the sheep to fold, or sell the manure.

But the great auxiliary of the Flemish farmer is the URINE TANK, wherein are collected not only the urine of cows and horses, but also the drainings of the dung-hills. The urine tanks are generally sunk below the level of the ground, and have the sides built of brick, and the bottom paved: they are of various dimensions, according to the number of cows and horses on the farm. Attached to the distilleries, where many beasts are constantly kept to consume the refuse wash, there are very large urine tanks of an oblong shape, divided by partitions into different chambers, so that the liquor may be of the proper age when it is used, which some farmers think ought to be six months. Each chamber is about eight feet square and six or eight feet deep; these are sometimes vaulted over, but frequently only covered with loose boards. As urine and the emptyings of privies are sold wholesale and retail, there are many large tanks near the rivers and canals, where the dealers have sometimes great quantities in store. Some of these

consist of many square pits like tan pits, bricked round, and the inside covered with a cement, which prevents loss by filtration. There is generally in a corner of each pit a graduated scale, by which the number of barrels, or tons of liquid in the tank may be ascertained by observing the height of the surface. These tanks are gradually filled by boatloads brought from the large towns; and when the season arrives for sowing, in spring and autumn, the farmers come with their carts and tubs, and purchase as much as they want. The price varies from three to five francs (two shillings and sixpence to four shillings) per hogshhead according to the quality. In a small farm of thirty to forty acres the tank is generally about twenty feet long, twelve wide, and six deep, with a partition in the middle, and arched over, leaving an opening for the pump, and another sufficient to allow a man to go in to empty out the earthy deposit which falls to the bottom. A trapdoor shuts over this aperture to prevent accidents. Sometimes the tank is round, like a well, with a domed top, and so deep in the ground, that it has a foot or two of earth over it. The situation of the tank is either in the farmyard near the entrance of the cowhouse, or immediately behind it; sometimes it is like a cellar under the building; but this is apt to cause a disagreeable smell in the cowhouse. We here describe those which we consider the most convenient: the form and capacity of the tanks vary according to the means and notions of the proprietors of the farms: but a tank of some kind or other is considered as indispensable an appendage to a farm as a barn or cowhouse. The farmer would as soon think of dispensing with his plough as with his tank: and no expense or trouble is spared to keep this well supplied. The numerous towns and villages in Flanders afford great help in the way of manure. The thrifty housewife and her active substitute the maid, know the value of what in our households is thrown away or wasted and lost. A small tank, or a tub sunk in the ground in some corner contains all the liquid which can in any way be useful; soap-suds, washings of ditches, &c., are carefully kept in this reservoir, until once a week, the farmer or contractor calls with his tub on a cart, and this, mixed with the contents of privies, which are frequently emptied, he keeps in large cisterns for use or sale.

But this supply is not always adequate to the wants of the farmer, and then he has recourse to rape cakes dissolved in water, or in the tank, which is expensive, and can only be profitable where flax bears a good price, this being the crop for which rape cakes are chiefly used as manure. Every means, therefore, of augmenting the supply of urine is had recourse to, and the most efficacious is the establishment of distilleries. These answer the double purpose of consuming produce and increasing manure by the number of beasts which are fattened on the refuse wash. It is calculated that every beast produces at the rate of ten or twelve tons of dung and twenty-six hogshheads of urine in the year. A moderate distillery has fifty or sixty head of cattle constantly stalled. Here then is a supply of manure for several hundred acres of land every year. Formerly there were a great many distilleries in Flanders, but the duty on spirits and the interference of the government has much reduced their number; so that the farmers complain of the loss of this manure, and the consequent deficiency of their crops.

The dung of pigeons and domestic fowls, where

it can be collected in any quantity, is highly valued. The mode of using it is either in a dry and powdered state, to which it is reduced by thrashing with a flail, when it is sown with the seeds of leguminous plants, or else dissolved in the urine tank, and thus spread over the land. This manure is chiefly reserved for kitchen gardens; it promotes the growth of vegetables and produces no weeds.

The solid dung, from which the liquid has been allowed to run off into the tank, must be carefully attended to, that it may not be too dry and become *fony*, as it is called, or burn. It is therefore, mixed up with earth and any useless vegetable matter which can be collected into a heap or compost; and when it appears too dry some of the liquid from the tank is poured over it, to excite fermentation and accelerate decomposition, or it is merely watered, when there is sufficient strength in it to produce heat.

In order to increase as much as possible the quantity of solid manure, there is in most farms a place for the general reception of every kind of vegetable matter which can be collected; this is a shallow excavation, of a square or oblong form, of which the bottom has a gentle slope towards one end. It is generally lined on three sides with a wall of brick to keep the earth from falling in, and this wall sometimes rises a foot or more above the level of the ground. In this pit are collected parings of grass sods from the sides of roads and ditches, weeds taken out of the fields or canals, and every kind of refuse from the gardens: all this is occasionally moistened with the washings of the stables, or any other rich liquid; a small portion of dung and urine are added, if necessary, and when it has been accumulating for some time, it is taken out; a portion of lime is added, and the whole is well mixed together; thus it forms the beginning of a heap, which rises gradually, and in due time gives a very good supply of rich vegetable mould, or compost well adapted to every purpose to which manure is applied. The place where this accumulation is made is called in French a *croupissoir*, and in Flemish or Dutch *smoor hoop*, which may be translated *smothering heap*.

Besides the manure which is collected on the farm, the *vidanges*, or emptyings of privies obtained from the towns, and the sweepings of streets, a large quantity of peat ashes imported from Holland are used, principally as a dressing for clover. These are the ashes of the common fuel in use in Holland, and are sold in Flanders by the bushel, as the Newbury ashes are in Berkshire.

Wood ashes, after the greater part of the alkali has been extracted for bleaching, are still considered as of great use to the land. Soapers' ashes are in great request for cold heavy soils; and sugar scum from the refiners, if it could be procured in sufficient quantity, would be an excellent manure for every kind of soil. Where it can be obtained, they usually throw it into the urine tank; and the mixture is then considered as almost equal to the *vidanges*, which are looked upon as the *ne plus ultra* of manures. Soot is used as a top-dressing for wheat, or clover in spring, as it is with us. It is thought to destroy insects and hasten vegetation.

The weeds, which grow abundantly in all ponds, canals, and ditches in this level country, where the current is never rapid, are mown in spring, and used in the green state as manure for potatoes. They are laid in the furrows, and the sets placed over them; the furrow is then filled up by the plough and the weeds decomposing very rapidly, great

assist the growth of the potato plants; so rapidly do these weeds ferment, that much of their value is dissipated, if they are left only forty-eight hours in heaps before they are put into the earth.

The manner in which manure is applied to the land for different crops will be explained as these are separately treated of: but the general principle, which pervades the whole system of manuring, is worthy of attention. Two great objects are always kept in view. The first is to obtain the most abundant crop of whatever is sown; the next is to impregnate the soil with an increasing power of production, if possible, or at least to maintain that which has been obtained. In consequence of this, almost every crop has a certain portion of manure applied to it, which varies according to the nature of the crop to be raised, and that which has preceded; experience having taught that some crops exhaust the soils more than others.

But it is not the mere surface that they desire to manure. They well know that the deeper the soil is fertilized, the greater will be the profit and the less the labor. They are not satisfied with enriching the land to receive the seed, they furnish food for the growing plant in different stages of its growth, if they think it necessary. There is in consequence no fluctuation in the growth, no check at a time when the plants require support. The seed is made to vegetate rapidly by being in contact with the rich juices of the manure; and hence a much smaller proportion of seed is required. The young blade is invigorated by judicious watering, and is soon out of danger of the attacks of insects.

Liquid manure is carried to the fields in common wicker-carts, which consist of two wheels and shafts, carrying a cask containing from sixty to one hundred and twenty gallons of liquid. The cask has in the under part a hole, two or three inches in diameter, secured inside by a valve: under this is a board a little slanting, to spread the liquid as it flows out of the cask. A man usually rides on the horse which draws the cart, and holds in his hand a string, which passes through a hole in the cask, and opens the valve when required. There is an advantage in riding on the horse, as it does not add to the weight of the load on the wheels, which in light soils would be apt to sink deep. In a momentary exertion it assists the horse by the weight on his back; and the heavy Flanders horses are well able to carry a man and draw a light load at the same time. When the cask is empty trots home for another load, and no time is lost. It is astonishing what advantage there is in accustoming horses to trot when they have no load; it actually fatigues them less than the continued sleepy walk. Who would suppose that the Flemish and Dutch farmers surpassed us in activity? but whoever has been in the Netherlands in hay-time or harvest must acknowledge it.

The dung which is carried in a solid state, is generally used at a time when it is in a state of active fermentation, as it is then supposed to have the best effect. To ensure this in some districts, as the Wales country, where the minutest attention is paid to every circumstance which can increase fertility, the dung is laid on the field in moderate heaps, and on each heap a certain quantity of urine is poured to excite and renew the fermentation: when it becomes sensibly heated, the dung is spread out and immediately ploughed in. After ploughing in the manure the land is left for some time, and

then a second deep ploughing is given to incorporate the decomposed dung with the soil, but so as not to bring any to the surface. A short time before sowing, the liquid manure is poured over; and this enriches the surface to make the seed germinate sooner.

Lime is not much used in the light soils, but commonly in the cold and stiff. As it is generally brought from a distance, it is dear; and this prevents any extensive application of it. Marl is found in a few spots, and serves to improve the poorer lands within reach of it.

From the Genesee Farmer.

TOADS.

There are few animals so universally disagreeable, or which are so generally considered an incarnation of every thing vile, as the toad, *bufo vulgaris* of the naturalist. Milton understood the amount of the prejudice against the toad, when he placed the arch fiend in the disguise of this reptile close to the ear of sleeping Eve, in Paradise; for we may be sure Lucifer would not have been guilty of the indiscretion of approaching her in that form when she was waking. But though the toad seems to have been marked out for the hate and aversion of mankind, there are few reptiles whose habits are more worthy of notice, none that are more harmless, and few that render more actual service to man. It is true, neither the frog or the toad, particularly the latter, would be an agreeable inmate of the "kneeding trough," or a pleasant companion in the "bed chamber," but in the field or in the garden, they devour multitudes of insects that prey on the labors of man, while they meddle with none of the plants or fruits that require his protection or cultivation.

With the approach of cold the toad retires into the earth, and in a torpid state awaits the return of the spring. If surprised in this state by any change in the face of the earth, that could have the effect of placing him beyond the influence of the seasons, the toad, it is supposed, can remain uninjured in this state for an indefinite length of time; and in this way the discovery of frogs and toads, in deep excavations, and even in solid blocks of stone, has been attempted to be accounted for. The celebrated geologist Buckland, however, seems to doubt whether the evidence in proof of such discoveries, is such as to warrant implicit confidence in the details. We should imagine that if correctly represented, the discovery of the one at Lockport, while excavating the limestone of the mountain ridge, was as little liable to deception or doubt, as such matters usually can be; and we know of no philosophical reason, why, if a toad can lie torpid for one year, as has been proved by burying them in pots, they might not as well exist one hundred or a thousand, if the proper temperature for ensuring torpidity was preserved.

Some writers have denied that the toad, under any circumstances, was poisonous; but this is a mistake. When in danger, or when irritated, the tubercular elevations on the backs and sides, have the power of secreting a milky fluid, as every one may readily ascertain, and every school-boy who is in the habit of pelting them with stones well knows. This fluid, given for defence, as we suppose, is decidedly poisonous, as its effects on cats, and other animals, fully prove. This is the only power of injuring it possesses: and this secretory and offensive power appears to reside in the skin,

as the animal is frequently skinned and sold with the frog in the markets of European cities, for food, and eaten with impunity.

Toads after the time of breeding is over, forsake the pools of water where they assemble in the spring, and in or near which, they usually pass the winter, and scatter themselves over the land; and when once they have chosen a favorable position, if not disturbed, they rarely quit it for the season and some have been known to retain possession for several years. From these retreats they emerge towards nightfall, or in the evening, and feast on snails, flies, bugs, or any living insect that falls in their way. In a garden their services are thus invaluable; and some gardeners introduce and protect them through the summer, for the aid they render in the destruction of worms, &c.

Notwithstanding his clumsy and ungainly appearance, there are few animals so quick of motion as the toad, and this is shown most distinctly in taking his insect food. It will not unfrequently, in a warm summer evening, when doors are open, make its entrance into the house, where it feeds on flies that approach. Seated on its haunches, it surveys the floor with great gravity, but if an unwary fly alights within four or five inches, it disappears with incredible quickness. There can be a slight motion of the toad discovered, a quick snap as of the jaws is heard, but the position of the animal is unchanged, while his prey vanishes with the velocity of light. A close examination shows, however, that there is a slight motion of the body forward, without moving the feet; and the snap is produced by the shutting of the mouth after the tongue has seized and secured the insect, though so quick is the operation performed, that the tongue is never distinctly seen. We have often seen this feat performed by placing a fly or a bug, on the end of a grass stalk, and pushing it gradually towards the toad, when he first makes his appearance at dusk. The lightning's flash is hardly more quick or fatal, than the snap of this reptile to the insect he aims at.

To enable the toad, frog, chameleon, and some other reptiles to seize their prey, the tongue has a curious conformation; "it is of great length, its root is attached close to the *fore part* of the lower jaw, while its point, which is cloven, is turned backwards, extending into the throat, and acting like a valve in closing the air passage into the lungs. If, when this animal has approached within a certain distance of the insect it is about to seize, we watch it with attention, we are surprised to observe the insect suddenly disappear, without our being able to determine what has become of it. This arises from the frog (or toad) having darted out its tongue upon its victim with such extreme quickness, and withdrawing it with the insect adhering to it, so rapidly that it is scarcely possible for the eye to follow its motion."—(Roget's Physiology.)

A fact which was related to us a few days since by a gentleman, will furnish a curious illustration of the habits of this animal. He was mowing in a field, when he disturbed a nest of the common humblebee. As they were quite numerous, and appeared very pugnacious withal, he concluded to let them alone until they became more quiet, when he determined to visit the nest again, and appropriate their stores to himself. In the course of a few hours he repaired to the spot, when to his surprise he saw a large toad had planted himself directly before the place of egress for the bees; and

he seemed so satisfied with his position that the gentleman determined to ascertain if possible, his business in that place. He soon saw that every bee that showed himself disappeared in some mysterious manner, and that a slight snap, invariably connected with their disappearance, convinced him it was in some way owing to the toad, and that in this way the animal was doing him a good service. It was but a short time before every working bee was despatched, not one escaping; and then, by slightly disturbing the nest, the queen bee or drones that generally are found to the number of three or four among humblebees, were induced to venture out, and instantly share the fate of their companions. The honey fell to the share of my informant; the toad appearing perfectly satisfied with his allotment of the "spoils."

TREATMENT OF WOUNDS ON HORSES.

MR. TUCKER—In the fifth number of the current volume of the *Monthly Farmer*, I noticed some remarks upon the "Treatment of wounds on Horses," and although the treatment there recommended, would, undoubtedly, under certain circumstances, prove highly beneficial, yet, as that article seems to direct it as generally applicable in every case, and in every condition of wounds, while in many, and indeed in most cases, it could not fail to prove injurious, I beg leave to offer for your consideration, a few observations upon the same subject.

It is truly painful to see an animal possessing such claims to our kindness and care, as the horse, so often subjected to empirical and cruel treatment, when laboring under disease. This arises from the prescription not being directed by any rational physiological and pathological principles; every one feeling at liberty to prescribe whatever remedy may have heard of, or can invent, and the more old and novel, the greater the merit of suggesting. Attention to a few well established principles, could prevent the fatal errors into which many are invariably led, and preserve many a noble and valuable animal from ruin.

Experience has abundantly proved that those general principles of physiology and pathology, which are applicable to the human subject in health and in disease, are also applicable to those animals that are taken from the hand of nature, and submitted to our care and nurture, and that similar diseases require in both, similar treatment. The principles, therefore, that would guide a skillful surgeon in the treatment of a surgical disease in an animal, should also direct the veterinary surgeon or farmer, in similar diseases in a horse, or other animal. In relation to this subject, the surgeon may well adopt, as his motto, lines that are perfectly adapted to every other, of which your paper proposes to treat.

"Take Nature's path and mad opinions leave."

The two processes by which nature accomplishes the healing of wounds, are, 1st, union by the first intention, as it is technically called, or in other words, the union of the divided parts immediately, without the formation of matter; and 2d, by granulation, in which the immediate union of the parts is not effected; but by accident or improper interference, are kept asunder, and the chasm has to be closed up, by the formation of new flesh. By the first process the cure is soon accomplished, without the trouble, with little or no pain, and little risk leaving an unsightly scar. By the second, the

cure is often protracted, interrupted in its progress, and more liable to leave a permanent disfigurement.

The principles by which the one or the other of these results is produced, are these; 1st, if the sides of a recent wound, made by a cutting instrument, be simply brought into perfect contact, and retained there from three to five days, a perfect union will take place, without the formation of matter. 2d, if the divided parts cannot be brought into perfect contact, or before contact have been irritated by improper applications, immediate union will not take place, but matter must be formed, new flesh must be interposed to connect the parts, and subsequently be removed by the slow process of absorption, to accomplish the same ultimate object. The first process is nature's own spontaneous effort to effect a cure, and the course which she would always pursue under favorable circumstances, if left to herself, or gently and judiciously aided by art. The second, is that to which she resorts from necessity, and when interrupted in her salutary process, by the rude and ill-timed interference of art—the first result therefore, should always be aimed at, as not only the most favorable, but also as attended by the least risk and trouble. To attain which, the principles just referred to, dictate the following course.

As nearly as may be, free the wound from all foreign substances, as dirt, gravel, hair, &c. &c., in the most gentle manner, by means of a soft sponge and simple warm water, then bring the sides of the wound into perfect contact, if possible, and retain them there by means of adhesive plaster, or stitches, or both, according to circumstances, and over the whole, apply a pledget of soft lint, which should remain until the cure is effected. Nothing more is required, unless inflammation should run too high, when keeping the parts constantly wet in cold water is the best application. Indeed, the numerous cleansing and healing nostrums so frequently resorted to, never fail of being hurtful by disturbing the salutary operations of nature.

With this mild and simple treatment, nature always produces that degree of inflammation which is necessary to effect a cure, in the best possible manner; but by the officious application of plasters, blue stone, detergent oils, &c. &c., her salutary operations are disturbed, too much inflammation is excited, and she is compelled to resort to the slower, more laborious, and imperfect process, of healing by granulation.—*Genesee Farmer*.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Sept. 8, 1838.

Pears.—From Mr Ives of Salem, Franceval D'Este, a very superior and productive fruit. Roi de Wertheimberg (formerly mis-called Capiaumont) and old Catharine.

From Mr Vose, President of the Society, Julienne, Cushing and Dearborn's seedling.

From Mr S. Phipps of Roxbury, a Pear without name.

From Mr Manning, Chair a dame, Vallee Franche, Julienne, Golden Beurre of Bilboa, Passans de Portugal, and a round sweet Pear from France, also Summer Rose of Coxe, a small round, breaking fruit, of an aromatic flavor.

From Dr J. C. Howard of Woodland, in Brookline, Bergamotte Rouge, so called, a fruit which appears identical with the Summer Rose of Mr Manning, but much more highly colored with red.

From Col. M. P. Wilder, a Pear for the Beurre d'Amaulis, which is a noted fine fruit; the specimen imperfect; a large fruit, of a pyramidal form, and green color, with a ruddy cheek, Beurre and of good flavor.

Apples.—From Edward Sparhawk, Esq. of Brighton; Princess Harvest, a very beautiful deep red striped fruit, over medium size, juice abundant, of an agreeable, sprightly, acid flavor.

From Mr Ives of Salem, Early Sweet Bow, fine.

From Mr John A. Kenrick, Early Sweet Bow, very beautiful.

From S. Davis, Esq. of Newton, Hawthorndean.

From Mr S. Bigelow, of Medford, a large red French striped Apple.

Peaches.—From Mr T. Bigelow of Medford, handsome yellow malacatanes.

From Mr W. T. Eustis of Brighton, specimens of Peaches of great beauty.

Mr E. M. Richards offered for exhibition, ninety seedling Peaches, of as many different varieties, raised by Mr Otis Pettee of Newton, all of them appeared fair and handsome, and some portion fine.

Plums.—Mr Manning offered specimens for exhibition of the Red Apricot Plum; a dark purple round fruit of rather large size and handsome. Also Hulings superb, a remarkably large fine fruit, but a shy bearer.

From Mr S. R. Johnson of Charlestown, Reine Claude or Green Gage, Princes Imperial Gage, both specimens fine; also Bolmer's Washington, very large and beautiful. This superb variety produces large crops of delicious fruit in the garden of Mr Johnson; and appears to differ from the fine Bolmer Washington of Mr Cruft of the city, the one being a clingstone and the other a freestone. The variety of Mr Cruft confirming more exactly to the description which authors have given of the Bolmer's Washington, is yet deemed a shy bearer.

From Messrs. Mason of the Charlestown Vineyard, a small, round, white seedling fruit, of a sweet flavor.

From Mr Henry Van Dyne of Cambridgeport, a seedling, very handsome Blue Plum, for a name; which we venture to name *Van Dyne Plum*. We may speak further of the merits of this fruit on a future occasion.

Grapes.—Mr Josiah Bradlee of the city, offered specimens of the Black Hamburg from the Grape House of Aaron Mitchell Esq. of Nantucket; clusters very large and beautiful. The soil and climate of that Island prove admirably adapted to the vine.

From Dr J. C. Howard, specimens of the Black Hamburg, White Chasselas, and the Meunier or Miller's Burgundy, corresponding in size and beauty to those of this gentleman's former exhibitions.

From Mr Otis Johnson of Lynn, splendid clusters of Black Hamburg.

From Mr Jacob Tidd of Roxbury, specimens of White Chasselas and Black Hamburg corresponding in beauty to those of his exhibitions in former years.

From Mr Davis of Newton, Black native grapes. For the Committee.

WILLIAM KENRICK, *Chairman*.

EXHIBITION OF FLOWERS.

Saturday, Sept. 8, 1838.

Dahlias.—From Messrs Howard, Wilder, Hovey and Walker, among them we noticed Prince George, Dennisii (fine) Ophelia, Desdemona, Cedo Nulli, and Queen of Wertheimburg by Dr Howard; Wilder's Juliet (superb) Brown's Beauty, Buist's Mrs

Rushton, Middlesex Rival (fine) and Conqueror of Europe, by Hovey & Co.; Fowler's Queen Victoria (very fine form) from Col. Wilder. Dennisii, Widdall's Perfection, Lady Ann, Napoleon, Jackson's Rival Yellow, Cleopatra, and Desdemona, from S. Walker

Bouquets.—By Messrs W. Kenrick, Winship, (very fine), Howard, (extra fine), Mason and Walker.

For the Committee,
S. WALKER, *Chairman*.

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, SEPTEMBER 12, 1838.

AGRICULTURAL IMPROVEMENTS. No. 1.

We spoke in a preceding paper of agricultural experiments. We mean now to say something of agricultural improvements. In essays for a weekly journal it is plain that no subject can be treated but in a very partial manner. All we propose is to suggest hints, by which others may be excited to reflection and experiment; and from which they may gather some practical rules for the amendment and advantage of their husbandry. We shall aim merely to throw out some ore from the quarry in its crude state; and leave to others to reduce and mould and fashion, and use it as they will.

Improvement implies making a thing better; and there is nothing which more concerns our farmers; there is nothing in which they could more directly or more effectually advance their own interest; and yet there is nothing in which they are more deficient; there is nothing at which, taken as a body, our farmers labor so little. In saying this we mean to except those men of property, who farm for their own pleasure; and professional men, tradesmen, mechanics, or manufacturers, who apply some portion of the proceeds of their profession, trade or business to agricultural embellishment, and improvement.—We speak of those, who are exclusively farmers; and of this class within our observation and knowledge there are certainly few, who make it a business to improve their farms; or who attempt and effect important, extensive, substantial, and permanent betterments. Now let us inquire what improvements are desirable; what can be done, and then what are the alleged reasons, and what the true reasons, why these improvements are not made. We write for common farmers in this case, who depend on their farms for their own and the subsistence of their families; and our object is to inquire what improvements can they make, for which the farm will itself pay. We set too high a value upon labor, to wish to see it applied by persons who have no other capital to trade upon, where there is not a moral certainty of remuneration and profit.

The condition of most of our farmers is in many respects straitened and severe. They begin life with small means; often with no means; or with the small earnings of two or three years' labor at service. They purchase farms and at once involve themselves in debt. The first purchase usually absorbs all their loose capital; they seek to get along solely by their own labor, hiring as little as possible. Agricultural returns are comparatively slow. They find it perhaps at first difficult to pay punctually the interest upon their debt. Too often they have not the courage, and perhaps more often, if they had the courage, they would not have the power or opportunity to borrow money. Individuals, who are capitalists, think in general they can find more profitable investments for their money than to lend it to farmers, who have no other

resource than in their own labor and enterprise. Bank loans are in general too short and capricious to be safe or convenient for farmers; besides that banks never were designed for farmers; they are only for merchants and manufacturers; and for a much more numerous class, who are the very core of every industrious community, gamblers and speculators who live upon the had earnings of labor. Under these circumstances the farmer finds his task difficult. An unfortunate year or a capricious market gives him a severe check, and perhaps produces entire discouragement. All thoughts of improvement then are at an end. He drags along from year to year continually embarrassed by a load of debt, which he can hardly stand under and which he cannot throw off; until at last when he can get on no farther, his mortgage is foreclosed, his premises pass under the hands of the auctioneer, and he is left again to shift for himself, to find what employment he can or to subsist his family as he may; or gathering the fragments of the wreck he leaves the home of his fathers to pitch his tent where chance may direct him in the seductive and perilous western land of promise, and to encounter all the difficulties and hardships of a new and untried country and climate. This is but the history of innumerable individuals among us. The frequency of these cases, we confess, throws a damper upon our hopes of agricultural improvement, unless some remedy or preventive can be pointed out. Let us then go a little farther into this matter.

Agricultural improvements may be properly divided into three classes; those which are mere embellishments; those which are necessary or useful but not immediately productive; and those which are directly productive. All that serves no other purpose than to improve the external appearance of our premises, paint, piazzas, colonnades, blinds, ornamental fences, pointed and faced stone walls; all within doors likewise that is mere matter of embellishment or luxury, papered walls, carpets, and sofas; and so likewise gravel walks, and arbors, and summer houses, and ornamental shade trees; and also all expensive vehicles and equipments, all chaises, and pleasure wagons, and plaited harnesses, these things though very gratifying to the taste and pride, and very reasonable luxuries and indulgences in some circumstances, cannot be brought into the class of productive improvements; and should not be thought of by the farmer or the farmer's wife, who are in debt to the smallest amount; or who have few or no other resources than in their own industrious habits and severe labor. Yet expenses like these are often incurred; and cripple the energy of the farmer and withdraw from him the means of making improvements on his farm of a productive character.

There is a second class of improvements, which may be deemed necessary and useful. The farm must in the first place be well divided and fenced. This is necessary in order to the safe keeping of the live stock; and to the protection of the crops. The division of a farm into enclosures of a proper size renders the cultivation more easy; permits with greater convenience a rotation of crops; and the appropriation to different objects, as it may be necessary, the different portions of the farm.—Then likewise by poor or insufficient fences crops are oftentimes seriously injured or destroyed; quarrels and heart-burnings and law-suits are engendered among neighbors; and the good morals of your cattle are destroyed. The preparing also of cellars for receiving your crops, of vaults under your stables for the manufacture and preservation of your manure; and also the building of convenient styes, stalls, stables and barns for the storage of your produce and the protection of your cattle; and the obtaining of valuable and labor-saving machines and implements for cultivation and the preparation of your pro-

duct for market, all these are useful, and properly speaking, necessary improvements on a farm, but which cannot be classed among productive improvements. They save much that might otherwise be lost, or injured, or perish; but they create nothing, unless it be according to Poor Richard's proverb, that a penny saved is two pence earned." A farmer may, as is often said, get along without any of these conveniences and facilities; but it is miserable husbandry when his crops are lost or wasted for the want of convenient store-houses and barns; when he dare not cultivate many valuable products, because he has no means of securing them from the wet or the frost; when his cattle suffer from the weather for want of commodious shelter; and when especially he is without ample means of securing and manufacturing manure, that most important and essential basis of successful husbandry. Improvements of this kind are to be considered as so much fixed and dead capital, as necessary as the store-houses and ships of the merchant, or the tools of the mechanic, or the machinery and fixtures of the manufacturer. The great points to be aimed at in these matters is to avoid multiplying these things beyond his necessities; and at the same time to make them as plain and as little expensive as possible consistent with durability and their exact adaptation to the purposes designed. The multiplication of conveniences beyond a certain point is often itself a great inconvenience. A machine for example, which performs a great many operations at the same time, is of necessity complicated, requiring therefore a much more careful superintendence in its management; and being much more liable to get out of repair. Another matter of importance is to avoid all needless expense in the construction of farming implements and buildings. The first object of every farmer, who depends on his farm for his subsistence should be utility. The great point to be aimed at in the construction of any and every machine utensil, building or fixture should be to accomplish the objects and purposes for which it is designed. In no cases taste and fancy may be consulted in consistent with cheapness and utility; but where they interfere with each other, every thing should be sacrificed to the proper objects of the work. Shall a farmer for example paint his barn? In general we have no doubt it is matter of sound economy. The next question is, of what color shall it be? White is the most neat; white furnishes the most agreeable contrast with green. But white is less durable; white is most liable to be defaced; white do not contrast in general very agreeably with the manure heaps usually in its vicinity. Red lead or yellow ochre are much cheaper, more lasting, and not so easily defaced. So likewise in regard to implements. A farmer can always afford to pay liberally for good materials, a careful and faithful workmanship; but he can afford pay nothing for any ornamental apparatus. It is but recently that we saw two very fine ploughs brought in competition. The construction of each was excellent. In point of strength of workmanship, and durability, a ease of handling, and power required for draft, there perhaps could be no choice between them; or if any preference would belong to the plough of cheap construction. The price of one of these ploughs was seventeen dollars; of the other six dollars seventy cents; and all this difference of ten dollars and twenty five cents between the two was chargeable to extraordinary polish, skill, and beauty of workmanship bestowed upon one of them, without a single practical advantage excepting the pleasure afforded to the eye. Such needless expenses as these no farmer should allow himself, if he is dependent upon his farm for his support, i.e. is in debt to the amount of a single dollar by what he has the means of paying at once; or if he without ample means of indulging his taste and fancy his pleasure.

We shall pursue our subject in a future paper. H. C. P. S. It has been requested that I should affix my initials to my communications. In a matter of so little importance it would be unwise to refuse, especially as it may sometimes save the reputation of others, who might suffer under uncomfortable charges. My good friend, J. B., likewise, though a sound believer in the doctrine of imputation, thinks, I dare say, that he has sins enough to answer for without incurring any responsibility for me. Until further advised I will therefore usually, but not always, affix my initials. I say not always, for when ever for example, I propose to attack any man's private character and perhaps ruin his reputation, or wish to circulate some vile story, which I know to be utterly false, because perhaps I have made it out of the whole cloth, why then I shall remember that the "soundest part of valor is discretion;" and give only the general and convenient authority with many editors in such cases, and remark, "They say so." It would be ridiculous to pretend to any literary ambition in the case. The farmer would hardly understand the term. My sole object is to be useful; and to be therefore as plain and practical as possible.

H. C.

HORTICULTURAL EXHIBITION.

The Annual Exhibition of the Massachusetts Horticultural Society will be held at the Society's new Rooms, No. 23, Tremont Row, (nearly opposite the Savings Bank), on Wednesday, Thursday and Friday, 19th, 20th and 21st September. The members of the Massachusetts Horticultural Society, and the public generally, are respectfully invited to contribute choice and rare specimens of Fruits and Flowers for the exhibition; and to send the same to 23, Tremont street, on Monday or Tuesday, 17th and 18th inst., where Committees will be in attendance to receive them, and will retain the same subject to the order of the contributors.

Members of the Society will receive their Tickets on application to the Chairman of the Com. of Arrangements.

Season tickets, and tickets for a single admittance, may be had at the door during the exhibition.

By order, **SAMUEL WALKER,**
Chairman of Com. of Arrangements.

Sept. 10, 1833.

BRIGHTON MARKET.—MONDAY, Sept. 10, 1833.

Reported for the New England Farmer.

At Market 560 Beef Cattle, 750 Stores, 4,000 Sheep, and 500 Swine.

Prices.—Beef Cattle.—The market to day was quite animated and the prices for the best cattle were supported. We quote, First quality \$7 37 1/2. Second quality, \$6 50 a \$7 00. Third quality, \$5 00 a \$6 25.

Stores.—Purchasers were plenty and a large number were sold. Yearlings, \$9 n \$12. Two Year Old \$16 a \$24. Three Year Old, \$22 a \$30.

Sheep.—About the usual prices were obtained. We offered the sale of lots as follows. \$1 42, \$1 62, \$2 00, \$2 25, \$2 37, and \$2 88.

Swine.—Lots to peddle were sold at 6 for sows, and 7 for barrows. Selected lot of barrows at 7 1-2 and 8. Retail, 7 a 7 1-2 and 8 a 8 1-2.

THERMOMETRICAL.

Reported for the New England Farmer.
Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded ortherly exposure, week ending September 9.

EMPLOYMENT WANTED.

A Gardener out of employment would be happy to attend orders for building or gardening of any description. Apply at the New England Farmer Office.

FRUIT AND ORNAMENTAL TREES, MULBERRIES, &c.

Nursery of William Kenrick.
The Catalogue of Fruit and Ornamental Trees for 1833 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Peaches, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Ironsuescas, Paeonies, Dahlias and other Herbaceous Flowering Plants.

225,000 MORUS MULTICALLIS are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Brausca and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. B. BACK, Commission Store, No. 132 Water Street, New York, M. S. PEWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston. August 1, 1833. **WILLIAM KENRICK.**

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more as may be wanted, of the most approved kinds—consisting of the best selected varieties now in use, for cultivation, feeding worms, and making silk;—being acclimated to this country, and adapted to either warm or cold climates, affording a rare opportunity for companies or individuals to be supplied, from the most extensive collection of mulberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and orders left with Messrs. I. B. Colt, Secretary of the Connecticut Silk Manufacturing Company, Hartford; Alouzo Wakeman, at the office of the American Institute, No. 157 Broadway, N. Y.; Thomas Lloyd, Jr. No. 236 Filbert street, Philadelphia, Pa.; Luther I. Cox, Baltimore, Md.; B. Snider, & Co. Savannah, Ga.; Bliss Jenkins, & Co. Mobile, Al; James Lyman, St. Louis, Mo.; Case and Judd, Columbus, O.; G. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass.

Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Mulberry Plantations.
Apply at the office of **D. STEBBINS.**
Northampton, Aug 22, 1833.

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dime, situated in Rochester, N. H. six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quantities of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to Joseph Back & Co., No. 54 and 52 North Market Street, Boston. August 15, 1833.

FOR SALE.

Five acres of good Salt Marsh, in Quincy, or (Squantum so called).
Also, Four acres of Salt Marsh in Brighton.
Also, Several full blood animals, cows and calves. Apply to A. Greenwood, on the Welles Farm, Dorchester, near Dr. Codman's meeting house. Sept. 12, 1833.

BULBOUS ROOTS.

Just received at the New England Farmer Office, a fine assortment of Hyacinths, Tulips, Paeonies, Crown Imperials, White Lilies and other bulbous roots.

WINTER RYE.

Just received at the New England Seed Store and Farmer Office, a few bushels of prime Winter Rye.
JOSEPH BRECK & CO.
Aug. 13, 1833.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham. **ISAAC PARKER.**

WANTED TO HIRE

A single Man, who is capable of taking charge of a small Farm. Inquire of **JOSEPH BRECK & CO.**
Sept. 5.

NOTICE TO SUBSCRIBERS.

Subscribers can have the New England Farmer neatly bound for seventy five cents per volume, by leaving them at this office.

Aug. 15, 1833.

MISCELLANEOUS.

SOMETHING NEW.—A writer in the United States Gazette, says that Cayenne Peppers, mixed with Indian meal, is excellent food for turkeys. The turkeys raised by this process are more hardy, less liable to perish from the cold storms and wet weather, and acquire their growth at an earlier period, than those that are reared upon the ordinary food.

PEDAGOGICAL WIT.—A class was reciting a lesson in Metaphysics—the chapter on *motives* operating on the human will—a mackerel vender went by, vociferating senatorially. "Mackerel, fine fat Mackerel!" Suddenly disturbed by the noise, the master inquired of the class what *motive* the man had for making such a noise? No answer being given, he said they must be *deaf as huddocks* and *flat as flounders* not to perceive it was a *selfish* motive.

REALITIES.—A person being asked what was meant by the "realities of life" answered—real estate, real money, and a real good dinner, none of which could be realized without real hard work.

CERTAIN CURE FOR THE DIARRHÆA.—Parch a half a pint of rice until it is perfectly brown—boil it down, as rice is usually done—eat it slowly, and it will stop the most alarming Diarrhæa, in a few hours.

SOOT.—As a top dressing for turnips or grass land there is nothing superior to it.

STATE OF MAINE.

LAND OFFICE,
Bangor, April 30, 1838. }

The twelfth section of "an act additional to promote the sale and settlement of the public lands," passed March 24, A. D. 1835, making it the duty of the Land Agent "to advertise the setting lands in market, once a year, for two months, in one paper in each county in the State, describing the quality and situation of said land and the terms of sale;" the Land Agent hereby gives public notice that Township number 4, in the fifth range of Townships west from the east line of the State, has been lotted for settlers, and is now in the market for sale and settlement under the provisions of the following law passed at the last session of the Legislature. The price will be from fifty to seventy-five cents per acre, according to the quality and situation of the lots. The lots average 160 acres each. The soil in this township is good, being remarkably free from stones, and the land lying in moderate swells. The location of this township is favorable for settlement, as the Aroostook road passes within one mile of the western line of the township. There are between 40 and 50 settlers in the adjoining township No. 4 in the 6th Range, and a good saw mill and grist mill have recently been built there by Ira Fish, Esq. only one mile distant from this township.

Townships No. 3 in the 4th Range, No. 7 in the 6th Range, and No. 8 in the 7th Range have been surveyed and lotted into mile sections. Lots of 160 acres will be run out from any of these sections to actual settlers, where the land is more suitable for farming than for timber. Townships Nos. 8, 10 and 12 in the 5th Range have been ordered to be surveyed, by the Surveyor General, forthwith, and will be open for settlers as soon as the lots can be run out. The Aroostook road passes directly through these townships and the soil is represented to be excellent for farming. The Aroostook road is laid out and cut out from the military road leading from Bangor to Houlton, near Mattawaukeg Point to the Aroostook river, a distance of about 75 miles.

About \$17,000 will be expended this year, upon this road by the Land Agents of Maine and Massachusetts, and with the part already finished the road will be completed about one half of the distance. The whole dis-

tance will probably be completed next year. All the land on this road has been sold for about two thirds of the distance, and in several townships all the lots upon the road have been taken up by actual settlers. The remaining part of the land upon this road, owned by this State is now offered for sale to settlers. The price of lots in these townships under the condition of the new land law will be from fifty cents to one dollar per acre, according to their situation and quality. Should any company of settlers select any unsurveyed township in this part of the State on which they should wish to erect mills under the provisions of the new land law, the Surveyor General would proceed as soon as practicable in the survey of such township.

The settling duties required by law, are "that the purchaser of each lot shall clear in a proper manner, fifteen acres thereof, ten or more of which shall be well laid down to grass, and build a house thereon, within four years from the time of the purchase."

The board of Internal Improvement for this State have just ordered an exploration and survey of all the lands situated in the Aroostook country in reference to their settlement and agricultural capabilities. This survey will be commenced forthwith under the charge of Dr Ezekiel Holmes, of Winthrop. His report of the situation, quality and value of the public land in this part of the State may be expected in the course of the season, and will give all needful information, to those persons who may feel desirous of making a settlement upon them.

The following extracts from the second report of Dr. Jackson on the Geology of the public lands, made to the Legislature, and now in the hands of the printer for publication, show the value of these lands for cultivation. The Speaking of the Aroostook country the Doctor says, "The average width of the alluvial region on the Aroostook river cannot be less than six or eight miles, and in some places it is much wider. It is a well wooded region and is the best settling land in the State, abounding in fertility the famed regions of the Western States, and capable even under a less genial climate, of producing crops of wheat and other grain, fully equal in abundance with any soils of which we have any records.

"We here found a yellow loam of a fine kind derived from the limestone rocks and luxuriant in its produce, and in some places covered to the depth of 4 or 5 inches by a black vegetable mould.

This yellow loam is remarkable for the tall rank grass called Blue joint, which skirts the margin of the river and from 4 to 5 feet high and extremely luxuriant. The forest trees are of a mixed growth, but the sugar maples are most abundant, and are of gigantic size. Elms, white birch, black and white ash also abound. The soft wood grows mostly on the low lands, while the uplands in the rear are densely crowded with hard wood trees, among which are scattered magnificent pines. In the course of two years, there will be a free communication between Bangor and the Aroostook and a great number of enterprising settlers will take up their residence in this fertile valley, and by farming, they will obtain an ample reward, and that region will become as it is destined by nature to be the granary of the north."

In another place Doctor Jackson says—"On the Aroostook it will be remarked, that very few if any hemlock trees exist, and the predominant growth is of a mixture of various hard wood trees, the sugar maple, ash and yellow birch abounding, while scattered, some of the most lofty pine trees ever beheld. There are evident reasons why this should be the case, for the richest soils are always most crowded with a mixed growth, and the Aroostook soils are mostly of limestone alluvion, and are exceedingly rich and good settling lands remarkable for their heavy crops of wheat, rye and other grains, and are certainly richer as an agricultural district, than any other portion of Maine. The present population on this river is estimated between 400 and 500 persons, chiefly emigrants from Maine."

Towards the conclusion, Dr Jackson says: "the researches of the present season have brought to light many important resources in the public domain which were before unknown. Beds of iron ore of immense magnitude favorably situated for advantageous operations occur on the Aroostook, and all the marked characteristics of a great regular coal formation exhibit themselves over a great belt of country from the Schooies to the Aroostook and St. John, and extend to the Temisquiotta lake near the frontier of Canada. It will be as once perceived, that the country which we have explored is a most valuable territory, possessing every advantage required by settlers. Heavy timber offers a reward to the enterprising lumber dealer. A rich soil capable of producing an average crop of 20 bushels of wheat to the acre, and in some cases producing from 30 to 40 bushels, offers an ample reward

to the husbandman. Inexhaustible supplies of limestone, valuable both for building materials and for agriculture, vast and inexhaustible mines of rich iron ore, amid innumerable forests which will furnish an abundance of charcoal, required for the manufacture of the finest kind of iron and steel—the country presents every natural advantage that might be required to call forth the enterprise and industry of the farmer and manufacturer."

By an inspection of the map of Maine, it will be seen that there are nearly one hundred townships of land situated on the Aroostook river and its tributaries, one half of which belongs to the State of Maine and is now open for sale and settlement under the new land law. Considering the remarkable fertility of the soil in this region and the high price of produce, and the ready market which it finds among the lumbering people on the Penobscot and St. John rivers, and the advantages on this road now making by Maine and Massachusetts into this region, it is believed that an uncommon opportunity is now offered to persons who may feel desirous of obtaining good farms at a low price.

The field notes of the surveys of all these townships are in the Land Office, open to the inspection of every person, and all information that may be received here, from time to time, from the progress of surveys, and the reports of Agents, will be cheerfully given to all inquirers, and every facility granted within the means of this office, to secure to individuals and companies, all the benefits and privileges intended by the Legislature, for actual settlers under the provisions of the following law.

ELIJAH L. HAMLIN,
Land Agent of Maine.

STATE OF MAINE.

In the year of our Lord one thousand eight hundred and thirty-eight. An act additional to promote the sale and settlement of the Public Lands.

SECTION 1. *Be it enacted by the Senate and House of Representatives in Legislature assembled,* That all lands allotted to settlers shall be sold to those only who will perform settling duties on the same as prescribed by law, the price to be fixed by the Land Agent, having reference to the field notes, not however at a less price than fifty cents per acre; three fourth parts of said price to be paid within three years from the time of said sale in labor to be laid out in making roads in such township where said lands so sold are situated, under the direction of the Land Agent; and the remaining fourth part to be paid in cash within four years from the time of said sale.

SEC. 2. *Be it further enacted,* That whenever twenty or a less number of individuals, shall each select a lot of one hundred and sixty acres of land in any township lotted for settlers, the same having no mill within its limit and shall give bonds satisfactory to the Land Agent, they will within the term of three years from the time said selection, erect in a proper and substantial manner a saw mill and grist mill, on such lot within said township, as shall be designated by the Board of Internal Improvement, the same shall be entitled to a deed of said lot; and each individual shall receive a deed from the Land Agent for his respective lot, without any further consideration, conditioned however, for the performance of the settling duties required by law.

SEC. 3. *Be it further enacted,* That from and after the passage of this act, all acts and parts of acts inconsistent with the provisions of this act, be and the same are hereby repealed.

In the House of Representatives, March 23, 1838. This bill, having had three several readings passed and enacted. ELISHA H. ALLEN, Speaker in Senate, March 23, 1838. This bill having had several readings, passed to be enacted.

N. S. LITTLEFIELD, President

NEW ENGLAND FARMER AND GARDENER'S JOURNAL.

For the New England Farmer.

ROXBURY, SEPT. 14, 1838.

MR. EDITOR:—I perceive by your valuable paper that Mr Ives of Salem presented to the Massachusetts Horticultural Society, a pear which the Chairman of the Fruit Committee, Mr Wm. Kenrick, calls the "Roi de Wirtemberg, formerly mis-called Capiaumont."

I beg to inquire by whom it was thus mis-called? Was it not by the first Pomologist in Europe, the President of the London Horticultural Society, Thomas Andrew Knight lately deceased? Nor is this all, the pear be sent by that name agrees precisely with the description of the Capiaumont in the *London Horticultural Transactions*. Now I am a friend to free inquiry, find no fault with our Horticulturalists in correcting the errors of Mr Knight. No name is so great with me, as to induce me to prefer its authority to truth. But I think the term "mis-called" rather too strong to use on the occasion, and I therefore humbly, and respectfully beg Mr Kenrick to lay before the Horticultural public, his authority for deciding, that Mr Knight did "mis-call" that pear. I beg to put to him the following queries:

1. There was a Beurre Capiaumont in the catalogues, long before a *Roi de Wirtemberg* appeared. Have you got it? Have you seen the real Beurre Capiaumont ripe in this country?

2. Are you sure, that the *Roi de Wirtemberg* is not a change of name merely, or what is called a synonyme?

3. Will you state the form, size, and qualities of what you say is the true *Beurre Capiaumont*? We may then see in what it differs from the *Capiaumont* of Mr Knight.

I cannot bring myself to believe, that gentlemen of our Society would ever distract and confuse all our cultivators, merely on the ground, that the "Capiaumont" is now called *Roi de Wirtemberg*. It would be puerile, to change our names every time it pleases the sellers of fruit to give a new name. What I want distinctly to know, is, whether they have ripened, and tasted two distinct pears, one called *Capiaumont* and the other *Roi de Wirtemberg*, and that they differ, and in what particulars they differ.

I am the more particular on this point, because the Chevalier Joseph Parmentier, who received a gold medal for his excellent catalogue (and it deserved it,) has the *Capiaumont* in his list, but has not the *Roi de Wirtemberg*. I suspect, therefore, that the charge has been made by a seller of trees. I, who have suffered for fifty years severely, by new names to old things in pomology and floriculture, dread these novelties as a burnt child dreads the fire. Many times have I nursed a *hauling with care* and at great expense, and when it came to flower, or give fruit, I have found that I have nursed an old and discarded friend with a new name. Hence probably my desire to protect my neighbors,

by checking the propensity to change names. I have often mentioned to my friends, the case of *Alonzoa incisifolia*, which in 30 years I have actually bought four times over under different names. It is rather a severe tax on one's good humor, and pure.

JOHN LOWELL.

Note Bene.—I beg it to be understood, that I have a high respect for Mr Kenrick's opinion. I have personally known his efforts to acquire, and transmit correct knowledge; but there is a wide difference, between changing names according to honest conviction, and speaking in terms so sharp of a man, whom no European cultivator would speak of, but with profound respect. I have seen no evidence, as yet, that Mr Knight ever "mis-called" the *Capiaumont*. I am, however, perfectly open to conviction.

There are probably now in fruit 10,000 *Capiaumont* Pear trees between Bangor in Maine, and Cincinnati in Ohio. They have gone from me to both those cities and to 200 towns between them. They have been called by that name for 13 years. Mr Kenrick's own celebrated work so calls them. Why then change the name? It is bringing confusion into our names instead of order.

From Parkinson's Treatise on Live Stock.

SLUT.

Of this most extraordinary animal, will here be stated a short history, to the veracity of which there are hundreds of living witnesses.—Slut was bred in, and was of that sort which maintain themselves in the New Forest, without regular feeding, except when they have young, and then but for a few weeks, and was given, when about three months old, to be a breeding sow, by Mr Thomas to Mr Richard Toomar, both at that time keepers in the forest.

From having no young, she was not fed, or taken very little notice of, until about eighteen months old; was seldom observed near the lodge, but chanced to be seen one day when Mr Edward Toomar was there. The brothers were concerned together in breaking pointers and setters, some of their own breeding, and others which were sent to be broke by different gentlemen: of the latter, although they would stand and back, many were so indifferent, that they would neither hunt nor express any satisfaction when birds were killed and put before them. The slackness in these dogs first suggested the idea, that by the same method any other animal might be made to stand and do as well as one of those huntless and inactive pointers. At this instant the sow passed by, and was remarked as being handsome: R. Toomar threw her a piece or two of oatmeal roll, for which she appeared grateful, and approached very near; from that time they were determined to make a sporting pig of her. The first step was to give her a name, and that of slut (given in consequence of her soiling herself in a bog,) she acknowledged in the course of a day, and never afterwards forgot. Within a fortnight she would find and point partridges or rab-

bits, and her training was much forwarded by the abundance of both, which were near the lodge; she daily improved, and in a few weeks would retrieve birds that had run as well as the best pointers, nay, her nose was superior to any pointer they ever possessed, and no two men in England had better. They hunted her principally on the moor's and heath's. Slut has stood partridges, black game, pheasants, snipes, and rabbits, in the same day; but was never known to point a hare. She was seldom taken by choice more than a mile or two from the lodge, but has frequently joined them when out with their pointers, and continued with them several hours. She has sometimes stood a jack-snipe, when all the pointers had passed by it; she would back the dogs when they pointed, but the dogs refused to back her until spoken to; their dogs being all trained to make a general halt when the word was given, whether any dog pointed or not, so that she has been frequently standing in the midst of a field of pointers. In consequence of the dogs not liking to hunt when she was with them (for they dropped their sterna, and shewed symptoms of jealousy), she did not very often accompany them, except for the novelty, or when she accidentally joined them in the forest.

Her pace was mostly a trot, was seldom known to gallop, except when called to go out shooting; she would then come off the forest at full stretch (for she was never shut up to prevent her being out of the sound of the call or whistle when a party of gentlemen had appointed to see her out the next day, and which call she obeyed as readily as a dog,) and be as much elated as a dog, upon being shown the gun. She always expressed great pleasure when game, either dead or alive, was placed before her. She has frequently stood a single partridge at forty yards distance, her nose in a direct line to the bird: after standing some considerable time, she would drop like a setter, still keeping her nose in an exact line and would continue in that position until the game moved; if it took wing, she would come up to the place, and draw slowly after it; and when the bird stopped, she would stand as before. The two Mr Toomers lived about seven miles apart, at Rhinefield and Broomey lodges. Slut has many times gone by herself from one lodge to the other, as if to court the being taken out shooting. She was about five years old when her master died; and at the accession of his pointers, &c. was included in the sale, and bought in at ten guineas.

Sir H. Mildmay having expressed a wish to have her, she was sent to Dogmersfield park, where she remained some years. She was last in the possession of Colonel Sikes, and she was then ten years old, had become fat and slothful, but would point game as well as before. When killed she was at Bassilden House. Slut weighed 700 lbs. Her death, to those who possess common feelings of humanity, appears (if one may use the expression,) at least animal murder: it would have cost but a trifling sum to have fed and sheltered her in the winter, and the park would have supplied her wants at no expense.

From the American Turf Register.

BOTS IN HORSES.

Belleville, Ill. August 14, 1838.

DEAR SIR:—Upon the 15th of June, one of my carriage horses was attacked with the grub or bots. For the first two hours the symptoms were such as induced many to suppose it was a fit of cholera. I administered three table spoonfuls of spirits of turpentine, in half an hour gave him a half pint of French brandy, with half an ounce of laudanum, this gave relief and he recovered. On the tenth day afterwards, I found him after a short ride attacked again in the same way. I administered a pint of French brandy and an ounce of laudanum, this dose was renewed in half an hour, without effect. I then gave a pint of molasses with a quart of milk, and in half an hour one pound of salts. He died in about eight hours.

On opening him after he died I found a quantity of the bots had fastened themselves in the inner coats of the stomach, and all together, with a few bots in his stomach with the food. My first object was, to ascertain what would induce the bot to loose its hold. I cut from the stomach a piece about twelve inches square, in which were the bots attached, closing the edges of the piece of the stomach together so as to exclude air. I put into the sack thus made, sweet milk and molasses, and tied them up for two hours, and on opening I found them fast to the stomach. I then tried oil, and other experiments, none of which had the effect to induce them to let go.

My next object was, to see what would kill the bots, having heard many things recommended. I made the following experiments:

I immersed six grubs or bots in linseed oil, a like number in indigo pulverized and mixed with water; also, powder and vinegar, strong decoction lye, strong decoction of alum, also alcohol, and nitric acid; after keeping them thus immersed for hours, I changed them from one to the other mixture or solution; where they remained from early in the day till evening, at which time they exhibited all the healthy appearance they did in the morning.

My observations resulted in the confirmation of an opinion I had previously formed, that the bot could not be killed, except by the administering of medicine that would destroy the life of the horse. It satisfied me of the fact, that when the bots fairly get hold, they are not induced to let go.

My opinion of the bots is as follows, that they are produced by the knit deposited on the animal by the fly known as the knit-fly, and are taken into the stomach of the horse. That the bot is there formed from the egg; that in the general way the bot is discharged from the stomach through the bowels. But where they do not pass off in this way, the attack is made to extricate themselves from their confinement by an attempt to eat through the stomach.

It occurs to my mind as most probable, that the bot passes through several changes from the form in which we have just described it. That before this change they make a desperate effort to free themselves, concentrating their attack to one spot; this soon deprives the horse of life, and the bot is extricated in a short time, and either goes into the ground, or by the action of the atmosphere changes its mode of existence.

I am satisfied, that upon the first discovery of the first attack, the bot may be induced to let go,

or postpone the effort to free itself from the stomach; this is best effected, in my opinion, by molasses and milk, which should be followed with one or two active cathartics, by which means the bots are carried off. Should these views and experiments be thought worthy of publication in your valuable work, they are submitted.

Respectfully, J. MITCHELL.

REMARKS ON THE ABOVE.—How doctors differ! As a comment on the above communication, we copy from the 'History of the Horse,' published by the society for the diffusion of useful knowledge in England, the following description of the bot. We do not adopt the opinions of either side of the question—whether the bot ever kills the horse, or is beneficial to it, but we do think Mr Mitchell mistaken in his theory of the 'desperate efforts they make to free themselves;' and that the writer of the following article is correct in that respect.—*Ed. Turf Register.*

BOTS.—In the spring and early part of the summer, horses are much troubled by a grub or caterpillar, which crawls out of the anus, fastens itself upon the tail, and seems to cause a great deal of itching or uneasiness. Grooms are sometimes alarmed at the appearance of these insects. Their history is curious, and will dispel every fear with regard to them. We are indebted to Mr Bracy Clark for almost all we know of the bot.

A species of gad-fly, the *æstrus equi*, is in the latter part of the summer exceedingly busy about the horse. They are observed to be darting with great rapidity towards the knees and sides of the animal. The females are depositing their eggs on the hair, and which adhere to it by means of a glutinous fluid with which they are surrounded. In a few days the eggs are ready to be hatched, and the slightest application of warmth and moisture will liberate the little animals which they contain. The horse in licking himself touches the egg, it bursts, and a small worm escapes, which adheres to the tongue, and is conveyed with the food into the stomach; there it clings by means of a hook on either side of its mouth, to the circular portion of the stomach; and its hold is so firm and so obstinate, that it will be broken before it will be detached. It remains feeding there on the mucus of the stomach during the whole of the winter, and to the end of the ensuing spring; when, having attained a considerable size, and being destined to undergo a certain transformation, it disengages itself from the cuticular coat, is carried into the villous portion of the stomach with the food, passes out of it with the chyme, and is at length evacuated with the dung.

The *larva* or maggot being thus thrown out seeks shelter in the ground, contracts in size, and becomes a chrysalis or grub; in which state it lies inactive for a few weeks, and then, bursting from its confinement assumes the form of a fly. The female becoming impregnated, quickly deposits her eggs on those parts of the horse which he is most likely to lick, and so the species is perpetuated.

There are several plain conclusions from this history. The bots cannot, while they inhabit the stomach of the horse, give the animal any pain, for they are fastened on the cuticular and insensible coat. They cannot stimulate the stomach and increase its digestive power, for they are not on the digestive portion of the stomach. They cannot by

their roughness, assist the irritation or rubbing down of the food, for no such office is performed in that part of the stomach—the food is softened, no rubbed down. They cannot be injurious to the horse, for he enjoys the most perfect health when the cuticular part of the stomach is filled with them and their presence is not even suspected until they appear at the anus. They cannot be removed by medicine, because they are not in that part of the stomach to which medicine is usually conveyed; and if they were, their mouths are too deeply buried in the mucus for any medicine, that can safely be administered, to affect them; and last of all, in due course of time they detach themselves and come away. Therefore, the wise man will leave them to themselves or content himself with picking them off when they collect under the tail and annoy the animal.

CATTLE SHOW.

The undersigned, having been appointed by the Worcester County Agricultural Society to make all necessary arrangements for a Cattle Show and Exhibition of Manufactures, on Wednesday, the 10th day of October next, have been attending to the duty assigned them, and have the pleasure of reporting that the annual address will be delivered by the Rev. HENRY COLMAN, the Commissioner appointed to make an agricultural survey of the Commonwealth. That the high character of the County in relation to its agriculture and manufactures may be fully sustained on this occasion, the Committee respectfully solicit from the farmers and manufacturers of the County, their co-operation in the endeavor to render this Show more interesting than any former one—and this can readily be done, if the owners of choice animals will place them in the Society's pens, and the manufacturers will deposit specimens of their work in the exhibition hall. They would ask from the ladies a continuance of their kindness in aiding to adorn the hall with their elegant work. Careful persons will be provided to take charge of the goods and preserve them from injury. The hall will be open for their reception on Monday, the 8th day of October, and it is desirable that they may be entered on that day that sufficient time may be had to arrange them properly and have them in readiness for the examination of the Committees. Those who may find it more convenient to forward articles previous to the time mentioned, may send them to the charge of the Chairman of the Committee, who will attend to have them seasonably entered and taken care of. The sum of \$50 dollars has been reserved, to be distributed in gratuities for articles of skill and utility deserving encouragement, and for which a particular premium has been offered.

Those disposed to compete in the Ploughing Match are reminded that notice of their intention must be filed with Edwin Conant, Esq. the Recording Secretary of the Society, at his Office opposite the Central Hotel, before the 25th day of September instant, that suitable ground may be obtained the proper number of lots measured and marked out, and the requisite arrangements made for the occasion. The ploughs must be on the ground which will be provided, in readiness to commence the work precisely at 9 o'clock, A. M., of the day of the Show, as this will be the first public business attended to.

Those who intend to enter for the Drawing Match, are informed, that to prevent unnecessary

clay, the Committee will arrange their names by lot, and it will be required that each person be on the ground with his team, in readiness to commence the work when his name is called by the Marshal.

All competitors are notified that the conditions prescribed by the Trustees, and published in their bill of premiums offered, must be strictly complied with. Those who have not been furnished with those bills, may obtain them of Edwin Conant, Esq., or of the Chairman of the Committee of Arrangements.

The Committee have the satisfaction of stating that the Trustees, for the purpose of rendering the show more interesting, have authorized them to offer a gratuity of \$50 for the exhibition of a team of working oxen, to consist of not less than 60 oxen, belonging to the same town, and such as shall be approved by the Committee on working cattle.

JOHN W. LINCOLN,	} Committee of Arrangements.
F. W. PAINE,	
ISAAC SOUTHGATE,	
THOS. CHAMBERLAIN,	
ISAAC DAVIS,	
T. W. BANCROFT,	
JAMES ESTABROOK,	

The Beet Sugar Company in this town have hired the buildings erected near the Canal House or an Iron Foundry, together with the Steam engine.

The manufacture will be carried on upon the German principle of drying, grinding and making of the powder a strong decoction of syrup for crystallizing. Farmers can get five dollars a ton for their beets—contracts have been made at that price where 20 tons to the acre is expected. This is doing well for the farmer, and if at this rate the manufacturer can do well too, the whole process, will succeed and drive out of use the cane sugar entirely, which has been manufactured in China every since the days of Moses.

The following is the first European account of the sugar manufacture of China, from which its great antiquity may be inferred. It would indeed be most astonishing if the sweet cane, warmed by a tropical sun furnishing for 4000 years the only material for sugar, should now give way to the cold under ground watery beet.

It is singular how sugar, like cotton and tobacco, the two first but little known to the nations of ancient Europe, the last not least of all, has become a principal article of commerce throughout the whole civilized world since the discovery of America. The first knowledge of Sugar was carried into Europe by the soldiers of Alexander, who returned from the expedition to India. It is described by one author as "honey extracted from canes or reed." Strabo says, on the authority of Nearchus, Alexander's Admiral, who sailed down the Indus to its mouth, that "honey is obtained in India without bees."

Pliny says it was obtained from reeds like a gum, and was light colored and hard when taken between the teeth. It is plain that the sugar thus described is sugar candy, and that it was obtained by the Romans and Greeks from China. It is well ascertained that the Chinese have known and practised the art of making sugar candy from the highest antiquity. The Saracens were the first to bring sugar into Europe in large quantities, and they also

brought with them the art of manufacturing and refining it. These people conquered some of the islands in the Mediterranean and some extent of coast on that sea, and among their fruits of the conquest was the introduction of the sugar plant.

From the shores and islands of the Mediterranean, the knowledge and use of sugar were spread over Western Europe by the crusaders. The plant was afterwards carried by the Spaniards to the Canary Islands, and thence, after the discovery of America, to the islands and continent of the New World. This is what the Spaniards pretend, and it may be true; but if we may believe Edwards's history of the West Indies, the plant grew wild both in the islands and in the continent long before the arrival of Columbus. Its use is now almost as universal as that of salt or flour, and throughout the whole civilized world, the rich and poor, the nabob and the day laborer, pay their daily tribute to the cultivator of the sugar cane.—*Hampshire Republican*.

CURE OR PREVENTION OF MURRAIN.

The Cultivator publishes a correspondence on the subject of this fatal disease in cattle, in which a Maryland farmer recommends tar as an efficacious cure and more perfect preventative. As a simple, cheap, and safe prescription, it deserves attention and farther experiment to test its efficacy. The mode of administering it is as follows:

"I tie my cow in the stable, then let a strong man hold her by the nose and horn, then take the piddle we commonly use for greasing the wagon, dip it in the tar bucket, taking up as much as will stick to it, say from a gill to half a pint, open the cow's mouth, and put it as far back on her throat as possible without hurting her; hold the piddle in her mouth long enough for her to work the tar off of it. I do the same to every cow, and repeat the operation every two or three weeks the year through at the same time rubbing a quantity of tar about the cow's horns and face, forehead and nose; likewise smear plenty of tar about the mangers and troughs. Before I commenced with the above remedy, I lost a number of my best cows, but we called the disease the horn distemper or murrain. I have had cows taken when in fine order, I might say almost fat enough for beef, they would linger a few days and die—the horns when examined would always be hollow, and mostly dry—urine sometimes bloody. It is a distemper sometimes caused by cows drinking impure water. I would advise you to try it, always bearing in mind that it is necessary for the cow to swallow a good portion of the tar. Since I have used the tar, about two years, I have not had one of my cows diseased in any way, and one of my neighbors, whose cows were formerly diseased, has used it for a long time with the most complete success. I give the tar to horses, sheep and hogs, and think it good for them."

MANCHESTER, (Miss.) July 28.

FATAL DISEASE AMONG ANIMALS.—Within the last two weeks a disease has prevailed among the stock on Silver Creek, in Washington County, which has swept off nearly every horse, mule, cow and hog in the neighborhood. The Creek is settled by extensive planters, who require large numbers of horses, oxen, &c. to cultivate their plantations; and we learn, that on Major Woolfolk's plantation, out of twenty-one horses, sixteen died in the last few days. Mr J. J. Hughes lost twelve

out of fifteen, and other stock in proportion. The disease makes its appearance on the breast of the animal, nearly between the fore legs, commencing at first with a slight swelling, extending finally to the throat, and generally proves fatal in about ten hours. No cause can be assigned for this singular complaint, as it attacks animals in good order, that are regularly fed and eat nothing but such feed as is given them, indiscriminately with those that are running at large. The disease always making its appearance on the same part of the animal, seems to preclude the belief that it can be from any poisonous insect. Numbers of deer are found dead in the neighboring wood, affected from appearances, in the same manner. The complaint seems to be confined to hoofed animals, as the dogs have fattened on the carcasses without being affected.

SHEEP WORM.—There is a fly that deposits its eggs in the nostrils of sheep, usually in August and September, where it hatches, and then makes its way up into the head and often causes death. The frequent application of tar to the noses of sheep, is considered the best preventive. Put tar on boards and strew on salt, and the sheep will sneer their noses with tar in eating the salt. The following method is recommended by some sheep master.—Take a small log, dress it a little upon the upper side, bore holes into it with a large augur at short intervals, about two or three inches deep, fill these holes with salt, and with a brush apply tar as often as once a week around the holes, and give the sheep daily access to the salt. A small quantity of tar frequently given to sheep is considered conducive to their health. Alexander Reed, Esq. of Washington Co. Penn. observes, "we have long been satisfied that the use of tar as a medicine or condiment for sheep has not been duly appreciated. The cough and foul nose, I am disposed to think, are both produced from the same disease. When we notice them we lose no time in removing them from the flock, and make a free use of tar. It rarely fails to effect a cure in a few days, unless the animal is old or unsound."—*Genesee Farmer*.

ROHAN POTATO AND FRUIT TREES.—J. D. Legare, of Grey Sulphur Springs, Va. wishes us to advise him, to whom he shall apply at Paris, for Rohan potatoes and fruit trees. All of these we can furnish to Mr Legare, as we are growing them all for sale on our grounds; but if Mr L. is particularly desirous of obtaining them from France, we recommend that he apply through Messrs. Vilmorin, Andrieux & Co. Seedsman, Paris. As to the character of the Rohan potato, we have no hesitation in saying, that, according to the seed sown, it is far the most productive of any variety we know. We cannot judge so well of its quality for the table, never having tasted of but one. We should class it second, though others class it first, among our good northern potatoes.—*Cultivator*.

INNATE APPETITES.—Sir George McKenzie, in his Phrenological Essays, mentions the following curious fact, witnessed by Sir James Hall: he had been engaged in making some experiments on hatching eggs by artificial heat, and on one occasion observed in one of his boxes, a chicken in the act of breaking from his confinement. It happened that just as the creature was getting out of its shell, a spider began to run along the box, when the chicken darted forward, seized and swallowed it.

GEOLOGY OF MASSACHUSETTS.

Continued from page 59.

Geine.—It may be well, to state the average quantity of geine in the different geological varieties of our soils, which is as follows:

	Soluble Geine.	Insoluble Geine.
Alluvium,	2.25	2.15
Tertiary argillaceous soils,	3.94	5.92
Sandstone	do. 3.28	2.14
Graywacke	do. 3.60	4.00
Argillaceous slate	do. 5.77	4.53
Limestone,	do. 3.40	4.04
Mica slate	do. 4.34	4.60
Talcose slate	do. 3.67	4.60
Gneiss	do. 4.30	3.40
Granite	do. 4.05	3.87
Sienite	do. 4.40	4.50
Porphyry	do. 5.97	4.10
Greenstone	do. 4.56	6.10

One fact observable in the above results may throw doubts over the fundamental principles that have been advanced respecting geine; viz., that it constitutes the food of plants, and that they cannot flourish without it. It appears that our best alluvial soils contain less geine, in both its forms, than any other variety, except those very sandy ones that are not noticed in the above results, because their number is so small. Ought we hence to infer that alluvium is a poor soil? I apprehend that we can infer nothing from this fact against alluvial soils, except that they are sooner exhausted than others, without constant supplies of geine. For if a soil contain enough of this substance abundantly to supply a crop that is growing upon it, that crop may be large although there is not enough geine to produce another. Now analysis shows that our alluvial soils contain enough of geine for any one crop: and I apprehend that their chief excellence consists in being of such a degree of fineness that they allow air, moisture, and lime, rapidly to convert vegetable matter into soluble geine, and yield it up readily to the roots of plants: but I presume that without fresh supplies of manure, they would not continue to produce as long as most of the other soils in the state. A considerable part of our alluvia are yearly recruited by a fresh deposit of mud, which almost always contains a quantity of geine and of the salts of lime, in a fine condition for being absorbed by the rootlets of plants. And on other parts of alluvial tracts, our farmers, I believe, are in the habit of expecting but a poor crop unless they manure it yearly. Yet so finely constituted are these soils, that even if exhausted, they are more easily restored than most others; so that taking all things into the account, they are among the most valuable of our soils; and yet I doubt whether they produce as much at any one crop as many other soils; though the others perhaps require more labor in cultivation.

Western Soils.—In addition to the arguments respecting the existence of phosphate of lime in the soils, I would state that I found it in every analysis which I have made of the Berkshire marl, the results of which I shall soon present. I have also recently analysed five specimens of soils from Ohio and Illinois, presented to me by H. G. Bowers, Esq., formerly of Northampton, in this state, and now resident in Illinois. They were taken from some of the most productive spots in those states, and, in regard to some of them, it is certain, that no animal or any other manure has ever been applied by man, and at least one of them seems not

to have been cultivated, so far as I can judge from its appearance. Yet all these soils contain phosphate of lime. The following are the results of their analysis; which I give, partly because of the subject under consideration, and partly because I thought it might be gratifying to compare the composition of some of the best soils at the west with those in Massachusetts.

	Rushville, Illinois	Soluble Geine.
Stangeon co. do.	4.9	Insoluble Geine.
Lazelle county, do.	5.6	2.5
Peora county, do.	1.3	3.4
Sciota Valley, Ohio.	1.9	0.6
	1.3	0.4
	3.3	0.4
	3.1	1.0
	3.1	0.9
	4.8	2.8
	6.7	8.0
	9.1	8.6
	2.1	1.3
	2.8	1.5
	8.3	8.6
	8.0	6.3
	5.3	9.5
	5.7	5.7
	5.3	5.3

Apparently never cultivated. Cultivated 14 years without manure.

Remarks.

The above soils are evidently of the very first quality: the geine being in large proportion, and the salts quite abundant enough, while there is still a small supply of carbonate of lime to convert more insoluble into soluble geine, whenever occasion demands. Still, if we compare the preceding analysis with some of those that have been given of the Massachusetts soil, the superiority of the western soils will not appear as great as is generally supposed. And there is one consideration resulting from the facts that have been stated respecting geine, that ought to be well considered by those who are anxious to leave the soil of New England that they may find a more fertile spot in the West. Such soils they can undoubtedly find: for geine has been for ages accumulating from the decomposition of vegetation in regions which have not been cultivated: and for many years, perhaps, those regions will produce spontaneously. But almost as certain as any future event can be, continued cultivation will exhaust the geine and the salts, and other generations must resort to the same means for keeping their lands in a fertile condition as are now employed in Massachusetts, viz., to provide for the yearly supply of more geine and more salts.

Importance of the Salts of Lime.—I apprehend that the importance of the salts of lime in a soil is but little appreciated by farmers in general. Their crops may fail, although they have manured and tended them well; but it is almost always easy to find a cause that satisfies, in the character of the

season; but hard to convince them that the failure may have been owing to the deficiency of a single grain in a hundred, of some substance, that can be discovered when present, only by chemical examination. And yet, I doubt not many a crop has failed from the want of that one per cent. of sulphate or phosphate of lime. Facts, indeed, seem to me to warrant the conclusion, that, without lime in some form, land will not produce any valuable vegetation.

General Conclusions.—Without stopping to notice some things of minor importance, I will state at once the most important conclusions that have forced themselves upon my mind, from all my examinations and analyses of our soils, respecting their deficiencies and the means of remedying them.

First, the grand desideratum in our soils is calcareous matter; that is, carbonate of lime.

The second desideratum is an additional quantity of geine; that is, a larger supply of the food of plants.

Hence, thirdly, the great object of the agricultural chemist should be, to discover and bring to light new supplies of both these substances.

The discovery of either of them would, indeed, be of no small value; but it is a principle that ought never to be lost sight of, that an additional quantity of lime in the soil, will commonly require an additional quantity of organic matter, and an increase of the latter, will be far more serviceable, if attended by an increase of the former.

These fundamental principles and conclusions I have kept in view continually; and will now proceed to show with what success I have searched for new sources of lime and of geine. I shall begin with the former as the most important, because the farmer already possesses the means of increasing the quantity of his manure, but not of obtaining calcareous matter; for, with the exception of Berkshire county, Massachusetts is very deficient in limestone.

Marls.—No form of calcareous matter is so valuable in agriculture as rich marl. This term, however, has been till recently very loosely applied; often meaning nothing more than loose clay, entirely destitute of lime. But all accurate writers now understand it to mean a friable mixture of lime and clay; although the term is extended to beds of calcareous shells that are somewhat hard. Till within a few years, this substance has been neglected in our country; but its remarkable effects in some of our middle and southern states have awakened the public attention; and it is now sought after with no small avidity. From the nature of our rocks, I had no hope of finding rich marls in any other part of the state except the county of Berkshire.

The purest of these marls when dry, are almost as white as chalk, and much lighter than common soil, as may be seen from the specific gravities of a part of them in the table of their analysis below. When wet they are of a light gray color, especially if they contain much organic and earthy matter: indeed the degree of their whiteness is no bad index of the quantity of lime that they contain. When wet they are quite plastic and adhesive: when dry, they fall into a fine powder. Hence they are in a most favorable state for being spread upon land. They are found almost exclusively in swampy ground, generally in quite wet swamps, and are always covered by a stratum, often several feet thick, of black vegetable matter approaching

to peat. Hence, as these swamps are rarely excavated, the marl is not apt to be discovered; or if found, it is supposed to be nothing more than white clay and sand, which, indeed, it does very much resemble. In order to ascertain the presence of marl in a swamp, I prepared an iron rod, several feet long, near the end of which was a groove, in fact it formed a sort of auger. When pressed into the ground and withdrawn, it would always retain in the groove some of the matter from the bottom of the hole, and in this way, in a few minutes, not only the existence of marl might be ascertained, but the thickness of the bed. Yet after all, since the swamps where it occurs are usually very wet, and easily penetrated, a rough pole is better for discovering marl and its thickness, than the iron borer which I have described. For some of it will adhere to a pole plunged into it, even though that pole must be drawn through several feet of vegetable mud above it. And if the pole be plunged to the bottom of the bed, the distance along the pole covered with marl, will show the thickness of the bed; except that the lower extremity of the pole will show beneath the layer of marl the clay or sand as far as they were penetrated; and this extent must be subtracted from the whole length covered with marl. I have been thus particular in describing the method of searching for marls, in the confidence that if gentlemen residing in the towns above mentioned will adopt it, many new beds will be brought to light.

There is a substance in the central and eastern parts of the state, in exactly the same situation as the marl of Berkshire, which resembles it also very precisely in external characters, and is also like marl very light; and yet it is not marl. It does not contain carbonate of lime, but is composed chiefly of silica. Specimens of it will be found in the collection from several places. (See No. 157, which is from Spencer; No. 169, from Barre, and No. 180, from Andover.) It is easy, notwithstanding its general resemblance, to distinguish it from marl by a few drops of vinegar, oil of vitriol, aqua fortis, or any other acid. If it be marl, the acid will produce in it small bubbles occasioned by the escape of gas—if not marl, no effervescence will be produced. And this is a universal test, which is almost infallible, for distinguishing marl in all circumstances.

One other circumstance respecting the Berkshire marl, which will aid in distinguishing it. It abounds every where with small fresh water shells, such as now occur in the ponds of that region, and therefore it is unquestionably true fresh water marl, and not shell marl. The epidermis of the shell is usually gone. Such shells are rarely found in much quantity where lime does not exist, although I have seen them in mud that did not effervesce. But their presence should lead us to search carefully for calcareous matter: for how can these animals form their shells without lime?

The manner in which these Berkshire marls were formed, is very obvious. They result from the carbonate of lime brought into ponds by water, and there at length deposited. After the pond is filled nearly up, vegetables begin to grow over the marl, and thus at length a deposit of peaty matter covers the marl. The process, I doubt not, is now going on in most limestone countries, and thus a vast amount of valuable matter for agriculture is accumulating in spots usually regarded as waste places.

The Berkshire marls, above described, appear to

me to be some of the richest and best that ever occur. Marls are usually valued only for the calcareous matter which they contain. But by adopting Dr. Dana's method of analysis, we find that they also contain no small quantity of soluble and insoluble geine, derived from the vegetable matter that covers them. This must make them still more valuable when applied to the soil. They contain likewise a small portion of phosphate of lime, increasing their value still more: while the granitic sand in them, the only part that is of no value, is in most cases extremely small.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Sept. 15, 1838.

Pears.—From S. Downer, Urbaniste, Dix, Cushing, and Wurtenberg.

From John Richardson, Beauty of Brussels.
From John Lowell, Beurre Spence, Bergamotte Paysans, Beurre, Crepeaux.

From Mrs Tim. Bigelow, Bartlett.
From Dr Harris, Bon Chretien.
From E. Vose, Julienne, Dutchesse d'Angouleme.

From S. Sweetser, Julienne, Fulton, Beurre d'Iel.
From D. Parks, Bartlett.

Apples.—From S. Downer, Porter.
From J. Dewolf, Spice Sweeting.
From E. Vose, Summer Pearmain.
From John Warren, American Nonpareil, (so called, but not rightly named.)

Peaches.—From S. Phipps, Red Rariper, Royal George.

From S. Vose, a Seedling.
From Mrs Bigelow, Rariper.

Nectarines.—From J. C. Howard, Violet.
From Thomas Mason, Elrige, Bromfield, Brynon.
Plums.—From S. Pond, Smith's Orleans, Corses Field Marshal, White Gage, Duane's Purple.

From Messrs Winship's, Small Plums, raised from stones brought from beyond the Rocky Mountains.

Grapes.—From S. Downer, Miller's Burgundy.
From J. C. Howard, Isabella, Sweetwater.

From Mrs Sarah Jones, White Sweetwater.
For the Committee,
L. P. GROSVENOR, Chairman.

ROXBURY, SEPT. 15, 1838.

SIR, I send to your society specimens of Beurre Spence, Beurre Crepeaux, and Bergamotte Paysans pears. You will find them all mentioned as succeeding well as standards near London, (in London's Magazine, vol. ii. p. 253.)

The Beurre Spence is mentioned by Mr Braddish, March 1, 1826, in a letter to London, in which he says, that Van Mons told him that the Beurre Spence was "inestimable, and had no competitor."

In that same letter, he mentions the "Roi de Wurtenberg," for naming which, Van Mons received from the king of Wurtenberg a snuff box, and it is rather singular, that Mr Braddish, who had often seen the "Capiamont" several years before in England, should not have mentioned, that it was the same pear with the Roi de Wurtenberg. Mr Knight had sent me the Capiamont three years before this letter of Braddish, and though he corresponded with me ten years after, he never corrected his alleged misnomer of the Capiamont, though he did those of every other pear.

But no doubt, our experienced pomologists have good reasons for charging Mr Knight with "mis-calling" that pear. They have no doubt seen and tasted the true Capiamont, and know, that it differs from ours. Nothing short of this, could justify such a change of names, and creating such confusion in our nomenclature, when there are now, at least 10,000 Capiamonts, between Bangor and Cincinnati to both of which cities, scions went from me nearly fifteen years since.

I am, Sir, respectfully yours,
JOHN LOWELL.

Nota Bene.—My estate suffers severely in dry seasons, and my pears have partaken of the evils of this uncommon season.

It is possible that Mr Van Mons may have changed the name of Capiamont in honor of his majesty of Wurtenberg, and in the reasonable prospect of a gold snuff box—but that is no reason for our doing it.

EXHIBITION OF FLOWERS.

Saturday, Sept. 15, 1838.

Dahlias.—By J. C. Howard, Esq., Brookline, viz., Lady Furdwich, Prince George, Beauty of Cambridge, Alba Perfection, Brown's Ophelia, Brown's Desdemona, Dennis's Beauty, Cedo Nulli, Pieta Formosissima, Royal William, Queen of Wurtenberg, and Duglass's Augusta.

By Mr W. E. Carter, from the Botanic Garden, Cambridge, Dennis's Perfection, Daniel O'Connell, Duke of Bedford, Metropolitan Calypso, Beauty of Camberwell, and several others.

By Mr S. Sweetser, of Cambridgeport, Quilled Perfection.

By S. Walker, Napoleon, Lady Ann, King of Dahlias, Mrs Broadwood, Duglass's Glory, Desdemona, and Urania.

From Samuel Phipps, Esq., of Dorchester, a fine specimen of Helianthus annuus plenus.

Bouquets.—From Messrs Winship, Hovey, Howard, John Hovey and others.

For the Committee,
S. WALKER, Chairman.

Smithfield, Sept. 12th, 1838.

To the Editor of the New England Farmer.

GENTLEMEN.—I saw a statement in the Farmer of August 29th, of early corn coming to maturity, sufficient for grinding, in ninety days from planting. I planted some sweet corn on the 19th of June, and on the 28th of August, seventy days, it was fully grown, suitable for cooking. Also some beans planted the 5th of July, which on the 8th of August, thirtyfour days, were in full blow. Last spring I planted thirtytwo small potatoes in four rows, about one foot distance, the first row containing nothing but the natural soil, which was rather light, in the second was strewed a small quantity of ashes, the third, the same of lime, and the fourth, of plaster; when harvested, the weight of the first row was four pounds four ounces, the second, four pounds ten ounces, the third, four pounds, and the fourth, four pounds eight ounces. I have been an observer for 70 years, and have no recollection of the southern or Virginia corn coming to maturity here, until this season, a number of stalks in my potatoe fields, on which the corn was fully grown and glazed in the month of August. There must be some cause for this, perhaps the severe drought. If any of your valuable corres-

pondents can render an explanation, it will much oblige
A SUBSCRIBER.

[The fine warm weather with which we have been favored the past summer, has made a difference of about three weeks in the ripening of corn and seeds of various kinds. The severe drought, has of course accelerated the ripening; but has been the cause of diminishing the quantity of the crop in many cases.]

J. B.]

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, SEPTEMBER 19, 1838.

AGRICULTURAL IMPROVEMENTS. No. II.

In a preceding number we spoke of three different classes of agricultural improvements; those which are merely for sake of appearance, for purposes of ornament or embellishment; those which are useful and necessary, and not in the proper sense of the term productive; and those, which come under the denomination of productive.

We said some things about labor-saving machinery; gave some cautions in regard to the expensiveness of its construction; and the multiplication of implements classed under that head. Mistakes in this matter are so common and often so expensive and vexatious, that we shall ask indulgence for dwelling longer on this subject. We have often been in the sheds and out-buildings of some of our friends, who are certainly entitled to much credit for their enterprise and their patronage of genius, where are stowed away one upon the other, labor-saving machines of extraordinary variety and construction, threshing machines, fanning machines, straw-cutters, drill-barrows, turnip slicers, cultivators, ploughs, hoes, harrows, and other implements of agriculture too numerous to be mentioned. These having been purchased at considerable expense have perhaps upon the first trial been condemned for incompetency, and with severe chagrin and vexation have been consigned to this general repository of useless lumber. There they remain a source of unceasing mortification, and perhaps at last, when repeated disappointments and downright deceptions have chafed the spirit, they call forth an eternal and indiscriminate anathema against all patent labor-saving machines whatever. Having been through this same mill ourselves, and not simply scratched but with the whole skin torn off, we confess that the very name of a newly invented patent labor-saving machine brings over us a kind of shudder.

It would be wrong however to pronounce in such case a sentence of indiscriminate condemnation. Improvements and discoveries have been made in labor-saving machines in agriculture of the highest utility; and it proves only gross ignorance or prejudice or want of judgment or a miscalculating parsimony to neglect or refuse to avail ourselves of them. Improvements have been made in ploughs, the great instrument of agricultural operation, which have been of immense benefit. In the construction of the mould board, in the material of which the mould board and points are made (cast-iron when polished occasioning less friction than wrought iron, and a worn-out or broken point being easily supplied) in the position of the beam, in the form of the coulters, in the addition of a wheel to gauge the depth of the furrow-slice, in a revolving cutter, and in the form of the clavis or hook by which the plough is drawn, the most valuable and useful improvements have been made.

We might go on to particularize other improvements

inplements of agriculture by which great facility has been given to its operations, and a large amount of toil and time has been saved. But there are some important rules, which ought to govern the farmer in this matter. Whatever labor-saving machine offers itself for his examination, let him first fully determine that it is competent to effect the object, which it proposes to accomplish; that it will do it in the cheapest manner; that it will do it in the best manner; that it is an object of so much importance that he can afford to incur the expense of the machine for the sake of having it accomplished. Let him weigh well its first cost; the probable expense of using it, and of keeping it in repair; its strength and substance, and how long it may be expected to last. Let him examine its construction, and inspect its liability to get out of repair, and ascertain his means, in case of its derangement or injury, of putting it again into repair; and especially let him settle the point, how well, at what expense, in what time, with how much more or how much less difficulty the same work could be effected by the usual process, or by the means already in his possession. We have seen so much waste of money, and so much vexation growing out of mistakes in this matter that we cannot too strongly urge it upon the farmers "to look before they leap;" and to weigh the case most thoroughly before they involve themselves in a needless expense. Labor-saving machines are in some measure like patent medicines. In reading the advertisements of these nostrums and catholicons in the public papers, what they *can* do, what they *have done*, the cures already effected and the threatened lives which they have saved, one is almost induced to conclude that sickness may be banished at our pleasure, and that man need never die. So likewise in looking at many of the labor-saving machines which are offered to the public, one would be led to infer from what they profess themselves able to accomplish that there would be scarcely any longer occasion for bending the back or soiling the hands. But while we admit that many of these machines are of decided and admirable utility, yet, in some other cases, it costs more time and labor and trouble to put and keep the machine in operation than it would do to perform the work itself with our own hands.

Suppose that in this case, by way of illustrating these positions, we relate the experience of an intelligent farmer, a friend of ours, as we received it from his own mouth. A threshing machine of an improved construction and of great promise was offered for his purchase. A horse-power and a thresher composed the machine. He saw it operated, and it worked to admiration. The other farmers, who witnessed its operation, were loud in its praises; and promised in case he would purchase the machine and the right of use for the town and vicinity, they would hire it for their work and thus alleviate the expense. It was warranted to thresh one hundred bushels of wheat and one hundred and fifty of oats per day; and in the cleanness with which it performed the work to make a saving of nearly one bushel in ten over the ordinary mode of using the flail. With these bright and flattering visions floating before his mind he was induced to purchase the machine and the right of using it in his own town and several towns in the county. Now mark the result. The machine was heavy and difficult of transportation. It required ordinarily five persons and a horse to operate and tend it to advantage. It was difficult to find a horse that would go in it; and it was certain to injure his gait or his temper. Then it was constantly getting out of order; the band would slip off; the chain would break; the teeth would be bent or forced out of their places. Accidents as they were called would happen continually, and the men employed would feel a pleasure in such delays and misfortunes, and frequently

through their own willing or designed mismanagement or carelessness produce them, first because there is among the ignorant an almost universal and inflexible prejudice against all improvements, and second because such delays favored their indolence. Then again, in the best cases, it always came out that not more than half was done that was usually promised to be done; the specimen of an hour's work was found to be no rule for the day. Then what was the warranty worth of a wandering vender, who like a yankee pedlar was born at sea, and had neither fixed residence, nor character, nor responsibility? To complete his mortification not a farmer in the vicinity, earnest as they were in recommending its purchase, would use it after it was purchased, unless they could have the use of it without charge; and then they would show their gratitude for the kindness of the loan by abusing the machine and sneering at the folly of the purchaser. To complete the whole series of vexations comes the agreeable discovery of the invention of some new machine, which is sure to supersede it, because it will do much more work in the same time and at half the expense.

Now this is a faithful picture of what, we do not say always but what often happens, a picture drawn from real life, and fact; and which we have been at pains to delineate for the special benefit of whom it may concern. We are far from passing any sweeping condemnation upon all labor-saving machinery. We know that great improvements are yet to be made, and many are to be desired. We believe that agriculture is as likely to be benefited by the invention of labor-saving machinery as any of the manufacturing or mechanic arts. But we deem it as much for the interest of the inventors of machines of real value and utility as of the farmers themselves, that we should caution the farmers, especially the young, who are disposed to make important experiments and improvements, to move with great deliberation and inquiry in the purchase of expensive machinery.

See in the first place, that the object to be answered by the machine is important; that the machine will certainly effect it in the best and the least expensive manner. See that the machine is well made; is likely to be kept in repair at a moderate expense. See that it is simple in its construction and does not propose to do too many things at one time. And lastly see that it is a machine, whose operation you can in general superintend yourself; and the care of which you will not be compelled of necessity ordinarily to entrust to persons, who will feel little interest in its success, who will use it with carelessness and it may be take a mean pleasure in its failure and in your disappointment. H. C.

PLUMS.

We have been highly gratified with a short visit to the garden of Mr Samuel Pond of Cambridgeport, who is well known to the horticultural community as a successful cultivator of the Plum. His garden contains about one and a half acres, and mostly filled with plum trees from the seedling plant up to those of a large size in full bearing. He has a goodly number of fine thrifty trees for sale, one, two, and three years from the bud, many of them we observed were bearing fruit. The soil of his garden, seems to be well adapted to the culture of this delicious fruit. Mr Pond assured us, that he had already picked and marketed 40 bushels for which he had obtained the high price of \$5 to 10 dollars per bushel. A number of trees of later sorts were bearing under the weight of their luxurious and abundant crops. Among the varieties cultivated we noticed Duane's purple, Bofner's Washington, White and Green Gage, Corse's Field Marshal, Smith's Orleans, and other fine varieties.

The young plum trees are all worked on plum stocks, which is of much importance to the health of the future tree, and successful cultivation of the fruit. It is a barbarous custom to bud the plum upon the peach stock, as is oftentimes the case. Disappointment will surely follow,

if trees of this description are selected by the cultivator. The plum will grow luxuriantly for a short time on the peach stock, but it never bears well, and it is known to all that the peach is not so hardy as the plum, and subject to more diseases and consequently soon falls. The walls and trellises of the garden, are covered with grapes mostly the Isabella, with some sweet watered, Catawbas, Pond's seedling, &c. The vines are richly laden with fruit and nearly ripe. We anticipate another call and hope to be as well satisfied in testing the quality of the grape as we were of the plums.

It is a pleasure to witness the reward of Mr Pond's labors. It should be remarked that the cultivation of the garden is not his primary business; it has been as we understand his recreation, or in other words the odd hours which have been devoted to this delightful employment.

J. B.

RECIPE FOR PRESERVING TOMATOES.—The following is an easy and safe mode for preserving tomatoes, to be used during the winter. Take the tomatoes and cut them open, and dry them in the oven, either upon the bottom of the oven or in pans; and when perfectly dried pack them away in some dry place, till wanted for use.—Communicated.

BRIGHTON MARKET.—MONDAY, Sept 17, 1838.
Reported for the New England Farmer.

At Market 520 Beef Cattle, 450 Stores, 3,200 Sheep, and 1,000 Swine.

PRICES.—Beef Cattle.—Sales were brisk and last week's prices were fully supported. First quality \$7 37 1/2. Second quality, \$6 50 a \$7 00. Third quality, \$5 00 a \$6 25

Wool.—In demand and sales quick at an advance We quote, Yearlings, \$9 a \$13. Two Year Old \$16 a \$28. Three Year Old, \$22 a \$33.

Sheep.—Sales were effected at \$1 50, \$1 62, \$1 84, \$1 88, \$1 92, \$2 12, \$2 42, \$2 50, and \$2 88.

Swine.—About all at market were sold. One entire lot at G 1-4 and one at 5 3-4 and 6 3-4. Loin to peddle at 6 and 7, and 6 1-1 and 7 1-4. Selected barrows at 7 1 2 and 8. At retail, from 7 to 9.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending September 16.

HORTICULTURAL EXHIBITION.

The Annual Exhibition of the Massachusetts Horticultural Society will be held at the Society's new Rooms, No. 23, Tremont Row, (nearly opposite the Savings Bank) on Wednesday, Thursday and Friday, 19th, 20th and 21st September.

The members of the Massachusetts Horticultural Society, and the public generally, are respectfully invited to contribute choice and rare specimens of Fruits and Flowers for the exhibition, and to send the same to 23, Tremont street, on Monday or Tuesday, 17th and 18th inst., where Committees will be in attendance to receive them, and will retain the same subject to the order of the contributors.

Members of the Society will receive their Tickets on application to the Chairman of the Com. of Arrangements.

Season tickets, and tickets for a single admittance, may be had at the door during the exhibition.

By order, SAMUEL WALKER, Chairman of Com. of Arrangements.

Sept. 10, 1838.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Iron Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham. ISAAC PARKER.

WANTED TO HIRE

A single Man, who is capable of taking charge of a small Farm. Inquire of JOSEPH BRECK & CO. Sept. 5.

FARM FOR SALE.

An excellent farm, near the centre of Framingham is offered for sale, on liberal terms. Inquire at this office. Aug. 22, 1838.

LAYING OUT GARDENS AND ORNAMENTAL PLANTATIONS.

E. SAYERS begs leave to inform his friends and the public in general that he will attend the laying out gardens and ornamental plantations, and hopes by strict attention to business to merit the approbation of those who may be pleased to employ him.

All orders left with J. Brock & Co. Agricultural Store, No. 52 North Market Street, will be punctually attended to.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders to any amount, which will be promptly attended to.

Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston.

Sept. 20. NAHUM WARD.

FRUIT AND ORNAMENTAL TREES, MULBERRIES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces,

Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honorables, Peonies, Dahlias and other Herbaceous Flowering Plants.

225,000 MORUS MULTICAULIS are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired.

Also, Broussa and other varieties Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. D. BRECK, Commission Store, No. 132 Water Street, New York, M. S. PEWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston. August 1, 1838. WILLIAM KENRICK.

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more as may be wanted, of the most approved kinds—consisting of the best selected varieties now in use, for cultivation, feeding worms, and making silk;—being acclimated to this country, and adapted to either warm or cold climates, affording a rare opportunity for companies or individuals to be supplied, from the most extensive collection of mulberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and orders left with Messrs. I. B. Colt, Secretary of the Connecticut Silk Manufacturing Company, Hartford; Alonzo Wakemau, at the office of the American Institute, No. 137 Broadway, N. Y.; Thomas Lloyd, Jr. No. 236 Filbert street, Philadelphia, Pa.; Luther C. Cox, Baltimore, Md.; E. Snider, & Co. Savannah, Ga.; Bliss Jenkins, & Co. Mobile, Al.; James Lyman, St. Louis, Mo.; Case and Judd, Columbus, O.; G. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass.

Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Mulberry Plantations. Apply at the office of D. STEBBINS, Northampton, Aug. 22, 1838.

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dame, situated in Rochester, N. H., six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with bars and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quarries of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to JOSEPH BRECK & Co., No. 51 and 52 North Market Street, Boston. August 15, 1838.

FOR SALE.

Five acres of good Salt Marsh, in Quincy, or (Squantum so called.) Also, Four acres of Salt Marsh in Brighton. Also, Several full blood animals, cows and calves. Apply to A. Greenwood, on the Welles Farm, Dorchester, near Dr. Codman's meeting house. Sept. 12, 1838.

PUDDING AND BEANS.

Oh! what is there *better than pudding and beans!*
Nor turkey; nor surlion; nor mutton and greens,
Can vie with the honest "old Indian," well done,
Well lathered with 'lasses, as bright as the sun.

'T was our forefathers' dish, in rough times of yore,
When first they "took lodgings," on old Plymouth shore;
The corn for their food; and cold water to drink,
Made hearts to resolve, and cool oodles to think.

'T is the pride of their sons on Saturday night,
When winds whistle loud, and the kitchen burns bright,
All round the oak table to huddle with glee,
And flourish their trenchers in right jollity.

Ah! what soaring succeeds among the "old folks,"
While the youngsters are slyly whipping the yolks
Of eggs, newly laid, and when mingled the "pop,"
All hands on the floor, for a reel or a hop.

Oh! pudding and beans!—the delight of my youth;
When loved all the lovely, with ardor and truth;
When women were true; and their lovers were gay
As roosters on barn-top, and hens in the hay.

J. E. D.

FAMINE IN INDIA.

The upper provinces of the Bengal presidency were (when the last despatches reached England,) the scenes of the most frightful misery and mortality. Owing to the extreme poverty of the natives, occasioned by the impolitic and ruinous system pursued by the government of India towards the occupiers and cultivators of the soil, tens of thousands have been reduced to utter starvation. On the 14th of April last, 78,000 pining wretches, men, women and children, were fed by bounty at Agra; and between the 1st and 15th of March 71,000 infirm and sightless creatures were relieved in a similar manner. So great have been the ravages of death that the air for miles is tainted with the effluvia from the putrefying carcasses of men and cattle, and the rivers of the Jumna and Ganges choked up and poisoned by the dead bodies thrown into their channels. The water and fish of these rivers are rejected as unfit for use, and men are kept constantly employed in pushing the accumulated bodies down the torrents. From the July number of the *Oriental Herald* we learn that starvation, disease and death, are doing their work at Cawnpore, Muttra, Gwalior, and Delhi, while the wealthier natives look on with listlessness and unconcern.—Though a famine fund has been established by the European public of India, it is found impossible to meet the necessities of the destitute and dying multitudes.

A correspondent in Calcutta thus writes on the 10th of April:—"Since the despatch of the overland mail for Berenice, which left Bombay at the close of that month, public attention in this quarter has been engrossed by the accounts which daily reach the capital of the horrid ravages of famine in the provinces to the west and northwest. It is impossible to compute the numbers who die in their tedious progress from the desolate districts to the towns where food is procurable. We hear almost daily of mothers deserting their children on the highways; of infants crawling around the gran-

aries to pick up the grains of rice accidentally scattered during the process of distribution at the doors; of the roads being lined with dead bodies, a prey to the vulture and jackal; of the courses of small rivers actually obstructed by the masses of bodies thrown therein, by those who are employed to clear the highways; of the inhabitants of the large towns of Agra, Cawnpore, &c. being compelled to abandon their evening drive, from the impossibility of encountering the effluvia from the putrid corpses around! And the worst of it is, that two months more must elapse before a fall rain can be expected, and the earth yield fruit wherewith to appease the irresistible cravings of hunger.

CURE FOR HYDROPHOBIA. As the Hydrophobia season has set in, we comply with the request of a correspondent by giving insertion to the following. What we happen to know of the extraordinary property of the chloride of lime induces us to put great faith in its properties, in the cure of the wound inflicted by dogs, above other means.—*Editors Mercury.*

We are indebted to M. Coster, a French physician, for the following valuable discovery, as a preventive to hydrophobia. Take two table spoonsful of fresh chloride of lime in powder, mix it with half a pint of water, and with this wash keep the wound constantly bathed, and frequently renewed. The chlorine gas possesses the power of decomposing this tremendous poison, and renders mild and harmless that venom against whose resistless attack the artillery of medical science has been so long directed in vain. It is necessary to add that this wash should be applied as soon as possible after the infliction of the bite.

Another plan which has been extensively tried at Breslau and Zurich, and many other parts of the continent, consists not merely in cutting out the bitten part, (mere incision has been found too often unavailing,) but in combining with the incision effectual means for keeping open the wound and maintaining it in a state of suppuration during a period of at least six weeks. Other curative means as the exhibition of mercury, bella-donna, or lytice, were also employed in these cases; but upon these, it is thought that but little reliance can be placed. The following are the results of this treatment:—From 1801 to 1824, the number of persons admitted into the Breslau hospital was 184, of whom two only died of Hydrophobia; from 1783 to 1824 inclusive, there were admitted into the hospital at Zurich 233 persons bitten by different animals, (182 by dogs) of whom only four died,—two on the second day of admission, and in whom the disease had probably become developed before they were submitted to the treatment, and the other two were bitten in parts (inside of the cheek and eyelid) where the prescribed means could not be employed with the requisite exactness.—*Liverpool Mercury.*

A writer in the Genesee Farmer says, "When I was a school boy I had a large wart upon my thumb. My teacher told me to rub it against my front teeth as soon as I awoke in the morning, for a number of mornings, and it would soon disappear. I obeyed, and my wart disappeared in less than two weeks, without pain, except in the act of rubbing. I may add that I have had warts at times since, (being now 54 years of age,) and the same means applied for a short time always removed them."

NEW ELEMENTARY WORK ON BOTANY.

Peter Parley's Botany; with descriptions of Trees, Shrubs and Plants; with a large number of fine engravings.

The publishers invite Teachers, and others interested in this subject, to examine this work, as they believe it will be found one of the most practically useful in use, being a complete manual of Botany for the adult and the pupil.

Parley's Cyclopaedia of Botany.—This work appears to be exactly what is wanted by young persons and in families. It not only contains the strictly scientific part of the subject, in an introduction and very full and complete genera of Plants, but it also contains a copious glossary of terms, and what is most important, a Dictionary of Plants, of nearly 300 pages, containing familiar descriptions of all the most interesting trees, plants, and shrubs.—These are alphabetically arranged, with an English index, so that the reader may immediately turn to any plant he wishes to read about. The work is illustrated by over 200 engravings, and is sold very cheap.—*Boston Paper.*

For sale at the New England Farmer Office, 51 & 52 North Market Street. JOSEPH BRECK & CO.

REMEDY FOR CANKER WORMS

The subscriber having obtained letters patent for his circular metallic trough and roof for preventing canker worms or other insects from ascending fruit or other trees, now offers his services to apply the same to any extent that may be wanted. They were put on to three orchards belonging to Jonathan Dennis in Portsmouth, R. I., in the autumn of 1837, and exterminated the canker worms so completely that some of the trees have so full of apples as to render it necessary to prop them, although they have been eaten by the worms for a number of years previous, notwithstanding the application of tar. The public are invited to examine the orchards above referred to. The trough and roof is made of lead and bent to conform to the shape of the tree, and the ends soldered together and made enough larger than the tree to allow the trees to grow ten years before it will fill the space. The space between the trough and the tree is filled with hay, straw, seaweed, or any substance that is easily compressed by the growth of the tree; the trough is kept in its place by three nails driven into the tree below it; when the tree has grown so as to fill the space, the trough may be enlarged by putting in a short piece so as to answer ten years more. A little cheap oil is sufficient to fill the troughs and filling them three times has been found to answer for one year, by stirring the oil once sometime after they are filled. Those who wish to have their trees fitted, would do well to make early application to the subscriber, postage paid. For sale, State, Town and County rights by

JONATHAN DENNIS, Patentee,
Portsmouth, R. I., August 22, 1837. 4w

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land, situated on Nonantum Hill, in Newton 5 1-2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

LOT WHEELRIGHT.

July 16th.

ALDERNEY STOCK FOR SALE.

For sale, a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27.

AMERICAN FLOWER GARDEN COMPANION.
The American Flower Garden Companion, adapted to the Northern States.

By Edward Sayers, Landscape and Ornamental Gardener. Published by JOSEPH BRECK & Co., and for sale at the Agricultural Warehouse and Seed Store, No. 51 and 52 North Market Street, Boston.

From the Genesee Farmer.

WARMING HOUSES.

Some of our subscribers and correspondents, who oppose building houses, have requested some information as to the best method of heating them during our winters, and this may serve as an apology, should one be deemed necessary, for the introducing of a topic more properly belonging to another season of the year.

The saving of fuel is daily assuming a greater importance among the inhabitants of this country, where the forests are rapidly disappearing, or here, as in many sections of the wide west, the country has always been destitute of timber. The road fire places of our paternal mansions have been superseded by stoves; and to supply these with fuel where a number are required, as in the usual method of warming houses, is found to occasion heavy drafts on the income of most individuals. The great waste of heat that takes place in all the ordinary stoves and fire places, has turned the attention of men of science to the providing a remedy for the evil, and to efforts to provide a suitable temperature at a less expenditure than is usually incurred. Various methods have been suggested for economizing heat, some of which we shall notice. All are on the principle of warming a house by a single fire, and all are more or less efficient for that purpose.

A few years since, Mr Fessenden, late editor of the New England Farmer, devised, and patented, we believe, a plan for warming rooms by hot water, and the system has been acted upon to a considerable extent in some of the eastern cities and large manufactories. It is founded on the well known fact that warm water always rises, and will continue to do so until the whole mass is brought to the boiling temperature, should the heat be continued to that point. A copper boiler is placed in the lower part of the building to be warmed, and pipes of copper connected with the boiler rise and pass through the various rooms to be warmed. These pipes, as well as the boiler, are water tight, and are filled to the top with water. When the fire is kindled, the water in the boiler being first warmed rises in the tubes, and displaces the cold water, which sinks into the boiler to be heated in its turn. Thus the circulation is kept up, and the rooms are gradually and equally warmed by the hot water contained in the pipes. This method has been highly approved for heating green houses, the heat being considered less drying and injurious to growing plants, than air heated by direct contact with iron stoves. That it will come into general use can hardly be expected, however, the apparatus requiring a nicer adjustment than can in ordinary cases be expected. It has one great advantage to recommend it, and that is, fires can hardly ensue from the use of such pipes; a difficulty which renders the ordinary stove most objectionable.

Several plans for warming rooms with heated air have been devised, one of which was described in the 6th vol. of the Farmer; but as our list of subscribers has since that time greatly increased, we shall for their benefit give the plan there presented, and which has, where adopted, succeeded admirably. The apparatus consists of a large box stove, surmounted with two flat cast iron drums, and these again by two sheet iron ones. These four drums are made to communicate with each other, and with the stove by short pieces of pipe, joined to their alternate ends. The smoke and heated current of air, after it leaves the stove, is thus broken in its course eight times, and is deprived of its heat before it finally passes away. The heat is communicated to the air outside the drums, which rises in large volumes about them, in consequence of the increased temperature; and is retained from escaping by a brick wall around the whole apparatus, except the door of the stove which is left even with the outside of the wall. A chamber is thus formed, from which the heated air (in tubes) is at once conducted to any part of the house. The apparatus is placed in a small open cellar, and renders all fires above stairs unnecessary." Perhaps if the drums were placed vertically, instead of horizontally, as suggested by the inventor, the current from the stove would be sooner and more effectually deprived of its heat.

In Prof. Silliman's Journal for April, 1838, there is a communication on this subject from a gentleman in Virginia, in which the objections against this mode of warming houses are pointed out and obviated. His dwelling was warmed by such a furnace and air chamber, and as the air was admitted into the chamber of the furnace from the hall, or basement room, the air ascended to the parlors loaded with coal dust and other impurities. This evil was at once remedied by obtaining the air in pipes from without the house. This, besides obviating the difficulty of the dust, furnished a constant supply of fresh air. In rooms warmed by heated air, (and the difficulty attends nearly in an equal degree those warmed by a common stove,) it is found that the thermometer indicates a higher temperature in the upper part of the room than in the lower part, frequently as much as six or eight degrees, thus keeping the feet almost constantly cold, while the person is comfortable in other respects. This state of the air, reverses the injunction of Boerhave, to keep the feet warm and the head cool, and as far as its influence extended was injurious to health. As the rooms were tight, it was evident that the warm air after parting with its caloric settled to the floor, and remained there causing the reduction shown by the thermometer. To remedy this, a pipe was led from the floor to the bottom of the air chamber in the furnace, and the cooled air passed off so rapidly, that when a supply of fresh air was admitted by a pipe into the parlor, to keep up the purity of the air, the quantity of which could be regulated by a valve, the thermometer gives a difference of only a degree and a half between the lower and upper part of the room.

This arrangement has been tested for five years, and has been perfectly satisfactory.

It may be here remarked, that where it is required to give out heat, as in the case of the stove and drums to the air chamber, rough and black bodies are far preferable to bright or polished ones; and for the same reason, the pipes that convey the heated air from the air chamber to the several rooms, should be smooth and bright, that the heat may not be given out on its passage. That a house may be warmed in this way from a single fire, does not admit of a doubt; and that it is far more economical than the usual process, is equally clear. We may, however, be permitted to suggest to those about to build, that a little additional expense in building, will do much more towards making a house comfortable, than a greater sum after it is built; and that it is better to shut out the cold air, than to devise ways and means for heating it, after it is once admitted. This is the true economy, and this our climate demands of us.

Since writing the above, we have seen in the London Chronicle an account of a new invention for warming rooms, which promises to supersede all others. A stove six inches in diameter and eighteen inches high, is enclosed in a cylindrical case of thin copper, the bottom of which, as well as that of the stove, is perforated for the admission of air, and the top of which is furnished with a damper or regulator to determine the heat. Such an apparatus will warm a room 25 feet square, and 12 feet high; does not require to be fed with fuel but once a day, and the expense of fuel daily is four pence. The fuel is charcoal. This fireplace has the form of a small column, is moveable, and may be made ornamental. It is evident from the fact of there being no flue or chimney required, that the charcoal is prepared in such a way as to prevent the formation, or secure the absorption, of carbonic gas; and since the patent has been secured, this preparation is all that remains a secret in the apparatus. Should it realize the benefits prophesied of it in the English journals, we may soon expect the method will be translated to our shores, and the wonderful properties of "Joyce's Heating Apparatus," as it termed, be tested among ourselves.

From the Farmer's Cabinet.

SOILING NEAT CATTLE.

The system of soiling has strenuous opponents, as well as many ardent advocates. But I believe that the system has never been fully settled by thorough and long tried experiments. A system is not to be established, nor overthrown in a day. We do not arrive at certain results in agricultural improvements by jumping conclusions. All improvement is the result or consequence of steady, progressive and judicious means. Those who undertake experiments are apt to abandon them at once, and in disgust, if success does not attend their first effort. This is wrong. It is important for us in establishing results to view both sides. It is altogether necessary that we know the failures of at-

tempted experiments. It is as essential as it is to be assured of successful results. All tend to increase the store of general knowledge. All knowing wherein there has been a failure, and the course pursued, we can then enter into an investigation of the causes. Let no one be discouraged because a first or second effort is not crowned with success: A farmer has this advantage, that he can experiment on a small scale. The soiling system, as I before remarked, has not been satisfactorily settled. Its opponents contend—

I. That the soiling of cattle in the house during the whole of the year, is not only not beneficial, but positively injurious. This position is maintained by the following grounds:—1. It is natural. 2. Animals, thus kept, are deprived of air and exercise, and the selection of their food. In the experience of some farmers, cattle thrive much better in the fields, or open air, than when housed.

On the other hand, the advocates of this system say—

I. That it is a considerable saving of land, that is, one acre of cut grass soiled being equal to three acres of the same field pastured. The grasses grow much more rapidly in consequence of not being trampled upon.

II. It is a great saving of food, for when, say the compilers of the Complete Grazier, "animals are suffered to go upon the field, many plants are necessarily trodden under foot, and bruised, or partly buried in the earth, in which state they are greatly disrelished by cattle, and are suffered to run to waste; a circumstance which never could occur, if the practice of cutting were adopted." If the consumption of plants is an object, that object is obtained by soiling, for all who have paid attention to the subject must have observed that cattle will readily eat plants cut, and given to them when housed, which they would discard in the pasture; yet, according to the authority above quoted, it is known that they will feed, when thrown to them on the ground, which they will reject when given in the stall. Many of the grasses which are sweet and succulent when young, and which cattle eat with the greatest avidity, are quite offensive when suffered to get into ear, and are thereby lost; but by this system of cutting, no loss can occur from this quarter. Plants rejected by one class of animals, when presented to them, even when housed, are not on that account less acceptable to others; indeed they appear to be eaten with greater avidity. "Thus grass, or other food, that has been blowed or breathed upon by any animal for a considerable time, becomes unpleasant to other beasts of the same species, but not so to a stock of another class or variety; for them, indeed, it appears to acquire a higher relish."

III. It is contended by the friends of the cutting system, that the balance, so far as regards the health and comfort of cattle, is decidedly in its favor over that of pasturing. Cattle are not only less liable to accidents, but do not suffer the same inconveniences or annoyances to which they are subject, when exposed to the sun in the open air—they suffer much less from heat, flies, &c., and it is perfectly reasonable to suppose that they take on flesh more readily. Tranquillity and ease are essential; otherwise animals cannot thrive. An instance in point was cited by one of your correspondents, (see Cab. Vol. ii. page 295,) from which it appears that animals housed for fattening, and well fed, did not take on fat, owing to the circumstance of their becoming lousy, in consequence of fowls roosting over

them. The reason why they did not thrive, is obvious—when cleansed of the vermin they fattened well. Heat, restlessness, the terrible annoyance of flies, &c., when cattle are exposed, as they must frequently be in pastures, operate against them.

IV. The Complete Grazier asserts that the proportioned increase of manure obtained by soiling and stall feeding abundantly evince their superiority over pasturing. "Manure is the life and soul of husbandry; and when tillage is an object of attention, there can be no comparison between the two modes of consumption, especially in regard to manure obtained by soiling live stock during summer with green food, for in consequence of the increased discharge of urine during that season, the litter, of whatever substance it may consist, is speedily converted into dung."—p. 81.

Nicholson, in his Farmers' Assistant, refers to a communication from Dr. Thayer, of Hanover, detailing the result of the experience of Baron de Bulow, and others: He lays down the following as facts, which he says, are incontrovertible.

"1. A spot of ground, which, when pastured, will yield only sufficient food for one head, will abundantly maintain four when left in the stable.

"2. Soiling affords at least double the quantity of manure from the same number of cattle: for the best summer manure is produced in the stable, and carried to the fields at the most proper period of its fermentation; whereas, when dropt on the meadow, and exposed to the action of the air and sun, its power is much wasted.

"3. Cows which are accustomed to soiling, will yield much more milk, when kept in this manner, and fattening cattle will increase much faster in weight.

"4. They are less subject to accidents and diseases—they are protected from the flies which torment them in the fields during the warm weather; and they do not suffer from the heat of summer."

Many other advantages are enumerated. Grazing also has its advantages. Experiments, however, render it certain that soiling, under favorable circumstances, is the most profitable. The Hon. Josiah Quincy, of Massachusetts, ascertained about 1820, that seventeen acres of land, under the soiling system, supported as much stock, and in as good, if not better condition, as had previously required fifty; and Sinclair states, that thirtythree head of cattle were soiled from the 20th of May to the first of October, 1835, on seventeen acres and a half, of which fifty were necessary in pasture. The saving of land was consequently thirtytwo and a half acres. From my own experience and observation, I am fully satisfied that there is no mode by which cultivated grasses will pay so well as by soiling. With us Jersey farmers, who can so readily derive the great advantage of top dressing by marl, lime, &c. it is nevertheless an object to turn all to the best account.

Burlington Co. July 23d, 1838.

BONE MANURE.

Bones possess very fertilizing powers as a manure. In an experiment of Mr. Watson, of Perth Amboy, with bone dust, who applied it to corn, at the rate of sixteen bushels to the acre, it exceeded in its effects the highest manuring with yard manure or with fish. It does not in general, produce much effect the first year, unless it has been fermented before the application to the soil; this process of fermentation is effected by mixing 25 bush-

els of leached ashes with 40 bushels of bone dust, moisten the whole with water, and at the end of twentyfour hours, the heap will commence smoking, when the whole should be turned—after laying ten days it will be fit for use. Bone dust is known to be in fermentation by the heat, and the strong smell; before being fermented, it is white, or of the color of bone; after, it assumes a yellowish cast.

The quantity of bone dust applied in ordinary cases, is about 20 bushels per acre—if the bones are coarsely broken, 40 bushels should be applied; but in this the farmer must be governed by the quality of the soil; poorer lands requiring more, and those in a higher state of cultivation, less.

Bone manure should be placed within about two inches of the surface; and owing to the small quantity used per acre, the seed should be brought as near to it as possible, without immediate contact, which it is thought better to avoid. In the preparation, a decided preference seems to be given to bones broken small, and the half inch bones are those most generally used. Mr Birks states, that were he to till for early profit, he would use bones powdered as fine as sawdust; if he wished to keep his land in good heart, he would use principally half-inch bones, and would prefer some remaining considerably larger. The reasons for which belief are, that by using bones of a larger size with the dust in them, there would be sufficient of the small particles of the dust to set the (turnip) crop forward, and sufficient of the large particles of the bone left, to maintain the land in good condition for the next crop—it is the small quantity needed to produce a given effect, that renders manures of this class so remarkable.

The soils to which they are best adapted, are those of a light and warm nature, for upon wet or cold ground, they have rarely been found to produce any sensible effect. On heavy loams and clay, the accounts of their operations have been almost invariably unfavorable, and it may be laid down as a necessary qualification, in a soil fit for the application of bones, that it should be dry.—*Salem Observer.*

IRRIGATION.—Irrigation is a practice which has not yet been introduced, to hardly any extent, into agriculture in this country; but which would, in most seasons and situations, abundantly repay the husbandman for all the expense and labor attendant on the practice. What an immense value in crops might have been saved during the late drought, had the watering of fields by artificial means been in use to the extent to which it is susceptible!—There is always water enough in the bowels of the earth; and the drawing of it forth and diffusion of it are not so difficult and expensive matters as might at first be imagined. A common well sunk in a favorable spot, with simple horse power applied to a common pump, would in a dry time, be found of great saving benefit even to acres. Many fields are so situated that the springs in the neighboring hills, with little ingenuity and not much expense, might be made to diffuse their animating contents over them, greatly to the advantage of any kind of crop. Artificial means of watering would be found beneficial in most ordinary seasons; but in times of great drought, of incalculable benefit. The most flattering promises of abundant crops, have in many cases, been destroyed by the recent hot and dry time which has been experienced in this State and elsewhere.

We speak not from self experienced knowledge in this matter: but from the dictates of common sense, from what we have read upon the subject. We believe that a method, which might be turned to much good, is hardly thought of among our agriculturists. Irrigation is much employed in many countries in Europe, and with great advantage. In Italy there is scarcely a field or garden which is not furnished with the means of artificial watering. The Milanese territory exhibits the greatest expanse of irrigation known in Europe. In that country are to be seen noble canals, running in every direction for this purpose. They are under the authority and protection of the government, which lets out the water to the various occupiers of meadows, at a fixed rate, according to the quantity supplied. Sometimes these canals are farmed out, by putting up the several sluices at auction; in other instances the canals go with the lands.

We contemplate nothing in this way on a public or so extensive a scale; but believe that much might be done in cheap way by individual enterprise. These few thoughts upon this subject are the suggestion of a *dry time*; and we believe that there is as much reason and utility in them as in most of the political essays and paragraphs, which meet us on every side.—*Salem Observer*.

SWINE.

The following observations respecting this ugly, uncouth, but useful animal, are mostly condensed from a number of authors on both sides of the Atlantic:—

It is best to begin to fatten hogs the latter part of August or the beginning of September, so that they may be fit for the butcher before the weather becomes very cold, as it is very difficult to put flesh on them in cold weather.

When you commence fattening swine, care should be used not to give them more than they will eat with appetite. If they become cloyed, their thriving is retarded, and there is danger from staggers and other diseases. Their troughs should be replenished with a small quantity of food at a time, and kept always clean and well seasoned with salt.

An English farmer fattened eight pigs in the following manner, which may be recommended in cases where a constant and regular attention cannot be given to feeding the animals. He placed two troughs in the sty; one he filled with raw potatoes, the other with peas, and gave no water. When the pigs were thirsty they ate the potatoes. In this way it is probable that the animal would not only thrive without water, but need no antimony, brimstone, nor other medical substances; for raw potatoes being cooling and loosening, might serve at once for food and physic. Instead of peas, perhaps dry Indian corn, or what would be better, Indian meal might be substituted. This mode of management with swine, was first recommended in the *New England Farmer* of Aug. 16, 1824, and we are glad to see that it has been adopted by a writer for the *Northern Farmer*.

Cunningham, in his *Two Years in New South Wales*, relates,—“I had often heard it said among sailors, that pigs would fatten on coals, and although I had observed them very fond of mashing up the coals and cinders that came in their way, still I conceived that they might relish them more as a condiment or medicine than as food, till I was assured by a worthy friend of mine, long in command of a ship, that he once knew of a pig's being

lost for several weeks in a vessel he commanded, and it was at last found tumbled into the coal hole, and there lived all that period without a morsel of any thing to feed on but coals: on being dragged out, it was found as plump and fat as if it had been feasting on the most nutritious food. Another friend told me of a similar case which came under his observation, and although these may be solitary instances, yet they serve at least to show the wonderful facility which the stomachs of certain animals possess of adapting their digestive powers to such an extraordinary species of food, and extracting wholesome nourishment therefrom. When we consider coal, however, to be a vegetable production, containing the constituent principles of fat, carbon, hydrogen, and oxygen, our surprise ceases.

I always cause as many peas as I want for feeding my hogs, which are not a few in a year, to be regularly malted in the same manner, nearly, as my barley; this management has succeeded very well with me. Young pigs require warm meat to make them grow. Corn and cold water will make them sleek and healthy; but warm beverage is considered requisite to a quick growth.

EVERY STYE SHOULD HAVE A RUBBING-POST. Having occasion to shift two hogs out of a sty without one, into another with a post, accidentally put up to support the roof, I had a full opportunity of observing its use. The animals when they went in were dirty, with broken ragged coats, and with dull heavy countenances. In a few days they cleared away their coats, cleaned their skins, and became sleekly haired; the enjoyment of the post was discernible even in their looks; in their liveliness and apparent contentment.

From experience, I have found that swine prefer lucerne to clover. A small quantity of corn, peas, or beans, is certainly necessary to be given to them. Potatoes, either whole or mashed in the water in which they are boiled, or mixed in the trough with barley meal scalded, is very good feed for swine. When rearing, a small quantity of food given once or twice a day, with lucerne, clover, grass and offals, is sufficient. When fattening, a constant supply is essentially necessary, so as not to leave the troughs encumbered with stale food, which should be cleaned out and given to store swine. An iron kettle is best to boil potatoes in, as copper, brass, and lead, are extremely dangerous and generate poison, if allowed to be left with any water in them, therefore it is necessary they should be immediately emptied and cleaned out. Swine while fattening should be kept as clean as possible and well supplied with dry litter. Two or three times in a week add about three table spoonfuls of salt to each bushel of their food, which assists digestion and promotes appetite.—*Essex Gazette*.

SILK FACTORY.

Norhampton, Visited Mr. Whitmarsh's establishment, and although I had heard much of his factory, I was most agreeably disappointed. Few men in this country deserve more credit for enterprise and industry. But a few years since he was a successful merchant in Broadway. He retired to this place, since which, he has visited various parts of Europe, to obtain information relating to the Mulberry, the worm, and the manufacture of silk; and, unlike nearly all his travelling countrymen, he has brought his knowledge into practical usefulness. He purchased a neglected spot, which he has im-

proved to such a degree, that it now presents one of the most tasteful country seats that adorn our country, and has erected a fine cottage, after the Corinthian order, not unlike in appearance the Hall of Record, in the Park. The grounds are laid out with a taste that would do credit to an English nobleman. The great objects of attraction, however, are his mulberry grounds, his cocoonery, and his factory. In the first are fields of the plant: they are placed in hedges, about four feet high and about eight feet apart, and men are constantly employed in hoeing them and keeping the ground perfectly clear of weeds and grass. He has every variety of plant, and is making valuable experiments as to which species will best suit the climate, and yield the finest and best silk. Many of these plants he brought from the villas of Italy. His cocoonery is a building of two stories, about thirty feet wide and a hundred and fifty feet long; here are different shelves or tables, on which are myriads of worms in all their different stages, from that of hatching from the egg, to that of winding up their balls. The whole labor of feeding and attending to these myriads of ‘manufacturers’ is done by a few females, and is neither arduous nor unpleasant. There are two manufactories, and a third now building. The smallest is the one I examined. It is beyond my power to detail the progress of the manufacture. Every thing appeared neat, and the girls cheerful and happy. The silk, from the raw to the manufactured state, is here perfected, and sells much higher than the imported.—*N. Y. Express*.

Town House, Hartford, Sep. 26, 1836.

MR BOSWELL: Sir—We present you with three stalks of corn, the product of one kernel; the main stalk measures from the root to the top 13 feet 8 inches, the longest sucker 12 feet 10 inches, and the shortest one 11 feet 11 inches—total 38 feet 5 inches—having three full ears of corn. The circumference of the largest ear is 11 inches; the circumference of the three stalks in the thickest part is 13 1-4 inches: it grew in the midst of a field of broom corn, 80 full-grown stalks of which growing within an inch of four feet from it. Now we do not exhibit this stalk of corn for the purpose of shewing our superior skill in farming, but having noticed in your paper that several exhibitions of the kind have been made the present season, it is to show that we have something that goes a little beyond any thing of the kind yet produced; but most of all it is that you may see that kind Providence in rewarding the rich with an abundant harvest, has not been unmindful of the poor.—*Con. Cowrant.* V. CORNISH.

WOOL.—The vast quantities of this article which have been transported from this wool-growing section to Boston and other markets, during the few past weeks are astonishing. Almost daily, eight-horse teams pass through our village, groaning beneath their loads of this commodity. We understand from a gentleman who is acquainted with the matter, that but little remains unsold in this vicinity. This circumstance, together with the overwhelming amount of every article of production, which our agriculturists are gathering to their granaries, with joyful hearts,—must of necessity, cause business to revive, and bring our farmers that ample return, which should ever be the just need of honest industry and the “sweat of the brow.”—*Newport, N. H. Argus*.

GEOLOGY OF MASSACHUSETTS.

[Concluded from page 93.]

Clay in Agriculture.—There is abundant evidence that our common clays are of great value when spread upon land. I find that they have been used to a considerable extent in the state; so commonly, indeed, that I abandoned the idea I had formed of giving a detailed account of particular instances. So far as my inquiries have extended, the testimony is decided that our blue clays exert a very favorable effect upon the soil. When spread upon sandy ground we might expect that they would render it a better reservoir for salts and geine. But thoroughly to ameliorate our sandy soils in this way, requires far more clay than is usually employed, and I am perfectly convinced that they exert other than a mechanical influence; that in fact, their effect is analogous to that of lime. I refer here to the blue clays which are far the most common. As to the white clay I have not learnt its effect upon the soil; but from the fertility of some of the soils in Kingston, Plymouth, and Barnstable, where white clay is mixed naturally with sand, I presume this sort is equally valuable with the blue.

In view of the wide extent of our beds of clay, and the use that might be made of it upon land, I felt desirous to ascertain to what principle it owes its fertilizing powers; and therefore subjected a few specimens to analysis in the ordinary way by solution in alkali. The following are the results. I omit however certain white clays, which I found destitute of iron, and therefore probably not very likely to be of much value upon land. But for other purposes, of which I shall speak shortly, they are of a good deal of importance.

Analysis in the Dry way by Alkali.

No.	Locality.	Water & Organic Matter.	Silica.	Alumina.	Protoxide of Iron.	Oxide of Magnesia.	Lime.	Magnesia.	Sulphur and Loss.
139	Northfield, blue.	10.8	46.93	28.97	9.9			0.1	2.9
140	Sunderland, light blue.	8.2	49.00	29.15	13.1	0.15	slight prec.	0.4	
142	Kingston, white.	3.5	71.00	16.30	7.3	0.30	do.	0.3	1.3
143	Lowell, white.	4.6	61.52	20.50	9.2	0.56	0.44	3.22	

I tried some of our blue clays also, for geine; but in general they yielded only very little, and perhaps none. For so strongly do they retain water, that not improbably all the loss, especially of soluble geine, might have been imputed to this substance, which had not been all expelled by a heat of 300° F.; and then the peroxidation of the iron by ignition, renders this method of analysis quite uncertain. I, therefore, omit the results; only observing, that the amount of sulphate and phosphate of lime obtained, was about the same as in good soils. I therefore suspect that we must impute most of the good effects of clay as a manure to the large quantity of iron which it contains. On this point, however, I will present some suggestions of Dr Dana, with which he has kindly favored me.

"If we attempt," says he, "to account for the action of *clay*, independent of its amending a sandy soil, we should bear in mind that all our common clays contain more or less of sulphuret of iron.—The conversion of this into the persulphate of iron

is the natural consequence of exposure; free sulphuric acid then results, which acts on any lime in the soil, forming sulphate of lime: (the Gay Head crystals of sulphate of lime are so formed;) so that by spreading clay, we spread plaster. The iron in clay also plays its part thus. It is evident from Chaptal's experiments, that protoxide of iron is not beneficial in agriculture. He attributes this to the oxidation of the iron, depriving the plant of its intended oxygen. Nature is no niggard; nor is the reason of Chaptal very philosophical. We have seen above that protoxide of iron does not act on geine. Now by exposure, the protoxide becomes peroxide; and then, I conceive begins an action similar to that of lime. If the free sulphuric acid, produced as we have supposed, finds not lime enough, it will decompose all earthy geates, and thus a fresh portion of nutriment is set at liberty. Both the effects of clay—the production of plaster and the formation of peroxide of iron, are speedily produced by burning the clay, as is often practised."²⁴

Still more recently, Dr Dana adds the following: "Some facts have lately come under my eye, and have recalled others to mind, which I have followed up experimentally; all tending to show, that *if iron peroxidizes itself in contact with vegetable fibre, the texture of the vegetable fibre is weakened*, and geine is produced, and that *in a few hours. It is during the passage from protoxide to peroxide that the 'saponifying' action takes place*, geine is produced, and then *combines with peroxide.*"

In the few analyses which I have given above of our clays, I have considered all the iron in them as existing in the state of protoxide; although I made no attempt to ascertain whether some of it might not be a peroxide. Very probably this may to some extent be the case: especially where the clay has a yellowish tinge. Yet for the most part, I doubt not it is a protoxide. A slight error here cannot affect the reasoning above presented.

I hope our farmers will make more numerous and accurate experiments upon the use of clay as a manure; not merely upon sandy land, but following the suggestions of Dr Dana, upon other soils, in the expectation that its action will be analogous to that of lime. Probably, the best clay for this purpose occurs in the valley of the Connecticut river; but it abounds in almost every part of the state, and perhaps it may in a good measure supply the deficiency of lime. It will of course require to be laid on in much greater quantity than marl, and probably, as in the case of marl, too much may be used. How much ought to be used is a fair subject for experiment.

* The agency of geine in the fermentation of manure is thus explained by Dr Dana with his usual clearness and felicity.

"By fermenting dung vast volumes of ammonia are liberated. I do not think that it is the action of gases as such, which we want or which nature intends as food of plants to be derived from the soil. The air is always full of all which this fermenting manure can supply in a gaseous form. The true actions of ammonia and carbonic acid resolve into their effects on geine. The ammonia combines as alkali with that, and thus it becomes very soluble, and the carbonic acid produces sur-salts of the earthy geates of lime and magnesia. It is these, liberated the moment the plant demands them, which cause all the geine of the manure to become alkaline soluble geates."

"How wide is the influence of geine! It not only enters by itself into the food of vegetables but becomes the very solvent which nature has proposed to act on the alkaline earths and oxides, dissolving them as they are liberated from decomposing granitic sand."

Peat Swamps.—The peat swamps of New England have become a vast repository of organic matter, which is, and has been, for ages increasing. In addition to the larger vegetables, which, as they die, fall and are enveloped in the soft matter on which they grew, there is a thick mat of moss, which—especially the sphagnum—continues to flourish at the upper part while the lower part dies and decays. In favorable circumstances as to wet and temperature, this mass of vegetable matter becomes converted into peat. Only a small part however, of what is thus accumulated, becomes peat of such a character that it answers well for fuel. Often it is too much mixed with mud to be easily burnt, and sometimes the vegetable fibre is scarcely changed. Yet the whole of it is capable of being converted into vegetable nutriment. And I am convinced, from all that I have seen and heard, that Massachusetts contains enough of this geine and vegetable fibre in her swamps, to render all her fields fertile for centuries. In other words, here is an exhaustless source of geine. Some of it is already in a soluble state; and therefore the black matter from swamps, is rarely spread upon soils without producing some benefit. Yet for the most part the geine is in such a state as to require some chemical change before it will become soluble nutriment, fit to be absorbed by roots. It is an important inquiry then, what is the best mode of accomplishing this change. This has been attempted, first, by mixing the peaty matter with good manure in alternating layers, and suffering them to ferment for a long time, the peat being in much the greatest quantity. Secondly, by mixing it in a similar manner with lime; and thirdly, by mixing it with alkali, or some compound containing alkali. The principles respecting geine which have been advanced in this Report, will probably enable us to decide as to the preference to be given to any one of these methods. And here I have it in my power to give the opinion of Dr Dana, whose remarks I am always happy to substitute for my own, on a subject with which he is so familiar, and which he has done so much to elucidate.

"The fact," says he, "that peat or turf is very soluble in alkali, seems not to be known among our farmers. The usual practice of mixing lime with peat or turf is decidedly the worst which can be followed. The geine which constitutes a large part of peat bogs, forms with lime a compound little soluble in water, requiring at least 2000 parts of water to one of geate of lime; and if the compound has been dried and sun-baked, a still larger portion of water is required; it becomes, in truth, almost insoluble. With alumina, geine forms a compound still more insoluble than with lime: and though the vegetable matter in combination with these earthy bases, is actually absorbed by the roots of growing plants, still the geine is in a state much less favorable than when in combination with alkali. Mix ley of wood ashes with peat, and we form a dark brown vegetable solution: the alkaline properties are completely neutralized by the geine, and very often ammonia escapes from turf when treated by caustic alkali. When we add, that this geine absorbs and retains nearly its own weight of water without seeming moist, it is evident, that with the use of ley or wood ashes, the value of peat as a manure will be very much increased."

I will only add, that in my opinion, it would be very desirable to have a series of experiments performed by a practical chemist upon the different

varieties of our peat, and especially upon the best mode of converting it into soluble geine. Since by the old methods of analysis the different varieties of peat would be found to differ from one another only in the quantity of organic matter which they contain, I supposed it would be useless to analyze them, and therefore did not collect specimens of the peat and other vegetable matters that occur in our swamps. The doctrines respecting geine put a new aspect upon the case, and lead me to regret that such a collection was not made. The labor of doing it now, however, is small; and when it is considered what an immense mass of organic matter now lies useless in our swamps, while the fields around them yield but a scanty crop, and that the chief reason why our farmers make so limited a use of this manure, is, that they find it difficult to convert it into soluble nutriment, I sincerely hope that the government will do all in its power to bring into use this important part of our fossil resources.

Marsh Mud.—Every intelligent farmer probably knows, that this substance forms an excellent manure; although I apprehend it is employed far less than its value demands. An intelligent farmer in Maryland states, that he “deems it more valuable than barn-yard manure;” and that “it never failed in any application he had made of it.” He also prefers it to marl, because “it is more accessible, its effects are quicker and much more can be done in the way of improvement for the same money.” At the same time he confesses, that the permanent advantages of marl are much greater; and thinks that marl and marsh mud will both be improved by combination.” This last remark appears still more important, when we ascertain what it is that gives an agricultural value to this substance. The fact is, it sometimes contains a large quantity of geine, and sometimes but little, while the quantity of the salts of lime, soda, and magnesia, is rather large; so that sometimes a mixture of marl will be of service, and sometimes not.

Concluding remarks upon Soils.—Though I have dwelt so long upon the analysis and improvement of our soils, it will be seen that I have touched only a few of its more important features, and that even these are but imperfectly considered. Many minor points, of no small importance, however, have been wholly passed over, or only alluded to; and sensible that I cannot do them justice at present, I shall not attempt to discuss them. My great object has been, after ascertaining the greatest deficiencies in our soils, to satisfy the Government that we have the means of remedying them and of making great improvements in them, by the aid of chemistry. If I may hope that I have accomplished this object, then I take the liberty to inquire, whether it be not important enough, and whether there is not enough still left to accomplish respecting it, to make the appointment of a *State Chemist*, desirable? We ought to have still further experiments made on the subject of geine, and the salts, which the soils contain; also accurate analyses of the crops grown on soils with different manures; and investigations as to the manner in which calcareous matter acts upon vegetable and animal substances; as also experiments directed by an able and experienced chemist, on the best mode of bringing into use the vast deposits of geine and vegetable fibre which our state contains. And since we have chemists of this character among us, why should not the services of at least one of them

be secured for this object? The geological surveyor might often collect substances for analysis; but if obliged to go as thoroughly into the chemistry of the subject as is necessary to valuable results, he cannot within any reasonable time accomplish the more appropriate objects of his appointment. In at least one state of the Union, where geological surveys are in progress, one gentleman is appointed, whose time and attention are exclusively devoted to the chemical examination of the soils, ores, &c., collected. And I would fondly believe, that Massachusetts will not rest satisfied, till this work is done at least as thoroughly as in any other state. I believe there is abundant labor, for an experienced chemist upon our soils alone; but many other substances, found in the state, ought to be analysed, that their real value may be known.

I do not doubt but the Government and every intelligent reflecting citizen will feel the vast importance of energetic efforts to improve our soils so that they may sustain a larger population. This is the only way to check the tide of emigration that sets so strongly to the great West. For if our sons can be made to see the soil of New England doubling its increase, as I verily believe they might in one or two decades of years, the rich alluvia and prairies of the West will not be able to draw them away from the graves of their fathers; especially if they learn that those fertile regions will at length become exhausted of their geine and salts, and then will probably require as much labor to cultivate as the soils of Massachusetts.

Some, however, may contend, that it is more important, to transfer the New England character to the unsettled West, than to multiply our numbers and wealth at home. But the history of the world leads us to fear, that New England character cannot long be preserved except upon New England soil; or upon a soil that requires equal industry for its cultivation. Place New England men where the earth yields spontaneously, and the locks of their strength will soon be shorn. If we look over the map of the world, and the history of the past, we shall find as a general fact, that the brightest exhibitions of human character have been made, in regions where nature has done less, but art and industry more. If, therefore, we wish to increase the moral power of New England, it must be done by improving her soil, and increasing her resources and her population. If these views are correct, which I acknowledge do not fall in with the prevailing notions, they furnish a new stimulus for vigorous effort in the improvement of our soils.

From the Genesee Farmer.

WHEAT WORM.

No apology can be necessary for introducing this subject so frequently into the columns of the Farmer. The extent of the interest involved in the progress of the wheat worm can only be estimated by those who have traversed Western New York, and witnessed the quantity of wheat annually sown in this district. We make the following extract from the Seneca Observer, for the purpose of calling the attention of farmers to the statements made in it, and particularly the one that the worm continues its ravages after the wheat is ripe and put in the barn.

We have had the impression, in common with most others, that after the berry had become hard, the ravages of the worm ceased, or was only con-

tinued on such kernels as were attacked before the wheat had become ripened. We have within a few days examined wheat in which worms were found in abundance, and could find no kernels injured, except such as from their shrunken and pale appearance had evidently suffered when in the milk, or before the berry had become ripe. That the *worm*, the product of a bug, destroys the grain in the mow or the granary, is well known; but that the *worm*, the product of a fly, does the same, we think requires further examination and proof before it is fully admitted. Should such prove to be the fact, it would indeed prove to be an alarming feature in the history of the wheat worm. At the east, where its ravages have been the most extensive and longest continued, we have never heard any apprehensions of injury after the wheat had ripened and was gathered. We have instituted some experiments having a bearing on this matter, and we hope farmers generally will lend their aid in elucidating this point. Is not the noise spoken of occasioned by the crawling of the worm and the rustling of the chaff, rather than by its feeding? and does not the pressure in a mow of wheat cause the speedy death of far the greater part of the worms in the gathered grain? It is well known that when wheat is threshed immediately after gathering, the worms will be many times more numerous than in the same wheat, if left in the barn for one or two months before threshing.

“It is curious as well as alarming to observe the operations of this destructive worm. It commences its work early, and continues it late. When in the field, it can be heard making a noise much resembling that of the silk worm while eating. After it commences, it devours with all greediness, until the crop is gathered; and, what is still worse, and perhaps, not generally known, it continues its work of destruction, after the crop is gathered. Of this fact there can now be no doubt. It has been witnessed by many of the most observing farmers of our neighborhood. This insect can be heard in the mow and stacks, and on examining the heads of wheat, they are found to contain many of these destroyers. This is the more alarming to the wheat grower, as it is next to impossible for him to thresh out his grain as soon as harvested, owing to the other necessary labor that is pressing upon him at this season of the year—the completion of his haying, and the preparing of his fallow ground for another crop. Yet he must thresh his wheat or lose a goodly portion of what has been gathered.”

We do not allow ourselves to indulge in the gloomy anticipations of the concluding paragraphs of the article in the Observer. We remember that when the Hessian fly became so destructive, and its ravages extended so rapidly, many were found who fancied that wheat could never again be grown in the United States. Such predictions have been utterly falsified by the event; and such we doubt not will be the result in regard to the grain worm. As yet we see no reason for deserting the fair fields of Western New York, or abandoning the culture of wheat. Partial failures may indeed be expected; but the beautiful wheat that finds its way in such quantities to our markets affords conclusive proof that our fields yet yield their increase, and that Providence has not ceased its kindness and its blessings.

A clergyman in New York advises his hearers to subscribe and pay for a good newspaper.

**NEW ENGLAND FARMER,
AND GARDENER'S JOURNAL.**

BOSTON, WEDNESDAY, OCTOBER 3, 1838.

AGRICULTURAL DEPOSITORY.

A CARD.—The Commissioner of Agricultural Survey respectfully solicits of the farmers in Massachusetts, or his correspondents in other places, small samples of any of their agricultural products, which they may regard as possessing any peculiar excellence. Corn in the ear, of any variety; Wheat; Rye; Barley; Oats; Buckwheat; Broom Corn; Cocoons; Silk; Wool; and valuable grasses. He would likewise be pleased to receive specimens or models of any valuable implement or invention connected with husbandry or the rural arts; or models or drawings of any improved farm buildings; or pictures of any valuable domestic animals. His objects are wholly public. His intention is to place such things in a situation where they may be examined by the farmers of the State; and to lay the foundation of an Agricultural Museum solely for the public benefit. He hopes so much public spirit will be felt in this case by his agricultural brethren, that their liberal contributions will soon render the collection worthy of public attention. The beginnings must be small; but in time the collection may be of great utility. It is important in respect to any article sent that a written account should accompany it.

He particularly solicits likewise the attention of intelligent shipmasters and others visiting foreign countries, to the collection of valuable agricultural seeds in places where they may go; and pledges himself, that if they will do him the favor to place them under his care, he will gratefully receive them and dispose of them in a manner to test their value and diffuse their benefits.

Any such donations may be forwarded for the present to the store of Messrs James K. Mills & Co. Kilby street, Boston; to his address. The expenses of freight or transportation will be cheerfully paid.

HENRY COLMAN,

Commissioner of Agr. Survey in Massachusetts.

Oct. 1, 1838.

Printers in Massachusetts, in town and country, favorably disposed to this object, are respectfully requested to give the above card one or two insertions.

ON PAINTING ROOFS.

Milford, Sept. 28, 1838.

MR EDITOR:—Sir,—I wish to make enquiry through your paper respecting the painting of roofs, and the best paint or composition for preserving them.

A SUBSCRIBER.

REMARKS.—We have seen different preparations applied for the preservation of roofs, and been acquainted with many recipes for composition for the same purpose; yet from our own observation and experience, we believe there is no great economy in expending much upon a roof for paint. The object of the greatest importance is to get good shingles and then have them well laid. There are those, however, who think differently. A mixture of black lead and linseed oil is perhaps as good a mixture as can be used if it is thought expedient to paint; but it is very difficult with any paint, to fill every crevice so that water will not find its way between the joints to the unpainted shingle, and here is the trouble; the wet gets under the shingle, and in consequence of their being painted do not dry so quick, and of course will decay sooner for being painted. It is sometimes the case when a man undertakes to build substantially he paints the shingles as they are laid, which no doubt adds much to the durability of the roof, but then does not the expense

of paint and additional labor and interest on the same, amount to as much, or more, than another shingling? We were much struck with the appearance of a noble barn, which was built two years since by our friends the Shakers at Shirley. They never do anything by the halves, but whatever they undertake is done in the very best style. The barn was finished in the most substantial manner, from the foundation to the ridge-pole, but we were forcibly reminded by it of Noah's Ark, for it was "pitched within and without." Our friends informed us that the shingles were laid in hot pitch, or a mixture of pitch and tar, and the building coated over with the same. This mode of laying shingles, has one advantage certainly; if fire should take hold of it, it would burn without much trouble.

Since writing the above, a gentleman of some experience has informed us that if shingles are dipped in strong alum water, they will last much longer, and it is also a security against fire. We find in Vol. 12, page 283 of the N. E. Farmer the following receipt and remarks, which we copy, as many of our present subscribers have not taken the work so far back.

"For painting the roofs of buildings, Mr Patterson of New Jersey, has, some years since, given the following directions, which have been highly approved, as the best composition known for preserving the roofs of houses; as it is found that it hardens by time, and is an effectual preservative against the roof taking fire from the sparks the chimney.

"Take three parts of air slacked lime, two of wood ashes, and one of fine sand, and add as much linseed oil as will bring it to a consistency for working it with a painter's brush. Great care must be taken to mix it perfectly.

"We believe grinding it as a paint would be an improvement. Two coats are necessary; the first rather thin; the second as thick as can be conveniently laid on."

We have not seen an application of the above composition, and therefore, give it as we find it. It is no doubt a good composition if it could be applied to every part of the shingle. We have answered our friend "A Subscriber" as well as we are able; if any of our correspondents who have more experience, can add anything which will meet his case or benefit the public, we shall be much obliged.

J. B.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Sept. 29, 1838.

From R. Manning, Esq. Salem, fine specimens of the following Pears: Bergamotte d'Automnal, Green Sugar, Styrian, Louise, Bonne of Jersey, Autumn Superb, Belle St. Bonne, and Webber's Yellow Autumnal. (Mr Manning is entitled to the thanks of every lover of Good Fruits for his exertions to introduce new varieties and to sustain the exhibitions of the Society.)

From Samuel S. Lewis, Esq. Brinley Place, Roxbury, (the late residence of Hon. H. A. S. Dearborn, a zealous friend and promoter of the best interests of this Society,) the following Pears: Autumn Bergamotte, Passe Colmar, Napoleon Doyenne Gris, Newton Vergaleau, Brown Beurre Capiamout, Lewis and Moorfovl's Eggs, and five other specimens not named. These specimens were all fine.

From E. M. Richards, Esq., fine seedling Clingstone Peach.

From Mr Eustis of South Reading, Isabella Grapes.
From Mr S. R. Johnson, Charlestown, very fine Black Hamburg and Sweetwater Grapes.

From M. P. Sawyer, Esq. Portland. Plums, variety

Imperatrice and Magnum Bonum; the latter were very beautiful the finest exhibited this season.

From Mr Pond, Cambridgeport; Semiana Plums, very large and fine; also Isabella Grapes, and a new seedling Grape called Pond's Seedling. This fruit was proved to be a very fine variety and far superior to the Isabella, worthy of cultivation.

From James L. L. F. Warren, fine specimens of Imperial Lemon Clingstone Peach.

The following letter, with the specimens of Fruits were received from the Hon. John Lowell of Roxbury.

Roxbury, Sept. 29, 1838.

To the President of the Massachusetts Hort. Society:

Sir—I send specimens of "Beurre Spence" nearly or quite ripe. It should be understood, that for 50 years I have thought the soil at my place, not adapted to produce the best years, except certain kinds which come to high perfection in it. I send an unripe sample of *Beurre Bronze*, which Parmentier highly commends. Also, a bunch of Grapes,* sent neither for its size nor quality, but novelty. It is one of the grapes sent by the American Consul at Ferrol, to Mr Cook, late Vice President of your Society. It is to me wholly new in foliage, wood, bunches, berries and taste. It is a prolific grape, and can be made to produce immense bunches for those who desire it; of its value, as a fruit, it is not for me to decide.

I have added *Beurre Crapreau* and *Milanaise* or *Great Britain*; a crisp pear when ripe.

I am, dear sir, very respectfully,

Your humble servant,

JOHN LOWELL.

For the Committee,

JAMES L. L. F. WARREN.

*The Grape was new to the Committee, but was found to be of very fine flavor.

The reports of the Horticultural Society are necessarily deferred until next week, as the committee have not fully completed them. We shall publish the whole in one paper, which will make it necessary for us to issue an extra.

THANKSGIVING IN MASSACHUSETTS.—The governor of this State has appointed THURSDAY, the 29th day of November next, as a day of Public Thanksgiving and Praise.

The heaviest Wheat and Rye crop, perhaps ever taken in this county, has been gathered within the last fortnight—in good order—plump and well filled. The grass crop is also good. The Corn crop, which, at the outset of the county, has been seriously injured in some parts of the county from a long prevailing drought. In the south and southwest portion of the county it will be an entire failure. Many of our farmers in Warwick—the southern part of Mimsink—and in Sussex Co. N. J. are now engaged in cutting R. up. The Oat, Potato, and was very promising, has been severely from like causes. In the other sections of the county, where the drought has not been so severely felt, the Corn crop particularly is very promising.—*Goshen N. Y. Republican.*

The Stockholders of the Eastern Railroad have resolved to complete their railroad as far as Newburyport, and to put the rest to the East line of the State under contract as soon as they have satisfactory assurances that it will be continued to Portsmouth.

The Trustees of the Maryland Agricultural Society have postponed the Fair which was to have been held on the 1st of November, on account of the deplorable drought which has prevailed throughout the Eastern Shore.

BRIGHTON MARKET.—MONDAY, Oct. 1, 1838.

Reported for the New England Farmer.

At Market 400 Beef Cattle, 350 Stores, 2,450 Sheep, and about 1,500 Swine.

Prices.—*Beef Cattle*.—Sales were brisk. First quality, \$7.50. Second quality, \$6.75 a \$7.00. Third quality, \$5.50 a \$6.00.

Stores.—In good demand. Yearlings, \$9 n \$14. Two Year Old, \$16, a \$28. Three Year Old, \$22 a \$33.

Sheep.—Sales brisk. At \$1 62, \$1 88, \$2 16, \$2 50 and \$3 25.

Swine.—Last week's prices were fully supported. Loins to peddle at 6 1-2 a 7 1-2. At retail, 7 1-2 a 9. Old hogs, 7 to 8.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending September 30.

SEPTEMBER, 1838.	7 A.M.	12, M.	5, P.M.	Wind.
Monday,	24	50	62	58 N. E.
Tuesday,	25	44	68	58 E.

FOR SALE.

The thorough bred Short Horned Durham Bull, Superior-Superior was calved in August, 1831. He was got by Frederick, and he by Wye Comet.

Dam, Yellow Rose, by Young Denton.
G. G. Dam, Arabella, (Imported,) by North Star.
G. G. Dam Aurora, " " " Comet.
G. G. G. Dam " " " Henry.
G. G. G. G. Dam " " " Dauby.

The above pedigree may be found in the English Herd Book.
He is a roan and perfectly gentle and docile; and his stock, which may be seen at the farm of the subscriber, will testify to his value. Price, \$250. Apply to G. N. Bennett, Esq. near Albany, N. Y., or to Wm. Augustus North, Mount Marie, Duaneburg, N. Y.
October 3, 1837. 4w

MULBERRY TREES.

1500 Morus Multicaulis.
1000 White Mulberry.
For sale, the entire lot, or in small quantities. They are very superior, and being raised so far north, have the advantage over southern raised trees, for this State.
JAMES STEWART,
Indian Hill Farm, near Newburyport, Mass.
October 3, 1837. 3w

NOTICE.

The subscriber offers for sale his real estate in Westford and Groton; consisting of his homestead, 35 acres, his farm, 117, one pasture, 17 acres, one do. 33 acres, one wood-lot, 13 acres, one do. 5 acres, one do. one do. 10 acres. For further particulars see his advertisement in the Lowell Journal, or inquire of the subscriber at his house, near the meeting-houses and academy in Westford.
EPMRAIM ABBOTT.

FARM FOR SALE.

In Cambridge, about one mile from Murdock's Hotel on the West Cambridge road with a valuable stone ledge on the same; containing forty acres of good land with the buildings on the same. It will be sold at a bargain if applied for soon, as the present owner is about removing to the West. Apply to the subscriber on the premises,
Sept. 25. 3w AMMI C. TEEL.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaquet's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham.
ISAAC PARKER.

WANTED TO HIRE

A single Man, who is capable of taking charge of a small Farm. Inquire of JOSEPH BRECK & CO.
Sept. 5.

LAYING OUT GARDENS AND ORNAMENTAL PLANTATIONS.

E. SAYERS begs leave to inform his friends and the public in general that he will attend the laying out gardens and ornamental plantations, and hopes by strict attention to business to merit the approbation of those who may be pleased to employ him
All orders left with J. Breck & Co. Agricultural Store, No. 52 North Market Street, will be punctually attended to.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders to any amount, which will be promptly attended to
Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston.
Sept. 20. NAHUM WARD.

FRUIT AND ORNAMENTAL TREES, MULBERRIES, &c.

Nursery of William Kenrick.
The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Feaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honeysuckles; Pæonies, Dahlias and other Herbaceous Flowering Plants.

100,000 MORUS MULTICAULIS are now offered for sale; the trees genuine and of the finest quality, at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Boussa and other varieties.
Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. D. BRECK, Commission Store, No. 132 Water Street, New York, M. S. PEWELL, Seed Store, 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston.
August 1, 1838. WILLIAM KENRICK.

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more as may be wanted, of the most approved kinds—consisting of the best select varieties now in use, for cultivation, feeding worms, and making silk;—being acclimated to this country, and adapted to either warm or cold climates, affording a rare opportunity for companies or individuals to be supplied, from the most extensive collection of mulberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and orders left with Messrs. I. B. Colt, Secretary of the Connecticut Silk Manufacturing Company, Hartford; Alonza Wakeman, at the office of the American Institute, No. 157 Broadway, N. Y.; Thomas Lloyd, Jr. No. 236 Filbert street, Philadelphia, Pa.; Luther I. Cox, Baltimore, Md.; B. Snider, & Co. Savannah, Ga.; Bliss Jenkins, & Co. Mobile, Al.; James Lyman, St. Louis, Mo.; Case and Judd, Columbus, O.; G. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass.

Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Mulberry Plantations.

Apply at the office of D. STEBBINS, Northampton, Aug. 22, 1838.

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dame, situated in Rochester, N. H. six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quantities of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to JOSEPH BRECK & Co., No. 51 and 52 North Market Street, Boston.
August 15, 1838.

FOR SALE.

Five acres of good Salt Marsh, in Quincy, or (Squantum so called.)
Also, Four acres of Salt Marsh in Brighton.
Also, Several full blood animals, cows and calves. Apply to A. Greenwood, on the Welles Farm, Dorchester, near Dr Codman's meeting house.
Sept. 12, 1838.

MISCELLANEOUS.

THE FIRST YELLOW LEAF.

Thou bring'st sad thoughts to me,
 First yellow leaf;
 Thou tell'st the change so soon to be,
 From Summer, bright and brief,
 To Autumn's sear and sadd'ning time,
 When gladness leaves our happy clime.

But few short mouths have gone,
 Thou fragile thing,
 Since first upon the grassy lawn
 So gaily drest by Spring,
 I watch'd thy beauties, one by one,
 Spring forth to greet th' enlivening sun.

And all this lovely earth,
 So fresh and green,
 Prais'd well the pow'r that gave it birth,
 And deck'd it all unseen.
 I gazed, and joy my bosom fill'd;
 Nor thoughts of blight, my transport still'd.

And now to see thee fall
 So soon to earth,
 And thus to see thy bright train all
 Resign their notes of mirth,
 Nor whisper to the breeze agao,
 'Tis sad, and well might give me pain.

But there are other tones
 Than fading leaf,
 That thus speak in thy dying moans:
 "Thy life, like mine, is brief;
 Thou, too, may'st bloom but for a day,
 Then fade, like Autumn leaves away."

SLEEPING CHAMBERS.

Is the philosophy of sleep enough considered? Are the circumstances connected with this condition of human nature, for one quarter or one third of human life, duly attended to?

While we are awake, our bodies are, as a general rule, more or less in motion; and the air, even in our rooms, more or less in motion also. But while we sleep we are quiet, the air is quiet, and is soon contaminated. Do people consider how fast?

The air is spoiled fast when but one person occupies a bed, and there is but one bed in the room. Franklin and others have supposed the air to be rendered unfit for breathing at the rate of a gallon a minute. But if so, how many of us breathe bad air in our sleeping rooms! We seldom lie quietly in our beds with the doors and windows closed, a heap of feathers under us, and thick clothes over us, more than an hour at most, before we begin to suffer. This is the case if the sleeping room is large; but if small, it is much worse. It is impossible to have a hoghead of poisoned air diffused through a sleeping room without doing mischief.

I know it will be said that the carbonic acid gas, produced by breathing, is heavier than atmospheric air, and soon settles to the floor; and if the bed-room is not so small that the room, like a culinary vessel, gets full of it up to the surface of the bed, before the individual wakes, there is no danger.

But it does not all settle to the floor. In hot weather, it scarcely settles at all; though in cold weather it does so much more. Nay, even in cold weather some of it falls on the bed, and much of it

is entangled in the bed clothes. This, however, is not quite all. The same poisonous gas which is formed by breathing, is also constantly formed by the whole surface of our bodies, in greater or less degree; and this, if improved under the bed clothes, between them and a thick bed of feathers, is not only injuring us by its contact with our skins, but still more by our breathing it. For nothing is more common than for a small quantity of this impure air to escape from the bed by the side of our bodies, especially upon the least motion; thus giving an opportunity—nay, a certainty—of inhaling a part of it.

To all these evils we are subjected, I have said, when under the most favorable circumstances; that is, when our sleeping rooms are large, and when only one person occupies a bed, and one bed in an apartment. But when two persons, or even more, sleep in the same bed, when the room is small, or has several beds in it, and when the beds are of feathers or down, the evil and the danger are very greatly increased.

I wish sleeping rooms were generally much larger than they are. Then I wish they were always freed as much as possible from unnecessary clothing, and every thing which could retain bad air. The bedstead should be rather high, and only broad enough to accommodate freely and fully one person. The bed should be of some material which is light and porous, as oat or wheat straw, corn husks split finely, grass, hay, &c.; and the clothing should be adapted to the season, but should never be so constructed as to prevent entirely the passage of the air through it. No dogs, or cats, or lamps, or fires without flues, should be found in the room. A window or door which will admit fresh air should be, in all seasons, but especially in hot weather, left open in such a direction from the bed as will not expose the occupant to have currents of air fall directly upon him;—to prevent the possibility of which, however, a screen might be placed before the window. Then, in the last place, and as I have already intimated, the bed should contain but one person, and unless the room is exceedingly large, there should be but one bed in it.

Perhaps it will be said that I require too much. Most persons, I shall be told, cannot have all this. No, they cannot. Sin is in the world, and has long been in it; and it will be long before we can get it out entirely. But sin has brought with it among other evils, that of poverty; and poverty does not always permit every thing which is best for health. But one thing at least we can do; which is, to come as near what we know to be truth as possible.—*Library of Health for September.*

SIGNS OF PROSPERITY.—Do you see that are house on that risin' hummock to the right there?—Well, gist look at it, that's what I call about right. Flanked on both sides by an orchard of best grafted fruit, a tidy little clever flower garden in front, that the galls see to, and a'most a grand sarge garden over the road there sheltered by them are willows. At the back side see them everlastin' big barns; and, by gosh! there goes the dairy cows; and a pretty sight too; that fourteen of 'em marchin' Indian file arter milkin', down to that are medder. Whenever you see a place snugged up and lookin' like that are, depend on it the folks are of the right kind. Them flowers too, and that are honeysuckle, and rose bushes, show the family

are brought up right; somethin' to do at home, instead of racin' about to quiltin' parties, huskin' frolics, gossippin', talkin' scandal, and neglectin' their business. Them little matters are like throwin' up straws, they show which way the wind is.—When galls attend to them are things, it shows that they are what our minister used to call, "right minded." It keeps them busy, and when folks are busy, they ha'n't time to get into mischief; and it amuses them too, and keeps the dear little critters healthy and cheerful.—*Sam Slick, second series.*

EXTRAVAGANCE IN THE UNITED STATES.—Do you see them are country galls there, said Mr Slick, how they are tricked out in silks, and touched off with lace and riband to the nine's, a mincin' along with parasols in their hands, as if they were afraid the sun would melt them like wax, or take the color out of their faces, like a printed cotton blind? Well, that's gist the ruin of this country.

It ain't poverty the blue noses have to fear, for that they needn't know without they choose to make acquaintances with it; but it's gentility.—They go the whole hog in this country, you may depend. They ain't content to appear what they be, but want to be what they aint; they live too extravagant, and dress too extravagant, and won't do what's the only thing that will support this extravagance; that is, be industrious. Gist go into one of the meeting houses, back here in the woods, where there ought to be nothin' but homespun cloth, and home made stuffs and bonnets, and see the leg-horn and palm-trees, and silks and shalleys, merinos, gauzes, and blonds, assembled there, enough to buy the best farm in the settlement. There's somethin' not altogether gist right in this.—*Samuel Slick, second series.*

ORIGINAL ANECDOTE.—A drunken fellow, not long since, staggered into one of our most respectable victualling cellars, and greeted the attendant with a familiar 'how are you?' 'Who are you,' said the host, 'are you drunk?' 'Aye,' said the bacchanalian, 'drunk enough! and have been every day for two years! My brother Josh and I am engaged in the temperance cause; he goes about delivering lectures, and I give samples of intemperance. Now shant we get up a reformation.'

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land, situated on Nonantum Hill, in Newton, 5 1/2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

LOT WHEELRIGHT.

July 16th.

ALDERNEY STOCK FOR SALE.

For sale a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27

FOR SALE.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

AGRICULTURAL.

ON THE MEANS OF INCREASING THE FERTILITY OF LAND.

The productiveness of any soil, we think, depends entirely on its natural or artificial capability of retaining and transmitting its moisture, the vehicle at least by which nourishment is conveyed to plants. This productive power may therefore not only be continued in its greatest vigor, but greatly increased by proper management. When we by any means give to the soil a permanently increased vegetative power, we also increase the yearly produce which it yields.

Some soils produce large crops often repeated without manure, five crops of corn and a fallow are the conditions entered in some leases in the neighborhood of Wisbeach in Lincolnshire, while other land will produce nothing without great expense of culture and manure, nor will an excess of manure make such land permanently productive; but if we change its constituent parts by the addition of those earthy materials of which it is deficient, so as to bring it nearer to the nature of those soils which we know to be fertile, then we shall permanently increase its productive powers.

Water being the vehicle by which nourishment is conveyed to plants, the soil, whose constituent parts is best adapted for retaining a sufficient supply and transmitting a proper portion in very dry weather to the plants growing in it without holding it in injurious quantities in the time of very wet weather, is possessed of the principle of vegetation and will be found to be of the most productive nature. Such a soil will give not only firmness to support the plants, but will facilitate the growth of their roots in search of moisture and nourishment to the greatest depth.

There is not an individual who cultivates a garden and who exercises his judgment in its culture, but knows that the addition of clay gives cohesion to sandy or gravelly soils, and that sand and gravel when mixed with a clayey soil diminishes its tenacious property; and that these changes thus effected permanently increase the productive powers of both.

In our endeavor to improve barren soils, we should examine them in connection with fertile soils in their neighborhood, on the same geological formation, and the difference of their constituent parts may lead us to the means of their improvement. If the cause of sterility be owing to some defects in their composition, these defects should be supplied. An excess of silicious sand is improved by the application of clay, peat earth, or calcareous matter, cold well rotten manure, and rolling or trampling with sheep or other stock, to consolidate its texture.

When clay is in excess, it is remedied by the application of sand, chalk marl, or burned clay, light unfermented manures, and perfect pulverization, to make the soil friable. An excess of vegetable matter as in peaty soils, in a dormant state

is corrected by burning, by the application of clay, sand, calcareous matter, gravel, rubble, or anything heavy, to give firmness to the soil. Lime not only destroys the injurious effects produced by sulphate of iron which abounds in some soils, particularly in those of a peaty and silicious gravelly nature, but is said to convert the sulphate of iron into a manure. None of these applications however, will have the desired effect, unless there be first a perfect subsoil drainage of all superfluous moisture conjoined with a perfect tillage. To alter the nature and properties of the constituents of any soils may be more expensive than to manure it; but the effect of the former will be lasting, while that of the latter is transitory; the one permanently improves the nature and quality of the soil, the other only imparts a temporary excitement to force a crop for a year or two.

The materials necessary for the permanent improvement of the soil are seldom far off, and the expense, though in some instances considerable, is soon repaid by the permanency of its increased fertility; the manure applied afterwards has a much greater effect, the expense of cultivation is greatly diminished, and the capital laid out is soon restored by its yearly increased produce. By these alterations we store the earth with hidden and inexhaustible treasures, which invisible to the eye put forth their strength and give us the evidence of their presence by the effects produced on vegetation.

In the process of vegetation, nature supplies soil, water, light, and heat; but the matter composing the soil may not be in such a state as to receive, and transmit these in such quantities as will produce a healthy vegetation.

Man may regulate the supply by cultivation, and by altering the texture of the soils.

When the materials of which the soil is composed are in proper proportion, the soil is most productive; when any one of the ingredients is in too great a proportion, the soil is unproductive.

Pure clay, siliceous lime, we have before stated, are barren, if they are found alone; but if they are mixed together, having a due portion of water, the influence of the sun, and a proper admission of air, (which are the prime movers in vegetable life) a fermentation amongst the materials is created; and if vegetable and animal manure in a state of decomposition be combined with these, the soil which was sterile when separate will become productive when combined, and this mixture of materials and mechanical alteration will change the texture, and improve the quality of the soil.

Neither the clay, the siliceous lime, nor the lime are decomposed by this process, but the soil composed of these materials in proper proportions has the power of combining with, and decomposing the vegetable and animal matter, the water, and air which it contains, and produce results which afford the necessary food for the growth of plants.

When the particles of earth which compose the soil are separate from each other, or well pulverized, it holds the greatest quantity of free or avail-

able moisture, and readily transmits it to the plants which are growing in it; but when the particles of the earth are closely packed together, like new made bricks, it neither can receive moisture, nor will it give out that which it already possesses.

Good soils are naturally possessed of certain powers, with which, by the aid of husbandry, we can produce certain effects; on poor sterile soils, these powers may be conferred by artificially altering their texture.

When the fluid in the soil is so connected with the fluid in the plant, and gives out to it a constant and healthy supply, then we say the soil is in good condition.

Manure applied to the soil increases its vegetative powers, but the way in which it acts is not well understood. The processes of the small rootlets are so very minute, that no crude substance can pass through them; it can therefore, only be taken up by them in the form of water or gas, and be absorbed by the leaves.

Well rotten manure gives an unctuous or cohesive property; but when in a loose or strawy state, it gives a porousness or looseness to the soil.

All mineral manures, as lime, chalk, marl, sand, gravel, ditch mould, road scrapings, and earthy matter, act on the soil merely as an alterative, by changing the constituents of the soil and improving its texture, and by giving it an increasing power of imbibing and decomposing water, air, and organic matter.

The most abundant ingredients in soil are sand and clay, and as a mixture of the one with the other tends to improve both, nature has so ordered it, that these are generally found in great abundance near to each other.

In the plastic clay formation, extensive tracts of sandy soil are found lying upon the brick clay; the soil of which is greatly improved by lifting up the clay, and spreading it over the sand at the rate of 100 cubic yards to the acre.

There is also a considerable extent of this formation covered with flinty gravel, mixed with clay and sand, with a thin covering of black mould or peat earth for its surface, which produces heath and furze.

This lies near the clay, and the whole of this may be greatly improved by trenching, or otherwise mixing the sand and gravel with the clay below. The most of this is near the chalk, and would be greatly improved by an admixture of 80 or 100 cubic yards of it per acre. Chalk or lime destroys the pernicious effects of the sulphate of iron in the gravelly soil, and makes the soil which was worthless, so productive as to pay the whole of the expense in a year or two.

Soil that is chiefly composed of finely divided or impalpable matter, is greatly improved by the application of small stones, gravel or coarse sand; as this prevents the soil from collapsing or consolidating during continual rain.

All alteratives should be put on the land in small quantities at a time, or if in large quantities it should be when the land is in fallow; and these

should be well mixed by repeated ploughings, or by Finlayson's harrow, which is an excellent implement for loosening and breaking the fallow slice. The best way of putting on small quantities of materials for altering the texture of the soil is to make a mixture of them with the manure you intend to apply to the field; and these ought to be well mixed by laying them loose together, turning them several times, and fermenting them in the mass. When this is properly done, it should be carted and spread on the soil when in fallow, and be ploughed in and well mixed, so as to be completely incorporated with the soil.—*Morton on Soils.*

Roxbury, Sept. 24th, 1838.

To the Editor of the New England Farmer.

SIR,—The inclosed letter was written three years since, (as its date imports) but withheld from a fear, that I had annoyed the public with lucerne grass, and that people would begin to call me the "man with one idea." My late success has induced me to publish it, and I invite all farmers who may have opportunity to visit my *third crop this dry year*. It will not be cut before the 6th of October. It is a beautiful sight in such a season.

JOHN LOWELL.

For the New England Farmer.

LUCERNE GRASS.

MR FESSENDEN: I recur once more, in spite of the ill success of my former efforts, to the subject of this invaluable grass. I feel a full conviction that it will be, sooner or later, the favorite grass of the New England States, for whose soil and climate, it is peculiarly adapted. It will finally take the place of the Dutch clover throughout New England. It is better adapted to our soil. It bears our severe droughts much better than any grass we have hitherto cultivated.

I begin by stating my own experience. It is of fifteen years duration. That is no trifling trial. I go on regularly in the extension of its culture and upon dry, sandy, and gravelly lands, it will forever be for me, the favorite grass. It may be asked, what are the peculiar advantages which you have experienced from this grass? I answer, first, double crops in weight at least, from the same extent of ground. The Lucerne will give in this state, two good crops, the first season in which it is sown. Is there any grass, which will do this? It will endure in good heart for five years? Will clover do this? It will endure the severest droughts when all other grasses fail. What grass will do this? It is the favorite grass of the horse and the cow. It will fatten them faster than any other grass. It will do as much for a horse as an ample supply of grass, and four quarts of grain a day, in keeping him in flesh and strength.

But many persons have failed in attempts to raise it. And what then? Does it follow that it is not worthy of culture? By no means. If one man uniformly succeeds for fifteen years, there must be some good reasons who others do not succeed. Let us try to seek out the causes of their ill success. It is not the climate, because it stands our severest winters unharmed, when clover fails. It stands our severe droughts, when clover dies.

It has been intimated, that my success is owing to peculiar care, and high culture. This is not so. It is treated exactly like the red clover, and I give to it, purposely, my worst lands. Not that it does

not do honor to the best. It will reward the cultivator in the best soils.

What then have been the causes of its failure with many cultivators? I will endeavor to state my opinion on that subject. The lucerne will not grow in most meadow lands at all. It cannot bear low lands. It will die, if water rests upon it in winter. On uplands, it has failed from an insufficiency of seed. It requires 20 pounds to the acre and the price of the seed has been so high that our farmers would not buy it or in too small quantities, but it can be afforded from Europe at 14 cents per pound, though our seedsmen cannot afford to sell it at that price on account of the limited demand. It is like every thing else, if the demand is small, the supply will be small and high. My object is, to recommend its culture, and when it becomes general, the seed will be abundant and cheap, but no man must expect a crop without 20 pounds to the acre of seed, but as it endures five years at least, and pays for its cost the first season, it is a miserable and wretched economy, which, withholding the seed, decries the plant as unproductive.

It is with me, the richest treasure. My farm is small, it is true, but it is a grazing farm, and my produce is 20 tons of hay. Surely the experience of such a farmer for 15 years, is worth something.

JOHN LOWELL.

August 6, 1835.

I have already cut two crops from lucerne, sown in April last; and two crops from lucerne two years old, and two crops of hay from lucerne three years old, at the rate of three tons per acre. I expect two crops more from each. These are facts, notorious to them, who pass by my grounds.

What have we like it? Lucerne must be, and will be the grass of the south shore of this state, and other light lands of New England.

Let farmers, who pass this way visit my lands, let them see the grass, and the hay produced from it, and inquire of those who feed my stock, and they will be satisfied, that the lucerne is yet to be a blessing to their farms.

For the New England Farmer.

INDIAN CORN.

More than a hundred fold!—Old Connecticut yet—Connecticut forever!!

MR EDITOR: In the year 1837, in the garden of Elias Tully, of Saybrook, Connecticut, there grew two kernels of corn. One of these kernels produced 5 stalks—11 ears and 2147 kernels. The other produced 6 stalks—15 ears and 2276 kernels! Let the rich prairies, the fertile river bottoms, and other parts of the great West beat this if they can.

Yours, as ever,

AN OBSERVER.

For the New England Farmer.

MEXICAN CORN.

MR EDITOR: A variety of corn, said to be from Mexico, and said to be a very large, and a very productive kind, was planted in several places in 1834. But one kernel, however, of this variety was known to vegetable. That one stalk stood a towering giant in the garden of Elisha Tully, of Saybrook Conn., and on the 13th of Sept. 1834, though it had neither tasselled out, or eared out, it measured 16 feet in height, without stretching up

any of its leaves, as it stood in the garden. The height was ascertained by setting up a pole by it, and measuring the pole. The reader will not be likely to realize the great height to which the corn above mentioned had arrived, unless he measures 16 feet up the side of a house, a tree, &c., and then looks at it. The frost cut off this corn before it had made any seed. Would not this kind of Mexican corn make a prodigious burden of green corn fodder if sowed broad cast on good ground?

Yours, Respectfully,

ASA M. HOLT.

For the New England Farmer.

Weston, Sept. 21, 1838.

FRIEND BRECK: The following is worthy a place in your useful and valuable paper.

Messrs Stearns & Crehore, merchants of Waltham, ten miles north west from Boston, planted 90 hills of the Marrow Squash from which they gathered over three tons of Squashes, which they sold from their store at 1 1-2 cents per pound, amounting to one hundred and about twelve dollars, making one dollar and twenty-two cents per hill. Who, who, can heat this?

JONATHAN WARREN.

From the Genesee Farmer.

FLIGHT OF GRASSHOPPERS.

The warm, dry weather of the present season has been favorable to the propagation and growth of these depredators, and in some sections of the country they have been productive of much injury. In their general habits they are much assimilated to the locust of Asia and Africa, and the present season has developed their migratory powers in an unprecedented degree. It seems from the Lancaster (Pa.) and Frederick (Md.) papers, that the grasshoppers, after having devoured the pastures of those sections, have taken wing in immense numbers for other as yet unvisited places. The Lan Jour. says:—About noon on Wednesday (Aug 8th) a cloud of grasshoppers passed over the city of Lancaster. Their course was from the north-east to the south-west. As we did not see the whole of the procession, we cannot say how long they were in passing, or what were the objects of their journey. The appearance of these insect was singular and beautiful. Their glossy transparent wings shone in the sunlight like stars, and their twinkling completed the illusion." A Frederick, the greatest appearance of their flight was on Thursday the 9th. The number floating was immense, and though the fact was not known at the time, it seems very probable that the clouds of them observed at Lancaster, were the same seen at Frederick making a very respectable flight for twenty-four hours. The Frederick paper says "birds were hovering around them picking up stragglers, and some came as low as the house tops. Their appearance was very splendid, and attracted the notice of all."

The migration of grasshoppers we have observed several times, and it appears to be governed by the same causes that impel the locusts of the Eastern world in their devastating movements. When hot and dry weather succeeds their hatching from eggs deposited in the ground the previous year, they quickly obtain a size and strength that enables them to set the ordinary chances of the summer

season at defiance, but which, in less favorable circumstances, would prove fatal to many, or the most of them. The dry weather that hastens their growth operates to prevent a proper supply of food, and thus causes or hastens their migrations. About noon or a little before on a hot dry day with little wind, the observer will see now and then one rising from the earth, and in a kind of circling flight, rising high into the air. The number will rapidly increase, until the whole atmosphere seems filled with them, or until all that are capable of a sustained flight have floated away. Many will fall to the earth, and the heavy gravid females with their clipped wings, are, of course, left to deposit their eggs for the continuance of the race.

The flight is with the current of the air, and when the sky is of a deep blue, and the sun is shining bright, the millions of them glancing in the sunbeams at an immense height, gives to the part of the heavens occupied by the sun an appearance the most brilliant imaginable. They seem like shining spangles laid on the deep blue, and glitter and glance in every direction. We do not recollect that we have ever seen a flight of them descend, repeatedly as we have seen them rise; and hence we conclude that in this country at least, they disperse in different bodies, or gradually waste away by the weaker ones falling to the earth. Be this as it may, wherever they appear they are a formidable scourge. Our ruta baga field this year is by the side of a meadow, and since that was mown, they have commenced feeding on the turnep, and the bare ribs and stems of the leaves on the plants most exposed, show plainly their ravenous appetites, and powers of feeding. To what extent they will injure the turneps remains to be seen. We have known them greatly damage corn fields, by eating off the silks before the corn was impregnated, and we once had a field of beans entirely destroyed by an irruption of grasshoppers from an adjoining meadow. We have, therefore, always hailed the beginning of their flights into the air as a proof that we were soon to be rid of their presence, and freed from their deprivations.

THE CROPS IN PENNSYLVANIA.—An intelligent correspondent of Bicknell's Reporter, writing from Pittsburg, gives the following valuable information respecting the crops in Pennsylvania, west of the Alleghenies.

"It affords me pleasure to inform you that the crops in this vicinity are by no means as bad as I understand they are in the agricultural counties east of the mountains. Indeed, I never remember a much better wheat and rye harvest than that of the present year. Wheat has been remarkably productive, and rye has shown a fair average crop. At that time, however, the drought had not been severely felt. We were only in the beginning of that calamity, and I regret to add that we have since suffered considerably from it.

In the counties of Westmoreland, Allegany, Armstrong, part of Indiana, Fayette, and Greene, the corn will perhaps turn out better than in any other districts of Pennsylvania; than that east. I should say, that in most instances, the crop will not fall short of a very fair average. But then it should be remembered that this is by no means a great corn country—the farmers chiefly growing wheat, rye, and potatoes; while for a supply of corn in the cities, towns and populous villages, we

chiefly depend upon Ohio and Virginia. A few days since, a miller near Pittsburg, purchased a large quantity of wheat as low as 75 cents per bushel, and it no where exceeds a dollar at the present time.

The chief loss occasioned to farmers by drought, will be in potatoes, the plantations this year positively promising to produce *next to nothing!*

In the counties north of this—Butler, Mercer, Venango, Crawford and Erie, the same remarks that I have made in reference to the better inhabited western counties, will also apply, with the single exception of the sandy districts, where nearly all the crops are lost. Population in those counties is yet but thin, and the loss, therefore, by no means considerable to the community at large, though it will fall heavily on individual farmers and cultivators.

The crops of Western Pennsylvania may be recapitulated:

In the rich lands,

Wheat—an excellent crop.

Rye—a very fair average.

Corn—almost an average crop.

Hay—the first crop abundant.

Hay—the second crop a total failure.

Oats—about two thirds.

In the mountain districts, nearly all the crops have failed.

It will be remembered, however, that the wheat and rye harvests were excellent and abundant.

(For the New England Farmer.)

Ma. Editor: Can you inform me why I cannot raise pumpkins? I have taken pains not only to get good seed, but also seed from abroad, and planted it apparently on good ground, and yet on account of the moon or the season, or the seed, or some other cause, I have not got half a dozen pumpkins fit for pies on my whole farm. It has been suggested to me of late by a friend, that it was for the want of *old seed*. An old farmer of his acquaintance tells him that he plants seed that is from 2 to 3 years old, and sometimes 4 years old. I asked a neighbor of mine the other day, if he ever heard of the thing? he said he had, and this neighbor, although not a farmer by profession, but a blacksmith, nevertheless has some good ideas about farming, and withal raises some large pumpkins, and has one now in his garden, which he and some others think will weigh fifty pounds. And now, Mr. Editor, seeing that pumpkins are of so much value, especially in this section of country, that we can hardly keep *Thanksgiving* without *pumpkin pie*, would it not be well to give the above considerations to the public, through the columns of your agricultural Journal. If you think so, you would oblige at least one agriculturist, if I may be permitted to use that term, by so doing, but if you have other matter of more importance or more interesting, please to lay this aside and take that. When I get a little more experienced in farming, perhaps you will hear from me again; for although I like your journal very well, yet it does not exactly coincide with all my views and experience about farming, but, at present, I shall *read, examine and practise* in silence.

Yours, &c.

J. MITCHELL.

Chester, Ct., Sept. 21, 1838.

REMARKS.

We are truly sorry that our correspondent has been so unsuccessful in his attempt to raise pumpkins. The thought of keeping *Thanksgiving* without a pumpkin pie is surely almost insupportable and especially for a Connecticut man. Should he fail in obtaining a supply in his immediate neighborhood for that important day, we shall be very happy to forward him one, if he will say in what way it shall be sent, as we have been more fortunate in our farming operations. The culture of the pumpkin is so simple, that we supposed every farmer raised them in abundance, without difficulty. The most common method is to plant them among corn. Sticking a seed in every other hill at the first hoeing, but the better way is to plant them by themselves, when fine pumpkins are wanted. The land should be made very rich in the first place. The hills should in this case stand 7 or 8 feet apart every way, or even ten feet if the ground is in first rate order. It is generally supposed that the seed, of all vines, is better for being 4 or 5 years old. Mr. Marshall, an Englishman, who published a book on gardening some years since when speaking of melon seed, observes, that "if new seed only can be had, it should be carried a week or two in the *breeches pocket*, to dry away some of the more watery particles!"

To which Mr. Cobbett in his treatise on gardening exclaims, "What should we do here, where no breeches are worn." We are of opinion that old seed is preferable to new, and perhaps new seed may be improved as Mr. Marshall directs by earrying it in the breeches pockets! we have never tried the experiment, but we know those who do prepare their melon seed by filling their pockets with it a few weeks before they wish to plant it, and who believe the quality of the seed is improved thereby. We have a few hills of pumpkins, which were planted by themselves that have given us a great quantity. One was picked a few days since which weighed 47 lb. and there are many others of nearly the same size. A vine accidentally came up in a rich part of our garden, and in consequence of a partial destruction of the young crop around it by worms, it was suffered to remain; it spread out in every direction 10 or 15 feet, giving a good supply of fine yellow pumpkins.

J. B.

MILK! MILK!—We have never visited any place where the milk was so bad as that used in the city of New York. We used to think its inferior quality arose from its being adulterated by a mixture of chalk and water. But our New York city exchanges tell us differently. There are 18,000 cows in the immediate vicinity of the city, from whose milk the inhabitants are supplied;—these cows are fed with 200,000 bushels of annually distilled grains in the city and neighborhood.—These grains are corrupt and unhealthy; so much so, that they consume the flesh around the cow's teeth, also rotting the teeth, so that all these cows becoming sickly in one year, are sent to the market to serve the people as a miserable substitute for beef, and 18,000 new and healthy cows are substituted in their place in one year, to share the fate of their predecessors. So poisonous is this milk, that out of 100 children fed with it, 49 die yearly. Thus 2,000,000 bushels of grain distilled, scatters disease among men and beasts. Our bread is destroyed, and a distilled deceiver sent into all the land. When will enlightened public sentiment put down the growing evil?—*Olive Branch.*

GEOLOGY OF MASSACHUSETTS.

Continued from page 85.

Theory of the action of Lime on Soils, Manure, and Vegetation.—“The action of lime is threefold; each distinct. 1. It is a *Neutralizer*: 2. a *Decomposer*: 3. a *Converter*. 1. I have already alluded to some acid soils: free phosphoric acid, geic, acetic, and malic acids, also occasionally exist in a free state in soils. Here lime acts as a neutralizer. 2. Soils may contain abundant geates; particularly geate of alumina, the least of all demanded by plants. Long formed and sun-baked, they are scarcely acted on by rain or dew, and are almost useless. Here lime, by decomposing these metallic and earthy geates, forms a combination, which, in its nascent state, is readily dissolved. If the carbonate of lime acts better than the hydrate, it is because, following a well known law, double decomposition is easier than single. If any acid geine exists in the soil, or any free acids, carbonic acid is then liberated; it acts on the geate of lime, supergeates result, and these are easily soluble.”

“3. The great use of lime is as a *converter*; turning solid and insoluble geine, nay, I go further, solid vegetable fibre, into soluble vegetable food. Here is the great puzzle, the point where our philosophy seems to leave us; giving us our choice, to refer this action to one of the numerous cases of mysterious ‘*catalytic*’ change, with which we are becoming every day more and more familiar, or to explain the process by referring the whole to *saponification*. I use this word as conveying to you at once what I mean;—but I do not mean to say that the product of lime and vegetable matter is soap; but I cannot make myself more intelligible to a farmer than by saying, this lime makes compounds of vegetable matter, just as it makes soapy compounds of oil and fat. The action of lime on geine I take to be of the same nature, as its action on oils and fat. It is well established that animal and vegetable oils and fats are converted into acids by the action of alkalis, earths, oxides, and even by vegetable fibre itself. The general law is, that whenever a substance, capable of uniting with the acid of fat or oil, is placed in contact with fat or oil, it determines the production of acid. Now we have seen that alkali produces a similar change on geine; it develops acid properties. I go further, if alkali has converted vegetable oil and geine into acids, I see no reason why a similar action may not be produced by all those substances which act thus on oil. Hence lime, earths, and metallic oxides, convert geine into acid; as fast as this takes place, so fast geine becomes soluble. Then to the acting action of air on insoluble geine, rendering it soluble, is it not analogous to the action of air on oils. Both evolve in this case, vast volumes of carbonic acid, the oil becomes gelatinous and soluble in alkali; is does not a similar change occur in geine? It is possible that during the action of lime on geine, a soluble substance may be produced, bearing the same relation to this process that glycerine does to saponification. These views you will see need to be followed out experimentally. If found tenable, the most signal benefit will result. We place manures on a new foundation, on which great practical results may be erected.

Practical application of the Theory of the action of Lime.—Taking the preceding principles as our guide, we may lay down a few general principles for the application of marls,

1. Enough ought to be applied to neutralise all the free acids in a soil; which may be known by its ceasing to produce acid plants, such as sorrel and pine. Generally, however, the amount required for this purpose is small.

2. It will be serviceable to add enough to convert the earthy geates of a soil into geate of lime. The richer a soil is, the greater we may conclude is the quantity of geates which it contains.

3. It will be serviceable to add enough to convert all the insoluble geine and vegetable fibre in a soil into soluble geine. Hence the richer a soil is, and the more manure is added, the more marl will it bear with benefit. Indeed, *there appears to be no danger of adding too much marl, provided a sufficient quantity of manure be also added.* Ignorance of this principle, I apprehend, is the source of most of the failures that have occurred in the use of lime upon soils. Farmers have supposed that its action was like that of common manure, viz., to serve as direct nourishment to the plant; whereas it only *cooks the food*, if I may be allowed the expression, which exists in the soil, or is added along with the lime. In nearly all cases of over marling which I have read of, a fresh supply of manure has been found to be the remedy; which shows the truth of the above principle. Agriculturalists have spread marl alone, or with very little manure, upon land that has been worn out, that is, whose geine has been exhausted; and because such soils have not thereby been recruited, they have inferred that lime was injurious. Without acids, or geine, or geates, or vegetable fibre, to act upon, much excess of lime appears to operate injuriously, so as to diminish, instead of increasing the crop. They have also expected a sudden and surprising increase of fertility; whereas in some cases the chief benefit seems to consist in causing the land to produce for a greater number of years, by preventing the ultimate decomposition and escape of the organic matter. In general, however, it will add also to the yearly product: but those who employ marl or lime in any form, ought to moderate their expectations, that they may not be disappointed, and to be satisfied if they can slowly and surely improve their lands as they most assuredly can do, by this substance, provided they do not expect to accomplish it by the use of lime alone.

These general rules can afford only a general guidance as to the quantity of marl proper to be used. Both marls and soils vary so much in their composition, that probably direct experiments will always be necessary to ascertain the quantity of any new variety of marl that will be most serviceable. And should any of the agriculturists of Berkshire county be disposed, as I doubt not they will be, to try the marls above described, I beg leave to recommend to them, as the best practical treatise that has been published in this country, on this subject, “*An Essay on Calcareous Manures*,” by Edward Ruffin, Esq. of Virginia, Shellbanks, 1835. This gentleman has tried a vast number of experiments on the subject, and the perusal of his work is almost indispensable to any one who would successfully prosecute it. He says, “if the nature of the soil, its condition and treatment, and the strength of the marl were all known, it would be easy to direct the amount of a suitable dressing; but without knowing these circumstances, it would be safest to give 250 or 300 bushels to the acre of worn acid soils, and at least twice as much to newly cleared, or well manured land.” (Essay pp. 54.) The marl which Mr. Ruffin used was the

shell marl; a large part of which has no action on the soil for several years; nor does it contain any geine. On both these accounts probably, the Berkshire marls should be used at first in a smaller quantity; and I suspect that great care will be necessary to avoid using too much.

As to the best mode of applying marl, theory would lead us in general to prefer the method usually adopted, viz.: to mix it with compost before spreading it on the soil. And I would here express a hope, that if experiments are made on the Berkshire marls, a portion of the black vegetable matter that lies above them, may sometimes be mixed with them, to see whether it may not become converted into a geate, and thus increase the value of the marl. It would, indeed, be an important discovery, if from the same swamp both the geine and the lime could be obtained, in a state proper to sustain vegetation.

Marly Clay.—Most of the clay in Massachusetts contain a very small proportion of carbonate of lime, the greater part of which, however, is converted into those curious concretions called claystones, which usually contain more than 50 per cent. of carbonate of lime. But it was only in the north part of Berkshire county that I found enough calcareous matter in the clay beds to be of any consequence in agriculture. In other parts of the county, I met with but few clay beds; though I doubt not that others, besides those described below, may be found. The following analysis gives the composition of one specimen from North Adams and another from Williamstown, a little southeast from the college. Both were taken from excavations for making brick.

No.	Locality.	Carbonate of Lime.	Silica and Alumina.	Protoxide of Iron.	Carbonate of Magnesia.	Water of Absorption.
146	Williamstown.	11.7	65.0	18.0	trace	2.3
147	North Adams.	28.0	43.4	26.9?	0.99	0.7

Can there be a doubt, but clays so rich in calcareous matter as the above, would prove very valuable in cultivation? especially when we recollect that clay alone, destitute of calcareous matter, is of great service to some kinds of land. The bed in Williamstown, from which the specimen analysed was taken, is composed of the common plastic clay; but that in Adams, (a little east of the village,) is usually sandy; although a part of the same bed, less calcareous, is used for making bricks. On some soils fine sand, so full of calcareous matter, must be excellent. The quantity of magnesia in it is too small to affect its value unless it be favorably. In applying it, the same principles should be our guide as in richer marls. Other beds of marly clay may be found probably, by the use of vinegar or other acids.

Magnesian Limestone in Agriculture.—Very many limestones contain magnesia, and it seems to be generally admitted, that where this is the case, a large quantity spread upon soil is injurious; that is, when the stone has been burnt so as to drive off the carbonic acid. In small quantities, however, it would seem that even calcined magnesia is useful; as we might presume it would be from the fact that most soils contain it in small quantity. Again, it appears probable, that magnesian limestone, if not burnt, but merely reduced to a fine powder, will operate favorably: or even if we admit that in such a case the magnesia exerts no action, it will not prevent the salutary action of the lime united with it. But since magnesia unites with geic acid

and forms a compound more soluble in water than gaeate of lime, there is reason to believe that magnesia, properly applied, may be of service in agriculture. It would be very desirable that some experiments should be made upon this subject; for it will be seen by the analysis of our limestones that has been given, that many of them are magnesian. In the southern part of Berkshire county, the real dolomite, which contains 40 per cent. of magnesia, is common; and it occurs in smaller quantity in many of the limestones of that country. Nor is it easy by the eye to determine whether a limestone be magnesian. The dolomite, however, is very liable to disintegration, and hence it is easily reduced to powder; and from the principles above suggested, I infer that this is the proper way to prepare magnesian limestone for agricultural purposes. Indeed, I would extend the remark to all limestones where fuel is not abundant. For the great object of burning lime, so far as its application to soils is concerned, is to reduce it to powder. Indeed, when applied in the state of quicklime it is very apt to prove injurious, like magnesia, until it has absorbed carbonic acid from the atmosphere: that is, until it is brought back to the state in which it was before burning. The inhabitants of Berkshire county will probably never need to use magnesian limestone for agriculture, or any other purpose, because they have enough that is free from magnesia. But much of their dolomite might be more easily reduced to powder than any limestone could be burnt. And if this suggestion about pounding and grinding limestone be of no importance in respect to that which contains magnesia, it may be of consequence in regard to that great quantity of fragments of pure white limestone, which are necessarily accumulated at the quarries, and which are now entirely wasted. How little additional labor would it require, by means of water power, to bring these into the state of powder admirably fitted for agriculture! and who can doubt, but this might become an article of exportation, when the contemplated rail-roads are completed, and the value of lime upon land shall be as much appreciated in this country as it is in Europe!

From the Farmer's Cabinet.

BEST TIME FOR CUTTING TIMBER.

For many years my attention has been turned to ascertain the proper time to cut timber to insure its greatest durability. I am satisfied that the spring, when the sap flows freely, is the best time to fall timber. I am borne out in this opinion by the following statements that I have collected.

J—C— informed me that a detachment of British troops crossed from Philadelphia the 1st day of May, in 1777, and on the 2d commenced cutting down his woods for the supply of the army, and at the same time to burn up his fencing, which they completely accomplished. "But," said he, "they taught me the proper time to cut timber to make it last. After they marched off, I found many trees that were not cut into cord wood; those I split into rails, believing, at the same time, they would soon decay, from their being cut in the spring—but I have been agreeably disappointed,—most of them are as sound now as when made into fence." This he related five-and-twenty or thirty years after the peace of '83.

Conversing with an old gentleman in the neighborhood of Haddonfield, he told me that in the

spring of the year he was making fence. "My fences," said he, "are all of cedar, but falling short of cedar rails, and having none from the swamp, I was induced to cut down a pine tree and convert it into rails to finish out my fence; they were the only pine rails I ever made use of. Ten or twelve years after this, when resetting my fence, I found the pine rails so sound that I let them remain; since then I have not seen them having left my farm." I proposed taking a ride and look if any of them were remaining. We did so, and found a number in the fence perfectly sound. I asked how long they had been there. He replied, between 28 to 30 years.

An old friend related the following:—"I served my apprenticeship to a carpenter.—During my apprenticeship my employer was sent for to build a barn for a farmer in the neighborhood, who was very particular to have every thing done in the best manner. In the old of the moon in the month of February, he cut down and hauled all the logs necessary for the frame. In the spring my employer was sent for, and when he came to hew the sills, one was so defective we were compelled to get another from the woods to supply its place. Whilst we were building the barn he would frequently lament the loss of the sill he cut in the winter, saying, 'in a few years I shall have to put in a new sill, for this one will rot,' pointing to the one cut in the spring. But, said this old friend, I lived to see the same barn moved, and before it could be effected, they were compelled to put three new sills under it; they were all rotten except the one cut in the spring." This satisfied me that the spring was the proper time to fall timber to insure its lasting well.

Being at Egg Harbor, fitting out a vessel and in company with several persons, the conversation turned us to the proper time to cut timber for ship building—an old man related the following:—"I well remember a gentleman coming from Philadelphia to Egg Harbor, and sending for a shipcarpenter to build him a schooner. When they entered into a contract, the gentleman bound him up to cut down all the timber when the sap run, and then take his own time to build her, provided he would get her round to Philadelphia before the winter set in. We all thought he knew but little about cutting timber, and would soon have a rotten vessel. Eighteen years after, said he, I saw the same vessel opened. Her timbers were then sound, and in good condition.

Yours, &c.,

AN OLD MAN.

TO PRESERVE PEARS, PLUMS, &c., FOR TARTS AND PIES.—Gather them when full grown and just as they begin to turn. Pick one third of the largest out and put to them as much water as will cover them, boil and skin them.—When the fruit is boiled soft, strain it through a coarse sieve, and to every quart of this liquor put a pound and a half of sugar: boil and skim it, and then throw in your fruit; just give them a scald, take them off the fire, and when cold put them into bottles with wide mouths, pour your syrup over them, lay a piece of white paper dipped in sweet oil over them, and cover tight.

Economical people will not, of course, think of either making or using many preserves, on account of the expense, and the rigid adherence to the teachings of experience will generally avoid them because they are unhealthy. In sickness, however,

they are frequently very grateful, particularly in pulmonary complaints, and most people who are well, like occasionally to taste of good preserves.

We have before published the following directions, but in this place the information may be of value, as it will lessen the expense of making preserves. Take 8 lbs. molasses—bright New Orleans or sugar house—8 lbs. pure water, 1 lb. coarsely powdered charcoal; boil for twenty minutes, then strain through fine flannel, double; put it again in a kettle with the white of an egg, and boil gently till it forms a syrup of the proper consistence, and strain again. This syrup is said to be better for preserving fruit, &c. than a syrup prepared from the best of loaf sugar, as it is not so liable to candy, nor to ferment.—*Hillyard's Prac. Farming.*

SPECIFD TOMATOES.—As this is the season for securing a supply of this healthful vegetable, we commend to all housekeepers to put up some after the following recipe. By so doing they may preserve them perfectly good until tomatoes come again:

Recipe for a bushel of Tomatoes.—Take your tomatoes and pour boiling water over them, skin them, then boil them well, after which add a teaspoonful of salt, a tablespoonful of black pepper, one tablespoonful of cayenne, an ounce of cloves, an ounce of mace, mix well, and put the tomatoes in jars, run mutton suet over them and tie them in jars, either with stone blue paper or buckskin. Prepared in this way they will keep a year.

[We had Tomatoes preserved in this manner, during the whole of the last winter. The quantity of cloves, however, in this recipe, is greater than is required. Half an ounce to the bushel is sufficient.—*Al. Ev. Jour.*]

TOMATO PIES EQUAL TO THE FINE ENGLISH GOOSEBERRY PIES.—The other day we partook, for the first time, of a Tomato Pie, and were so much pleased with the treat, that we enquired into the mode of making them. The tomatoes are skinned, sliced, and after being mixed with sugar, are prepared in the same manner as other pies. The tomato is likely to become one of the most useful of plants.—*Springfield Pioneer.*

CATTLE FEED.—To the people of the Eastern States, it may appear incredible, that cattle actually thrive as well or better here in the woods, than in the best clover and timothy of any state; such we believe is the unvarnished truth. This fact is mainly to be attributed to the vast abundance of the wild pea that starts early, grows large and luxuriantly, and furnishes cattle with excellent feed until about the first of July; when the wild bean succeeds it and supplies succulent food in great profusion until late in the fall. Besides these, there are some kinds of grasses that flourish to some degree, and the greatest variety of other herbage we have ever observed in any country. Here the lover of the science of botany has a grand field for the exercise of his patience, and delightfulness, as well as useful investigations. Here the votary of Flora can procure from nature's own gardens, varieties to compose the richest bouquets, and can for months in succession gratify his taste with flowers, worthy of a place in the most splendid gardens.—*Wisconsin Cultivist.*

NEW ENGLAND FARMER,
AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, SEPTEMBER 26, 1838.

AGRICULTURAL IMPROVEMENTS.
No. III.

We come now to speak of the third class of agricultural improvements, those which are directly productive. These consist in the reclaiming of waste or unproductive lands, in rendering them productive; and in increasing the number, and value, and quantity of the products of the farm. We maintain that the great object of all agriculture ought to be production—the obtaining from the earth as large an amount of the means of human subsistence and comfort in the form of food, clothing, shelter, and fuel as it can be made to yield. In doing this we are to be restrained but by a single condition, and that is not so to cultivate it as to impoverish the soil; and for a long [and indefinite] period of time afterwards render it barren and unproductive. The earth is a liberal benefactor. There are few cases in which she refuses to answer fully the claims of industry and good management. But it is not reasonable to expect, it is not in the order of Providence, that she should expend continually without being replenished. There can be little doubt that the earth can be made to furnish from its own stores the means of maintaining its own fertility. By the application of all decayed substances vegetable and animal, by an exchange and intermixture of soils, by the occasional use of mineral substances, by the direct return to the earth of its own productions in the turning in of green crops, divine Providence has afforded the means of securing forever the productiveness of the earth. It is man's province and duty to use and apply these means; and it is thus in his power not only to secure but to increase its productiveness. Under these reasonable conditions man need not fear to tax the earth to the fullest extent of its powers, and to keep them in constant requisition. The limit of its capacities has perhaps in no case as yet been reached; in most cases it has not even been approached. The object of intelligent agriculture should be then to obtain from the earth all that it can be made to yield without impoverishment; to cultivate such crops and products as are most needed and consequently most valuable; and to put it into an advancing and improving condition.

If we try now the agricultural state of our farms by this standard of what it should be, it will be found greatly inferior and deficient. In respect to Massachusetts's itself we have no hesitation in saying that even with present prices of labor, on the supposition that the prices of agricultural produce should maintain the same relation to the prices of labor, which they now do, the agricultural products of the state might be profitably quadrupled; and we think we might even double this measure. We have no doubt that the agricultural resources of Massachusetts, if properly brought out, would be ample to the support of four times the population, which now belong to her.—Where she now produces one bushel of grain, and of excellent vegetables and one ton of hay, she might be made to produce four times that amount. Her beef, pork, wool, butter, cheese, are very small compared with what they might be. Her broom-corn, teasles, and tobacco are crops, which were never seen by a large portion of her inhabitants. Her maple sugar which is now in some parts of the state a considerable product, amounting in one town to several thousands of pounds yearly, might be vastly increased. Her apples, which, to say nothing of the value of the fruit for market or exportation, yet for feeding neat cattle and swine, are beginning to be appreciated at more than half the value of potatoes, are never-

theless comparatively a very small product. Hemp and flax are articles scarcely cultivated among us; yet in many cases would furnish an ample remuneration to labor. The cultivation of madder has not yet we believe been even tried among us. The cultivation of beets for sugar and of silk give a fair promise of the most abundant returns; but as yet can scarcely be said to be commenced. Now the question is not whether other countries can produce these articles in much greater abundance and at much less cost than we can; but whether Massachusetts can produce these articles in sufficiency for the supply of her own wants; and at such cost as to afford a full and profitable compensation for the labor necessary to their production. Without speculating on future contingences we can only say that at present she could do it to advantage and an ample profit; that an increased production would promote an increase of population and consequently increase the demand; and that an increased production would be followed by an increased use of the products; and that this likewise would stimulate the demand. The great and often vexed question whether a state for example should under all circumstances be advised to raise its own bread, when the same labor applied to other products or purposes would furnish the means of purchasing this bread at less cost, we shall reserve for discussion on another occasion. At present we rest upon the great position that agriculture in Massachusetts may be made to afford an ample and liberal compensation to well-directed labor, and to any amount of labor, which is available or can be brought to bear upon it; and therefore we feel at liberty to urge the subject of agricultural improvement, and the extension of our cultivation.

In New England in the common use or rather misuse of the term improve it means simply to use or to occupy. A man is said to improve a farm or a piece of land, when he merely uses or occupies it; and although under his management it should be in a course of impoverishment. It is a very different sense in which we employ the term. We understand a farm to be improved only when under the course of husbandry pursued it is continually becoming more fertile and productive. With this understanding what is the condition of agricultural improvement?

In looking then at the farms in Massachusetts, of which we feel more at liberty to speak than of other parts of the country, we are struck at once with the fact that a considerable portion of most of them is comparatively neglected and unproductive. There are large portions, which require draining. Perhaps in their present state they are overrun with bushes, and saturated with water, so as to be wholly inaccessible excepting when hard frozen. There are other portions so filled with water, that although containing a soil, which little more than the removal of the water would render eminently productive, they now yield nothing excepting a few cranberries, flags, and water-grasses, which will not compensate for the trouble of collecting them. Our peat meadows, of which we have a large extent in the Commonwealth, are among the best grass-lands, which can be found, yielding when properly subdued and managed in many cases two and even three tons of hay to the acre, and a large amount of after feed; and having proved in many cases highly productive in potatoes, wheat, and rye. There are other extensive tracts of meadow land of an alluvial character, of a soil of black mud, decayed vegetable matter, resting upon a gravelly subsoil, whose product in its present condition is comparatively worthless, which at a reasonable expense of draining and manuring, might be converted into the best of English mowing. Of these two descriptions of land there are thousands and thousands of acres in the state, which remain untouched. The many highly creditable examples of

distinguished improvements of such soils in Hamilton, Wenham, Lynn, Frammingham, Lexington, Groton, Concord, and many other places, show what may be done, and to the highest advantage and profit. We shall hereafter refer to them. H. C.

PUBLIC HEALTH.

There seems to be a strong impression prevailing with many intelligent and observing persons, that the health of our young people, young men and young women, is much less perfect than formerly; they are more feeble; there prevails a general debility; they are more subject to disease; and there are more deaths among the young than formerly; and especially the capacity for labor is greatly reduced. The younger part of the community are not only less disposed, but much less able for physical exertion than formerly. We do not state this as a determined fact; but as a strong, and, to a considerable extent, a general impression. Others can judge as well as ourselves how far it is confirmed by their own observation. For ourselves we believe the fact; and that in muscular energy, activity, and power the race is degenerating. We are aware that it is a fact of rather difficult proof; and that the judgment may be fairly made up it would require such a variety of statistical returns as are not easily obtained. But we not only have come to the melancholy conviction of the fact in the case but we think we see many reasons, why such a result should be certainly expected. What these reasons are we cannot enter upon at present; but we may do it hereafter if opportunity should admit; and if the discussion be likely to prove useful. From the number of patent nostrums, the advertisements of which crowd the columns of our newspapers, there would seem to be no necessity that mankind should ever be sick, much less that they should ever die. It may be that this wholesale quackery is one of the principal reasons of the evil, which we deplore. We have nothing farther however to add on this subject than to remark that there exists an intimate and inviolable sympathy between the mind and the body; that any general decline of the latter must be followed by a corresponding imbecility of the former; that considering the subject in a general view, intellectual health and energy must essentially depend on physical health and energy; and that any attempt to purchase the former at the sacrifice of the latter is commonly idle and vain; and in cases of the most brilliant success is but a miserable bargain. H. C.

FLAX.—A patent has been taken out for a mode of preparing flax that it may be spun by machinery like cotton. It is not water or dew-rotted and all the original strength of the fibre is preserved. We are not at all apprized of the mode by which it is prepared. We have seen the article. It is very beautiful and has the appearance of silk. We are comforted with the hope, therefore, of being able to wear linen shirts and sleep in linen sheets still longer; a luxury of which the increasing manufacture and the extraordinary cheapness of cotton cloth threatened to deprive us.

The Plymouth County Agricultural Society will hold their Annual Exhibition at Bridgewater, on Wednesday, October 10th. We have not learnt who is to deliver the address on the occasion. The Worcester County Cattle Show is to be held on the same day.

A man in Albany bought 7000 melons for \$400, and having a boat he took them down the canal, and sold them as he went down, at an average of twenty cents, thus realising about \$1000 in less than a week.

A frost was experienced in the northern part of New York state, on the 10th, which did some damage to corn, potatoes, etc.

Massachusetts Horticultural Society.

The annual exhibition at the Society's Hall took place last week much to the satisfaction of the numerous visitors who crowded the rooms for three successive days.—The display of fruits was never excelled, but on account of the failure of the Dahlia, the show of flowers was not so brilliant as that of last year. We shall devote the greater part of the next paper to the detailed report of the Committee on fruits and flowers.

NOTICE.

Those gentlemen who forwarded fruits for the late exhibition of the Massachusetts Horticultural Society, and did not leave minutes of the same with the Committee, are respectfully requested to forward lists of the same, directed to Mr Manning, to the care of Messrs Breck & Co. New England Farmer office, Boston, that they may be no omissions in the report.

For the Committee,
Sept. 22. **WILLIAM KENRICK, Chairman.**

FLOUR.—It is said that a few days since, 23 Stores in New York on the North River, were filled with flour; and that there were 30,000 barrels stored in Albany and Troy. If this is a fact, why is it that we at the North have to pay 8 and 9 dollars per barrel, when we ought to have it for \$5.00. We are inclined to think that the New York dealers have missed a figure, when they say that the price the present season will be 8, 9, and \$9.00 per barrel, for so long as we can raise such crops of corn as we shall the present season, we will not encourage, nor had Maine, for a decent price, we will not encourage, such nonpollers of bread stuffs, as those merchants who deal in the article— as there is no question but they are keeping it for the purpose of raising the price.

Mr Samuel Lewis, of Great Barrington, has raised 220 bushels of rye on five acres of land, being 46 bushels to the acre.

BRIGHTON MARKET.—Monday, Sept. 21, 1838.
Reported for the New England Farmer.

At Market 525 Beef Cattle, 570 Stores, 4,000 Sheep, and 650 Swine.

Prices.—Beef Cattle.—We quote, First quality, \$7 37 1-2. Second quality \$6 50 a \$7 00. Third quality, \$5 00 a \$6 25.

Stores.—Yearlings, \$9 a \$13. Two Year Old \$17 a \$23. Three Year Old, \$24 a \$35.

Sheep.—Lots were sold at \$1 50, \$1 58, \$1 75, \$1 92, \$2 12, \$2 33, \$2 58, and \$2 85.

Swine.—Lots to peddle were sold at 6 a 6 1-4 for sows, and 7 a 7 1-4 for barrows. Two lots of selected barrows at 7 1-2 a 8. At retail, from 7 to 9.

NOTICE.

The subscriber offers for sale his real estate in Westford and Groton; consisting of his homestead, 33 acres, his farm, 117, one pasture, 17 acres, one do. 33 acres, one wood-lot, 13 acres, one do. 5 acres, and one do. 10 acres. For further particulars see his advertisement in the Lowell Journal, or inquire of the subscriber at his house, near the meeting houses and academy in Westford.

EPHRAIM ABBOTT.

FARM FOR SALE.

In Cambridge, about one mile from Murdock's Hotel on the West Cambridge road with a valuable stone ledge on the same; containing forty acres of good land with the buildings on the same. It will be sold at a bargain if applied for soon, as the present owner is about removing to the West. Apply to the subscriber on the premises.

Sept. 25. 3w AMMI C. TEEL.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham.

WANTED TO HIRE

A single Man, who is capable of taking care of a small Farm. Inquire of **JOSEPH BRECK & CO.**
Sept. 5.

FARM FOR SALE.

An excellent farm, near the centre of Framingham is offered for sale, on liberal terms. Inquire at this office.
Aug. 22, 1838. 3m

LAYING OUT GARDENS AND ORNAMENTAL PLANTATIONS.

E. SAYERS begs leave to inform his friends and the public in general that he will attend the laying out gardens and ornamental plantations, and hopes by strict attention to business to merit the approbation of those who may be pleased to employ him.

All orders left with J. Breck & Co. Agricultural Store, No. 52 North Market Street, will be punctually attended to.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders to any amount, which will be promptly attended to.

Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston.
Sept. 20. **NAHUM WARD.**

FRUIT AND ORNAMENTAL TREES, MULBERRIES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces,

Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Azaleas, Peonies, Dahlias and other Herbaceous Flowering Plants.

100,000 MORUS MULTICAULIS now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Breeds and other varieties.

Malberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. D. BRECK, Commission Store, No. 132 Water Street, New York, M. S. PCWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantoin Hill, near Boston.
August 1, 1838. **WILLIAM KENRICK.**

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more as may be wanted, of the most approved kinds—consisting of the best selected varieties now in use, for cultivation, feeding worms, and making silk;—being acclimated to this country, and adapted to either warm or cold climates, affording a rare opportunity for companies or individuals to be supplied, from the most extensive collection of mulberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and orders left with Messrs. I. B. Colt, Secretary of the Connecticut and the American Institute, No. 187 Broadway, at the office of the American Institute, No. 187 Broadway, N. Y.; Thomas Lloyd, Jr. No. 236 Filbert street, Philadelphia, Pa.; Luther I. Cox, Baltimore, Md.; B. Snider, & Co. Savannah, Ga.; Bliss Jenkins & Co. Mobile, Al.; James Lyman, St. Louis, Mo.; Case and Judd, Columbus, O.; G. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass. Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Mulberry Plantations
Apply at the office of **D. STEBBINS.**
Northampton, Aug 22, 1838.

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dime, situated in Rochester, N. H. six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quarries of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to **JOSEPH BRECK & Co., No. 51 and 52 North Market Street, Boston.**
August 15, 1838.

FOR SALE.

Five acres of good Salt Marsh, in Quincy, or (Squamot so called.)
Also, Four acres of Salt Marsh in Brighton.
Also, Several full blooded animals, cows and calves. Apply to A. Greenwood, on the Welles Farm, Dorchester, near Dr Codman's meeting house.
Sept. 12, 1838.

SCHOOL HOUSES.

To the miserable condition of some of our school-houses, many can bear witness. In truth, there are but few, who have not seen an old-fashioned one. The floor abounding in hills and valleys, seems to have been laid for the purpose of excluding the blind, or to learn the pupils to "look before they"—step. Every board is a "*cave ne titubas*" to the careless scholar; every nail a stumbling block. The benches are hacked as if they were so many Agags, who had been under the fatal instrument of Samuel. The cobwebs are so numerous and dense, that they resemble so many oaks spread out to entangle the bushy hair of the young Absaloms. The dust is so closely matted to the walls and ceiling, that one would suppose himself in an old, worn-out coal-pen. Then the stove, placed in the centre for heating the room, draws half and quarter hurricanes through every crevice in the sides of the building; and these enter like the sounds of innumerable musical instruments, abstracting the pupils' attention from their studies by their charming melody. This probably suggested the idea of teaching singing in some of our district schools. The shivering urehins, clattering windows and roaring draught defy all attempts to learn. Some of the most breezy apertures are now sought, and their tunes stopped by the insertion of rags. Thus the process advances till every avenue is blocked up; and though the stove seemed to send invitations to all the winds to aid it, these stubborn rags execute their veto. Now the breaths of seventy or eighty gain the ascendancy. The room is tight, and in fifteen minutes the oxygen is consumed, or the air is poisoned. Instead of the most beneficial, the most deleterious gas, carbonic acid, pervades it. One after another yawns—then drops upon his elbow—becomes drowsy—is roused up for a few moments, and if the Argus-eyed monarch remits his vigilance, he is fast locked in the arms of Somnus. The whole grow restless. Even the teacher begins to open his mouth for a gape; and the confined air, confusion, sleepy sounds and laborious exertions, monotonous in the extreme, commence their operation. His eyes grow heavy; his limbs lose their elasticity; his head aches; and he hangs to the back of his turned-up chair in drowsy silence till the long expected minute arrives.

Such is the effect of a deficiency in ventilation. The pupils are compelled to misapp a great part of their time, and hence do not make the intended progress. The energies of the teacher become partially paralyzed, and he is in a measure incapacitated to perform his duty; hence he is unable to do so much as under other circumstances. But where rests this item of fault? With the overseers of the schools. Yet, to whose neglect and responsibility is a want of progress, arising from this, attributed? To the teacher's; and he must be discharged.

The public calculate the teacher's ability to instruct, without taking into consideration any of the very disadvantages they know to be in his way, and which some of them even purposely throw in his way. They suppose him to be put into a perfectly convenient house, with regularly attending scholars, exactly qualified to be taught in the studies of the school, all of an age, with equal talents, unwavering habits, industrious inclinations, faultless self-command, and every other quality to exceed perfec-

tion. He is stationed in a building similar to that described; and if he does not answer the expectations of the cold calculating world, they heap all the blame upon his innocent head.

These accusations effect another injury. They draw away the attention from a great evil. The health of seventy or eighty children in every such school house is undermined by the inhalation and absorption of the carbonic acid. Their lives are shortened; and more so, as they are in a very precarious and critical period of existence, which is to govern their future years. A partial absence of oxygen would be hurtful; but a supply of carbonic in its stead is destructive. Now what an immense amount of mischief is done to all the children of the United States, if cooped up as above stated! And what must be the loss of time and usefulness in the havoc committed against the whole human race!—*Essex Banner.*

NEWSPAPERS.—The following is an extract from Rev. Mr Winslow's Fourth of July Oration:

"As ready vehicles of public intelligence and instruction, newspapers are of indispensable service; they are eminently republican. They are the most constant companion and teachers of the people. In their daily visits, they are at the doors of their patrons to give them the news, first in the morning and first in the evening; frequently they breakfast and dine and sup with them; they entertain them in the parlor, and advise them in the counting-room; they travel with them in all the coaches, cars and steamboats, upon the public ways; there is not an Athenæum, nor reading room, nor house of entertainment, nor any place of public daily resort, where their forms are not seen, and their voices heard. They are in truth the omnipresent geniuses and tutelary goddesses of the people,—and if there be any truth in the proverb, that they who perpetually have our ears, have at last our faith, their influence must be great and decisive upon the destinies of this republic. Considering their immense power over the public mind, every good citizen must see the importance of endeavoring to save them from perversion, of elevating their character, and disseminating them as widely as possible. Every family that can afford it, should take at least one paper, and should exercise the most wise discrimination in the selection. Few men confer more benefit upon the community than good editors, and few do more harm than bad ones."

A thrifty old dame, in by-gone years, built a pudding for a family dinner. Extravagant as she thought she had been, she was rather mortified to find that her boarders were too *hoggyish* to appreciate her kind attentions to their wants, and in relating her trials to a neighbor, she pathetically exclaimed: "I made a pudding to-day, and put a *whole egg* in it; but *after all* our folks would eat *butter* on it!"

A Stove has been invented in New York, called the "poor man's stove," which the patentee offers to furnish together with the pipe, and coal enough to burn through the winter, for *fifteen dollars*. We shall order one immediately.

By driving your business before you, and not permitting your business to drive you, you will have opportunities to indulge in innocent diversions.

NEW ELEMENTARY WORK ON BOTANY.

Peter Parley's Botany; with descriptions of Trees, Shrubs and Plants; with a large number of fine engravings.

The publishers invite Teachers, and others interested in this subject, to examine this work, as they believe it will be found one of the most practically useful in use, being a complete manual of Botany for the adult and the pupil.

Parley's Cyclopaedia of Botany.—This work appears to be exactly what is wanted by young persons and in families. It not only contains the strictly scientific part of the subject, in an introduction and very full and complete genera of Plants, but it also contains copious glossaries of terms, and what is most important, a Dictionary of Plants, of nearly 300 pages, containing familiar descriptions of all the most interesting trees, plants, and shrubs.—These are alphabetically arranged, with an English index, so that the reader may immediately turn to any plant he wishes to read about. The work is illustrated by over 200 engravings, and is sold very cheap.—*Boston Paper.*

For sale at the New England Farmer Office, 51 & 52 North Market Street. JOSEPH BRECK & CO.

REMEDY FOR CANKER WORMS

The subscriber having obtained letters patent for his circular metallic trough for preventing canker worms or other insects from ascending fruit or other trees, now offers his services to apply the same to any extent that may be wanted. They were put on to three orchards belonging to Jonathan Dennis in Portsmouth, N. H., in the autumn of 1837, and exterminated the canker worms so completely that some of the trees hang so full of apples as to render it necessary to prop them, although they have been eaten by the worms for a number of years previous, and notwithstanding the application of tar. The public are invited to examine the orchards above referred to. The trough and roof is made of lead and bent to conform to the shape of the tree, and the ends soldered together and made enough larger than the tree to allow the trees to grow ten years before it will fill the space. The space between the trough and the tree is filled with hay, straw, seaweed, or any substance that is easily compressed by the growth of the tree; the trough is kept in its place by three nails driven into the tree below it; when the tree has grown so as to fill the space, the trough may be enlarged by putting in a short piece so as to answer ten years more. A little cheap oil is sufficient to fill the troughs and filling them three times has been found to answer for one year, by stirring the oil once sometime after they are filled. Those who wish to have their trees fitted with this, will do well to make early application to the subscriber, postage paid. For sale, State, Town and County rights by

JONATHAN DENNIS, Patentee, Portsmouth, R. I., August 22, 1837. 4w

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land, situated on Numontum Hill, in Newton, 5 1/2 miles from the city. The garden occupies nearly two acres is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

LOT WHEELRIGHT.

July 16th.

ALDERNEY STOCK FOR SALE.

For sale a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27

AMERICAN FLOWER GARDEN COMPANION.

The American Flower Garden Companion, adapted to the Northern States.

By Edward Sayers, Landscape and Ornamental Gardener. Published by JOSEPH BRECK & Co., and for sale at the Agricultural Warehouse and Seed Store, No. 51 and 52 North Market Street, Boston.

FOR SALE.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

THE NEW ENGLAND FARMER.

NEW ENGLAND FARMER AND GARDENER'S JOURNAL.

From the Genesee Farmer.

WARMING HOUSES.

Some of our subscribers and correspondents, who propose building houses, have requested some information as to the best method of heating them during our winters, and this may serve as an apology should one be deemed necessary, for the introducing of a topic more properly belonging to another season of the year.

The saving of fuel is daily assuming a greater importance among the inhabitants of this country, where the forests are rapidly disappearing, or where, as in many sections of the wide west, the country has always been destitute of timber. The broad fire places of our paternal mansions have been superseded by stoves; and to supply these with fuel where a number are required, as in the usual method of warming houses, is found to occasion heavy drafts on the income of most individuals. The great waste of heat that takes place in all the ordinary stoves and fire places, has turned the attention of men of science to the providing a remedy for the evil, and to efforts to provide a suitable temperature at a less expenditure than is usually incurred. Various methods have been suggested for economizing heat, some of which we shall notice. All arc on the principle of warming a house by a single fire, and all are more or less efficient for that purpose.

A few years since, Mr Fessenden, late editor of the New England Farmer, devised, and patented, we believe, a plan for warming rooms by hot water, and the system has been acted upon to a considerable extent in some of the eastern cities and large manufactories. It is founded on the well known fact that warm water always rises, and will continue to do so until the whole mass is brought to the boiling temperature, should the heat be continued to that point. A copper boiler is placed in the lower part of the building to be warmed, and pipes of copper connected with the boiler rise and pass through the various rooms to be warmed. These pipes, as well as the boiler, are water tight, and are filled to the top with water. When the fire is kindled, the water in the boiler being first warmed rises in the tubes, and displaces the cold water, which sinks into the boiler to be heated in its turn. Thus the circulation is kept up, and the rooms are gradually and equally warmed by the hot water contained in the pipes. This method has been highly approved for heating green houses, the heat being considered less drying and injurious to growing plants, than air heated by direct contact with iron stoves. That it will come into general use can hardly be expected, however, the apparatus requiring a nicer adjustment than can in ordinary cases be expected. It has one great advantage to recommend it, and that is, fires can hardly ensue from the use of such pipes; a difficulty which renders the ordinary stove most objectionable.

Several plans for warming rooms with heated air have been devised, one of which was described in the 6th vol. of the Farmer; but as our list of subscribers has since that time greatly increased, we shall for their benefit give the plan here presented, and which has, where adopted, succeeded admirably. The apparatus "consists of a large box stove, surmounted with two flat cast iron drums, and these again by two sheet iron ones. These four drums are made to communicate with each other, and with the stove by short pieces of pipe, joined to their alternate ends. The smoke and heated current of air, after it leaves the stove, is thus broken in its course eight times, and is deprived of its heat before it finally passes away. The heat is communicated to the air outside the drums, which rises in large volumes about them, in consequence of the increased temperature; and is retained from escaping by a brick wall around the whole apparatus, except the door of the stove which is left even with the outside of the wall. A chamber is thus formed, from which the heated air (in tubes) is at once conducted to any part of the house. The apparatus is placed in a small open cellar, and renders all fires above stairs unnecessary." Perhaps if the drums were placed vertically, instead of horizontally, as suggested by the inventor, the current from the stove would be sooner and more effectually deprived of its heat.

In Prof. Silliman's Journal for April, 1838, there is a communication on this subject from a gentleman in Virginia, in which the objections against this mode of warming houses are pointed out and obviated. His dwelling was warmed by such a furnace and air chamber, and as the air was admitted into the chamber of the furnace from the hall, or basement room, the air ascended to the parlors loaded with coal dust and other impurities. This evil was at once remedied by obtaining the air in pipes from without the house. This, besides obviating the difficulty of the dust, furnished a constant supply of fresh air. In rooms warmed by heated air, (and the difficulty attends nearly in an equal degree those warmed by a common stove,) it is found that the thermometer indicates a higher temperature in the upper part of the room than in the lower part, frequently as much as six or eight degrees, thus keeping the feet almost constantly cold, while the person is comfortable in other respects. This state of the air, reverses the injunction of Boerhaave, to keep the feet warm and the head cool, and as far as its influence extended was injurious to health. As the rooms were tight, it was evident that the warm air after parting with its caloric settled to the floor, and remained there causing the reduction shown by the thermometer. To remedy this, a pipe was led from the floor to the bottom of the air chamber in the furnace, and the cooled air passed off so rapidly, that when a supply of fresh air was admitted by a pipe into the parlor, to keep up the purity of the air, the quantity of which could be regulated by a valve, the thermometer gives a difference of only a degree and a half between the lower and upper part of the room.

This arrangement has been tested for five years, and has been perfectly satisfactory.

It may be here remarked, that where it is required to give out heat, as in the case of the stove and drums to the air chamber, rough and black bodies are far preferable to bright or polished ones; and for the same reason, the pipes that convey the heated air from the air chamber to the several rooms, should be smooth and bright, that the heat may not be given out on its passage. That a house may be warmed in this way from a single fire, does not admit of a doubt; and that it is far more economical than the usual process, is equally clear. We may, however, be permitted to suggest to those about to build, that a little additional expense in building, will do much more towards making a house comfortable, than a greater sum after it is built; and that it is better to shut out the cold air, than to devise ways and means for heating it, after it is once admitted. This is the true economy, and this our climate demands of us.

Since writing the above, we have seen in the London Chronicle an account of a new invention for warming rooms, which promises to supersede all others. A stove six inches in diameter and eighteen inches high, is enclosed in a cylindrical case of thin copper, the bottom of which, as well as that of the stove, is perforated for the admission of air, and the top of which is furnished with a damper or regulator to determine the heat. Such an apparatus will warm a room 25 feet square, and 12 feet high; does not require to be fed with fuel but once a day, and the expense of fuel daily is four pence. The fuel is charcoal. This fireplace has the form of a small column, is moveable, and may be made ornamental. It is evident from the fact of there being no flue or chimney required, that the charcoal is prepared in such a way as to prevent the formation, or secure the absorption, of carbonic gas; and since the patent has been secured, this preparation is all that remains a secret in the apparatus. Should it realize the benefits prophesied of it in the English journals, we may soon expect the method will be transplanted to our shores, and the wonderful properties of "Joyce's Heating Apparatus," as it termed, be tested among ourselves.

From the Farmer's Cabinet.

SOILING NEAT CATTLE.

The system of soiling has strenuous opponents, as well as many ardent advocates. But I believe that the system has never been fully settled by thorough and long tried experiments. A system is not to be established, nor overthrown in a day. We do not arrive at certain results in agricultural improvements by jumping conclusions. All improvement is the result or consequence of steady, progressive and judicious means. Those who undertake experiments are apt to abandon them at once, and in disgust, if success does not attend their first effort. This is wrong. It is important for us in establishing results to view both sides. It is altogether necessary that we know the failures of at

tempted experiments. It is as essential as it is to be assured of successful results. All tend to increase the store of general knowledge. All knowing wherein there has been a failure, and the course pursued, we can then enter into an investigation of the causes. Let no one be discouraged because a first or second effort is not crowned with success. A farmer has this advantage, that he can experiment on a small scale. The soiling system, as I before remarked, has not been satisfactorily settled. Its opponents contend—

I. That the soiling of cattle in the house during the whole of the year, is not only not beneficial, but positively injurious. This position is maintained by the following grounds:—1. It is natural. 2. Animals, thus kept, are deprived of air and exercise, and the selection of their food. In the experience of some farmers, cattle thrive much better in the fields, or open air, than when housed.

On the other hand, the advocates of this system say—

1. That it is a considerable saving of land, that is, one acre of cut grass soiled being equal to three acres of the same field pastured. The grasses grow much more rapidly in consequence of not being trampled upon.

II. It is a great saving of food, for when, say the compilers of the Complete Grazier, "animals are suffered to go upon the field, many plants are necessarily trodden under foot, and bruised, or partly buried in the earth, in which state they are greatly disrelished by cattle, and are suffered to run to waste; a circumstance which never could occur, if the practice of cutting were adopted." If the consumption of plants is an object, that object is obtained by soiling, for all who have paid attention to the subject must have observed that cattle will readily eat plants cut, and given to them when housed, which they would discard in the pasture; yet, according to the authority above quoted, it is known that they will feed, when thrown to them on the ground, which they will reject when given in the stall. Many of the grasses which are sweet and succulent when young, and which cattle eat with the greatest avidity, are quite offensive when suffered to get into ear, and are thereby lost; but by this system of cutting, no loss can occur from this quarter. Plants rejected by one class of animals, when presented to them, even when housed, are not on that account less acceptable to others; indeed they appear to be eaten with greater avidity. "Thus grass, or other food, that has been *blowed or breathed upon* by any animal for a considerable time, becomes unpleasant to other beasts of the same species, but not so to a stock of another class or variety; for them, indeed, it appears to acquire a higher relish."

III. It is contended by the friends of the cutting system, that the balance, so far as regards the health and comfort of cattle, is decidedly in its favor over that of pasturing. Cattle are not only less liable to accidents, but do not suffer the same inconveniences or annoyances to which they are subject, when exposed to the sun in the open air—they suffer much less from heat, flies, &c., and it is perfectly reasonable to suppose that they take on flesh more readily. Tranquillity and ease are essential; otherwise animals cannot thrive. An instance in point was cited by one of your correspondents, (see Cab. Vol. ii. page 295,) from which it appears that animals housed for fattening, and well fed, did not take on fat, owing to the circumstance of their being confined lousy, in consequence of fowls roosting over

them. The reason why they did not thrive, is obvious—when cleansed of the vermin they fattened well. Heat, restlessness, the terrible annoyance of flies, &c., when cattle are exposed, as they must frequently be in pastures, operate against them.

IV. The Complete Grazier asserts that the proportioned increase of manure obtained by soiling and stall feeding abundantly evince their superiority over pasturing. "Manure is the life and soul of husbandry; and when tillage is an object of attention, there can be no comparison between the two modes of consumption, especially in regard to manure obtained by soiling live stock during summer with green food, for in consequence of the increased discharge of urine during that season, the litter, of whatever substance it may consist, is speedily converted into dung."—p. 81.

Nicholson, in his Farmers' Assistant, refers to a communication from Dr. Thær, of Hanover, detailing the result of the experience of Baron de Bulow, and others: He lays down the following as facts, which he says, are incontrovertible.

"1. A spot of ground, which, when pastured, will yield only sufficient food for one head, will abundantly maintain four when left in the stable.

"2. Soiling affords at least double the quantity of manure from the same number of cattle: for the best summer manure is produced in the stable, and carried to the fields at the most proper period of its fermentation; whereas, when dropt on the meadow, and exposed to the action of the air and sun, its power is much wasted.

"3. Cows which are accustomed to soiling, will yield much more milk, when kept in this manner, and fattening cattle will increase much faster in weight.

"4. They are less subject to accidents and diseases—they are protected from the flies which torment them in the fields during the warm weather; and they do not suffer from the heat of summer."

Many other advantages are enumerated. Grazing also has its advantages. Experiments, however, render it certain that soiling, under favorable circumstances, is the most profitable. The Hon. Josiah Quincy, of Massachusetts, ascertained about 1820, that seventeen acres of land, under the soiling system, supported as much stock, and in as good, if not better condition, as had previously required fifty; and Sinclair states, that thirtythree head of cattle were soiled from the 20th of May to the first of October, 1835, on seventeen acres and a half, of which fifty were necessary in pasture. *The saving of land was consequently thirtytwo and a half acres.* From my own experience and observation, I am fully satisfied that there is no mode by which cultivated grasses will pay so well as by soiling. With us Jersey farmers, who can so readily derive the great advantage of top dressing by marl, lime, &c. it is nevertheless an object to turn all to the best account.

Burlington Co. July 23d, 1838.

BONE MANURE.

Bones possess very fertilizing powers as a manure. In an experiment of Mr. Watson, of Perth Amboy, with bone dust, who applied it to corn, at the rate of sixteen bushels to the acre, it exceeded in its effects the highest manuring with yard manure or with fish. It does not in general, produce much effect the first year, unless it has been fermented before the application to the soil; this process of fermentation is effected by mixing 25 bush-

els of leached ashes with 40 bushels of bone dust, moisten the whole with water, and at the end of twentyfour hours, the heap will commence smoking, when the whole should be turned—after laying ten days it will be fit for use. Bone dust is known to be in fermentation by the heat, and the strong smell; before being fermented, it is white, or of the color of bone; after, it assumes a yellowish cast.

The quantity of bone dust applied in ordinary cases, is about 20 bushels per acre—if the bones are coarsely broken, 40 bushels should be applied; but in this the farmer must be governed by the quality of the soil; poorer lands requiring more, and those in a higher state of cultivation, less.

Bone manure should be placed within about two inches of the surface; and owing to the small quantity used per acre, the seed should be brought as near to it as possible, without immediate contact, which it is thought better to avoid. In the preparation, a decided preference seems to be given to bones broken small, and the half inch bones are those most generally used. Mr Birks states, that were he to till for early profit, he would use bones powdered as fine as sawdust; if he wished to keep his land in good heart, he would use principally half-inch bones, and would prefer some remaining considerably larger. The reasons for which belief are, that by using bones of a larger size with the dust in them, there would be sufficient of the small particles of the dust to set the (turnip) crop forward, and sufficient of the large particles of the bone left, to maintain the land in good condition for the next crop—it is the small quantity needed to produce a given effect, that renders manures of this class so remarkable.

The soils to which they are best adapted, are those of a light and warm nature, for upon wet or cold ground, they have rarely been found to produce any sensible effect. On heavy loams and clay, the accounts of their operations have been almost invariably unfavorable, and it may be laid down as a necessary qualification, in a soil fit for the application of bones, that it should be dry.—*Salem Observer.*

IRRIGATION.—Irrigation is a practice which has not yet been introduced, to hardly any extent, into agriculture in this country; but which would, in most seasons and situations, abundantly repay the husbandman for all the expense and labor attendant on the practice. What an immense value in crops might have been saved during the late drought, had the watering of fields by artificial means been in use to the extent to which it is susceptible!—There is always water enough in the bowels of the earth; and the drawing of it forth and diffusion of it are not so difficult and expensive matters as might at first be imagined. A common well sunk in a favorable spot, with simple horse power applied to a common pump, would in a dry time, be found of great saving benefit even to acres. Many fields are so situated that the springs in the neighboring hills, with little ingenuity and not much expense, might be made to diffuse their animating contents over them, greatly to the advantage of any kind of crop. Artificial means of watering would be found beneficial in most ordinary seasons; but in times of great drought, of incalculable benefit. The most flattering promises of abundant crops, have in many cases, been destroyed by the recent hot and dry time which has been experienced in this State and elsewhere.

We speak not from self-experienced knowledge in this matter: but from the dictates of common sense, from what we have read upon the subject. We believe that a method, which might be turned to much good, is hardly thought of among our agriculturists. Irrigation is much employed in many countries in Europe, and with great advantage. In Italy there is scarcely a field or garden which is not furnished with the means of artificial watering. The Milanese territory exhibits the greatest expense of irrigation known in Europe. In that country are to be seen noble canals, running in every direction for this purpose. They are under the authority and protection of the government, which lets out the water to the various occupiers of meadows, at a fixed rate, according to the quantity supplied. Sometimes these canals are farmed out, by putting up the several sluices at auction; in other instances the canals go with the lands.

We contemplate nothing in this way on a public or so extensive a scale; but believe that much might be done in cheap way by individual enterprise. These few thoughts upon this subject are the suggestion of a *dry time*; and we believe that there is as much reason and utility in them as in most of the political essays and paragraphs, which meet us on every side.—*Salem Observer*.

SWINE.

The following observations respecting this ugly, uncouth, but useful animal, are mostly condensed from a number of authors on both sides of the Atlantic:—

It is best to begin to fatten hogs the latter part of August or the beginning of September, so that they may be fit for the butcher before the weather becomes very cold, as it is very difficult to put flesh on them in cold weather.

When you commence fattening swine, care should be used not to give them more than they will eat with appetite. If they become cloyed, their thriving is retarded, and there is danger from staggers and other diseases. Their troughs should be replenished with a small quantity of food at a time, and kept always clean and well seasoned with salt.

An English farmer fattened eight pigs in the following manner, which may be recommended in cases where a constant and regular attention cannot be given to feeding the animals. He placed two troughs in the sty; one he filled with raw potatoes, the other with peas, and gave no water. When the pigs were thirsty they ate the potatoes. In this way it is probable that the animal would not only thrive without water, but need no antimony, brimstone, nor other medical substances; for raw potatoes being cooling and loosening, might serve at once for food and physic. Instead of peas, perhaps dry Indian corn, or what would be better, Indian meal might be substituted. This mode of management with swine, was first recommended in the *New England Farmer* of Aug. 16, 1824, and we are glad to see that it has been adopted by a writer for the *Northern Farmer*.

Cunningham, in his *Two Years in New South Wales*, relates:—"I had often heard it said among sailors, that pigs would fatten on coals, and although I had observed them very fond of mashing up the coals and cinders that came in their way, still I conceived that they might relish them more as a condiment or medicine than as food, till I was assured by a worthy friend of mine, long in command of a ship, that he once knew of a pig's being

lost for several weeks in a vessel he commanded, and it was at last found tumbled into the coal hole, and there lived all that period without a morsel of any thing to feed on but coals: on being dragged out, it was found as plump and fat as if it had been feasting on the most nutritious food. Another friend told me of a similar case which came under his observation, and although these may be solitary instances, yet they serve at least to show the wonderful facility which the stomachs of certain animals possess of adapting their digestive powers to such an extraordinary species of food, and extracting wholesome nourishment therefrom. When we consider coal, however, to be a vegetable production, containing the constituent principles of fat, carbon, hydrogen, and oxygen, our surprise ceases.

I always cause as many peas as I want for feeding my hogs, which are not a few in a year, to be regularly malted in the same manner, nearly, as my barley; this management has succeeded very well with me. Young pigs require warm meat to make them grow. Corn and cold water will make them sleek and healthy; but warm beverage is considered requisite to a quick growth.

EVERY STYE SHOULD HAVE A RUBBING-POST. Having occasion to shift two hogs out of a sty without one, into another with a post, accidentally put up to support the roof, I had a full opportunity of observing its use. The animals when they went in were dirty, with broken ragged coats, and with dull heavy countenances. In a few days they cleared away their coats, cleaned their skins, and became sleekly haired; the enjoyment of the post was discernable even in their looks; in their liveliness and apparent contentment.

From experience, I have found that swine prefer lucerne to clover. A small quantity of corn, peas, or beans, is certainly necessary to be given to them. Potatoes, either whole or mashed in the water in which they are boiled, or mixed in the trough with barley meal scalded, is very good feed for swine. When rearing, a small quantity of food given once or twice a day, with lucerne, clover, grass and offals, is sufficient. When fattening, a constant supply is essentially necessary, so as not to leave the troughs encumbered with stale food, which should be cleaned out and given to store swine. An iron kettle is best to boil potatoes in, as copper, brass, and lead, are extremely dangerous and generate poison, if allowed to be left with any water in them, therefore it is necessary they should be immediately emptied and cleaned out. Swine while fattening should be kept as clean as possible and well supplied with dry litter. Two or three times in a week add about three table spoonfuls of salt to each bushel of their food, which assists digestion and promotes appetite.—*Essex Gazette*.

SILK FACTORY.

Northampton, July 27th, 1838.

Yesterday I visited Mr. Whitmarsh's establishment, and although I had heard much of his factory, I was most agreeably disappointed. Few men in this country deserve more credit for enterprise and industry. But a few years since he was a successful merchant in Broadway. He retired to this place, since which, he has visited various parts of Europe, to obtain information relating to the Mulberry, the worm, and the manufacture of silk; and, unlike nearly all his travelling countrymen, he has brought his knowledge into practical usefulness. He purchased a neglected spot, which he has im-

proved to such a degree, that it now presents one of the most tasteful country seats that adorn our country, and has erected a fine cottage, after the Corinthian order, not unlike in appearance the Hall of Record, in the Park. The grounds are laid out with a taste that would do credit to an English nobleman. The great objects of attraction, however, are his mulberry grounds, his cocoonery, and his factory. In the first are fields of the plant: they are placed in hedges, about four feet high and about eight feet apart, and men are constantly employed in hoeing them and keeping the ground perfectly clear of weeds and grass. He has every variety of plant, and is making valuable experiments as to which species will best suit the climate, and yield the finest and best silk. Many of these plants he brought from the villas of Italy. His cocoonery is a building of two stories, about thirty feet wide and a hundred and fifty feet long; here are different shelves or tables, on which are myriads of worms in all their different stages, from that of hatching from the egg, to that of winding up their balls. The whole labor of feeding and attending to these myriads of 'manufacturers' is done by a few females, and is neither arduous nor unpleasant. There are two manufactories, and a third now building. The smallest is the one I examined. It is beyond my power to detail the progress of the manufacture. Every thing appeared neat, and the girls cheerful and happy. The silk, from the raw to the manufactured state, is here perfected, and sells much higher than the imported.—*N. Y. Express*.

Town House, Hartford, Sep. 26, 1838.

MR BOSWELL: Sir—We present you with three stalks of corn, the product of one kernel; the main stalk measures from the root to the top 13 feet 8 inches, the longest sucker 12 feet 10 inches, and the shortest one 11 feet 11 inches—total 38 feet 5 inches—having three full ears of corn. The circumference of the largest ear is 11 inches; the circumference of the three stalks in the thickest part is 13 1-4 inches: it grew in the midst of a field of broom corn, 80 full-grown stalks of which growing within an inch of four feet from it. Now we do not exhibit this stalk of corn for the purpose of shewing our superior skill in farming, but having noticed in your paper that several exhibitions of the kind have been made the present season, it is to show that we have something that goes a little beyond any thing of the kind yet produced; but most of all it is that you may see that kind Providence in rewarding the rich with an abundant harvest, has not been unkind to the poor.—*Con. Courant*. V. CORNISH.

WOOL.—The vast quantities of this article which have been transported from this wool-growing section to Boston and other markets, during the few past weeks are astonishing. Almost daily, eight-horse teams pass through our village, groaning beneath their loads of this commodity. We understand from a gentleman who is acquainted with the matter, that but little remains unsold in this vicinity. This circumstance, together with the overwhelming amount of every article of production, which our agriculturists are gathering to their garner, with joyful hearts,—must of necessity, cause business to revive, and bring our farmers that ample return, which should ever be the just meed of honest industry and the "sweat of the brow."—*Newport, N. H. Argus*.

GEOLOGY OF MASSACHUSETTS.

[Concluded from page 93.]

Clay in Agriculture.—There is abundant evidence that our common clays are of great value when spread upon land. I find that they have been used to a considerable extent in the state; so commonly, indeed, that I abandoned the idea I had formed of giving a detailed account of particular instances. So far as my inquiries have extended, the testimony is decided that our blue clays exert a very favorable effect upon the soil. When spread upon sandy ground we might expect that they would render it a better reservoir for salts and geine. But thoroughly to ameliorate our sandy soils in this way, requires far more clay than is usually employed, and I am perfectly convinced that they exert other than a mechanical influence; that in fact, their effect is analogous to that of lime. I refer here to the blue clays which are far the most common. As to the white clay I have not learnt its effect upon the soil; but from the fertility of some of the soils in Kingston, Plymouth, and Barnstable, where white clay is mixed naturally with sand, I presume this sort is equally valuable with the blue.

In view of the wide extent of our beds of clay, and the use that might be made of it upon land, I felt desirous to ascertain to what principle it owes its fertilizing powers; and therefore subjected a few specimens to analysis in the ordinary way by solution in alkali. The following are the results. I omit however certain white clays, which I found destitute of iron, and therefore probably not very likely to be of much value upon land. But for other purposes, of which I shall speak shortly, they are of a good deal of importance.

Analysis in the Dry way by Alkali.

No.	Locality.	Water & Oxide of Iron.	Silica.	Alumina.	Protoxide of Iron.	Oxide of Magnesia.	Lime.	Magnesia.	Specific Gravity.
139	Northfield, blue.	10.8	46.93	23.97	9.9			0.1	2.9
140	Sunderland, light blue.	8.2	49.00	29.15	13.1	0.15	slight prec.	0.4	
142	Kingston, white.	3.5	71.00	16.30	7.3	0.30	do.	0.3	1.3
143	Lowell, white.	4	61.52	20.50	9.2	0.56	0.56	0.41	3.22

I tried some of our blue clays also, for geine; but in general they yielded only very little, and perhaps none. For so strongly do they retain water, that not improbably all the loss, especially of soluble geine, might have been imputed to this substance, which had not been all expelled by a heat of 300° F.; and then the peroxidation of the iron by ignition, renders this method of analysis quite uncertain. I, therefore, omit the results; only observing, that the amount of sulphate and phosphate of lime obtained, was about the same as in good soils. I therefore suspect that we must impute most of the good effects of clay as a manure to the large quantity of iron which it contains. On this point, however, I will present some suggestions of Dr Dana, with which he has kindly favored me.

"If we attempt," says he, "to account for the action of *el ty*, independent of its amending a sandy soil, we should bear in mind that all our common clays contain more or less of sulphure of iron.—The conversion of this into the persulphate of iron

is the natural consequence of exposure; free sulphuric acid then results, which acts on any lime in the soil, forming sulphate of lime: (the Gay Lard crystals of sulphate of lime are so formed); so that by spreading clay, we spread plaster. The iron in clay also plays its part thus. It is evident from Chaptal's experiments, that protoxide of iron is not beneficial in agriculture. He attributes this to the oxidation of the iron, depriving the plant of its intended oxygen. Nature is no niggard; nor is the reason of Chaptal very philosophical. We have seen above that protoxide of iron does not act on geine. Now by exposure, the protoxide becomes peroxide; and then, I conceive begins an action similar to that of lime. If the free sulphuric acid, produced as we have supposed, finds not lime enough, it will decompose all earthy geates, and thus a fresh portion of nutriment is set at liberty. Both the effects of clay—the production of plaster and the formation of peroxide of iron, are speedily produced by burning the clay, as is often practised.*"

Still more recently, Dr Dana adds the following: "Some facts have lately come under my eye, and have recalled others to mind, which I have followed up experimentally; all tending to show, that if iron peroxidates itself in contact with vegetable fibre, the texture of the vegetable fibre is weakened, and geine is produced, and that in a few hours. It is during the passage from protoxide to peroxide that the 'saponifying' action takes place, geine is produced, and then combines with peroxide."

In the few analyses which I have given above of our clays, I have considered all the iron in them as existing in the state of protoxide; although I made no attempt to ascertain whether some of it might not be a peroxide. Very probably this may to some extent be the case: especially where the clay has a yellowish tinge. Yet for the most part, I doubt not it is a protoxide. A slight error here cannot affect the reasoning above presented.

I hope our farmers will make more numerous and accurate experiments upon the use of clay as a manure; not merely upon sandy land, but following the suggestions of Dr Dana, upon other soils, in the expectation that its action will be analogous to that of lime. Probably, the best clay for this purpose occurs in the valley of the Connecticut river; but it abounds in almost every part of the state, and perhaps it may in a good measure supply the deficiency of lime. It will of course require to be laid on in much greater quantity than marl, and probably, as in the case of marl, too much may be used. How much ought to be used is a fair subject for experiment.

* The agency of geine in the fermentation of manure is thus explained by Dr Dana with his usual clearness and felicity.

"By fermenting dung vast volumes of ammonia are liberated. I do not think that it is the action of gases as such, which we want or which nature intends as food of plants to be derived from the soil. The air is always full of all which this fermenting manure can supply in a gaseous form. The true actions of ammonia and carbonic acid resolve into their effects on geine. The ammonia combines as alkali with that, and thus it becomes very soluble, and the carbonic acid produces sur-salts of the earthy geates of lime and magnesia. It is these, liberated the moment the plant demands them, which cause all the geine of the manure to become alkaline soluble geates."

"How wide is the influence of geine! It not only enters by itself into the food of vegetables but becomes the very solvent which nature has proposed to act on the alkaline earths and oxides, dissolving them as they are liberated from decomposing granitic sand."

Peat Swamps.—The peat swamps of New England have become a vast repository of organic matter, which is, and has been, for ages increasing. In addition to the larger vegetables, which, as they die, fall and are enveloped in the soft matter on which they grew, there is a thick mat of moss, which—especially the sphagnum—continues to flourish at the upper part while the lower part dies and decays. In favorable circumstances as to wet and temperature, this mass of vegetable matter becomes converted into peat. Only a small part, however, of what is thus accumulated, becomes peat of such a character that it answers well for fuel. Often it is too much mixed with mud to be easily burnt, and sometimes the vegetable fibre is scarcely changed. Yet the whole of it is capable of being converted into vegetable nutriment. And I am convinced, from all that I have seen and heard, that Massachusetts contains enough of this geine and vegetable fibre in her swamps, to render all her fields fertile for centuries. In other words, here is an exhaustless source of geine. Some of it is already in a soluble state; and therefore the black matter from swamps, is rarely spread upon soils without producing some benefit. Yet for the most part the geine is in such a state as to require some chemical change before it will become soluble nutriment, fit to be absorbed by roots. It is an important inquiry then, what is the best mode of accomplishing this change. This has been attempted, first, by mixing the peaty matter with good manure in alternating layers, and suffering them to ferment for a long time, the peat being in much the greatest quantity. Secondly, by mixing it in a similar manner with lime; and thirdly by mixing it with alkali, or some compound containing alkali. The principles respecting geine which have been advanced in this Report, will probably enable us to decide as to the preference to be given to any one of these methods. And here I have it in my power to give the opinion of Dr Dana, whose remarks I am always happy to substitute for my own, on a subject with which he is so familiar, and which he has done so much to elucidate.

"The fact," says he, "that peat or turf is very soluble, in alkali, seems not to be known among our farmers. The usual practice of mixing lime with peat or turf is decidedly the worst which can be followed. The geine which constitutes a large part of peat bogs, forms with lime a compound little soluble in water, requiring at least 2000 parts of water to one of geate of lime; and if the compound has been dried and sun-baked, a still larger portion of water is required; it becomes, in truth, a most insoluble. With alumina, geine forms a compound still more insoluble than with lime: although the vegetable matter in combination with these earthy bases, is actually absorbed by the roots of growing plants, still the geine is in a state much less favorable than when in combination with alkali. Mix ley of wood ashes with peat, and we form (dark brown) vegetable solution: the alkaline properties are completely neutralized by the geine, and very often ammonia escapes from turf when treated by caustic alkali. When we add, that this geine absorbs and retains nearly its own weight of water without seeming moist, it is evident, that with the use of ley or wood ashes, the value of peat as manure will be very much increased."

I will only add, that in my opinion, it would be very desirable to have a series of experiments performed by a practical chemist upon the differ-

varieties of our peat, and especially upon the best mode of converting it into soluble geine. Since by the old methods of analysis the different varieties of peat would be found to differ from one another only in the quantity of organic matter which they contain, I supposed it would be useless to analyze them, and therefore did not collect specimens of the peat and other vegetable matters that occur in our swamps. The doctrines respecting geine put a new aspect upon the case, and led me to regret that such a collection was not made. The labor of doing it now, however, is small; and when it is considered what an immense mass of organic matter now lies useless in our swamps, while the fields around them yield but a scanty crop, and that the chief reason why our farmers make so limited a use of this manure, is, that they find it difficult to convert it into soluble nutriment, I sincerely hope that the government will do all in its power to bring into use this important part of our fossil resources.

Marsh Mud.—Every intelligent farmer probably knows, that this substance forms an excellent manure; and although I apprehend it is employed far less than its value demands. An intelligent farmer in Maryland states, that he "deems it more valuable than barn-yard manure;" and that "it never failed in any application he had made of it." He also prefers it to marl, because "it is more accessible, its effects are quicker and much more can be done in the way of improvement for the same money." At the same time he confesses, that the permanent advantages of marl are much greater; and thinks that marl and marsh mud will both be improved by combination." This last remark appears still more important, when we ascertain what it is that gives an agricultural value to this substance. The fact is, it sometimes contains a large quantity of geine, and sometimes but little, while the quantity of the salts of lime, soda, and magnesia, is rather large; so that sometimes a mixture of marl will be of service, and sometimes not.

Concluding remarks upon Soils.—Though I have dwelt so long upon the analysis and improvement of our soils, it will be seen that I have touched only a few of its more important features, and that even these are but imperfectly considered. Many minor points, of no small importance, however, have been wholly passed over, or only alluded to; and sensible that I cannot do them justice at present, I shall not attempt to discuss them. My great object has been, after ascertaining the greatest deficiencies in our soils, to satisfy the Government that we have the means of remedying them and of making great improvements in them, by the aid of chemistry. If I may hope that I have accomplished this object, then I take the liberty to inquire, whether it be not important enough, and whether there is not enough still left to accomplish respecting it, to make the appointment of a *State Chemist*, desirable? We ought to have still further experiments made on the subject of geine, and the salts, which the soils contain; also accurate analyses of the crops grown on soils with different manures; and investigations as to the manner in which calcareous matter acts upon vegetable and animal substances; as also experiments directed by an able and experienced chemist, on the best mode of bringing into use the vast deposits of geine and vegetable fibre which our state contains. And since we have chemists of this character among us, why should not the services of at least one of them

be secured for this object? The geological surveyor might often collect substances for analysis; but if obliged to go as thoroughly into the chemistry of the subject as is necessary to valuable results, he cannot within any reasonable time accomplish the more appropriate objects of his appointment. In at least one state of the Union, where geological surveys are in progress, one gentleman is appointed, whose time and attention are exclusively devoted to the chemical examination of the soils, ores, &c., collected. And I would fondly believe, that Massachusetts will not rest satisfied, till this work is done at least as thoroughly as in any other state. I believe there is abundant labor, for an experienced chemist upon our soils alone; but many other substances, found in the state, ought to be analysed, that their real value may be known.

I do not doubt but the Government and every intelligent reflecting citizen will feel the vast importance of energetic efforts to improve our soils so that they may sustain a larger population. This is the only way to check the tide of emigration that sets so strongly to the great West. For if our sons can be made to see the soil of New England doubling its increase, as I verily believe they might in one or two decades of years, the rich alluvia and prairies of the West will not be able to draw them away from the graves of their fathers; especially if they learn that those fertile regions will at length become exhausted of their geine and salts, and then will probably require as much labor to cultivate as the soils of Massachusetts.

Some, however, may contend, that it is more important, to transfer the New England character to the unsettled West, than to multiply our numbers and wealth at home. But the history of the world leads us to fear, that New England character cannot long be preserved except upon New England soil; or upon a soil that requires equal industry for its cultivation. Place New England men where the earth yields spontaneously, and the locks of their strength will soon be shorn. If we look over the map of the world, and the history of the past, we shall find as a general fact, that the brightest exhibitions of human character have been made, in regions where nature has done less, but art and industry more. If, therefore, we wish to increase the moral power of New England, it must be done by improving her soil, and increasing her resources and her population. If these views are correct, which I acknowledge do not fall in with the prevailing notions, they furnish a new stimulus for vigorous effort in the improvement of our soils.

From the Genesee Farmer.

W H E A T W O R M .

No apology can be necessary for introducing this subject so frequently into the columns of the Farmer. The extent of the interest involved in the progress of the wheat worm can only be estimated by those who have traversed Western New York, and witnessed the quantity of wheat annually sown in this district. We make the following extract from the Seneca Observer, for the purpose of calling the attention of farmers to the statements made in it, and particularly the one that the worm continues its ravages after the wheat is ripe and put in the barn.

We have had the impression, in common with most others, that after the berry had become hard, the ravages of the worm ceased, or was only con-

tinued on such kernels as were attacked before the wheat had become ripened. We have within a few days examined wheat in which worms were found in abundance, and could find no kernels injured, except such as from their shrunken and pale appearance had evidently suffered when in the milk, or before the berry had become ripe. That the *worm*, the product of a bug, destroys the grain in the mow or the granary, is well known; but that the *worm*, the product of a fly, does the same, we think requires further examination and proof before it is fully admitted. Should such prove to be the fact, it would indeed prove to be an alarming feature in the history of the wheat worm. At the east, where its ravages have been the most extensive and longest continued, we have never heard any apprehensions of injury after the wheat had ripened and was gathered. We have instituted some experiments having a bearing on this matter, and we hope farmers generally will lend their aid in elucidating this point. Is not the noise spoken of occasioned by the crawling of the worm and the rustling of the chaff, rather than by its feeding? and does not the pressure in a mow of wheat cause the speedy death of far the greater part of the worms in the gathered grain? It is well known that when wheat is threshed immediately after gathering, the worms will be many times more numerous than in the same wheat, if left in the barn for one or two months before threshing.

"It is curious as well as alarming to observe the operations of this destructive worm. It commences its work early, and continues it late. When in the field, it can be heard making a noise much resembling that of the silk worm while eating. After it commences, it devours with all greediness, until the crop is gathered; and, what is still worse, and perhaps not generally known, it continues its work of destruction, after the crop is gathered. Of this fact there can now be no doubt. It has been witnessed by many of the most observing farmers of our neighborhood. This insect can be heard in the mows and stacks, and on examining the heads of wheat, they are found to contain many of these destroyers. This is the more alarming to the wheat grower, as it is next to impossible for him to thresh out his grain as soon as harvested, owing to the other necessary labor that is pressing upon him at this season of the year—the completion of his haying, and the preparing of his fallow ground for another crop. Yet he must thresh his wheat or lose a goodly portion of what has been gathered."

We do not allow ourselves to indulge in the gloomy anticipations of the concluding paragraphs of the article in the Observer. We remember that when the Hessian fly became so destructive, and its ravages extended so rapidly, many were found who fancied that wheat could never again be grown in the United States. Such predictions have been utterly falsified by the event; and such we doubt not will be the result in regard to the grain worm. As yet we see no reason for deserting the fair fields of Western New York, or abandoning the culture of wheat. Partial failures may indeed be expected; but the beautiful wheat that finds its way in such quantities to our markets affords conclusive proof that our fields yet yield their increase, and that Providence has not ceased its kindness and its blessings.

A clergyman in New York advises his hearers to subscribe and pay for a good newspaper.

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, OCTOBER 3, 1838.

AGRICULTURAL DEPOSITORY.

A CARD.—The Commissioner of Agricultural Survey respectfully solicits of the farmers in Massachusetts, or his correspondents in other places, small samples of any of their agricultural products, which they may regard as possessing any peculiar excellence. Corn in the ear, of any variety; Wheat; Rye; Barley; Oats; Buckwheat; Broom Corn; Cocoons; Silk; Wool; and valuable grasses. He would likewise be pleased to receive specimens or models of any valuable implement or invention connected with husbandry or the rural arts; or models or drawings of any improved farm buildings; or pictures of any valuable domestic animals. His objects are wholly public. His intention is to place such things in a situation where they may be examined by the farmers of the State; and to lay the foundation of an Agricultural Museum solely for the public benefit. He hopes so much public spirit will be felt in this case by his agricultural brethren, that their liberal contributions will soon render the collection worthy of public attention. The beginnings must be small; but in time the collection may be of great utility. It is important in respect to any article sent that a written account should accompany it.

He particularly solicits likewise the attention of intelligent shipmasters and others visiting foreign countries, to the collection of valuable agricultural seeds in places where they may go; and pledges himself that if they will do him the favor to place them under his care, he will gratefully receive them and dispose of them in a manner to test their value and diffuse their benefits.

Any such donations may be forwarded for the present to the store of Messrs James K. Mills & Co. Kilby street, Boston; to his address. The expenses of freight or transportation will be cheerfully paid.

HENRY COLMAN,

Commissioner of Agr. Survey in Massachusetts.

Oct. 1, 1838.

Printers in Massachusetts, in town and country, favorably disposed to this object, are respectfully requested to give the above card one or two insertions.

ON PAINTING ROOFS.

Milford, Sept. 28, 1838.

MR EDITOR:—Sir,—I wish to make enquiry through your paper respecting the painting of roofs, and the best paint or composition for preserving them.

A SUBSCRIBER.

REMARKS.—We have seen different preparations applied for the preservation of roofs, and been acquainted with many recipes for composition for the same purpose; yet from our own observation and experience, we believe there is no great economy in expending much upon a roof for paint. The object of the greatest importance is to get good shingles and then have them well laid. There are those, however, who think differently. A mixture of black lead and linseed oil is perhaps as good a mixture as can be used if it is thought expedient to paint; but it is very difficult with any paint, to fill every crevice so that water will not find its way between the joints to the unpainted shingle, and here is the trouble; the wet gets under the shingle, and in consequence of their being painted do not dry so quick, and of course will decay sooner for being painted. It is sometimes the case when a man undertakes to build substantially he paints the shingles as they are laid, which no doubt adds much to the durability of the roof, but then does not the expense

of paint and additional labor and interest on the same, amount to as much, or more, than another shingling? We were much struck with the appearance of a noble barn, which was built two years since by our friends the Shakers at Shirley. They never do anything by the halves, but whatever they undertake is done in the very best style. The barn was finished in the most substantial manner, from the foundation to the ridge-pole, but we were forcibly reminded by it of Noah's Ark, for it was "pitched within and without." Our friends informed us that the shingles were laid in hot pitch, or a mixture of pitch and tar, and the building coated over with the same. This mode of laying shingles, has one advantage certainly; if fire should take hold of it, it would burn without much trouble.

Since writing the above, a gentleman of some experience has informed us that if shingles are dipped in strong alum water, they will last much longer, and it is also a security against fire. We find in Vol. 12, page 283 of the N. E. Farmer the following receipt and remarks, which we copy, as many of our present subscribers have not taken the work so far back.

"For painting the roofs of buildings, Mr Patterson of New Jersey, has, some years since, given the following directions, which have been highly approved, as the best composition known for preserving the roofs of houses; as it is found that it hardens by time, and is an effectual preservative against the roof taking fire from the sparks the chimney.

"Take three parts of air slacked lime, two of wood ashes, and one of fine sand, and add as much linseed oil as will bring it to a consistence for working it with a painter's brush. Great care must be taken to mix it perfectly.

"We believe grinding it as a paint would be an improvement. Two coats are necessary; the first rather thin; the second as thick as can be conveniently laid on."

We have not seen an application of the above composition, and therefore, give it as we find it. It is no doubt a good composition if it could be applied to every part of the shingle. We have answered our friend "A Subscriber" as well as we are able; if any of our correspondents who have more experience, can add anything which will meet his case or benefit the public, we shall be much obliged.

J. B.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Sept. 29, 1838.

From R. Manning, Esq. Salem, fine specimens of the following Pears: Bergamotte d'Autumnal, Green Sugar, Syriam, Louise, Bonne de Jersey, Autumn Superb, Belle St. Bonne, and Webber's Yellow Autumnal. (Mr Manning is entitled to the thanks of every lover of Good Fruits for his exertions to introduce new varieties and to sustain the exhibitions of the Society.)

From Samuel S. Lewis, Esq. Brinley Place, Roxbury, (the late residence of Hon. H. A. S. Dearborn, a zealous friend and promoter of the best interests of this Society,) the following Pears: Autumn Bergamotte, Passe Colmar, Napoleon Doyenne Gris, Newton Vergaleau, Brown Beurre Capiamont, Lewis and Moorfools Egg, and five other specimens not named. These specimens were all fine.

From E. M. Richards, Esq., fine seedling Clingstone Peach.

From Mr Eustis of South Reading, Isabella Grapes.

From Mr S. R. Johnson, Charlestown, very fine Black Hamburg and Sweetwater Grapes.

From M. P. Sawyer, Esq. Portland. Plums, variety

Imperatrice and Magnum Bonum; the latter were very beautiful the finest exhibited this season.

From Mr Pond, Cambridgeport; Semiana Plums, very large and fine; also Isabella Grapes, and a new seedling Grape called Pond's Seedling. This fruit was proved to be a very fine variety and far superior to the Isabella, worthy of cultivation.

From James L. L. F. Warren, fine specimens of Imperatrice Lemon Clingstone Peach.

The following letter, with the specimens of Fruits were received from the Hon. John Lowell of Roxbury.

Roxbury, Sept. 29, 1838.

To the President of the Massachusetts Hort. Society:

Sir—I send specimens of "Beurre Spence" nearly or quite ripe. It should be understood, that for 50 years I have thought the soil at my place, not adapted to produce the best pears, except certain kinds which come to high perfection in it. I send an unripe sample of Beurre Bronz, which Parmentier highly commends. Also, a bunch of Grapes,* sent neither for its size nor quality, but novelty. It is one of the grapes sent by the American Consul at Ferrol, to Mr Cook, late Vice President of your Society. It is to me wholly new in foliage, wood, bunches, berries and taste. It is a prolific grape, and can be made to produce immense bunches for those who desire it; of its value, as a fruit, it is not for me to decide.

I have added Beurre Crapeau and Milanais or Great Britain; a crisp pear when ripe.

I am, dear sir, very respectfully,

Your humble servant,

JOHN LOWELL.

For the Committee,

JAMES L. L. F. WARREN.

*The Grape was new to the Committee, but was found to be of very fine flavor.

The reports of the Horticultural Society are necessarily deferred until next week, as the committee have not fully completed them. We shall publish the whole in one paper, which will make it necessary for us to issue an extra.

THANKSGIVING IN MASSACHUSETTS.—The governor of this State has appointed THURSDAY, the 29th day of November next, as a day of Public Thanksgiving and Praise.

The heaviest Wheat and Rye crop, perhaps ever taken in this county, has been gathered within the last fortnight—in good order—plump and well filled. The grass crop is also good. The Corn crop, which, at the outset was very promising, has been seriously injured in some parts of the county from a long prevailing drought. In the south and southwest portion of the county it will be an entire failure. Many of our farmers in Warwick—the southern part of Minisink—and in Sussex Co. N. J. are now engaged in cutting it up. The Oat, Potato, and Buckwheat crops have suffered severely from like causes. In the other sections of the county, where the drought has not been so severely felt, the Corn crop particularly is very promising.—*Gov'n N. F. Republican.*

The Stockholders of the Eastern Railroad have resolved to complete their railroad as far as Newburyport, and to put the rest to the East line of the State under contract as soon as they have satisfactory assurances that it will be continued to Portsmouth.

The Trustees of the Maryland Agricultural Society have postponed the Fair which was to have been held on the 1st of November, on account of the deplorable drought which has prevailed throughout the Eastern Shore.

BRIGHTON MARKET.—MONDAY, Oct 1, 1838.

Reported for the New England Farmer.

At Market 400 Beef Cattle, 350 Stores, 2,450 Sheep, and about 1,500 Swine.

Prices.—Bref Cattle.—Sales were brisk. First quality, \$7 50. Second quality, \$6 75 a \$7 00. Third quality, \$5 50 a \$6 00.

Stores.—In good demand. Yearlings, \$9 a \$14. Two Year Old, \$16 a \$23. Three Year Old, \$22 a \$33.

Sheep.—Sales brisk. At \$1 62, \$1 82, \$2 16, \$2 50 and \$3 25.

Swine.—Last week's prices were fully supported. Lots to peddle at 6 1-2 a 7 1-2. At retail, 7 1-2 a 9. Old hogs, 7 to 8.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending September 30.

FOR SALE.

The thorough bred Short Horned Durham Bull, Superior-Superior was calved in August, 1831. He was got by Frederick, and he by Wye Comet.
Dam, Yellow Rose, by Young Denton.
G. Dam, Arabella, (Imported,) by North Star.
G. G. Dam Aurora, " " Comet.
G. G. G. Dam " " Henry.
G. G. G. G. Dam " " Danby.
The above pedigree may be found in the English Herd Book.

He is a roan and perfectly gentle and docile; and his stock, which may be seen at the farm of the subscriber, will testify to his value. Price, \$250. Apply to C. N. Bement, Esq. near Albany, N. Y. or to Wm. Augustus North, Mount Marie, Danesburgh, N. Y.
October 3, 1837. 4w

MULBERRY TREES.

1500 Morus Multicaulis.
1000 White Mulberry.
For sale, the entire lot, or in small quantities. They are very superior, and being raised so far north, have the advantage over southern raised trees, for this State.
JAMES STEWART,
Indian Hill Farm, near Newburyport, Mass.
October 3, 1837. 3w

NOTICE.

The subscriber offers for sale his real estate in Westford and Groton; consisting of his homestead, 35 acres, his farm, 117, one pasture, 17 acres, one do. 33 acres, one wood-lot, 13 acres, one do. 5 acres, and one do. 10 acres. For further particulars see his advertisement in the Lowell Journal, or inquire of the subscriber at his house, near the meeting houses and academy in Westford.
EPHRAIM ABBOTT.

FARM FOR SALE.

In Cambridge, about one mile from McDock's Hotel on the West Cambridge road with a valuable stone ledge on the same; containing forty acres of good land with the buildings on the same. It will be sold at a bargain if applied for soon, as the present owner is about removing to the West. Apply to the subscriber on the premises.
Sept. 25. 3w AMMI C. TEEL.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most luttler of any stock in this country. Inquire of the subscriber near the factories in Waltham.
ISAAC PARKER.

WANTED TO HIRE

A single Man, who is capable of taking charge of a small Farm. Inquire of
JOSEPH BRECK & CO.
Sept. 5.

LAYING OUT GARDENS AND ORNAMENTAL PLANTATIONS.

E. SAYERS begs leave to inform his friends and the public in general that he will attend the laying out gardens and ornamental plantations, and hopes by strict attention to business to merit the approbation of those who may be pleased to employ him.

All orders left with J. Brock & Co. Agricultural Store, No. 52 North Market Street, will be punctually attended to.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders to any amount, which will be promptly attended to.
Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston.
Sept. 20. NAHUM WARD.

FRUIT AND ORNAMENTAL TREES, MULBERRIES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and I eatches now ready for sale is large. Also, Ornamental Trees, Shrubs, Roses, Honeysuckles; Pæonies, Dahlias and other Heraceous Flowering Plants.

100,000 MORES MULTICAULIS are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussa and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. D. BAECK, Commission Store, No. 132 Water Street, New York, M. S. POWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston.
August 1, 1838. WILLIAM KENRICK.

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more as may be wanted, of the most approved kinds—consisting of the best selected varieties now in use, for cultivation, feeding worms, and making silk—being acclimated to this country, and adapted to either warm or cool climates, affording a rare opportunity for companies or individuals to be supplied, from the most extensive collection of mulberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and orders left with Messrs. I. E. Colt, Secretary of the Connecticut Silk Manufacturing Company, Hartford; Alonzo Wake-man, at the office of the American Institute, No. 157 Broadway, N. Y.; Thomas Lloyd, Jr. No. 236 Filbert street, Philadelphia, Pa.; Luther I. Cox, Baltimore, Md.; B. Snider, & Co. Savannah, Ga.; Bliss Jenkins, & Co. Mobile, Al.; James Lyman, St. Louis, Mo.; Case and Judd, Columbus, O.; G. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass.

Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Mulberry Plantations.

Apply at the office of D. STEBBINS, Northampton, Aug. 22, 1838.

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dame, situated in Rochester, N. H. six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and sweet wood, including a good portion of heavy timber. There are also on the premises, large quantities of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to JOSEPH BRECK & Co., No. 51 and 52 North Market Street, Boston.
August 15, 1838.

FOR SALE.

Five acres of good Salt Marsh, in Quincy, or (Squantum so called.) Also, Four acres of Salt Marsh in Brighton. Also, Several full blood animals, cows and calves. Apply to A. Greenwood, on the Welles Farm, Dorchester, near Dr Codman's meeting house.
Sept. 12, 1838.

MISCELLANEOUS.

THE FIRST YELLOW LEAF.

Thou bring'st sad thoughts to me,
First yellow leaf;
Thou tell'st the change on soon to be,
From Summer, bright and brief,
To Autumn's sear and sadd'ning time,
When gladness leaves our happy clime.

But few short months have gone,
Thou fragile thing,
Since first upon the grassy lawn
So gaily drest by Spring,
I watched thy beauties, one by one,
Spring forth to greet th' enliven'ing sun.

And all this lovely earth,
So fresh and green,
Prais'd well the pow'r that gave it birth,
And deck'd it all unseem.
I gazed, and joy my bosom fill'd;
Nor thoughts of blight, my transport still'd.

And now to see thee fall
So soon to earth,
And thus to see thy bright train all
Resign their notes of mirth,
Nor whisper to the breeze again,
'Tis sad, and well might give me pain.

But there are other tones
Than fading leaf,
That thus speak in thy dying moans:
"Thy life, like mine, is brief;
Thou, too, may'st bloom but for a day,
Then fade, like Autumn leaves away."

SLEEPING CHAMBERS.

Is the philosophy of sleep enough considered? Are the circumstances connected with this condition of human nature, for one quarter or one third of human life, duly attended to?

While we are awake, our bodies are, as a general rule, more or less in motion; and the air, even in our rooms, more or less in motion also. But while we sleep we are quiet, the air is quiet, and is soon contaminated. Do people consider how fast?

The air is spoiled fast when but one person occupies a bed, and there is but one bed in the room. Franklin and others have supposed the air to be rendered unfit for breathing at the rate of a gallon a minute. But if so, how many of us breathe bad air in our sleeping rooms! We seldom lie quietly in our beds with the doors and windows closed, a heap of feathers under us, and thick clothes over us, more than an hour at most, before we begin to suffer. This is the case if the sleeping room is large; but if small, it is much worse. It is impossible to have a hoghead of poisoned air diffused through a sleeping room without doing mischief.

I know it will be said that the carbonic acid gas, produced by breathing, is heavier than atmospheric air, and soon settles to the floor; and if the bed-room is not so small that the room, like a culinary vessel, gets full of it up to the surface of the bed, before the individual wakes, there is no danger.

But it does not all settle to the floor. In hot weather, it scarcely settles at all; though in cold weather it does so much more. Nay, even in cold weather some of it falls on the bed, and much of it

is entangled in the bed clothes. This, however, is not quite all. The same poisonous gas which is formed by breathing, is also constantly formed by the whole surface of our bodies, in greater or less degree; and this, if improved under the bed clothes, between them and a thick bed of feathers, is not only injuring us by its contact with our skins, but still more by our breathing it. For nothing is more common than for a small quantity of this impure air to escape from the bed by the side of our bodies, especially upon the least motion; thus giving an opportunity—nay, a certainty—of inhaling a part of it.

To all these evils we are subjected, I have said, when under the most favorable circumstances; that is, when our sleeping rooms are large, and when only one person occupies a bed, and one bed in an apartment. But when two persons, or even more, sleep in the same bed, when the room is small, or has several beds in it, and when the beds are of feathers or down, the evil and the danger are very greatly increased.

I wish sleeping rooms were generally much larger than they are. Then I wish they were always freed as much as possible from unnecessary clothing, and every thing which could retain bad air. The bedstead should be rather high, and only broad enough to accommodate freely and fully one person. The bed should be of some material which is light and porous, as oat or wheat straw, corn husks split finely, grass, hay, &c.; and the clothing should be adapted to the season, but should never be so constructed as to prevent entirely the passage of the air through it. No dogs, or cats, or lamps, or fires without flues, should be found in the room. A window or door which will admit fresh air should be, in all seasons, but especially in hot weather, left open in such a direction from the bed as will not expose the occupant to have currents of air fall directly upon him;—to prevent the possibility of which, however, a screen might be placed before the window. Then, in the last place, and as I have already intimated, the bed should contain but one person, and unless the room is exceedingly large, there should be but one bed in it.

Perhaps it will be said that I require too much. Most persons, I shall be told, cannot have all this. No, they cannot. Sin is in the world, and has long been in it; and it will be long before we can get it out entirely. But sin has brought with it among other evils, that of poverty; and poverty does not always permit every thing which is best for health. But one thing at least we can do; which is, to come as near what we know to be truth as possible.—*Library of Health for September.*

SIGNS OF PROSPERITY.—Do you see that house on that risin' hummock to the right there?—Well, gist look at it, that's what I call about right. Flanked on both sides by an orchard of best grafted fruit, a tidy little clever flower garden in front, that the galls see to, and a most a grand sarce garden over the road there sheltered by them are willows. At the back side see them everlastin' big barns; and, by gosh! there goes the dairy cows; and a pretty sight too; that fourteen of 'em marchin' Indgian life arter milkmin', down to that are madder. Whicenever you see a place snugged up and lookin' like that are, depend on it the folks are of the right kind. Them flowers too, and that are honeysuckle, and rose bushes, show the family

are brought up right; somethin' to do at home, instead of racin' about to quiltn' parties, huskin' frolics, gossippin', talkin' scandal, and neglectin' their business. Then little matters are like throwin' up straws, they show which way the wind is.—When galls attend to them are things, it shews that they are what our minister used to call, "right minded." It keeps them busy, and when folks are busy, they ha'n't time to get into mischief; and it amuses them too, and keeps the dear little critters healthy and cheerful.—*Sam Slick, second series.*

EXTRAVAGANCE IN THE UNITED STATES.—Do you see them are country galls there, said Mr Slick, how they are tricked out in silks, and touch'd off with lace and riband to the nine's, a mincin' along with parasols in their hands, as if they were afraid the sun would melt them like wax, or take the color out of their faces, like a printed cotton blind? Well, that's gist the ruin of this country.

It ain't poverty the blue noses have to fear, for that they needn't know without they choose to make acquaintances with it; but it's gentility.—They go the whole hog in this country, you may depend. They ain't content to appear what they be, but want to be what they ain't; they live too extravagant, and dress too extravagant, and won't do what's the only thing that will support this extravagance; that is, be industrious. Gist go into one of the meeting houses, back here in the woods, where there ought to be nothin' but homespun cloth, and home made stuffs and bonnets, and see the leg-horn and palm-trees, and silks and shalleys, merinos, gauzes, and blonds, assembled there, enough to buy the best farm in the settlement. There's somethin' not altogether gist right in this.—*Samuel Slick, second series.*

ORIGINAL ANECDOTE.—A drunken fellow, not long since, staggered into one of our most respectable victuallin' cellars, and greeted the attendant with a familiar 'how are you?' 'Who are you,' said the host, 'are you drunk?' 'Aye,' said the bacchanalian, 'drunk enough! and have been every day for two years! My brother Josh and I am engaged in the temperance cause; he goes about delivering lectures, and I give samples of intemperance. Now shant we get up a reformation.'

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land, situated on Nonantum Hill, in Newton, 5 1-2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

LOT WHEELRIGHT.

July 16th.

ALDERNEY STOCK FOR SALE.

For sale a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27

FOR SALE.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

MASSACHUSETTS HORTICULTURAL SOCIETY'S ANNUAL MEETING.

EXHIBITION OF FLOWERS.

"———Let one great day
To celebrated sports and floral play
Be set aside!"

The annual exhibition of Flowers and Fruits by the MASSACHUSETTS HORTICULTURAL SOCIETY, took place at their Rooms, 23 Tremont Row, on Wednesday, Thursday, and Friday, 19th, 20th, and 21st of September.

The specimens of Fruit (the particulars of which are here withgiven by the Chairman of the Fruit Committee) were very fine, and exceeded, both in quantity and quality those of any former season.

Owing to the extreme heat of the weather, and the continued drought in July and August, Autumn's Queen, the gorgeous Dahlia, did not appear at the exhibition in all her glory. But notwithstanding the almost total failure of the Dahlia bloom, the floral part of the show was much better than our friends or ourselves anticipated. When it was made known to the cultivators, and to the lovers of flowers, that the place of the Dahlia must be filled up, by such cut flowers as could be procured, the disposition to contribute became general, and the supply was equal to our wants. Before the appointed hour had arrived to open the Rooms for the public, every vial, dish and basket, was filled, and all was in readiness for the inspection, and we trust gratification, of the lovers of Flora and Pomona.

The contributors will please accept our thanks and acknowledgments, for their liberal contributions, and their kind aid. If we have omitted, in our annexed statement, the name of any contributor, or an account of any specimens sent for exhibition, we solicit the favor of a communication giving us a list of the plants or flowers omitted, that they may be added to our report.

From the Hon. John Lowell of Roxbury.

Pandanus utilis, *Eugenia myrtifolia*, *Araucaria excelsa*, (rare and valuable.) This is a most superb plant. The inhabitants of Chili call this noble ornament of their forests *araucanos*. "This genus" Sweet observes "may be termed the handsomest genus of plants with which we are acquainted." *Bignonia discolor*, *Acrostichum alciorne*, *Asplenium* (?) *Casuarina equisetifolia*.

From J. P. Cushing, Esq. Watertown.

Astræa Wallichii, *Epiphyllum Ackermani*, *Maranta zebra*, *Amaryllis Belladonna*, (several pots in bloom,) *Hippeastrums*, (seedlings in bloom,) *Erica glauca*, *Alpinia mutans*, *Rochea falcata*, *Trevirana coccinea*, *Phenicia dactylifera*, *Hippeastrums*, (seedlings in bloom,) *Mespilus* (?) and a fine cut blossom of *Crimum anabile*.

From Marshall P. Wilder, Esq. of Hawthorn Grove, Dorchester.

Stanhopea quadricornis, (Air plant from South America in fine bloom.) "The true species of this

genus," says Loudon, "are beyond comparison the most delightful productions of the vegetable world." This specimen was very beautiful, and was greatly admired. *Maranta zebra*, *Acacia*, (four varieties,) *Ardisia crenulata*, *Mannettia glabra*, *Erythrina Crista-galli*, *Nerine Fothergillii*, &c.

From John Lemist, Esq. of Roxbury.

Citrus myrtifolia, (two plants,) *Erica cruenta*, (two plants,) *Cycas revoluta*, *Ilex aureo-marginata*, and a very splendid Bouquet.

From Mrs Bigelow, of Medford, two very fine specimens of *Cupressus stricta*. These plants were placed at the entrance of the rooms and made a handsome appearance.

From John C. Gray, Esq.

Two very fine specimens of *Cockscomb*.

From the Botanic Garden Cambridge, by Mr W. E. Carter.

Ficus elastica, *Ficus australis*, *Diosma ericoides*, *Taxus Chinensis*, *Streitzia regina*, *Bignonia Evansiana*, *Laurus crassifolia*, do. evaltata, do. indica, *Banksia*, *Rhododendron arboreum*, do. hybridum, *Eugenia australis*, *Pelargonium*, *Erica Caffra*, do. concinna, *Erica empetroides*, *Myrtus flora pleno*, do. narrow leaved, three seedling *Camellia japonica*, *Metrosideros saligna*, *Eriobotrya japonica*, *Bauera rubrifolia*, *Acacia divaricata*, *Magnolia grandiflora*, *Eucalyptus perfoliata*, *Ilex crassifolia*, *Morus mucronata*, *Melastoma nepalensis*, *Acacia* (?) do. saligna, *Hakea*, Double flowering *Myrtle*, *Acacia decipiens*, *Petunia hybrida*, *Fuschia grandiflora*, *Lantana Cammara*, *Melaleuca tenuifolia*, *Calothamnus pubescens*, do. quadrifida, *Menziesia globularis*, *Bouvardia coccinea*, *Beaufortea decussata*.

From Messrs Winship of Brighton.

Cassia sopheræ, *Citrus nobilis minor*, in fine fruit, *Eugenia Australis*, *Agave Americana variegata*, *Sparmannia africana*, 2 varieties of *Cyclamen persicum*, *Vinea rosea*, *Aucuba japonica*, *Gloxinia speciosa*, *Eupatorium odoratum*, *Maranta zebra*, *Erica gracilis*, and spuria, *rallota purpurea*, *Merpilus japonica*, *Atriplex halimus*, *Asclepias persicifolia*, *Begonia argyrostigma*, *Ficus elasticus*, *Daphne variegata*, *Laurus*, *communis fol* : *variegata*, *Ruscus*, *racemosus* in fruit, *Melaleuca diosmefolia*.

From Mr H. Bowditch, Boston.

Five specimens of *Myrtles* and *Orange trees* in fruit, *Aloysia citriodora*, *Fuchsia*, *Erica*, *Acacia*, &c.

From Messrs Hovey, *Oxalis Bowellii*.

From Jno. Hovey, Roxbury.

Yellow tea rose, *Verbena melindre*, *Passiflora racemosa*.

From Mr Mason of Charlestown.

Phylica ericoides, *Acacia armata*, and two other varieties, *Verbena melindre*, great variety of double tea week stocks, *Viburnum tinus*, three varieties of *Erica*, *Rhododendron arboreum*, *Orange tree* with fruit, and *Diosma ericoides*.

From Mr William Meller, Roxbury, four plants *Citrus Decumana*.

From Dr J. C. Howard, Woodland, Brookline.

A fine specimen of *Yucca* and other plants.

From Thomas Lee, Esq. Brookline, several beautiful little plants in bloom and a great variety of cut flowers, *Roses*, &c.

From J. D. H. Williams, Esq. Roxbury, *Taxus communis*, *Callistenum lanceolatum*.

From Mr T. Rundle, Fig and Dwarf apple tree, both in fruit.

From Mr John Arnold, Boston, *Camellia japonica alba pleno*, in fine bloom.

DAHLIAS.—From Col. Wilder, var. *Suffolk Hero*, *Elphinstones Diana*, do. *purple Perfection*, *Marquis of Northampton*, *Conqueror of Europe*, *Brown's quilled Perfection*, &c.

From E. Breed, Esq. Charlestown.
Widnall's Triumphant.

From Messrs Hovey, var. *Mrs Rushton*, *Liberty*, *Juliet*, *Rival Yellow*, *Middlesex Rival*, *Conqueror of Europe*, *Rosa Superba*, *Ruby*, *Diadema of Flora*, &c.

From Dr J. C. Howard, var. *Prince George*, *Ophelia*, *Royal William*, *Countess of Liverpool*, *Dennisii*, *Beauty of Cambridge*, *Desdemona*, *Alba purpurea*, *Picta formosissima*, *Lady Fordwich*, &c.

From Messrs Winship, var. *Countess of Liverpool*, *Royal William*, *Barrett's Susanna*, *Prince George of Cumberland*, *Dutchess of Buccleugh*, &c.

From the Botanic Garden, Cambridge, by Mr W. E. Carter, *Dennis's Perfection*, *Lord Liverpool*, *Dennisii*, *Countess of Liverpool*, *Prince George*, *Ophelia*, *Mrs Broadwood*, *Desdemona*, *Augusta*, *Picta formosissima*.

From Mr Jno Richardson, Dorchester, var. *Lord Liverpool*, *Countess of Mansfield*, *Dennisii*.

From W. Phipps, Esq. and W. Farnsworth, Esq. of Roxbury, each a few fine flowers.

From Messrs O. and W. Wales of Dorchester, var. *Red Rover*, *Lady Fordwich*, *Widnall's Perfection*, *Dennisii*, and *Dutchess of Buccleugh*.

On the second and third days of exhibition, there was a basket of choice specimens handed to the committee, with a request that they should be placed in the stands incog. The request was complied with. All that we feel permitted to say in our report is, that the flowers were much admired; we classed them among the fairest of the fair.

By Samuel Walker of Roxbury, var. *Napoleon*, *Desdemona*, *Dennisii*, *King of Dahlias*, *Metropolitan*, *Calypto*, *Widnall's Perfection*, *Mrs Broadwood*, *Dutchess of Buccleugh*, *Jackson's Rival Yellow*, *Lady Ann*, *Douglas Glory*, *Belledonna*, *Autro purpurea*, *Granta*, *Well's white*, *Harding's bride*, *Ophelia*, *Beauty of Cambridge*, *Urania*, *Barrett's Susanna*, and *Beauty of Bedford*.

BOUQUETS.—From Mrs. J. H. Gardner, of Roxbury; Dr J. C. Howard of Brookline; John Lemist, Esq. of Roxbury; W. E. Carter of Cambridge; Messrs Hovey, and S. Sweetser, Esq. of Cambridgeport; Messrs Winship, Brighton, W. Kenrick, Newton, and S. Walker.

A small bouquet, presented by Mrs. E. Breed,

of Charlestown, containing specimens of *Stapelia pulchella*, and *Bignonia Evansiana*, was much admired.

Cut flowers of various descriptions from T. Lee, Esq. Col. Wilder, E. Breed, Esq. Hon. E. Vose, Messrs Richardson, Phipps, Farnsworth, Gardener, Sweetser, Breck, Warren, Winship, Hovey and Co. Jno. Hovey, Mason, Miller, and Carter.

From Joseph Breck & Co., a superb collection of German Asters of every variety. Thirteen distinct varieties of *Zinnia elegans*, of the following colors:—white, blush, pink, violet, light purple, dark purple, salmon, yellow, orange, light scarlet, dark scarlet, light crimson, and deep crimson.—Specimens of *Euphorbia variegata*, *Centaureis* of sorts; improved variegated, and other Marigolds, together with great a variety of other annuals, and cut flowers.

The wreaths were made and presented by Messrs D. Haggerston, J. W. Russell, and E. Sayers.

We shall close our report with a few brief remarks, and some quotations from various authors on the love, and use made of flowers by the inhabitants of several parts of the world.

"Flowers!" says Mr Bowring, "what a hundred associations the word brings to my mind! Of what countless songs, sweet and sacred, delicate and divine, are they the subject! A flower in England, [and we will add America,] is something to the botanist,—but only if it be rare; to the florist,—but only if it be beautiful: even the poet and the moralizer seldom bend down to its eloquent silence. The peasant never utters to it an ejaculation—the ploughman (all but one) carelessly tears it up with his share—no maiden thinks of wreathing it—no youth aspires to wear it: but in Spain ten to one but it becomes a minister of love, that it hears the voice of poetry, that it crowns the brow of beauty. Thus how sweetly an anonymous cancionero sings:

"Put on your brightest richest dress,
Wear all your gems, blest vale of ours!
My fair one comes in her loveliness,
She comes to gather flowers.

"Garland me wreaths, thou fertile vale;
Woods of green your coronets bring;
Pinks of red, and lilies pale,
Come with your fragrant offering.
Mingle your charms of hue and smell,
Which Flora wakes in her spring-tide hours!
My fair one comes across the dell,
She comes to gather flowers.

"Twilight of morn! from thy misty tower
Seatter the trembling pearls around,
Hang up thy gems on fruit and flower,
Bespangle the dewy ground!
Phœbus, rest on thy ruby wheels—
Look, and envy this world of ours;
For my fair one now descends the hills,
She comes to gather flowers.

"List! for the breeze on wings serene
Through the light foliage soils;
Hidden amidst the forest's den
Warble the nightingales!
Hailing the glorious birth of day
With music's best, divinest powers,
Hither my fair one bends her way,
She comes to gather flowers."

LONDON MAGAZINE, *Spanish Romances*, No. 3.

It was, perhaps, the general power of sympathy

upon the subject of plants, which caused them to be connected with some of the earliest events that history records. The mythologies of all nations are full of them; and in all times they have been associated with the soldiery, the government, and the arts. Thus the patriot was crowned with oak; the hero and the poet with bay; and beauty with the myrtle. Peace had her olive; Bacchus his ivy; and whole groves of oak-trees were thought to send out oracular voices in the winds. One of the most pleasing parts of state-splendor has been associated with flowers, as Shakspeare seems to have had in his mind when he wrote that beautiful line respecting the accomplished prince, Hamlet:

"The expectancy and rose of the fair state"

It was this that brought the gentle family of roses into such unnatural broils in the civil wars; and still the united countries of Great Britain have each a floral emblem: Scotland has its thistle, Ireland its shamrock, and England the rose. France, under the Bourbons, had the golden lily.

The different festivals in England, have each their own peculiar plant or plants, to be used in their celebration; at Easter the willow as a substitute for the palm; at Christmas, the holly and the mistletoe; on May-day every flower in bloom, but particularly the hawthorn or May-bush. In Persia they have a festival called the Feast of Roses, which lasts the whole time they are in bloom. Formerly, it was the custom, and still is in some parts of the country, to scatter flowers on the celebration of a wedding, a christening, or even of a funeral.

It was formerly the custom also, to carry garlands before the bier of a maiden, and to hang them, and scatter flowers over her grave:

The Queen scattering flowers:

"Sweets to the sweet. Farewell!
I hoped thy bride-bed to have decked, sweet maid,
And not have strewed thy grave."

HAMLET, Act v. Scene 1.

In Tripoli, on the celebration of a wedding, the baskets of sweetmeats, &c. sent as wedding presents, are covered with flowers; and although it is well known that they frequently communicate the plague, the inhabitants will even prefer running the risk, when that dreadful disease is abroad, rather than lose the enjoyment they have in their love of flowers. When a woman in Tripoli dies, a large bouquet of fresh flowers, if they can be procured, if not, of artificial, is fastened at the head of her coffin. Upon the death of a Moorish lady of quality, every place is filled with fresh flowers and burning perfumes: at the head of the body is placed a large bouquet, of part artificial, and part natural, and richly ornamented with silver: and additions are continually made to it. The author who describes these customs also mentions a lady of high rank, who regularly attended the tomb of her daughter, who had been three years dead; she always kept it in repair, and, with the exception of the great mosque, it was one of the grandest in Tripoli. From the time of the young lady's death, the tomb had always been supplied with the most expensive flowers, placed in beautiful vases; and, in addition to these, a great quantity of fresh Arabian Jessamines, threaded on thin slips of the palm-leaf, were hung in festoons and tassels about this revered sepulchre. The mausoleum of the royal family, which is called the *Turban*, is of the purest white marble, and is filled with an immense quantity of fresh flowers; most of the tombs being

dressed with festoons of Arabian Jessamine and large bunches of variegated flowers, consisting of Orange, Myrtle, Red and White Roses, &c. They afford a perfume which those who are not habituated to such choice flowers can scarcely conceive. The tombs are mostly of white, a few inlaid with colored marble. A manuscript Bible, which was presented by a Jew to the Synagogue, was adorned with flowers; and silver vases filled with flowers were placed upon the ark which contained the sacred V.S.*

The ancients used wreaths of flowers in their entertainments, not only for pleasure, but also from a notion that their odour prevented the wine from intoxicating them; they used other perfumes on the same account. Beds of flowers are not merely fictitious. The Highlanders of Scotland commonly sleep on heath, which is said to make a delicious bed; and beds are, in Italy, often filled with the leaves of trees, instead of down or feathers. It is an old joke against the offensive Sybarites, that one of them complaining he had not slept all night, and being asked the reason why, said that a rose-leaf had got folded under him.

In Naples, and in the vale of Cachemere (I have been told also that it sometimes occurs in Chester,) gardens are formed on the roofs of houses: "On a standing roof of wood is laid a covering of fine earth, which shelters the building from the great quantity of snow that falls in the winter season. This fence communicates an equal warmth in winter, as a refreshing coolness in summer, when the tops of the houses, which are planted with a variety of flowers, exhibit at a distance the spacious view of a beautiful chequered parterre." The famous hanging gardens of Babylon were on the enormous walls of that city.

A garden usually makes a part of every Paradise, even of Mahomet's, from which women are excluded,—women, whom gallantry has so associated with flowers, that we are told, in the Malay language, one word serves for both.† In Milton's Paradise, the occupation of Adam and Eve was to tend the flowers, to prune the luxuriant branches, and support the roses, heavy with beauty. Poets have taken pleasure in painting gardens in all the brilliancy of imagination. See the garden of Alcinoüs in Homer's *Odyssey*; those of Morgana, Alcina, and Armida, in the Italian poets: the gardens fair

"Of Hesperus and his daughters three,
Who sing about the golden tree;"

and Proserpina's garden, and the Bower of Bliss in Spenser's *Fairie Queene*. The very mention of their name seems to embower one in leaves and blossoms.

It is a matter of some taste to arrange a bouquet of flowers judiciously; even in language, we have a finer idea of colours, when such are placed together as look well together in substance. Do we read of white, purple, red, and yellow flowers, they do not present to us so exquisite a picture, as if we read of yellow and purple, white and red. Their arrangement has been happily touched upon by some of our poets:

"Th' Azores send
Their jessamine; her jessamine, remote
Caffira: foreigners from many lands,
They form one social shade, as if convened
By magic summons of th' Orphean lyre

* See Tully's Narrative of a Residence in Tripoli. † See Lalla Rookh, page 303. Sixth edition.

Yet just arrangement, rarely brought to pass
But by a master's hand, disposing well
The gay diversities of leaf and flower,
Must lend its aid t' illustrate all their charms,
And dress the regular, yet various scene.
Plant behind plant aspiring, in the van
The dwarfish; in the rear retired, but still
Sublime above the rest, the statelier stand."

COWPER.

What is here said on the subject of arrangement is of course addressed to those who are unacquainted with botany; those who study that delightful science will, most probably, prefer a botanical arrangement, observing however to place the smaller plants of each division next the spectator, and thus proceeding gradually to the tallest and most distant; so that the several divisions will form strips irregular in their width.

A friend has obliged me, says a celebrated writer, with the following lines, paraphrased from the Greek of Meleager. "This delicious little Greek poem," says he, "is one of those which I always seem to scent the very odor of, as if I held a bunch of flowers to my face.

"A flowery crown will I compose—

I'll weave the crocus, weave the rose;

I'll weave narcissus, newly wet,

The hyacinth, and violet;

And myrtle shall supply me green,

And lilies laugh in light between:

That the rich tendrils of my beauty's hair

May burst into their crowning flowers, and light the painted air."

Per order,

S. WALKER,

Chairman of the Committee of Arrangements.

EXHIBITION OF FRUITS.

The exhibition of the fruits, of all kinds, far surpassed that of all former years, not only in the variety, but also in the increased proportion of the new and finest kinds which never yet have been seen or known at any former exhibition. Generally speaking, all the fruits which were on these days exhibited, were fine. The fruits offered by Messrs Manning and Ives, whose gardens are contiguous, occupied nearly the whole of the Western table, and amongst those especially of Mr Manning were many of the new kinds of Pears, so lately introduced, and which are now fast coming into bearing. These above constituted the finest selection of the kind, which has ever yet been witnessed in the country.

The following is the account of the exhibition.

From the Hon. John Lowell, specimens of two varieties of Pears; one the *Beurre Spence*, which M. Van Mons had once designated as the finest pear he had ever raised; the specimen an oblong good sized fruit, contracted near the summit, of a yellow russet color, the flavor delicious. Also the *Beurre Crappeaux*, another variety sent to Mr Lowell by the Chevalier Parmentier of Engbien; a fruit of medium size and turbinate form, bright scarlet next the sun and yellow in the shade, *beurre* and of delicious flavor.

From the Hon. Mr Vose, President of the Society.

Pears.—Williams Bon Chretien, Andrews, Passe Colmar, Lewis, Napoleon, Duchesse D'Angouleme, Urbaniste, Brocaus Bergamotte, Julienne, Mouille Bouche.

Apples.—Hawthorndean, English Codlin, Large Red Sweeting.

Peaches.—Grosse Mignonne, George IV., Red and Yellow Rarierpe.

Grapes.—Chasselas; and an ornamented basket of fruit.

Melons.—A fine large yellow variety of the Rock Melon from Paris.

Presented by S. Walker, from the garden of Madam Eustis, Roxbury, a fine specimen of Sweet-water *Grapes*, of out-door culture. Also a large basket of fine *Peaches*.

From J. L. Moffat, Esq. Roxbury, a basket of yellow Tomatoes.

From Enoch Barlett, Esq. Vice President of the Society.

Pears.—Bartlett or Williams Bon Chretien, Sylvanche Vert, Wurttemberg, formerly received as Capiaumont, Dix.

Apples.—Ribston Pippin.

Lemon Peach.

From Mr Downer, a variety of fine fruits as follows.

Pears.—Heathcot, *Beurre d'Aremberg*, *Passe Colmar*, Dix, Knight's seedling, *Bezi Vaet*, *Forelle*, Iron, Lewis, *Catillac*, *Beurre Diel*, *Roi de Wurtemberg*, Williams Bon Chretien, Andrews Moorwood Egg, and Wilkinson.

Apples.—Pumpkin sweeting, Siberian Crab, *Pomme d'api*, Pound, Porter, Seaver sweet, Hales, Lyscom, None such, Gardener's sweeting, Spice and other varieties.

Grapes.—Isabella, Catawba, Miller's Burgundy, white Chasselas and another variety, all from the open air.

Peaches.—Rarierpe.

From Mr Richards, numerous fine specimens as follows.

Pears.—Howard.

Apples.—Ribstone pippin, and Fall Sops of wine.

Peaches.—Two varieties, one a seedling.

From Messrs Winship of Brighton, beautiful specimens of the *Shepardia Eleagnoides*, consisting of branches loaded with fruit; the fruit fine for jellies and preserves, and highly grateful to the taste when ameliorated by frost.

From William Oliver, Esq. of Dorchester.

Pears.—Dix, Wurttemberg, Broca's Bergamotte, St. Ghislain, Duchesse D'Angouleme.

Peaches.—President, Petite Mignonne.

Grapes.—Chasselas, very fine, open culture.

From Mrs Bourne of Boston, Clingstone peach. From Mr John Arnold of Milton.

Grapes.—Black Hamburg, two fine clusters, one weighing 2 3-4 lbs., and the other 3 3-4 lbs.; also fine clusters of the Muscat of Lunel.

From Mr George Newhall of Dorchester.

Pears.—Wurttemberg and Fulton, Williams Bon Chretien, and Broca's Bergamotte.

Apples.—Porter and Pearmain.

Peaches.—Jacques Rarierpe, Moore's Rarierpe, Yellow Red Rarierpe, a seedling variety, also another large Yellow Seedling Rarierpe, very fine.

From E. Breed, Esq. of Charlestown.

Pears.—Orange, Julienne, Seckel, Duchesse D'Angouleme, and Williams Bon Chretien.

Plums.—Green Gage.

Grapes.—White, Muscat of Alexandria, and a basket containing fine peaches and a variety of other fruits.

From Mr Wm. Meller of Roxbury.

Grapes.—Black Hamburg, and Sweet Water.

Peaches.—Seedling varieties.

From Mr Joseph Balch of Roxbury.
Pears.—Blauquette, Williams Bon Chretien, and a variety from France.

Apples.—A variety from England.

Grapes.—A basket of Black Hamburg, and Black Prince, &c. all fine.

From Messrs Mason of the Charlestown vineyard.

Grapes.—Purple Constantia, Lombardy, Black Hamburg, and White Chasselas. All affording ample evidence of the most skilful cultivation.

From Isaac P. Davis, Esq. of the city. A superb Black Apple, resembling polished ebony. A most beautiful fruit from the garden of Mr Cushing at Belmont, from a dwarf tree received from France, and said to be of American origin, name unknown.

From Dr J. C. Howard, Woodland, in Brookline.
Pears.—Golden *Beurre*, Cambridge, St. Michael, *Beurre Rouge*, and Bergamotte.

Apples.—Maiden's Blush or Hawthorndean, Greening, and Ruddy Greening.

Grapes.—Miller's Burgundy, White Chasselas, and Black Hamburg, two splendid bunches of the latter on one lateral shoot, weighing together 5 lbs. and 4 oz.; also, from out of door culture, Sweet-water, and Isabella.

Col. M. P. Wilder, sent for exhibition the following kinds of fruit.

Pears.—D'Aremberg, Belle et Bonne, Alpha, Gloux, Merceau, *Buerre Thouin*, St. Michael, Archangel, D'Amaulis, *Beurre Von Marum*, Bergamotte de Paques, Bourgeois of Boston, *Passe Colmar*, Sageret Easter *Buerre*, Heathcot, Wurttemberg, *Beurre Diel*, Bleeckers Meadow, a pear imported for Urbaniste, and a pear name unknown from France. Fortune, a new and celebrated pear, but not yet at maturity; also Kenrick Pear from Van Mons, but may be wrong.

Plums.—Coes Golden Drop. Also the Black Rock musk melon.

From Mr B. V. French from his estate in Braintree, the following kinds.

Pears.—Cushing, Harvard, Wilkinson, Roman *Beurre*, Long Green, Saint Lezain, Old winter, *Roi de Wurtemberg*, Williams Bon Chretien, Tillington, Spanish Bon Chretien, King's Bon Chretien.

Apples.—Monstrous Pippin, Yellow Bellflower Orley Pippin, Mela Carla, Fameuse, Duke of Wellington, Hawthorndean, Fall Sopsavine, Garden Royal, Devonshire Quarendon, Porter, Dutch Codlin, Garden Striped, Yellow Newton Pippin, Sweet Greening, Nonsuch, Sour sweet, Black Apple, Contepundu Plat, Well's pippin, Royal do, Scarlet nonpareil, English do., Danvers sweet, Red Doctor, High top sweeting, Esopus Spitzenberg, Green's everlasting, Bun, Newark King, Snow, King of the Pippins, Fearn's pippin, Conway, Osgood, Ribstone pippin, Alexander, Vandevere, Jonathian, Surprise, Priestley, Moor's red winter, Cumberland spice, Pumpkin spice, Mela de Rosemarino, French Bellflower, Golden Reinett, Reinett de Autom, Templeton winter sweet, Russett, Long Nonsuch, Old Pearmain, Side hill, Lady finger, Greening, Lewis, French's sweet, Seaver sweet, York russett, Downton pippin, Pomme d'api, Siberian Crab, Murphy, Burraove, Virginia, Rock, Adam's sweeting, Red Calville.

Melons.—Long Carolina water, Pine, Green Flesh.

Plums.—Red Queen's Mother, a fine fruit.

From Mr Ebenezer Holden of Dorchester, Porter apples, a beautiful specimen.

From Dr J. Greene of Groton, the Foundling apple, a fine looking large red fruit.

From Dr Joel Burnett of Southboro', specimens of Burnet pear.

From William Kenrick, Duchesse D'Angouleme pear.

From Mr John Rayner, Brown's Buerre, Broca's Bergamotte, and St. Mibhael pears.

From Mr Haggerston.

Grapes.—Black Hamburg, &c. from the garden of Mr Cushing at Belmont, specimens of the most perfect cultivation.

From Dr Z. B. Adams from his garden in Pearl street. Fine specimens of the old St. Michael which is still generally fine in cities. Also Seckel.

From Mr Richard Ward of Roxbury.

Pears.—Seckel, Williams Bon Chretien or Bartlett, Andrews, and Pondlilly, Wurtemberg, and Bergamotte.

Peaches.—Old Mixon, Red Rarieripe, Sweetwater, Yellow Rarieripe, White do., Cooledges Favorite, Jacques, Franklin Seedling.

From Mr A. D. Williams.

Pears.—Williams Bon Chretien, Summer Thorn, Harvard; also a seedling pear, small, turbinate in form, and handsome, fine scarlet next the sun.

Apples.—Fall, Sopsavine, Porter, and Horn Apple, a large red beautiful fruit.

Grapes.—Several very large and beautiful clusters of Black Hamburg.

From Mr Sweetser of Cambridgeport.

Pears.—Fulton, Andrews, Chelmsford, Julienne, Seckel, and Williams Bon Chretien.

From Mr John Barnard of Dorchester, a pear for a new variety.

From Mr Eames of Framingham, specimens of an apple from Detroit, a large, splendid red fruit.

From Mr Rufus Howe of Dorchester, Urbaniste Pears.

From Mr Joshua Gardner, Dorchester.

Pears.—Cushing.

Apples.—Gravenstein, and Pomme D'Api or Lady Apple, beautiful specimens.

From Mr George Brown, Beverly.

Pears.—A variety without name from France, said to be fine; a variety from Holland, a winter fruit, Seckel, and Brown Buerre.

Apples.—A large fine Sweeting, a superior fruit, Pomme D'Api, and the Drap D'Or of France.

From Mr J. Hovey, a basket of Grapes of out of door cultivation.

From C. F. W. of Charlestown, Isabella Grapes.

From Mr Alexander McLennan, from Oaklands in Watertown, Pomme D'Api and a variety of fine Peaches, &c.

From Mr Charles Johnson of Weston, and from the farm formerly owned by Capt. John Mackay of the city, Hawthorndean apples, very beautiful.

From Mrs T. Bigelow of Medford.

Apples.—Monstrous Pippin, and beautiful specimens of Red apples from France.

Peaches.—some fine specimens.

Grapes.—Fine Chasselas, and Black Hamburg, Shaddocks very large, from her green-house, a variety of the *citrus* or orange tribe.

From the garden of Mr Lemist of Roxbury, fine Black Hamburg grapes; also a tree of the lime in fruit.

From Mr Samuel Pond, from his garden at Cambridgeport.

Pears.—Beurre Diel, Cushing, Wurtemberg, and Andrews.

Plums.—White Gage, and a variety supposed to be Hulings superb, Corse's Field Marshal, Blue Imperatrice, a fine fruit which sometimes has been called Semiana; also Duane's Purple Plum. All the Plums exhibited by Mr Pond were exceedingly fine; and Duane's Purple was very large and superb. Mr Pond has been very successful with Plums, having raised large quantities of this fine fruit during the past season. His situation is highly protected, the soil low, flat, moist, and but recently reclaimed from a salt marsh. Though very bad and not at all suited to the Peach it proves fine for the Plum.

From L. Baldwin, Esq. of Brighton.

Apples.—specimens of very large Red, of fine appearance.

From Mr John Hill of West Cambridge, Lemon Rarieripe so called, a synonyme of Yellow Red Rarieripe, the specimens very superb. This is one of the finest of all Peaches.

From Mr J. L. L. F. Warren, from his garden at Brighton, an ornamented basket of fruit as follows.

Pears.—Seckel.

Apples.—Baldwin, Greening, Autumn superb, Porter, Lady apple, Siberian Crab.

Peaches.—Royal George, George IV. Melacaton, Royal Kensington, Warren's Favorite.

Plums.—Danson.

Melons.—Cantaloupe, and Green Citron.

Grapes.—Chasselas, Black Hamburg, Purple, Malaga, and Isabella.

Mr Cooledge, from his garden in Cambridge street, Boston.

Plums.—A fine looking yellow, oblong, and excellent fruit.

From Messrs S. & G. Hyde of Newton, a large collection of fine fruit of varieties as follows.

Pears.—Forelle, Seckel, Coffins Virgalieu, Urbaniste, Tucker's Bon Chretien.

Apples.—Doctor Sweeting, High Top Sweeting, Winter Pumpkin Sweeting, Fall Sopsavine, Pound apple, Hubbardston Nonsuch, Greening from South Reading, Dutch Codlin, Flanders Pippin, Gravenstein, Smith's Gilliflower, Berlin apple, Ben apple, Peony apple, Vandevere, July flower, Bough Harvest, Fenler Sapsons, Coggswell, Grand Schem, Red Calville, Washington Pearmain, Lyscom, Scalloped Gilliflower. This last with many others were very beautiful.

Also *Watermelons*, of extraordinary size, one weighing 39 3-4 lbs. and one 44 3-4 lbs.

From Mr Philip P. Spaulding of Chelmsford.

Apples.—A seedling Green apple, and another seedling fruit, also a new French fruit called Mons le Cure, and another, De Marseilles, a noble large red fruit of fine flavor.

From Mr Ives from his garden in Dearborn street, Salem.

Pears.—Beurre Capiaumont of Van Mons, Frederic of Wurtemberg, Raymond, Beurre Bosc, Andrews, Bleeckers Meadow, Bourgomestre of Boston, Napoleon, St. Germain Panache or striped St. Germain, a new and curious striped fruit, similar in form to St. Germain, but the specimens were not quite so large. Passe Colmar, Cushing, Lewis, and a new Flemish variety, name lost.

Apples.—Pickman, Swaar, Michael Henry Pippin, Mela Carla, but not that kind which has been so lately received from the London Horticultural Society; Wellington, Rambo or Romanite, Carhouse or Gilpin, Bullocks Pippin.

From Mr Manning from his garden, Dearborn street, Salem, the following specimens, many of them new and rare and such as have never yet been produced in this country.

Pears.—Andrews, Green Catherine of Cox, Jackman's Melting, large and handsome, Autumn, superb, Belle Lucrative, Belle et Bonne, Beurre Diel, Easter Bourre, Brown Bourre large and handsome, from Standard Tree, Bezi Montigny, Bishop's Thumb, Bleeckers Meadow, Bon Chretien Fondante, Williams' Bon Chretien, Spanish Bon Chretien, Fondante d'Brest, Catillac, Cumberland, Cushing, Doynne Gris, D'Angouleme, Glout Morceau, Henry Sugar, Hason's Incomparable, Harvard, Green Quatre, Jalousie, Johonnot, Lewis, Marie Louise, Messin Jean, Long Green of Coxe, Long Green of Autumn of new edition of Duhamel, Naumkeag, Newtown Vergaleau, Winter Orange, Passe Colmar, Popes Quaker, Prince St. Germain, Roussette de Rheims, Rousselette Panache, new, Winter Royal, St. Ghislain, Siuelle, Stevens' Genesee, new, Styrian, Surpass St. Germain, Swans Egg of Coxe, Egg Pear of Duhamel, Urbaniste, Washington, Beurre Bollwiller, Beurre Comte du Fresnel, Beurre Duval, Hooper's Bilboa, large and beautiful, new, Figue de Naples, Frederic of Prussia, Fulton, Garnstone, Green Pear of Yair, Josephine, Janenette, Austrasia, Sabine of the French, Louise Bonne of Jersey, fine, large, great bearer, new, Roi de Wurtemberg, Present Royal of Naples, Reine des Poires, Surpass Vergoleuse, Beurre Van Marum, Webber's Yellow Autumnal, Alpha, Brugmansbirne, English Autumn Bergamotte, French Autumn Bergamotte, Bezi de Chaumontelle, Crasane, Knight's seedling, Coffin's Vergouleuse, Petre, very superior, great bearer, Striped Long Green, Wilkinson, Ronville, Cassolette, Summer Thorn of Thoulouse, Doyenne Blanc.—84.

Apples.—Cambuthethan Pippin, Crownshield Sweet, new seedling fine, two sorts new seedling Crabs, Rambuour d'ete, Orttley Pippin, Ribstone Pippin, Fall Harvey, Swaar, Yellow Bellflower, Blue Pearmain, Murphy new, fine, large, Putnam's Harvey.—13.

From Mr J. Clapp, South Reading; 3 fine Melons, beautiful Peaches, Siberian Crabs and Lady Apples, York Russet, basket containing Apples, Grapes and Peaches, Platts Bergamotte.

From Jacob Dean, Mansfield, Mass.; Pine apple Peaches, Hay Boy's, Golden Sweet, Golden Russet Apples, large Early Peaches.

From Thomas Banks, Roxbury; seedling Pear, Beurre du Roi, Andrews, Bargonaster, St. Michael's, Hunt's Connecticut Pears, and Red Calville Apples.

From John A. Kenrick, Newton; Pumpkin Sweet Apples, Kenrick's Heath Peaches, and fine Orange Quince.

From Dr Howard, Cambridge; 2 baskets containing variety of Pears, Apples, Nectarines, &c.

Large basket of Sweetwater Grapes, raised in the open ground by Wm. Oliver, Esq.

For the Committee,

WILLIAM KENRICK,
Chairman.

Sept. 28, 1838.

VISIT TO THE FARM OF B. V. FRENCH, Esq.
MOUNT MONATIQUOT, BRAINTREE.

We have had the pleasure of a call at the farm of B. V. French, Esq. of Baintree, who is well known to the horticultural community as a gentleman who has devoted much time to the cultivation of fine fruits, especially the pear and apple. His farm contains about 100 acres, naturally a cold unpromising soil, but by good management has been brought into a highly productive state. The improvements made upon it since it came into his possession, about 14 years, have been very great, and consist of clearing the ground of stones, draining, walls, gates, barns and other out buildings, and cellars for fruit, vegetables, manure, &c., and above all in the extensive collection of choice fruits. These improvements have been accomplished by a steady system of operations, giving evidence of the perseverance and skill of the operator. His orchards cover an extent of 23 acres; most of the trees have been planted by his own hand. Not only have the principal nurseries of the United States, been laid under contribution for their choicest varieties, but those of France, Germany, and England have also contributed to make his assortment complete. In one field we were shown 140 standard pear trees of various sorts, many of them in a bearing state. Some of the apple trees we should judge, would produce the present year, four or five barrels each. Some of the Baldwins presented as beautiful a sight as any thing of the sort we have ever seen, loaded with their showy fruit so heavily, that it had been necessary to prop them up, to prevent the destruction of the trees; even the sight itself, richly repays all the pains that have been taken to rear the trees. In looking over his orchard, and calculating the probable increasing annual profits, which may reasonably be expected for an age to come, we could not help wondering at the indolence and want of foresight in many of our farmers, in suffering fruit of a worthless character to remain to encumber the ground, when every healthy tree, however unpalatable its fruit, may be transformed by grafting, in three years time, into any desirable variety; or if necessary to set out young trees they may lay the foundation for a handsome income in their old age, or at least do much to benefit those who succeed them. Although pears and apples have received the principal attention, his place is well stocked with cherries, peaches, plums, quinces, &c. We were pleased also to observe, that while he has bestowed much attention upon fruit, the kitchen garden has not been neglected; but every vegetable desirable for the table had its appropriate place.

Mr French does not pretend to have much taste for flowers, yet he has set off a generous portion of ground which is devoted to their culture, well laid out, and well stocked with plants; but over this he holds no dominion; this he leaves to the management of the ladies. This is all right, every intelligent farmer, will encourage floriculture, and esteem it a pleasure to gratify and encourage a taste so pure and pleasing as the culture of flowers; and if he takes no delight himself in ornamenting his grounds, he will not prevent his wife and daughters from performing the pleasant task, by withholding the necessary funds and labor.

In the garden we noticed a neat apiary, but were sorry to learn that the bee moth had been very destructive to his bees. We were shown a board, the top of a hive, or some part of it, which had

been pierced like a riddle by these voracious vermin.

The poultry are well accommodated with a capacious yard, which appears to us much more economical than to let them run at large, destroying twice their value in the garden, besides the vexation it occasions a man to see them scratching up his plants.

His whole farm is enclosed with a substantial stone wall, and some portions upon the road are handsome faced. All his mowing lands and orchards are accommodated with gates, hung upon stone posts, and built in the nicest manner and so fixed that there is no danger of having any trouble from their swagging. With Mr French's permission we design to give a more particular description of his gates illustrated by plates in some future number, as we do not often see them that open and shut, so easy, and secure after they are shut as his.

The main pasture is divided in the centre by a stone wall, and each of the divisions is subdivided into three equal portions. The cattle are turned into each in succession, thereby making the most of the pasturing. In every department we witnessed the great advantage of system. A small river runs through this farm, known by the name of Monatiquot river—affording him a good mill privilege, plenty of water for cattle, accommodations for ducks, geese, &c. and adding much to the interest of his place.

In his efforts to raise wheat the present season he has had a complete failure, although a liberal application of lime and other manure was made, and the best variety of seed procured, yet he has had the mortification, after his field has exhibited the most flattering appearance, to see the whole of it blight, and totally fail; but having sowed a liberal allowance of clover seed, (at the rate of 22 lbs. to the acre,) he will not have occasion to say that his labor has been wholly in vain.

Our farmers do not generally allow sufficient clover seed to the acre, and are thereby great losers. The English sow from 20 to 28 lbs. where clover alone is sowed. In this case no other seed was sown. We have never seen a more promising field of clover.

The unfavorable season for the last two years and the failure of the corn crop in consequence, has led the agriculturalists to seek for an earlier variety. There was a great enquiry in a particular manner the last spring for seed corn. Mr French among others turned his attention to the subject, and fancied if he could procure the genuine golden Sioux from the north it would prove the variety wanted; this he procured with some difficulty; but not fancying it, he rejected it, with the exception of enough to plant one row. It is probably the same as the Dutton, but the specimen he obtained was much inferior to what is grown among us. He procured also some of the Parker corn so called, a beautiful variety to look at, with long ears, eight rows, and very large kernel. He planted about one half his field with the Parker corn and one half with the Dutton, with the exception of the one row of Sioux. Part of the Dutton corn was soaked in saltpetre water, the other was not; there was a striking difference in favor of that which had not been soaked. After examining critically the Sioux and Dutton, we do not hesitate to pronounce them to be the same originally; our Dutton is an improvement upon the Sioux, and we believe that after all that has been said, the Dutton is the most desirable variety, and shall recommend it before the

Parker or any other sort we are acquainted with, for our country.

We noticed an abundant supply of agricultural implements and tools of every description. The order in which they are kept is worthy of imitation. Even when there is a house for tools, as there is, or should be on every farm, we often see the implements and tools, thrown in promiscuously, without order, and to get at some particular tool, the whole must be overhauled; but here, we saw a room of ample dimensions, with a place for every thing—all arranged in order; the shovels, hoes, forks, rakes, &c. in separate racks; the ploughs, well cleaned, by themselves, and every article ready for service; a person acquainted with the place might place his hand upon any thing that was needed in the darkest night, if desirable.

As we were about to leave, Mr French introduced us into his library, and here we saw the secret spring which moved the operations without. We had the evidence before us that he is guilty of book-farming. We saw the place where his long winter evenings are passed, and now we were almost moved to envy. We noticed upon his table all the prominent agricultural periodicals of the day, and on his shelves were displayed a rare collection of agricultural books; the most conspicuous was the N. E. Farmer, in 16 volumes. After giving the library a hasty glance we were compelled to leave, regretting that we had no more time, as we might have spent half a day with much pleasure in looking over his books, and various curiosities with which his room is enriched.

As we returned home, we could not but reflect upon the importance of a steady, well directed system of efforts on the part of the husbandman, and how much may be accomplished by patience and perseverance guided by knowledge, in the course of a few years. J. B.

The Claremont Eagle chronicles a squash which grew in the garden of N. Whittlesey, in that town, and weighs one hundred and one pounds, and measures six feet in circumference! A squash was exhibited at the Horticultural Rooms, Boston, this week, which grew in Cambridge, weighing one hundred and thirty pounds!

Messrs Faulkner and Colony of this town, have raised this season eight winter squashes from one hill, only two seeds being planted, weight as follows:—

Four middling sized ones—	
One weighing,	134
“ “	115
“ “	114
“ “	111
Total weight of the four,	474
Four small ones—	
One weighing,	58
“ “	52
“ “	47
“ “	47
Total weight of the four,	204
Weight of the first four,	474
Weight of the whole,	678

Now for Pumpkins. Mr Daniel Thompson of this town, has raised this season from one seed *thirty-nine* PUMPKINS, nineteen of which were ripe and sound, weighing altogether, *five hundred and thirty-one* pounds.—Keene Museum.

NEW ENGLAND FARMER,

AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, OCTOBER 10, 1838.

AGRICULTURAL IMPROVEMENT.

No. IV.

In speaking of productive improvements we mentioned first the reclaiming or recovery of lands now laying waste, saturated with water, unenclosed, or in forest. Of land in this condition there is a very great amount in the State, as every considerable farmer may easily satisfy himself, if he will take the trouble of looking over his own premises. The facts in the case, the actual amount of land on almost every place, even of moderate extent, susceptible of being brought under cultivation and improvement, and rendered productive, would surprise almost any one, who would be at the pains to examine the subject: to go over every field and pasture, every wet meadow and woodland, and see how many pieces now make no return; and in how many instances the returns made are nothing compared with what they might be. We should in most cases do wrong to speak of them as returns; a return implies something first given; that is labor done or expense incurred in order to obtain it. Much of the land of which we are speaking, has never felt the hand of improvement; nor even so much as the lifting of a finger upon it. Men are fond of extending their territories; and of looking round upon a wide enclosure, whether cultivated or improved or not, and feeling like Alexander Selkirk on his island, that they are monarchs of all they survey. The rapacious propensity is not uncommon, which was ascribed to one man, who was determined, if possible, to possess all the land which joined his. It is often said, that it is better to cultivate a little land, and cultivate it well, than to cultivate a good deal poorly. We certainly agree to this; but we have another axiom, which we think quite as sound. In situations where farming is made a profession, where agriculture yields a fair compensation to labor, and labor and capital can be procured, it is best to cultivate a good deal of land, and cultivate it well. If agriculture is only a losing concern, then abandon it; for why should you expend time and care and money to no purpose; but if, like the other business pursuits of life, to persevering industry, a commendable and proper frugality, and the intelligent application of all available means to its successful prosecution, it yields a fair and liberal return, then pursue it with the industry, frugality and exertion and development of your powers and means, which are the indispensable elements of success in all other departments of active life.

We hold in the case of the farmer and the possessor of lands, as in all cases of other wealth, learning, or talent, that a serious moral responsibility rests upon him to use all these means for good. Among the Romans, six acres were the apportionment for a family, and deemed ample for their support. In our condition of society sixty will seldom suffice, and the nature of our institutions admits of no arbitrary division or restriction under the form of an agrarian law. We despair of a condition of society in which any improvement shall take place in the present form of holding and dividing the land, rejoicing most thankfully in the great advance made by a constitution of things, where the rights of primogeniture are not admitted, and no lengthened entailments are practicable. But this we hold as a high moral duty, that the possessor of land should, in all favorable circumstances, seek to render that land as productive as possible; and we hold it likewise matter of just regret, when large possessions, susceptible of improvement and of being made highly productive, are held by persons, who, like the dog in the man-

ger, will neither use nor suffer them to be used. In our country, where wild and unoccupied land is so abundant, and where there exists so great a disparity between the quantity of land and the labor available to make it productive, this is a point of far less importance than in countries where the population is redundant; but it would be well not to lose sight of the great principle that the possession of land rests upon a different basis from that of other property. Wealth, which a man creates by his labor, as bread is the product of his own cultivation, the fruit and clothing raised and framed by his own industry it would seem might, as much as his own person, be claimed as legitimately his own; and so too the money, which represents the accumulations of former labor. But property in the land itself, which he in no sense creates, and which is given to man as a common field of labor, and a common source of subsistence, is appropriated and enclosed on grounds of a different character and by no means so obvious.

Without entangling ourselves, however, in these questions of political economy, or of moral duty, we should be glad, if we could see every farmer in the State examining his possessions; and seeking to make every rood of his farm productive in some form or another to its utmost capacity. But how totally different the case is among us may be best illustrated by an example, which came under our own observation. Some few years since, as a part of a committee of an agricultural society for awarding premiums on the most productive and best cultivated farms which should be presented, we were invited to visit the farm of a respectable gentleman, when as near as we can remember, something like the following dialogue occurred. Of how much land does your farm consist? Three hundred acres. (A very large portion of this was susceptible of cultivation.) How much have you under tillage? Four acres of corn; two of potatoes; and three or four in oats. (These were all the crops.) How many laborers do you employ and how much team do you keep? I keep one yoke of oxen; and employ one man seven months in the year; and he "works out enough upon hire with the team to pay his own wages." This the man called specimen farmer, and entered the list of competitors for the highest honors of the Society. He was disposed to show at how little expense a farm could, as he termed it, be carried on. The farm in truth was not carried on at all; and, if it could be said to go, it must be said also that it "went of itself!" Situated as he was in the immediate neighborhood of a quick market, instead of four acres of corn, he ought to have had forty; men and teams enough to perform the necessary labor; and other products and crops in proportion. But it probably never occurred to this man to look over his farm, and ascertain how every acre, susceptible of being made productive, should have been brought into profitable use. This is most certainly what every intelligent and enterprising farmer should do. But at present it seems to be a cardinal point with a great majority of farmers to bring themselves down in their agricultural operations to the lowest quantum possible of labor and expense; we say possible, in many cases, consistent with the supply of the first necessities of their family, and the humblest claims to the character of practical farmers. To this point we wish to call particularly the attention of the farming community; to the actual condition of their farms; to the great number of acres, which lay neglected, waste, and unproductive, from which under proper management a liberal return might be obtained. We hope, that if considerations of duty, of self respect, and honest pride, are without power to move them to put their farms in better condition, they will, by our further inquiries and their own patient consideration, be at last aroused by the strongest convictions of interest.

We shall solicit their farther indulgence. H. C.

CATTLE SHOW AT CONCORD, MASS.

The Annual Cattle Show and Exhibition of Domestic Manufactures was held at Concord on Wednesday, 3d of October inst. It was very fully attended, and went off with great success.

The show of Cattle was respectable. Some valuable milch cows, several fine pairs of steers, and some promising calves were in the pens. A capital cow (being a cross of the improved Durham Short Horns, and a bull of native stock), was sent by Mr Meriam of Lowell. Some valuable short horns were exhibited by Mr Wright of Lowell, and Mr Morse of Marlboro'. The latter gentleman is engaged in raising this stock of the pure blood; and is entitled to much credit for his enterprise.

As the Committees will undoubtedly give a full account of the exhibition in their reports, which we shall publish as soon as received, we shall forbear further discrimination; other than to add, that we do not believe a finer exhibition of swine was ever seen at any show in our country. Every one remarked too how clean they were. It would almost seem as though they had all put on clean linen for the occasion; and whole shirts too, none of your dickies and false bosoms and collars. Then too the owners or superintendents were all careful to speak well of their good temper and good manners. They were quiet, gentle, easily satisfied, bland in their temper as a June zephyr. Only think of this. The swinish multitude are rising in the scale of civilization. What are we coming to in these halcyon days of the glorious march of mind!

A large and merry company sat down to a good dinner at Shepard's Hotel. The display of fruit at table, especially through the kindness of Mr Clapp, and Mr Eustis of South Reading, and other gentlemen, whose names we could not catch in their hasty annunciation, was most liberal and beautiful. Most of the toasts were of the highest order of wit and sentiment; and the occasion was enlivened by the addresses of several gentlemen.

We came near omitting a notice of the ploughing match. Thirteen teams were entered; and the work taken together, was executed in a first rate manner.

The sensible and practical address of William Buckminster, Esq. on the occasion, we had prepared to offer to our readers this week, but the crowded state of our columns, on account of the Horticultural Reports, forbid it.

SEEDLING DAHLIAS.—Mr Gardener Parker of Billerica, has presented us with a box containing eighteen varieties of Seedling Dahlias, of which six varieties are very good and two of them extra fine. One he has named the Village Belle, is a fine white flower, very delicately tipped with purple. Another variety we named the Billerica Rival, which will pass for a superb flower. It is large, fine shape, cupped petals, and of a fine rosy crimson. A third flower resembles Newick Rival, is named Beauty of Middlesex. Some of the others were fair, but, as we have so many stars of the first magnitude, they were not worthy of a name.

J. B.

(For the New England Farmer.)

MR EDITOR—I take the liberty to address to you a few inquiries respecting the Tomato, and require the favor that you or some of your correspondents will give some information through the N. E. Farmer how to preserve this vegetable, which is pronounced by some of the most learned M. D.'s to be "one of the most wholesome and valuable esculents that belong to the vegetable kingdom."

I have a large quantity of Tomatoes on hand, and have heard a good deal said about Tomato Catsup, but am ignorant as to the mode of making it. By furnishing a receipt for making the same, you will doubtless oblige some of your numerous readers as well as myself.

Sheburne, Sept. 26, 1838.

A READER.

REMARKS BY J. B.—We presume "A Reader" has not taken the farmer many years back, as a recipe was published in Vol. 10, page 101, which we republish for his benefit, as well as others, who may not have access to the back volumes.

"To make Tomato Catsup.—Take one gallon skinned Tomatoes, four table spoons salt, four of black pepper, two of allspice, eight pods red pepper, eight table spoons of mustard seed. Brise all these fine, and simmer them slowly in a pint of vinegar three hours; then strain them through a hair sieve—to be stewed down to half a gallon of catsup—put the catsup into the bottles and cork it tight."

We have tried catsup made from the above receipt and

find it good. This wholesome vegetable is getting much into use: where one bushel was sold in our market three years since, ten are sold now. There is such a thing as puffing a good article a little too much, and we are not sure but it will be so with the Tomato; it bids fair to be blown as high as Brandereth's pills, and a hundred other humbugs, for the quacks are beginning to get the "concentrated extract of Tomatoes" as a panacea for a long list of "aches and ails."

It will probably be a very safe medicine, and may be taken without endangering life. We have found the Tomato to have a fine effect upon the system, especially when taken in a moderate quantity of two or three, well cooked and seasoned, accompanied by a good cut of roast beef and other et ceteras.

ROHAN POTATO.—Mr O. Holmes of Bedford, has shown us a Rohan Potato, weighing 25 ounces. He stated that he purchased of us in the spring one and a half pounds, from which he has obtained 85 pounds, making a yield at the rate of 56 bushels from one planted.

There is no doubt but that this is a valuable potato for stock on account of its extraordinary productive properties; but as a potato for the table we do not think highly of it. It cannot be called more than second rate.

J. B.

We are frequently asked, when is the most suitable time for transplanting fruit trees. We would notify those who intend to set out trees, that now is the time. After a heavy autumnal frost, of all seasons, it is the best for apples, pears, plums, and all other hardy fruit trees and shrubs.

The Report of the Massachusetts Horticultural Society, for last week, is unavoidably omitted. It shall appear in our next.

BRIGHTON MARKET.—MONDAY, Oct. 8, 1838.

Reported for the New England Farmer.

At Market 650 Beef Cattle, 475 Stores, 2,500 Sheep, and 425 Swine.

Prices.—Bref Cattle.—The market today was quite spirited, nearly all the best cattle were purchased before they arrived at Brighton. We quote first quality, \$7 50. Second quality, \$6 75 a \$7 00. Third quality, \$5 75 a \$6 25.

Barrelling Cattle.—We are not able to give prices today, several lots were sold on the last without weighing. **Stores**—Yearlings, \$9 a \$11. Two Year Old, \$13 a \$28. Three Year Old, \$22 a \$38.

Sheep.—Sales quick at advanced prices. We quote lots at \$1 75, \$1 92, \$2 12, \$2 25, \$2 42, \$2 62, \$3 00, and \$3 50.

Swine.—Sales quick, several prime lots were sold to peddle at 7 a 12 a 7 1-2. At retail, 7 1-2 a 9. Old 7 a 8 1-2. **Error.**—In our last week's report old hogs were reported half a cent too high.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northerly exposure, week ending October 7.

DECEMBER,	1838.	7 A.M.	12 M.	5 P.M.	Wind.
Monday,	1	50	68	60	E.
Tuesday,	2	52	70	58	S. E.
Wednesday,	3	48	68	50	N. E.
Thursday,	4	40	65	56	E.

Saturday,	5	52	75	62	W.
Sunday,	6	50	58	48	S. W.

RASPBERRY BUSHES.

For sale at the Charlestown Vineyard, fine plants of the following Raspberries, viz.
 Red Antwerp,
 White do.
 Barnet,
 Franconian, and
 Mason's Seedling.

Orders left with **JOSEPH BRECK & CO.** will meet with prompt attention. **THOMAS MASON.**
 Charlestown, Oct. 10, 1838.

PEAR TREES FOR SALE.

At the Pomological Garden, Salem, Mass., a good collection of Standard Pear Trees, all of which have been proved. They comprise the choicest of the old and new varieties. Also 5,000 superior Buckhorn Plants for hedges.
 Salem Oct. 8, 1838. **ROBERT MANNING.**

LAYING OUT GARDENS AND ORNAMENTAL PLANTATIONS.

E. SAYENS begs leave to inform his friends and the public in general that he will attend the laying out gardens and ornamental plantations, and hopes by strict attention to business to merit the approbation of those who may be pleased to employ him.
 All orders left with J. Breck & Co. Agricultural Store, No. 52 North Market Street, will be punctually attended to.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders in any amount, which will be promptly attended to.

Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston.
 Sept. 20. **NAHUM WARD.**

FOR SALE.

Five acres of good Salt Marsh, in Quincy, or (Squantum so called).
 Also, Four acres of Salt Marsh in Brighton.
 Also, Several full blood animals, cows and calves. Apply to A. Greenwood, on the Welles Farm, Dorchester, near Dr Codman's meeting house.
 Sept. 12, 1838.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham. **ISAAC PARKER.**

NOTICE.

The subscriber offers for sale his real estate in Westford and Groton; consisting of his homestead, 35 acres, his farm, 117, one pasture, 17 acres, one do. 33 acres, one wood-lot, 13 acres, one do. 5 acres, and one do. 10 acres. For further particulars see his advertisement in the Lowell Journal, or inquire of the subscriber at his house, near the meeting houses and academy in Westford.
EPHRAIM ABBOTT.

FARM FOR SALE.

In Cambridge, about one mile from Mudrock's Hotel on the West-Cambridge road with a valuable stone ledge on the same; containing forty acres of good land with the buildings on the same. It will be sold at a bargain if applied for soon, as the present owner is about removing to the West. Apply to the subscriber on the premises.
 Sept. 25. **AMMI C. TEEL.**

FOR SALE.

The thorough bred Short Horned Durham Bull, Superior. Superior was calved in August, 1831. He was got by Frederick, and he by Wye Comet.
 Dam, Yellow Rose, by Young Denton.
 G. Dam, Arabella, (Imported), by North Star.
 G. G. Dam Aurora, " " Comet.
 G. G. G. Dam " " Henry.
 G. G. G. G. Dam " " Danby.

The above pedigree may be found in the English Herd Book.

He is a roan and perfectly gentle and docile; and his stock, which may be seen at the farm of the subscriber, will testify to his value. Price, \$250. Apply to C. N. Bement, Esq. No. Albany, N. Y., or to Wm. Augustus North, Mount Marie, Danversburgh, N. Y.
 October 3, 1837. **4w**

MULBERRY TREES.

1500 Morus Multicaulis.
 1000 White Mulberry.
 For sale, the entire lot, or in small quantities. They are very superior, and being raised so far north, have the advantage over southern raised trees, for this State.
JAMES STEWART,
 Indian Hill Farm, near Newburyport, Mass.
 October 3, 1837. **3w**

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dame, situated in Rochester, N. H. six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quantities of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to **JOSEPH BRECK & Co.,** No. 51 and 52 North Market Street, Boston.
 August 15, 1838.

EMPLOYMENT WANTED.

A Gardener out of employment would be happy to attend to orders for budding or gardening of any description. Apply at the New England Farmer Office.

WINTER RYE.

Just received at the New England Seed Store and Farmer Office, a few bushels of prime Winter Rye.
JOSEPH BRECK & CO.
 Aug. 13, 1838.

MISCELLANEOUS.

From the Springfield Republican.

THE SUMMER BLOOM IS PAST.

The summer bloom is past and dead,
And blight on leaf and flower is shed,
And silent groves and forest dross,
Are clad in robes of fading year.

But late, and Spring, with haughteous hand,
Spread joy around the smiling laud,
And o'er the ground like carpet thrown,
The gaudy flowers were mix'd and strown.

In forest deep, by fount unseen,
On sunny banks, on meadows green,
The silent flowers were blooming there
To deck the earth, and lade the air.

And smiling morn with dewy tread,
Or eve, like holy calmness shed,
And sights of love, and sounds of mirth—
All came to cheer the gladden'd earth.

Where'er our steps we turned the while,
The earth was clad in boundless smile;
The hills in sunny robes were seen,
And trees were drest in living green.

But colder winds from northern zone,
Have o'er the blooming landscape blown,
And faded leaves, all brown and sere,
Proclaim that winter's gloom is near.

The early flowers lie wither'd and dead
On many a cold and leafy bed;
Their light no more shall deck the plain,
Till summer comes again to reign.

But few and lone the blossoms stand,
Pale sisters of that lovely band;
As oft, when earthly hopes are torn,
The spirit lingers but to mourn.

We grieve to see the verdant bough,
And tender grass, all faded now;
And fragrant herb and flowers in bloom,
All gathered to their silent tomb!

But frail as these, life's transient ray,
That shines an hour and melts away;
Fit emblems of our being brief—
The fading flower and falling leaf!

C.

PRESERVING WINTER APPLES.

Winter apples should be gathered as soon as the mature ones begin to fall from the trees; they should be carefully picked by the hand, and never shaken from the trees. If intended to be carried to market this fall, they may be packed in chaff or soft straw to prevent bruising. But it would doubtless, in most instances, be more profitable to keep apples till spring, on account of their high prices at that time. The same apples that are sold in autumn for 25 cents, often, when kept till spring, bring 75 cents or a dollar per bushel: while the loss by rotting, when proper precautions are taken to preserve them, is but comparatively trifling. An excellent mode of preserving them, is to pack them away in dry sand. The sand should be previously well dried in the sun. This mode prevents them from rotting one another by contact; the sand absorbs all unnecessary moisture from the fruit and thus lessens the liability of rotting; and

partially excludes the air. Well dried saw dust would probably be still better, providing it is prevented from absorbing moisture by being excluded from the air: but it should be of a kind of wood which will not injure the flavor of the apples.

Where this method cannot be adopted, a good way to keep them is to spread them in shallow bins, (say 5 or 6 inches in depth,) in a dry, cool place, where the temperature should be kept as nearly as possible a little above freezing.

The following, according to Kenrick, is a mode of preserving apples, almost universally adopted by the most experienced in the vicinity of Boston, where large quantities of winter fruit are cultivated and put up for use. By this mode, we are assured, apples under very favorable circumstances, are frequently preserved in a sound state, or not one in fifty defective, for a period of seven or eight months. "The fruit is suffered to hang on the tree to as late a period as possible in October, or till hard frosts have loosened the stalk, and they are in imminent danger of being blown down by high winds; such as have already fallen are carefully gathered and inspected, and the best put up for early winter use. They are carefully gathered from the tree by hand, and as carefully laid in baskets. New, tight, well seasoned flour barrels from the bakers, are usually preferred; the baskets being filled, are cautiously lowered into the barrels, and reversed. The barrels being quite filled, are gently shaken, and the head is gently pressed down to its place and secured. It is observed that this pressure never causes them to rot next the head, and is necessary, as they are never allowed to rattle in removing.—No soft straw or shavings are admitted at the ends, it causes mustiness and decay.—They are next carefully placed in wagons and removed on the bulge, and laid in courses in a cool, airy situation on the north side of buildings near the cellar, protected by a covering on the top of boards, so placed as to defend them from the sun and rain, while the air is not excluded at the sides. A chill does not injure them, it is no disservice;—but when extremely cold weather comes on, and they are in imminent danger of being frozen, whether by night or day, they are carefully rolled into a cool, airy, dry cellar, with openings on the north side, that the cold air may have free access; they are laid in tiers, and the cellar is, in due time closed and rendered secure from frost. The barrels are never tumbled or placed on the head. If fruit is gathered late, and according to the above directions, re-packing is unnecessary, it is even ruinous, and should on no account be practised till the barrel is opened for use. It has been fully tried."

A PLEA IN ABATEMENT.—In one of the Quarter Session courts in Tennessee, one Joe Phillips was indicted for an assault and battery. The solicitor called him to the bar and addressed him thus: "You are indicted for a misdemeanor, and stand charged in these words: 'The jurors, upon their oaths, present that Joe Phillips, late of the county of —, on the 10th day of August 18—, with force and arms, in and upon the body of one John Scroggins an assault did make, with guns, pistols, swords, dirks, and clubs, with malice aforethought.'" —

"Stop, Mr Lawyer," says Joe, "there was something of it, but you're making it a — deal worse than it was."

"Well, how was it Joe?" says the solicitor.

"Why, I and John met one day on the road, and

says I to John, 'this is a bad day for snakin.'—Then says he to me, 'Not very bad neither, for I killed one near upon a rod long.' Then says I, 'That's a lie, for there's nary snake in this country half so long.' Then, after a good many such compliments passed between us, says John to me, says he, 'I doesn't milk my neighbors' cows as some folks do.' And then I hit him a lick with my fist on the side of his head, and then we had a real scuffle; a fair fight; then just so. And we hadn't no gun, nor pistol, nor club, nor dirk, neither; so you needn't be talking all that nonsense over to the Court when there's no such thing; and John says he's willing to fight again, if I'll let him strike first."

APPRENTICES.—When serving your apprenticeship you will have time and opportunity to stock your minds with useful knowledge. The only way for a young man to prepare himself for future usefulness, is to devote himself to study during his leisure hours. First, be industrious in your business—never complain that you have to work; go to it with alacrity and cheerfulness and it will become a habit which will make you respected and beloved by your master and employer, make it your business to see and promote his interest; by taking care of his you will learn to take care of your own.

Young men at the present day are too fond of getting rid of work, they seek for easy and lazy employment, and frequently turn out to be miserable vagabonds. You must avoid all wishes to live without labor; labor is a blessing instead of a curse—it makes men healthy, it procures them food, clothing, and every other blessing, and frees them from temptation to be dishonest.—*American Presbyterian.*

PAT ASTONISHED.—An unfortunate Hibernian, ruminating upon the bank of a southern creek, espied a terrapin pluming itself. "Och, honey!" he exclaimed, solemnly, "that iver I should come to America to sa a snuff box walk!"—"Whist," said his wife, "don't ye be arter making fun of the birds!"

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres land situated on Nonantum Hill, in Newton 5 1-2 miles from the city. The garden occupies nearly two acres, is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.

LOT WHEELRIGHT.

July 16th.

ALDERNEY STOCK FOR SALE.

For sale, a full blooded Bull, 3 years old the first of July next—one Cow, five years old—and a Heifer three years old. The Cows are said to be the richest Milkers of any imported. For further particulars address L. M. WHEATON, Norton, Mass., or a line left at this office, will meet with prompt attention. June 27

FOR SALE.

A Ram and Ewe from the Cape Good Hope. Inquire at this office.

THE NEW ENGLAND FARMER.

Is published every Wednesday Evening, at \$3 per annum payable at the end of the year—but those who pay within sixty days from the time of subscribing are entitled to a deduction of 50 cents.

AGRICULTURAL.

From the Genesee Farmer.

CARBON IN PLANTS.

At the late meeting of the British Association at Liverpool, Dr Dalton communicated a paper on the Non-decomposition of carbonic acid gas by plants.*

"He calculates that in 5000 years the animals supposed to live upon the earth would produce but 101 of carbonic gas, so that the assistance of plants to purify our atmosphere is not necessary. By experiments he found that a hot house does not contain more or less carbonic acid by night or by day than the external air, and the results were the same when the experiments were a number of times repeated."[†]

Dr Dalton is a great name in chemical philosophy, but we think the present system of vegetable physiology is too well established to be shaken by experiments so liable to fallacy as those mentioned above. To account for what is called the Aeration of sap in plants, long exercised the skill and ingenuity of philosophers. The first step to its solution was made by Dr Priestley, the founder of pneumatic chemistry; to Senneber we are indebted for the observation, that the presence of carbonic acid is required for the disengagement of oxygen gas during the day by the leaves of plants and that the oxygen is derived from the decomposition of carbonic acid by plants has been fully established by the researches of Woodhouse of Pennsylvania, Saussure and Palmer. The most satisfactory demonstration of this fact, however, was the following experiment by De Candolle:

"Two glass jars were inverted over the same water bath; the one filled with carbonic acid gas, the other with water, containing a thrifty sprig of mint; the jars communicating below by means of the water bath, on the surface of which oil was poured, so as to intercept all communication between the water and the atmosphere. The sprig of mint was exposed to the light of the sun for twelve days consecutively; at the end of each day the carbonic acid was seen to diminish in quantity, the water rising in the jar to supply the place of what was lost, and at the same time the plant exhaled a quantity of oxygen exactly equal to that of the carbonic acid that had disappeared. A similar sprig of mint, placed in a jar of the same size full of distilled water, but without having access as before to carbonic acid, gave out no oxygen, and soon perished. In another experiment with the same apparatus as at first, oxygen gas was substituted in the first jar instead of carbonic acid gas, and no gas was disengaged in the jar, which contained the sprig of mint. It is evident, therefore, that the oxygen gas obtained from the mint in the first experiment, was derived from the decomposition, by the leaves of the mint, of the carbonic

acid, which the plant had absorbed from the water."[†]

This experiment, which has been repeated frequently since and with every variation, is conclusive as to the decomposition of carbonic gas, and directly opposed to the conclusion of Dr Dalton.—

Dr D. may be right as to the quantity of this gas produced by animals, though it is evidently only an approximation to the truth in such a case can be made by calculation: but that plants do decompose carbonic gas we think does not admit of a doubt, and we further believe that in this way most of the carbon appropriated by plants, and which constitutes so large a portion of their structure is obtained in this way. When one considers the structure of a hot house, the manner in which it is supplied with external air, and the consequent continual change of the atmosphere in such a building, it would have been more surprising had a difference existed between the internal and external air, than that no such difference was discovered by Dr Dalton.

That the carbon obtained by the decomposition of carbonic gas is retained by the plant is proved by a beautiful series of experiments conducted by Saussure the younger, who found that this process is attended with a sensible increase in the quantity of carbon, which the plant had previously contained. He further discovered that it is in the green substances of the leaves alone that this process is conducted; a process which from its strong analogy to a similar function in animals, may be considered as the respiration of vegetables. It takes place only in the living plants, for if a leaf be bruised so as to destroy its organization, and injure its vitality, its substance is no longer capable of decomposing carbonic acid under the influence of the sun, or of absorbing oxygen in the dark.

The respiration of man and animals appears to be for the purpose of obtaining oxygen; and this is accomplished by the decomposition of the air in the lungs, the oxygen being retained, while the carbonic gas is rejected. In plants, however, the food of which consists mostly of carbon, the object of respiration appears to be, to retain the carbon gained by decomposition, while the oxygen is mostly rejected. It is clear therefore, that the atmosphere is continually receiving from the vegetable kingdom a large accession of oxygen, and is at the same time freed from an equal portion of carbonic acid gas, both of which effects tend to its purification, and its remaining adapted to the respiration of animals. Nearly the whole of the carbon accumulated by vegetables, is so much taken from the atmosphere, which is the primary source from which they derive that essential aliment.

The power of absorbing and retaining carbon possessed by plants, depends on their vital power or irritability; hence the advantage of manures, of lime, gypsum, &c. The quantity of these substances taken up by the plants themselves is small, but

the quantity of carbon appropriated is rapidly increased, and hence the vigorous growth of the plant. This effect may be as clearly seen where gypsum is applied to clover, as perhaps in any other case; and here the growth is not because the gypsum itself goes into the circulation and substance of the plant in any considerable quantity, but because the power of appropriating carbon is increased by the additional circulation or irritable energy of the plant. When it is remembered that carbon is the base of most nutritive substances, and that this is in most cases, in the first place drawn from the air by plants, the decomposition of carbonic gas by vegetables cannot be viewed otherwise than as a most wonderful proof of divine wisdom and design in providing for the health and nourishment of plants and animals.

DEMONSTRABLE FACTS.

WEIGHT OF CREAM AND MILK.

In No. 24 of the Farmer, we published a communication from "Truth" in which he thinks we must have been mistaken in the experiment published in a former paper, with regard to the specific gravity of cream and milk, and requested a new experiment should be made. We have not had an opportunity to comply with his request until recently, but have now done it with a great deal of care and accuracy. Our cow goes upon the common, and usually we give her a few potato tops or corn stalks, night and morning. She gives about ten quarts of milk per day. The milk with which the experiment was made, was milked at night and strained into a tin pan. It was set in a cool situation and the cover but partially laid over it, in order to let it cool. The next morning the cover was placed entirely over it and in this condition it set 37 hours. The cover was then removed and the cream taken off as carefully as possible into a glass tumbler. Then all remaining particles of cream, which could not be so perfectly separated from the milk, were taken off and a portion of the milk put into another tumbler, and both were taken to an accurate balance and weighed very carefully, and a vial which will hold 1000 grains of distilled water, when filled with the cream, weighed 978 grains and when filled with skimmed milk it weighed 1,032 grains. A portion of new milk from the same cow was found to weigh 1,025 grains, showing a difference of 54 grains in the specific gravity of cream and skimmed milk, and a difference of 47 grains between cream and new milk. Or that cream is 5 per cent. lighter than milk.

This experiment was made with more accuracy and care than the former, and shows a greater difference, which proves most conclusively the position taken, that cream is lighter than milk. Altho' there is a difference in the weight of milk from different cows, and there will probably be a difference in the specific gravity of different parcels of milk and cream; but the principle we hold to and have proved, is no new one. It has been established by the best Chemists for years, and when

*London Atheneum, No. 519.

[†]Roget's Bridgewater Treatise, Animal and Vegetable Physiology.

we advanced it, we did not suppose and did not even presume, that any one else would think we were advancing any new theory.

Turner, in his elements of Chemistry says, milk carefully deprived of its cream, has a specific gravity of 1,033 and 1,000 parts of it are thus constituted butter 948,75 caseous matter with a trace of butter 28; sugar of milk 35; muriate and phosphate 1,95; lactic acid, acetate of potassa, and a trace of lactate of iron 6, and earthy phosphates 0,3. Subtracting the caseous matter, the remaining substance constitutes whey.

He states the specific gravity of cream to be 1024 and 100 parts of it to consist of butter 15, caseous matter 3,5, and whey 92. By agitation, as in the process of churning, the butter assumes a solid form and is thus obtained in a separate state. During the operation there is an increase of temperature amounting to about 3 or 4 degrees, oxygen gas is absorbed, and an acid is generated; but the absorption of oxygen cannot be an essential part of the process, since butter may be obtained by churning, even when atmospheric air is entirely excluded.—*Maine Farmer.*

From the Maine Farmer.

UP EAST versus DOWN EAST.

WE never yet understood the reason why the region hereabouts should be called "down East." Is it because it is nearer to sunrise that the regions farther west? Certainly that should not give it the cognomen by which it is so commonly known. When the sun is setting, it is usually said the sun is going down. Surely, then, it would be more proper to say *down West*, than down East.

We therefore contend that the term should be changed, and Up East be used instead of Down East.—There are divers other reasons why that appellation should be used by our sister New-England States, a few of which we will mention. And first—we are the largest in point of extent of territory. If examined in that point of view, the others must *look up* to us, something as the mouse looks up to the elephant, and surely it would sound rather odd to hear Mr Mouse say, I am going *down* upon the Elephant. In the next place, we have more lumber than all the rest of New England. There is no mistake but that they must *look up* to us in that line of business. We are certainly up East in that respect. Again, we have more granite than all New England besides, so that here again we must be *looked up* to for a supply of that valuable article. Again we have more lime than all the rest of New England, and they have long been in the habit, especially in the maritime ports, of *looking up* to us for that article. Again, we have more slate than all the rest of New England—and the day is not far distant when those who want this article, will *look up* to us for it, with the same solicitude that they do for the others. We have also long been in the habit of sending out immense herds of beef cattle and horses—and it is well known that Old Massachusetts, at least, has habitually *looked up* to us for this kind of stock; and that her drovers come *up* to us for their supply of cattle every fall, as regularly as the falls come round. Another reason is, we are beginning to "*look up*" ourselves.

Our agriculture is improving. Our farmers are rousing up their energies and intellects; they are brushing up their farms; they are clearing up the

forest; they are breaking up their fallow ground, they are putting up new houses; they are filling up their store houses and granaries with bread; they are bringing up their children to take a pride in the calling of a FARMER. Every thing is *upward*; it is no longer *down East*. The Mechanics, too, are *looking up*. They have got up a splendid Fair, which was held last week. They, too, are waking each other up and doing. They are calling upon one another to be up and doing. They are every year introducing new inventions, and giving up old ones for better. Every thing begins to be *UPWARD*, and no longer *downward*. Why, then, should the old phrase "*down East*" be used? We move, Sir, that it be changed to *UP EAST*, and call for the yeas and nays.

ON COWS.

MR EDITOR,—Permit me to intimate that I believe that we farmers have not paid attention enough to the properties of our cows.

I, for one, have noticed the following failings or bad properties in cows.

1. One gives poor, or skimmed milk, or what is little better.
2. Another gives very little of it.
3. So hard to milk, that the milk is worth little if any more than the labor of milking.
4. So easy to part with her milk, that she scatters it wherever she is found, in a few hours after milking.
5. The milk comes from one side of the end of the teat, and spatters all around.
6. Gives milk from less than four teats.
7. Often gargetty and unhealthy.
8. A miserable feeder—will eat nothing but the best.
9. Breachy—jumps and breaks down fences.
10. She will kick one over when near her or attempting to milk her.
11. So cross to other stock as to render it dangerous to leave her with them.
12. A great rawny built creature; made, it would seem, to eat much more than she earns—or more than her milk is worth.
13. Teats so small that it is difficult to milk her.
14. Goes dry nearly half the time while with calf.
15. Fails to discharge what is necessary after calving.

Hence, if we wish to purchase a cow, we should always do it of a person of truth,—one who will charge a *fair* price for a cow which he says has *none* of the before-named failings. Such a cow, of suitable age, we need not fear of giving too high a price for; instead of this, most cows are sold because they have some of the failings I have named, and of course are only fit for beef; and the sooner they are in the beef barrel, the better,—as beef now bears a good price.

Some of the failings I have mentioned, may, it is true, be borne with for a time, until we can get a cow as clear of them as may be.

I only add that we keep cows with some of the worst failings named,—such as giving poor milk,—and do not even know it, having never placed the milk by itself, to test it.

Size is not to be regarded much, merely for a milk cow; although a large one may be better to breed oxen from.

—*Maine Far.*

IMPORTANCE OF AGRICULTURAL IMPROVEMENT.

From the Indiana Farmer.

It is by comparison that we estimate the value and qualities of things. If our stock of cattle, horses, sheep and hogs are as good as those in our neighborhood or as any that may have been noticed, we call them good. We have good crops of corn, and grain of all kinds, if we see no better; and a good or poor farm by the same comparison. But when we extend our researches a little beyond our own precincts, we often find that what we have been accustomed to call good or poor, will not be applicable in the same sense that we have heretofore viewed the terms, and a different standard is necessary. Some, after visiting Rocky river, or Black Hawk country, come home with different ideas of the quality of soils and look upon their heretofore good farms, with an eye of indifference, and naught will do but to sell off and commence anew in the wilds of the farthest west. They are highly delighted with the rich prairie country, and dwell largely on the advantages untold. They are too often partial in their comparisons, and forget that the soil of their farms is susceptible of great improvement, and that they possess many comforts and privileges at home, that they must for a long time be deprived of in their new location. Such perhaps had better migrate, and leave their improvements to be occupied by those better able to appreciate their value, and with minds imbued with the spirit necessary to a further improvement.

Such persons extend their comparisons for a different object. They see and hear of a land more productive than their own, without that itching desire to pull up stakes and make many sacrifices for the purpose of occupying it; knowing full well that all cannot abide in one place, they feel satisfied with their location, put themselves about improving their own soil with the means they possess—and they will soon find they need not go from home to look for the standard of excellence, for they have it on their own premises.

Because a man has a farm inferior to his neighbors, or that some distant place is better than the land in his vicinity, we conceive to be no reason for him to change his location, if he is otherwise suited. Various motives and causes often make it proper to change, but when a man is fully determined to make the best of his situation, and set about improving his soil, improving his crops, improving his stock: he at the same time is improving his mind; and his children are not forgotten; for improvement is his motto, and is adhered to, in all the various departments of his household—he will generally find it as profitable to remain at home, and enjoy the comforts of an older settlement.

We hardly thought of lecturing on emigration when we commenced this article, but wished to impress on the minds of our farmers the importance of improving their farms, and their system of farming.

A pretty uniform system is adopted in new settlements and for aught we know as good as any, but after a considerable portion of the farm becomes cleared it is time to look toward the introduction of the improvements of older settlements. We are favored with varieties of soil, adapted to the raising of different articles of produce, and in order to farm it profitably, we must as far as possible suit the crop to the soil. Wherever the soil will admit of

It, a rotation of crops is desirable, and on almost every farm a portion of the land can be profitably occupied in this way; but much of the land through the central parts of our state is much better adapted to growing grass than grain; and on such land it would be improper to make the raising of corn and fattening of hogs the main business. Here the raising and keeping of cattle will be more profitable. Again on the dry and rich soil of the river bottoms, corn is the most appropriate crop with a rotation of other grains. By a little observation, a farmer will discover the most profitable course of culture, and on lands adapted to the purpose he ought not to remain contented with smaller crops than are obtained in older settlements on inferior soil. "What has been done can be done again" is a remark frequently made, and we see no reason why a farmer who has good corn land should be satisfied with fifty bushels to the acre when one hundred can be obtained. We have seen the land and the stalks, from which one hundred and twenty-seven and a half bushels of shelled corn were taken from the acre, and in several instances over one hundred and fifty have been obtained, in the state of New York. It was by manuring and superior cultivation that it was done. Let us bestow the same care and much larger crops than we now get, will be the result. Just so with stock, and every production of the farm.

Much land that is now unfit for grain by proper draining may be made excellent for the purpose. When a farmer is fully resolved to make every improvement in his power, he will find many ways of doing it he had not before thought of. One of the most important considerations will be the saving of manual labor, for which purpose machines of various kinds are in use in the east; some of which will soon be introduced among us.

When one or more individuals in a neighborhood are fully impressed with the necessity, and a desire for improving their farms, their example will have a very beneficial influence. The standard of excellence will be raised, and others will follow their example. Many who are trudging along in their half measures, would not rest satisfied with their imperfect and unprofitable system, when they saw their neighbors enjoying superior comfort, and realizing greater profits, in consequence of the improvements they have adopted. Much good will result from the spirit of improvement when it becomes general. Roads will be vastly improved. Schools will be better supported, and the minds of the people better informed; and may we not reasonably suppose their morals will be improved.

EGGS AND POULTRY.

Among all nations, and throughout all grades of society, eggs have been a favorite food. But in all our cities and particularly in winter, they are held at such prices that few families can afford to use them at all; and even those who are in easy circumstances, consider them too expensive for common food.

There is no need of this. Every family or nearly every family, can, with very little trouble, have eggs in plenty during the whole year; and of all the animals domesticated for the use of man, the common dunghill fowl is capable of yielding the greatest possible profit to the owner.

In the month of November, I put apart eleven hens and cock, gave them a small chamber in a wood-house, defended from storms, and with an

opening to the south. Their food, water and lime were placed on shelves convenient for them, with warm nests and chalk nest-eggs in plenty. These hens continued to lay eggs through the winter. From these eleven hens I received an average of six eggs daily during the winter; and whenever any of them was disposed to set, viz. as soon as she began to cluck, she was separated from the others by a grated partition, and her apartment darkened; these cluckers were well attended and well fed; they could see and partially associate through their grates with the other fowls, and as soon as any one of these prisoners began to sing, she was liberated, and would very soon lay eggs. It is a pleasant recreation to feed and tend a bevy of laying hens; they may be tamed so as to follow the children, and will lay in any box.

Egg shells contain lime, and in winter, when the earth is bound with frost or covered with snow, if lime is not provided for them, they will not lay, or, if they do, the eggs must of necessity be without shells. Old rubbish lime, from old chimneys and old buildings, is proper, and only needs to be broken for them. They will often attempt to swallow pieces of lime plaster as large as walnuts.

I have often heard it said that wheat is the best grain for them, but I doubt it; they will sing over Indian corn with more animation than over any other grain. The singing hen will certainly lay eggs, if she finds all things agreeable to her; but the hen is much a prude, as watchful as a weasel, and as fastidious as a hypocrite; she must, she will have secrecy and mystery about her nest; all eyes but her own must be averted; follow her or watch her, and she will forsake her nest, and stop laying; she is best pleased with a box covered at top, with a backside aperture for light, and a side door by which she can escape unseen.

A farmer may keep an hundred fowls in his barn, may suffer them to trample upon and destroy his mows of wheat and other grains, and still have fewer eggs than the cottager who keeps a single dozen, who provides secret nests, chalk eggs, pounded brick, plenty of Indian corn, lime, water and gravel, for them; and who takes care that his hens are not disturbed about their nests. Three chalk eggs in a nest are better than a single nest egg, and large eggs please them; I have often smiled to see them fondle round and lay into a nest of geese eggs. Pullets will commence laying earlier in life where nests and eggs are plenty, and where other hens are cackling around them.

A dozen dunghill fowls, shut up away from other means of obtaining food, will require something more than a quart of Indian corn a day; I think fifteen bushels a year a fair provision for them. But more or less, let them always have enough by them; and after they have become habituated to find enough at all times a plenty in their little manger, they take but a few kernels at a time, except just before retiring to roost, when they will take nearly a spoon-full into their crops; but just so sure as their provision comes to them scant or irregularly, so surely they will raven up a whole crop full at a time, and will stop laying.

A single dozen fowls, properly attended, will furnish a family with more than 2,000 eggs in a year, and 100 full grown chickens for fall and winter stores. The expense of feeding the dozen fowls will not amount to eighteen bushels of Indian corn. They may be kept in cities as well as in the country, and will do as well shut up the year round as to run at large; and a grated room, well

lighted, ten feet by five, partitioned from any stable or other out-house, is sufficient for the dozen fowls, with their roosting place, nests and feeding troughs.

At the proper season, viz. in the spring of the year, five or six hens will hatch at the same time, and the fifty or sixty chickens given to one hen. Two hens will take care of 100 chickens well enough, until they begin to climb their little stick roosts; they should then be separated from the hens entirely; they will wander less, and do better away from the fowls. I have often kept the chickens in my garden; they keep the May bugs and other insects away from the vines, &c.

In cases of confining fowls in summer, it should be remembered that a ground room should be chosen: or it will do just as well to set into their pen boxes of dried sand or kindried, well pulverized earth, for them to wallow in, in warm weather.—*Con. Courant.*

APPROVED METHOD OF MAKING GOOD CIDER.

Mr Anderson, a gentleman in England, famed for good cider, gives the following account of his method of making it:

"I should first tell you that my orchards are upon a clay soil, which I think conduces much to the goodness of my cider. I will be short in my practical account, making but few observations, and leave the curious to draw speculative reflections on it. I permit my fruit to remain on the trees till a great part falls by ripeness; then gently shaking the trees, take in the apples in dry weather, laying them in heaps of equal ripeness in a loft over my press. There they remain until they have perspired, and that perspiration ceases. As soon as convenient afterward, I grind my apples and press out the juice; if it casts a pale color, I suffer the pulp to stand twelve or twentyfour hours, which will heighten the color of the juice. As soon as it is expressed, I pour it into vats through a sieve, where it remains about two days according to the state of the weather and the nature of the apple—the longest when frosty or cool weather—till a thick head of scum rises upon it. Then I draw off a little into a glass to see if it is fine, and as soon as I catch it so, I rack it off without delay into open vats, or into hogsheads. If the juice is racked into vessels larger at top than the bottom, and I rack it off as soon as fine, I need not take off the head or scum, as it will not mix with the cider; but if the cask is straight, or I have neglected to draw it off until it begins to come foul again, I find I do best to take off the head with a wooden skimmer and then draw off as soon as possible. Whenever the brown head begins to open in the middle, or elsewhere, and a witness appears at the openings, I am certain it is time to draw off; but I find from experience, that the surest token is to observe its state by what is drawn off in a glass, and this method should be closely attended to. I have drawn a glass of cider out of a vat at eight o'clock, foul; another at ten, fine, almost candle bright, without any appearance of the heads opening, as above observed; at eleven, it was growing foul fast, without high winds, or any extraordinary event that I could perceive, to occasion it. If then drawn off into open vessels, a fresh head may arise in twentyfour hours, then it may be racked into a close hogshead, or other receiver, where it will begin to ferment after a day or two, according to circumstances; I then permit it to ferment three or four days, (never exceeding a week for the hardest fruit.) then I fumigate a

clean sweet hoghead with matches of coarse cloth dipped in melted brimstone, and rack off my cider into the cask as quick as possible. If the fermentation still goes on, I give it one more racking in this way, and cover the bung with a tile, until I am sure the fermentation has ceased; I then bung close for the winter.

Remarks.—The most important parts of this method of making good cider, are,

1. The time and manner of gathering the fruit.
2. The care and attention in sorting it, in separating the hard from the mellow.
3. The rackings which separate the liquor from the lees, or fine pounce, which causes the fermentation."—*Yankee Farmer.*

PRESERVING GRAPES.

I last year made a little experiment in preserving grapes on the vine, which I am induced to make public from its success, hoping it may be of service to others who wish to have this fine fruit both in season and out of season. To almost every one it is known that there are many kinds of grapes that will remain sound on the vine for a long time, if they are not destroyed by birds or wasps. To prevent this, I have several small bags made, of proper size to contain one or more clusters of grapes. (where they may be contiguous,) from some old musquito netting, which was otherwise useless. When the fruit was ripe, I drew them over the finest bunches and tied them tight around the stem. From the season being somewhat wet, I was under the apprehension they might rot, and from time to time gathered some: but I never found one rotten grape. The last I gathered was on the morning of the first frost, last autumn; which I think was on the 20th November. They were all of the finest flavor possible, and almost as transparent as glass.

The experiment I tried on the Warrenton grape only. But I have no doubt it would succeed as well with the Bland Madeira, Catawba, Isabella, and every other variety of native grapes. Any material will answer for bags that will admit a circulation of air.—S. ROSE.—*Farmer's Manual.*

A MULBERRY FEVER has been raging for a few days past with great virulence in this town and vicinity. It is not quite local in its origin, although premonitory symptoms have been seen here for some months past. The immediate cause of its outbreaking, however, was the arrival of a gentleman from Philadelphia, who was highly impregnated with the disease. Communicating with other persons previously disposed to receive it, like the contact of flint and steel, the disease, in its fierce state, at once was struck into existence. The symptoms, like the "Eastern Land Fever," are much the same with each individual infected. The tongue becomes oily and grows supple and wags vague and unmercifully. Its lucubrations are entirely of a vegetable kind, and the patient is heard to expatiate largely on the subject of Silk Worms and Mulberry Trees. "Morus Multicaulis," an unintelligible sound, is forever running, like water, from the tip end of the tongue. What is curious, the young, old, and middle aged of the masculine gender, (it has not yet seized the tender sex) are equally infected, and each take it easily in the natural way. It operates somewhat like a certain kind of gas when inhaled, making the head swim and the mind visionary, and the imagination full of

beautiful images—at once creating a desire for rapid locomotion about the country. Various remedies have been prescribed, such as soothing drinks and cooling appliances, but they don't avail. Extensive acquisitions in the mulberry line have been thought good, but this only aggravates rather than checks the disease; for, like live, this epidemic "grows by what it feeds on."

Morus Multicaulis trees continue to be in great demand in this vicinity. Applications from New York, Philadelphia, and as far South as Virginia, arrive here daily after Morus Multicaulis trees. The prices range from 25 to 50 cents the tree, in proportion to its age and size. Those who have been cultivating this mulberry, will now reap a rich reward. The liberal premiums offered by the legislature of Pennsylvania for Raw Silk and Cocoons, it is said, have given this impulse to the sale of the tree. The Canton and Alpine, in many respects, however, is its superior. That tree is not the rage yet, but it will enhance in value, with the Multicaulis.—*Northampton Courier.*

WHEN IS THE BEST TIME TO PLOUGH?—In a late number of your paper you copied an article from the "Maine Farmer" with the above interrogation; and which, as therein stated, is a question of no small importance.—But the writer makes one admission, which as a general rule should not be adopted, viz. that "farmers should embrace the opportunity when their leisure time allow." It is true the proper time for ploughing depends in some measure on the condition of your land. The question will arise—is your land in sward or tillage? Is the soil silicious or argillaceous? If your land is in sward and you intend it for corn, potatoes or any autumnal ripening crops, the best time to plough it is in the spring, a few days before you put in your seed. Draw out your fresh unfermented manure, spread it on the sward and immediately plough it under; by this process you save all your manure and much labor; for by this time the grass begins to show itself, and on good soil indicates vigorous vegetation, which turned under at this season of the year, the vegetable matter covered with the soil in its green and succulent state, combined with the manure readily undergoes fermentation and forms a most fertilizing substance for the crop. As a general rule (and one to which I know of no exceptions) plough no sward lands in the fall, but always in the spring just before you are ready to put in your seed. But if your soil is argillaceous and in tillage, plough in the spring, summer, fall or winter, "when your leisure time will allow;" only be sure to plough in the fall, that the frosts of winter may pulverize it—plough it again in the spring that the influences of the sun and atmosphere may warm and invigorate it for the succeeding crops.—*Yankee Farmer.* C.

Matakees, Plymouth Co., Jan. 1835.

FLOUR.—Every body is astonished at the high price of wheat flour at this time—\$9,50 in New York, and \$10,25 to 10,50 here. There is no other way to account for it, but the management of the speculators. It is agreed on all hands, that take the country through, there is a better crop of wheat, rye and corn, than has been known for at least three years. Advices from Europe, by the Great Western, arrived at New York on Tuesday, inform us, that the crops there, turn out much better than was expected; that on the whole, the grain

crops are good. In France, the crops are the best that have been known for some years. The principal flour speculator in New York, is a Mr Hart, a leader of the loco loco party in that city. If he and his confederates in business, must speculate, we hope they will choose the luxuries rather than the necessities of life. The latest New York prices for rye was \$1,12 1-2—for corn \$1.

To all poor people and lovers of good living.—One pound of well cooked white beans will go as far to support strength of body as three pounds of beef steak. The one will cost six cents, the other three or four shillings.

One loaf of good home baked bread will feed you as long as a leg of mutton, and an Irish potato is better for you than a pound of pork. The Editor is requested to republish the following list of ailments, that you may see the relative value and expense of different articles of human subsistence. It is as follows:

100 lbs. Wheat contains	85 lbs. nutritious matter.
" Rice	80 "
" Barley	83 "
" Beans	89 to 92 "
" Peas	93 "
" Lentils	94 "
" Meat (average)	35 "
" Potatoes	26 "
" Beets	14 "
" Carrots	10 "
" Cabbage,	7 "
" Greens	6 "
" Turnips	4 "

Newark Daily Advertiser.

Thorburn's Dahlias.—The most brilliant and beautiful exhibition of nature's purest gems that we ever beheld, was at our friend and neighbor's seat at Hallett's cove. Some twenty-five hundred plants of the dahlia, of every hue and shade, presented themselves to the eager gaze of the true epicurean. We understand that Mr Thorburn will show off a great portion, if not all, of these splendid flowers at his *depot* in John street during this week. If the ladies of our city would enjoy a rich treat when it is offered them, they will run down and see Lawrie Todd and all the young Thorburns, who will be ready on that occasion to pay them as usual all respect and attention; and we can readily assure them that they may live a hundred years, and never see the like of this exhibition again.—*N. Y. Sunday Morning News.*

GRIND YOUR PROVENDER.—Those who have much provender to give to their cattle, or hogs, will find themselves to be gainers by grinding their grain, be it oats, barley or corn. One reason of this undoubtedly is, that as it is deprived of the external coating, which was given it by nature to defend it from external operations, the gastric and other juices, which are necessary to be incorporated with the food in digestion, can have more complete and thorough access to it, and consequently more of the nutritive matter will be converted into chyle, and be more perfectly assimilated with the animal system. Some who have used provender both ways and marked carefully the results, do not hesitate to say that the ground is twice as good, or will produce twice the amount of nourishment and fat, that the unground will.—*Maine Farmer.*

NEW ENGLAND FARMER,

AND GARDENERS' JOURNAL.

PUBLISHED BY JOSEPH BRECK & CO., NO 52 NORTH MARKET STREET, (AGRICULTURAL WAREHOUSE.)

VOL. XVII.]

BOSTON, WEDNESDAY EVENING, OCTOBER 17, 1838.

[NO. 15.

NEW ENGLAND FARMER AND GARDENER'S JOURNAL.

We have great pleasure in laying before our readers the subjoined address. We listened to it with much interest at the time of its public delivery. Some of its doctrines may be deemed heretical. Let them be fully considered. We neither deny nor endorse them; but we express the hope that they will lead to a full discussion among some of our intelligent correspondents. Mr Buckminster is entitled to great regard for his agricultural spirit and enterprise; for his successful and profitable management of his own farm, of which we published an account in January last in his letter to the Trustees of the Massachusetts Agricultural Society; and for the invention of several valuable agricultural implements. His drill planting machine of which hereafter we shall give a full account with a plate, is an admirable machine; and we have had the pleasure of witnessing the perfection of its operation. Nothing could be executed more skillfully or exactly than the planting of field of corn, which we inspected. It contained half an acre; and the work was executed in thirty minutes by this machine, held by a man and drawn by a horse. His machine for sowing grass seeds in grass promises to do excellent work. He has effected likewise, what he conceives, a valuable improvement in the horse rake. We thank him in the name of the agricultural community for all his improvements and wish him all possible success.

The matter of renovating worn out lands, particularly described in this address, deserves the careful attention of the farmers. Its efficiency and multiplied advantages are not matter of question. Experience has emphatically determined them.

— AN ADDRESS

delivered before the Middlesex Society of Husbandmen and Manufacturers, at the Annual Cattle Show in Concord, Mass. Oct. 3, 1838. By Wm. BUCKMINSTER, Esq., of Framingham.

FRIENDS AND BROTHER FARMERS,—We meet this day to compare the results of the labors of a year.

We are members of a profession—ancient and noble indeed—but are still imperfect masters of the science of agriculture.

The earth is given us "To dress it and to keep it." Shall we not annually give an account of our stewardship?

We find its surface—a portion in which we are principally concerned—in total disorder; and in general not furnishing gratuitously the simplest wants of nature.

Even fishing and fowling, the first efforts of the tribes of earth to appease the calls of the stomach, require efforts not precisely congenial to the feelings of the slothful. Necessity therefore, calls loudly on us to be diligent, and what our senses find to do, to do with all our might. This order and barrenness of uncultivated earth, and

the pressing wants and necessities of our race suggest to all, who do not choose to beg, this stern alternative, "be not ashamed to dig."

If we examine the works of creation and study diligently their structure, we find that everything beyond our reach moves in perfect harmony and order. Those heavenly lights that assist and cheer us on our way, which move with such velocity through boundless space, which note how rapidly "time rolls his ceaseless course," need not the hand of man to point their way. Harmony—perfect harmony, marks their movements. The Creator of these distant lights, from us asks no correction—no improvement.

Not so that portion of creation with which we come in contact. We find it in disorder—unproductive—barren. It was thus presented to us for the wisest purposes. It was left to us in this state that we might have employment. It was given us, "to dress and to keep," to be improved for our use. The necessity of exertion to supply our wants shows the wisdom of him who imposed it; and we discover that those portions of the earth that require least from the hand of cultivation are by no means most favorable to our moral or intellectual culture.

Our inquiry now is,
How shall we "dress it?"
How shall we "keep it?"

Shall we not first endeavor to imitate Him, who in his perfect works has brought order out of confusion.

Order is his first law. Farmers! let everything be done in order. If you regard your own peace—the happiness of those around you—the comfort of the animals entrusted to your care, regard order. Let your fields be laid out in order. Let your fences be kept in order, if you would have orderly cattle, and let all be fed in order.

Your meanest vegetables must be planted in order, or you fail of a full crop.

In drill-husbandry you gain much by perfect order in the drills. Your teams can then perform what must otherwise be done with the hand-hoe or the fingers.

In regard to the kinds of crops we should cultivate, the general rule should be,—Select the most profitable—always taking into the account the exhaustion of the soil.

Culmiferous plants, or those that have but little leaf, are found in general to impoverish the soil more than those that have large leaves in proportion to their stalk. And plants that ripen their seed exhaust more than those we cut while green. All kinds of grain, therefore, impoverish the soil, which must be often replenished with manure.

The various grasses may be continued a long time—cutting them in a green state—provided we can keep the soil from binding, or their roots from choking the circulation of sap.

Of all the root crops potatoes are believed to be the most exhausting. They impoverish light soils even more than corn does, and we obtain better crops of grass after corn than after potatoes with

the same manuring for both. We pull potatoes as we do flax and hemp, and we leave but few roots to be decomposed for the benefit of the following crop. After obtaining a crop of corn we leave the soil filled with sweet roots that are converted into manure the following season.

On some accounts it would be desirable that our own soil should furnish us with all the productions we use. But providence has otherwise ordained, and we must depend on other climes for many of the necessities of life. We cannot be entirely independent. How mortifying to our pride! Dependent on other climes for the supply of our wants! And can we see no wisdom in this ordination?

What else gave birth to commerce—the golden band that unites the distant nations, brings intelligence and civilization in its train—overcomes the prejudices of man, and almost bids defiance to famine.

Shall we lament the evils of dependence if these are among its fruits?

Ought we to desire the entire independence of any nation, even our own? Nations as well as individuals are better for being dependent.

If more fertile regions can supply our cities with grain at a cheaper rate than we can, let us not lament. We shall find full employment in furnishing what cannot so well be transported from a distance. Fresh meats, butter, hay, and the small market vegetables must be supplied by the farmers of N. England.

Beef cattle cannot cross the North river to compete with ours, and if we fail to supply all the wants of our own markets we can furnish those that are most to our advantage. It is believed that the raising of grain of any kind and fitting it for market is the most laborious and the least profitable employment we engage in; and we should bear in mind that grain is the greatest exhauster of the soil.

The times are changed and we must change with them. We cannot now, as formerly raise much grain for the market.

The virgin soils of the west and the increasing facilities of intercourse with that region render it probable that much of our grain will be imported thence; and when no obstacles are thrown in the way of commerce, this is no evil. We purchase, not because we cannot produce the same commodity, but because we can produce others to more profit.

Let them supply our cities with grain. We will manufacture their cloth and their shoes. Our artists may eat bread from the west—we will supply them with what cannot be brought from a distance.

Most of our soils of easy tillage are exhausted by cropping with grain. They have become destitute of vegetable substance and must again be replenished with it.

At present the various proceeds from the grass-land are the most profitable productions, and they will probably continue so.

Pork cannot here be made at a profit without the

aid of the dairy. The fattening of beef is usually a losing game as soon as we begin to feed on grain.

Hay usually remunerates the producer. It is easily prepared for market, and it does not exhaust the soil. A field that has lain twenty years in grass is not thereby impoverished. It will produce as much on being ploughed again as if it had lain but six.

The soil has become choked and dried by a superabundance of roots—roots that are still half alive and therefore not subject to decomposition.

When soils have become thus choked, or as we say bound out, they must be moved or loosened again. In low ground, this is partially effected by a top dressing—in high grounds the process of planting and sowing is resorted to that an opportunity may be had of manuring again.

Now instead of going through with this tedious process of planting, and sowing, and cropping, with grain, till we have reduced the soil lower, in reality, than when we began, we may renovate all our mowing lands with much less labor and less manure.

About the first of September plough in the grass crop that is growing, and cover it up completely. Then roll down the furrows close with a heavy roller. Put on a dozen loads of compost manure to the acre. Harrow thoroughly, lengthwise and diagonally but not crosswise.—Then sow grass seed and cover it with a bush harrow.—The clover seed should not be sown till winter.

By this process you convert, on one acre, many tons of green grass and roots to manure, putting it into a rapid state of decomposition for your hay crop that is to follow. By repeating this process once in three or four years we can bring our soils to any degree of fertility we please, when we shall need no manure!

We can then turn to the surface a mass of decomposed vegetable matter that needs no enriching, while we turn down in its place a new supply, ready again to be turned to the surface when the soil again becomes choked with abundance of roots.

This renovating process is attended with but little expense. We plough at the most leisure season; when our teams are strong and cheaply fed. They find their supper in the field they work in, as soon as the yoke is loosed; and in the morning they are in the field long before their masters and ready to renew the task.

Low land—wet land that cannot be planted or touched in spring, may be thus managed, and its sour, coarse grass be put to rotting, and its place be supplied by a richer crop. Such land will not often require the plough.—A top dressing will long continue its productive powers and keep at bay the poorer grasses.

What valuable interest do we sacrifice by this course of tillage? We miss no crop as in case of a summer fallow. But we lose a part of the profits arising from hoed crops and grain crops. We forego the advantages of laboring the whole of April on spring grain—the whole of May and June in planting corn and potatoes and rooting out the weeds with handhoes, and at the season when teams are kept at the greatest expense—and the whole of autumn in harvesting a scanty crop on land half manured.

We may raise grain enough for our own supply at small expense.

One acre of corn and another of English grain, well managed, will usually supply a family with

bread. And though we cannot afford to raise grain to be carried to market, neither can we afford to resort to our seaports to buy it. It may cost us one eighth of its value to send it to market. It has often cost us an eighth to purchase and bring it home.—By raising our own grain we avoid both these charges—these two eighths or one fourth of the value. I have known farmers to make still greater sacrifices. They have sold themselves short in autumn, when bread was plenty, to purchase again in spring when it is usually more scarce. Hence the maxim that farmers should live principally on their own productions.

Our pasture lands are much neglected. We mow the bushes in them from age to age, in order to kill them. Now although this may be the best mode of treating the mulberry bush, to make it thrive, it cannot be the best mode to destroy the fern and the whortleberry. We should not mow bushes till they are large enough for fuel. To kill small bushes take the plough. If the land be too rough for this let the bushes grow, and let it return to its original wildness, from which state it should never have been called. Pasture lands that deserve the name may be renovated without dividing them—without manuring—without planting.

Let them be ploughed, harrowed, and seeded down anew as in the case recommended for mowing lands. Pastures are usually the most distant lands. We cannot so easily manure them. A little plaster or ashes, sown on seeding down, will give the new crop a start. But if nothing is applied as a top dressing the pasture will yield the better for ploughing, and the bushes will die. We are often deterred from meddling with old pastures on account of the trouble and expense of fencing off a portion to keep out the cattle while a hoed crop is growing. By the mode here recommended we need no fencing off. We can plough and seed down again any portion of a large pasture we may choose. If we manure such land it will not require one fourth so much to the acre as a hoed crop requires.

Our low lands are much neglected. They are generally our richest lands and want draining and seeding merely to produce good crops of grass. I have one acre of such land that has borne me ten successive crops of grass and grain and potatoes, and it has never been manured. It bore two tons of good English hay last summer at the first cutting, and the purchaser agreed to take it without weighing at within a fraction of two tons. A second crop was cut in August and gave us one good load. The cattle are now taking their turn on it and are getting a good share. Twelve years ago this acre produced nothing. It had produced nothing for fifty years. It was too wet. I caused it to be drained, then carted on about twenty loads of loam from the road side, to render the surface more compact than the grass seed might vegetate, and I have had two crops of corn and one of potatoes from it within the ten years—have fed it every autumn when in grass, and have often cut two crops from it in a year. Nothing in the shape of manure has been put on the main body of this acre for these ten years except about half a dozen loads of leached ashes. When the wild grass begins to show itself we plough it under in September and seed down again.

Our high pasture lands may be renovated in this way without planting—without manuring—without fencing off. They are usually the most distant from the barn and do not get a share of the manure.

We think we have none to spare for these lands. We can do better with it near home.

If we plant any portion of a pasture we must fence it from the rest. If we take a crop of grain or potatoes from it we must manure or it is impoverished by the operation.

Thousands of acres of such lands may be made to produce double the feed they now do merely by a proper use of the plough and a little grass seed. And the plough is quite as good an instrument to kill the bushes with as a bush-scythe. The silt growers cut the mulberry bush annually, and think it grows the better for it. We mow our bushes in pastures from age to age. Can the same kind of trimming make the mulberry thrive, and be destructive to the fern and the whortleberry?

If the pasture be quite too rocky for the plough—if we cannot pull up half the bushes and bury the rest with it, let the land return again to its native wildness, whence it should never have been called. It is not profitable to cut bushes before they are tall enough for wood.

Bear with me a little longer while I say a few words on the subject of farming tools.

Our ploughs have been much improved within thirty years. We now turn our green sward with half the team we formerly employed. Thirty years ago who attempted to plough green-sward with an yoke of oxen? Three yoke were usually employed in this service.

The moulder now fits close to the share. The furrow rises without any check from the unevenness of the inclined plane. The plough cuts as regular, tapering, smooth wedge. But we have not yet brought it to perfection. We have much improved upon the post, with which the north African stirs his soil—holding the top of it in bands and gauging its point according to the strength of his team. In some districts in England they still use something not much superior to the African model. Our grass ploughs are too short for even or plane ground—the furrow breaks before it is put in its place. The advocates for short ploughs allege that they are attended with less friction. This is a mistake. A long tapering wedge raises a weight with less friction than a short one. A long plough keeps the furrow suspended and unbroken, and the falling sod assists to help the rising portion, as the sinking bucket in a well helps to draw up the rising one.

Our hay forks and our manure forks are no made of better metal than formerly, and if we perform no more labor with them, we do it with more ease.

We begin to use the horse-rake in haying; but we are far behind Pennsylvania and New Jersey. New Hampshire and Rhode Island in the use of them. There are three or four kinds in the United States. Yet not a farmer (?) shall I say in a thousand, in Massachusetts, has ever seen one. A load of them was passing, last summer, to Boston many inquired what those sharp wooden-tined things were made for, and whether they were used to dig potatoes with?

In tolerably smooth ground I have very often seen an acre raked perfectly clean by one of these in half an hour. Your hired-man will be half a day, with a hand rake, in performing the same.

A seed planter, or planting harrow has been invented this season and may be seen at the store of D. Prouty & Co., Boston. It will plant an acre of corn in an hour, furrowing out, dropping, covering and rolling down at one operation. Several fields

were planted handsomely with it last spring. It planted an acre of ruta бага, (4,000 hills), in fifty-five minutes. The turnips look finely.

A machine for sowing grass-seed and grain, is much wanted. I have seen at Washington and at New York a machine for sowing plaster and grain—the gearing seems to be more complicated than is necessary, but it is said to perform well.

A very simple machine has been planned this summer to sow grain, or grass-seed. It is a box four or five feet long placed forward of a common harrow. A sieve forms the back side of the box. By shifting the sieve, grain of any kind may be sown as well as grass-seed, and the team performs the whole without extra labor. It is quite impossible to sow grass-seed well by hand. We sow some too thick and some too sparse. For this service I feel sure "*My hands were never made.*" By regular, methodical sowing we save much expense in seed. We used only half the quantity of ruta бага seed that is usually sown.

We are often accused of being backward in adopting improvements. The spinner is said to tend, now, one hundred spindles instead of one.

The traveller progresses four miles while he formerly advanced one. And shall farmers alone remain stationary? Shall we not also make inquiry whether our pace may not be quickened? Shall we be skittish and fear to examine new machinery to facilitate the operations of husbandry, because we have discovered that the very newest patent churns, and washing machines will not go alone? Let us not fear to examine new modes of operation. Let us ever attempt improvement.

VARIETIES OF EARLY INDIAN CORN.

The Maine Farmer, of Aug. 21, says, "the Dutton corn grows luxuriantly, but is much later than many of the old varieties."

The Farmer and Gardener, of the same date, printed at Baltimore, states two cases of the Dutton corn being gathered, in a ripe state, in less than 90 days from the time of its being planted, viz. Mr Giles planted on the 17th May, and gathered perfectly ripe samples on the 15th August; and Mr Harrison planted, on the 16th May, and gathered on the 14th August.

The Franklin Farmer, printed at Frankfort, Ky. of Aug. 18, says, "Our Dutton corn, planted April 30, has been gathered more than a week. It is perfectly ripe, hard and well cured. Though a dwarf species, it is a generous bearer, and we are satisfied, from the experiment of this season, that an acre of it will produce as good an average crop as our larger eared corn."

Some of our Dutton corn, planted on the 19th May, had perfectly ripe ears on the 15th Aug. and this part of our crop was harvested, that is, cut up, on the 28th Aug. though it might safely have been done on the 21st; and most of the Dutton corn in our neighborhood, was harvested either in August or the first week in September.

We have recorded these facts, to explain their seeming contradictions, and to make some suggestions, which we think of importance to the farmer, in regard to seed.

We have before observed, that there is a spurious, as well as a genuine, Dutton corn, the former of stouter growth, and later in ripening, than the latter. We would remark, that this difference may result from the seed planted—seed of the same variety, grown at the south, giving a larger growth

of stalk, and maturing later than seed grown at the north. This is evidenced by the fact, that southern seed always gives a comparatively large and late growth at the north; while northern seed gives a dwarfish growth and early maturity at the south—and that they both become acclimated in a few years, and take the habits of their new location. These considerations suggest, that so far as early maturity is sought for, it is advisable, when a change of seed is desired, to obtain it from a more northern latitude, or elevated district.

But we adopt the opinion of Joseph Cooper, so far at least as relates to maize—which was, that a change of seed is *not necessary*, when due regard is paid to *selecting the seed*. We have cultivated the Dutton variety of corn eighteen years—we have always selected the earliest and fairest ears, assisting in person, for seed, which we immediately braided, and hung in an airy loft. It has ripened as early this, as it did the first year we received the seed from the far north; while we are satisfied it has increased in productiveness—that it has larger ears, and more of them, and taller stalks, than it had when we first began its culture. The seed is left to mature on the stalk, till the crop is gathered from the field—the earliest ripened, being then easily determined by the appearance of the shuck, or husk, and the rich color of the corn. Hence the importance of every farmer taking care to secure, in person, his best seed.

There is one other fact that should not be lost sight of—the influence of soil and location upon vegetable growth. A moist, rich soil, will give the largest growth, both of foliage and fruit, and a light and dry one the earliest maturity, and the richest or most concentrated product. Prof. Ives states, that plants from the seed of the *morus multicaulis*, have the foliage of the parent in a rich humid soil, while they resemble those of the *M. alba*, on a thin light soil; and it is believed that a pound of the leaves of the latter are intrinsically more valuable to the silk-worm than a pound of the former. It is not the size that indicates superiority in the animal or vegetable. A very large apple is seldom a very good one. The cider from a hilly, dry, calcareous soil, is always superior to that from a low and rich one. A very large beet contains much less sugar than the same weight of small beets. Indian corn, grown upon a light dry soil, comes to earlier maturity, but is inferior in its growth, and in the size of its ears, than when it is grown upon a highly manured loam. Indeed the difference is so great, on our own grounds, this season, that the growth and product in two locations, would hardly be taken for the same variety.

We have another suggestion to make, in regard to the influence of steepness. It will be remembered, that in our last volume, we referred to a communication of Senator Johnson, inserted in the first volume of the transactions of the old agricultural society, showing that the crop from seed wheat, steeped in a solution of salt-petre, ripened two weeks earlier, and gave 25 per cent. more product, than the crop from seed which was not thus steeped. We began to plant our main crop of corn on the 12th May, and finished on the 16th. All the seed was steeped 12 hours in a solution of nitre, in quantities sufficient for one day's planting. A few quarts of seed, which remained, was set in the cellar, where it remained, partially covered with pickle, till the 19th, when it was planted in a vacant patch of thin soil, in which we also planted, the same day, six other varieties, all reputed to be

remarkably early, and the seed of all which had been soaked in salt-petre water. The last planted Dutton corn, was decidedly the earliest of the seven sorts in coming to maturity, and was at least two weeks earlier than the main crop, planted from three to six days earlier. Its maturity may have been in some measure accelerated by the porosity of the soil, compared with that of the main field, which was highly manured with unfermented dung, and to the consequent influence of the dry weather; yet ye think it not improbable that it was principally owing to the seed having remained saturated, 96 hours, in the nitrous solution.

Having referred to our specimen plat, we will add, that it consists of the following varieties of corn:

1. Dutton; 2. and 3. Lake Superior and Squaw from Lake Michigan; 4. Early white, not recollected where from; 5. Early Canada, from Poughkeepsie; 6. Red Blaze, from Elmira; 7. Early yellow, from Vermont. These varieties were all planted the same day, two rows of each, with intervals between the different kinds of 20 or 30 feet. On examining them to day, Aug. 28, we find No. 1 mostly ripe, the husks dry and separating from the grain; No. 2, Lake Superior, an 8 rowed yellow, growing 4 1-2 feet high, but very prolific in succors and ears, next to the Dutton in maturity. The early white is an 8 rowed corn, 5 1-2 feet high, and is third in ripeness. The Vermont is a yellow 8 rowed corn, grows 6 feet high, and is next in ripeness to the early white. The Squaw, No. 3, is an 8 rowed colored grain, grows 6 feet high, and is fifth in its earliness. The Red Blaze comes next, and the early Canada is the latest. Both are eight rowed, and, like the Dutton, they grow seven and eight feet high. As to number of ears on a stock, they are about alike, except the Lake Superior, which is far the most prolific in its succors and ears, though they are very small. As to the size of ears, the Dutton has a manifest superiority; as to length of ears, the early Canada and the Red Blaze, 8 rowed, are equal, if not a little superior to the Dutton. Several gentlemen, who have visited the plat, concur in the correctness of this statement. We intend to exhibit samples of each of these varieties, at the fair of the American Institute. We omit the notice of later ripening varieties—*Cultivator*.

Experiments in Manuring Turnips.—S. W. Smith has given to the public, in the Farmers' Cabinet, the result of an experiment with various manures upon his turnip crop, which are worth recording and remembering. He divided an acre of land into four equal parts, and gave to No. 1 a dressing of common stable dung; to No. 2, an extra quantity of compost manure; to No. 3, ten bushels of lime and two and a half of wood ashes; and to No. 4, two bushels of bone dust. They all escaped the fly, and were treated alike. They were sown the 15th and 16th June, and harvested the 10th November. The product was as follows:

No. 1	yielded 98 bushels	= to 390 per acre.
No. 2	" 124 "	= to 496 "
No. 3	" 185 "	= to 740 "
No. 4	" 213 "	= to 852 "

Men of limited capacities generally condemn everything that is above the level of their understandings.—*Roche foucault*.

MANURE.

The article which follows goes to prove three facts, of primary importance to the farmer, which we have strenuously endeavored to inculcate, viz :

First, That the resources for manure, on almost every farm, are sufficiently abundant, when properly husbanded and applied, to keep up, or improve, its fertility ;

Secondly, That blending unfermented dung with earth, or the soil, accelerates its decomposition ; while,

Thirdly, A vast amount of fertilizing matter is saved by such admixture being made, *before fermentation has taken place*—the earth “absorbing and retaining that excess of putrescent fluids and effluvia which is otherwise lost by filtration and evaporation ; that is, by soaking away and drying up.”—*Cultivator*.

From the Farmer's Cabinet.

What is the greatest quantity of manure to be obtained from given means ?

MR EDITOR.—There are in agriculture, as perhaps in every science, some leading propositions, calculated in a particular manner to arrest attention by their prominent importance. Such I hold that of a “Subscriber” in your May number—“*What will an acre of land produce ?*” and also the question which heads this article.

Were it possible at once to afford a complete and palpable solution to these two propositions, what mind can calculate the vast increase of treasures that would instantly become accessible to humanity ? As, then, we cannot inquire too strictly, or know too much regarding them, I propose, after recapitulating a few of the principal statements of a “Subscriber,” concerning the latter question, to furnish my own experiments upon the former.

He informs us that a single acre of his land, with abundant manuring and superior cultivation, was made to produce the sum of \$348,40 per annum, for five successive years, besides the vegetables used in a small family. He further states, in substance, as his present conviction, that the quantity of soil cultivated has nothing to do with the secret of gathering money out of it ; that “this altogether depends on a judicious selection of soil, on the facility of obtaining manure, and on the proper application of it as food for plants,” &c. ;—that he found, by actual experiment, made upon a large scale, “that the profit of capital laid out in land produced an interest of only five per cent. per annum, the capital laid out in manure upon the same land produced twenty per cent.”

Now, my own experience, as I shall presently show, abundantly confirms the probable accuracy of all these statements. Let us distinctly understand, then, that it is not the great quantity of land, but the abundance of manure upon a little, that is alone required to give wealth and independence ; that the man who owns five or six acres, may, (according to the above data,) with the aid of manure and good management, draw from \$1,800 to \$2,000 from them each year, while he of a hundred acres may scarcely obtain half of it upon the common plan.

But where is the requisite manure to be obtained that shall so suddenly and surely enrich the farmer ? In reply to this, I will simply give my own experience, and by it endeavor to convince the reflecting farmer what amount can, and in fact has

been made from means incomparably more limited than is generally imagined possible.

Previous to 1829, I had followed in Philadelphia a sedentary occupation, which, by excessive application in it, had so enfeebled my constitution, that I was obliged to seek in the country for that measure of health which I might no longer hope for in the city. So I bought, with my scanty savings, a small place of ten and a half acres, and moved upon it the same fall of 1829.

Not being acquainted with farming, I hired a man to plough two and a half acres, and sow it in rye. The cost of seed and labor, in putting in, gathering and thrashing the said crop, was \$8,56. The crop yielded five and a half bushels of very poor black rye, fit only for hay feed—say at forty cents per bushel, (as good rye was then selling at fifty and fifty-six cents per bushel,) was worth \$2,20, and the nett loss sustained upon farming the ground was \$6,36. The season was moderately good for grain, and the two and a half acres rather a favorable specimen of the rest of my land ! I planted a potato patch the following spring, (1830,) of about the fourth of an acre, which I manured in the hills with one load of marl only, and the crop yielded but three and a half bushels !

Being a total stranger to the nature and character of soils, but having previously, from some cause, entertained the notion that land in general produced about twenty-five bushels of wheat, or forty bushels of corn, or four or five loads of hay to the acre, the conviction I had now received of the absolute worthlessness of my land fell upon me like the shock of a thunder-clap. Discouraged by the greatness of my disappointment, but not quite confounded, I determined that manure, in future, should be every thing to me, and stand in the stead of both land and crop. Being greatly improved in health, by the change of situation and exercise, I plied my avocation with increased diligence for the maintenance of my family, and made it the amusement of my leisure hours and leisure moments to collect from every corner, and panel of fence, every thing that I imagined could furnish a vegetable nutriment, and placed it in the cow yard, so combined with the litter as to absorb and retain every thing of the putrescent character that might be deposited there. By such means I have gone on, every year increasing the quantity of my manure, to an extent that I believe astonished most of my neighbors. The following is a sketch of the means I possessed, and the methods I took to obtain manure for the present year.

I commenced last summer by collecting into the outer part of my hog pen every thing of the weed kind I could find about the place, till I had a layer about twelve inches deep, which I covered with a layer of earth about five inches thick, continuing the process till the pen was filled to about two and a half feet deep. In the fall I littered my loose corn-cobs and the principal part of the buckwheat straw into the pen, interspersed with layers of earth in the same manner. The two stalls of my stables I served also the same, taking care to save therein all the chaff and refuse straw after thrashing. In these stalls I poured weekly, through the fall and winter, (for I had no cattle in them except in bad storms,) the soap-suds and such putrescent fluids that might be obtained, keeping the corners and outsides, and under the mangers carefully saturated.

As soon as my corn was gathered in the fall, I cut the stubs close to the ground, and wheeled them immediately, while yet heavy, into the barn-

yard, where I packed them in every part of it, and also under the shed, being an area of ground about forty feet by twenty, and in a few days covered them also with a layer of earth, from a fence-row, close by, to the depth of about eight or ten inches. Upon this earth I foddered my three cattle during the winter, occasionally depositing more earth upon the litter as it collected there.

Your readers will readily judge, that the object of all this preparation was not so much for the sake of saving the materials collected there as to obtain a menstruum, or rather sponge, if I may so call it, calculated to absorb and retain all the urine deposited in the yard during the winter. The compost masses, however, or layers, thus collected together, are not to be considered as manure prepared for the soil, but only as materials that require to be thoroughly mixed, in order to reduce them to a state fitted for a rapid and complete incorporation with the soil. Accordingly, with this view, I commenced late in April the operation of turning it, which, from its having become closely packed to the depth of twenty inches, with the stalks at the bottom, could only be done with the aid of a grubbing hoe, turning it in strips about a foot wide, reaching across the yard, and throwing the loosened manure back a sufficient space to allow a trench between, wide enough to work in. After removing the whole cover from the stalks, along a strip, as before mentioned, they were easily grubbed up, by first cutting them through all along the solid edge of the strip with the hoe, it being made pretty sharp for the purpose. In addition to this pile of yard manure, I have also emptied the contents of my hog pen and stables, extending the pile several feet, and lying upon the ground, when first loosened, more than two and a half feet deep. Of this manure I have used sixteen loads this spring, for truck and garden, and, judging from the size of the pile yet remaining, there cannot be less than sixty loads, which, being turned once more, I intend to use for wheat next fall.

In this manner, from only three head of cattle, and the fattening of four hogs, I have made from seventy to eighty-two horse loads of manure, the highly fertilizing properties of which are abundantly attested by my own former experience. I will not say that it is stronger than the best barn-yard manure, but from its closer affinity to the nature of the soil, and greater facility for being rapidly combined and incorporated, without loss by evaporation, I have no doubt it will be frequently found, upon trial, more effective and more durable.

In the process of turning manure, thus prepared, I hold it of the highest importance to mix well the earthy and vegetable parts together. Few persons are perhaps aware how rapidly the earth facilitates vegetable decomposition, and to what a surprising degree it absorbs the excess of fertilizing effluvia, which must otherwise be evaporated during the process of decomposition. This circumstance, I believe, taken in connection with the careful economizing of all animal excretions, constitutes chiefly the great secret (I might, perhaps, add alleged necromancy,) that has added already so much verdure to my previously exhausted soil, and been so profitable to me, and so surprising to my neighbors.

No farmer can imagine, that has not tried the experiment, what a prodigious quantity of rich, vegetable, and fibrous earth may be collected from corners and by-places which lie out of the way of cultivation, and which, from their retired position, have perhaps, never so much as attracted his notice.

All such refuse trash, and fibrous earths and weeds, by being conveyed to his barn-yard, at intervals, during the fall and winter, and judiciously combined with its contents, will be converted into a rich, fertilizing, and durable manure, merely by absorbing and retaining that excess of putrescent fluids and effluvia which is otherwise lost by filtration and evaporation; that is, by soaking away and drying up.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Oct. 6, 1838.

From Thomas Lee, Esq., Brookline, Isabella, Pond's Seedling, and Elsinburg Grapes, the clusters of the Elsinburg were large, the berries small, the flavor very fine, and far exceeds any former specimens of this grape which has been exhibited.

From George Lee, Esq., Fresh Pond, large and handsome specimens of the Ribstone Pippin, one of the most celebrated English dessert apples.

From Mr. John M. Ives, Salem, a Pear, name unknown to the committee; it was received from France as the Beurre Bose, (a very different fruit), a large handsome, and delicious pear, worthy of a place in every good collection.

From Hon. John Lowell, specimens of Great Britain, Bezi Vaet, and Queen Caroline Pears, the Great Britain not yet at maturity, the Queen Caroline is a new and beautiful fruit of medium size and very fine, it cannot be too extensively disseminated. Mr Lowell's specimens were accompanied by the following letter, containing the liberal offer of some rare plants and bulbs for distribution among the members of the society.

ROXBURY, SEPT. 15, 1838.

Hon. E. Vose, President of the M. H. S.

SIR,—I send specimens of Great Britain, Bezy Vaet and Queen Caroline Pears. The first and last I have translated from Grand Bretagne and Reine Caroline, because I think when foreign names can be rendered into English, retaining the sense, it is better. Thus, "Roi de Wurtemberg" will in a few years be corrupted into a barbarous, unpronounceable word of no meaning. "King of Wurtemberg" will be understood. Let me here remark, that there is no such name in existence, lawfully known, as Roi de Wurtemberg. The pear which some persons call by that name was raised by Van Mons, and called by him "Frederick of Wurtemberg" and is so printed in his catalogues. Some Belgian nurseryman thinking that the high sounding title of king would sell better, corrupted the name, and some prefer the corruption to the true name. The evil is, that we shall soon receive the same pear under both names.

I place, at the disposal of the society, two plants of Muse rosacea, and twenty bulbs of Amaryllis Equestris.* If any gentlemen wish them, they will be delivered on their order.

I am, sir, respectfully yours,

JOHN LOWELL.

From Hon. Judge Heard, Marie Louise, and Louise Bonne of Jersey (England) Pears, they are both great bearers, and are very justly placed among our best autumn pears.

From Mr J. L. F. Warren, Brighton, 4 baskets

containing Isabella, Sweetwater, and oval Malaga Grapes.

From R. Manning, Salem, Beurre Diel, Buffum, Beurre Bose, Belle et Bonne, Fulton, Popes Quaker, Jalouse, and Marie Louise Pears.

From E. M. Richards, Esq. Dedham, Capsheaf and Harrison's Fall Baking Pears, yellow Ingestrie, Red Ingestrie and Fall Sops of Wine Apples, and one unnamed sort from a dwarf tree, imported from France. Also Hill's Madeira Peaches.

From Miss S. Seaver, Roxbury, a basket of beautiful Catawba Grapes, the clusters and berries were large, perfectly ripe and of excellent flavor. Also a Seedling Grape, raised from the Catawba.

For the Committee,

ROBERT MANNING.

REPORT ON VEGETABLES

Exhibited at the Annual Meeting, Sept. 19, 20, 21.

Six very large crook neck Squashes from Samuel Prescott, Elm Hill, Roxbury.

Tomatoes, from John Howe, Roxbury.

Squash (six feet 4 inches circumference, weight 88 lbs) from seed received from Paris, Mrs Welles.

African Acorn Squash, from T. Thompson, Jr. Two Drumhead Cabbages from J. D. W. Williams, Roxbury, Elm Hill: and also 2 squashes weighing 24 lbs.

Lima Beans, (extra fine,) Richard Ward, Roxbury.

Crook neck squash, J. Clapp, South Reading.

Pine Apple Potatoes and Acorn, Autumnal, and one other variety of Squashes (name unknown), Samuel Pond, Cambridgeport.

Love Apples, (Tomatoes,) Hon. John Lowell, Roxbury.

Sweet Potatoes, from do.

1 Chili Squash, from James Eustes, South Reading, (weight 62 lbs.)

1 Large Potato, from Jonathan Warren, Weston.

Yellow Tomatoes, J. L. Moffatt, Esq., Roxbury. Autumnal Marrow Squash.

Smyrna or Palermo Squash. A prolific variety, and runs very little, from John M. Ives, Salem. Mangel Wurtzel, Samuel Hyde, Newton.

3 Valparaiso or Lima Squashes; 1 African Blue Skin Squash, from Rufus Howe, Dorchester.

Seven years Pumpkin, from Mrs Timothy Bigelow, Medford. (The above, the growth of last year, and shown at the annual exhibition of 1837.)

Weight 46 lbs. in perfect condition, and it is said will remain sound for seven years.

Autumnal Marrow, from Abbott Lawrence, Jr. Park Street.

Canada Crook Neck, a trim specimen, curious, from Perez Smith, Weston.

Crook Neck Squash (weight 46 lbs.) from E. Sparhawk, Brighton.

Lima Beans, (superior) from Richard Ward, Roxbury.

Squash, mammoth size, 130 lbs. weight, from Capt Geo. Lee, West Cambridge.

2 Seven Years Pumpkins, weight 81 lbs.

2 Baskets Tomatoes.

1 Basket Horticultural Beans.

Cuba Love Apple, from James L. L. F. Warren, Brighton.

SAMUEL POND, Chairman.

A gentleman and his wife, while on a whortleberry excursion near Sang Run, in Maryland, killed eighty rattlesnakes, and wounded four which escaped.

From the Old Colony Memorial.

CATTLE SHOW.

The Plymouth County Agricultural Society held its anniversary Exhibition and Cattle Show at Bridgewater on Wednesday last. The sky looked threatening all day, but the rain held off until nearly night. There was as large a concourse of people as usual, and the crowd at the hall of exhibition was very great. The articles of manufacture were not so numerous as last year, but they failed not in quality. The Ploughing Match was a very interesting trial, and attracted the attention of an unusual crowd of spectators—the number of competitors was also greater than common. The officers of the last year were generally re-elected. The dinner was plain and plentiful, suitable to the occasion; but, in conformity to the temperance and sobriety of the times, there was no wine, no toasts, no song, no music in the hall. The address, by C. J. Holmes, Esq. was appropriate and interesting. The efficiency and perseverance of the Marshals in driving from the grounds those individuals who came there with the intention of selling rum, is worthy of all praise. The award of premiums, we believe, gave general satisfaction. We publish below the Report of the Committee on Manufactures.

Premiums awarded by the Committee on Manufactures.

Lydia Dawes, Plymouth, piece carpeting,	\$5 00
Mrs Abiezer T. Hervey, Middleboro'	4 00
" Olive S. Pratt, Bridgewater,	do. 3 00
" Abisha Stetson, E. Bridgewater,	do. 2 00
" Eleanor Sampson, Pembroke,	do. 1 00
" Helen Taylor, Plympton, stair carpet,	do. 2 50
" Abiah Bassett, Bridgewater,	do. 1 50
" Wilkes Wood, Middleborough, hearth rug,	do. 3 00
" Lavina Taylor, Plympton,	do. 2 50
Miss Elizabeth Briggs, Middleboro',	do. 2 00
Mrs Joseph Clark,	do. 1 50
" Louisa S. Jackson, Plymouth,	do. 1 50

MORTON EDDY, *Chairman*.

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, OCTOBER 17, 1838.

WORCESTER CATTLE SHOW.

The annual exhibition of Worcester Agricultural Society took place at Worcester, Oct. 10th. The day was cloudy, and rain anticipated, but it held off until evening, giving a favorable opportunity for the display, and multitudes of the hardy and intelligent yeomanry of the county, were present to participate in the business and festivities of the day.

Two long ranges of substantial pens, 120 or 130 in number, were filled to overflowing, at an early hour of the day, with a fine display of neat cattle, sheep, swine, &c., and many cattle were tied outside for want of room.

Among the working cattle we noticed a number of pairs of beautiful oxen and steers, which appeared to be the pride of their owners, and well they may be proud of such fine creatures, for they seemed to partake of the intelligence of their owners, and were perfectly obedient to their voice, and quick at the word of command, to haw and gee, to back and forward, &c. In fact we never saw oxen better trained than some of them were. \$150 per yoke were asked for those of this description, and others, we suppose could hardly be bought for money. One pair of twin steers belonging to Mr Lovett Peters, of Westborough, attracted much attention, being a perfect match, large, and of good shape; their weight as marked on the yoke was 3233 lbs., one of them about 25 lbs. heavier than the other, their age about 3 1-2 years.

We noticed a number of lots of cows and heifers of good symmetry of shape, but we did not see so many fine animals of this description as we could have wished. Of bulls there was a number of different ages and blood, some of them fine looking creatures. There were also good specimens of fat oxen. One of the most interesting sights was a family of 5 swine of the Bedford breed, from the Insane Hospital, whose weight would average, probably, 400 lbs each when dressed. They appeared to be an oblong mass of fat with a little short nose sticking out at one end and a tail at the other, standing upon legs hardly long enough to clear their bellies from the ground, of a clean white, without stripes or spots,—we saw none of the striped breed upon the ground. There was in another pen a fine sow with a family of ten beautiful little

spotted pigs. Other pens contained a variety of boars, breeding sows, pigs, &c. The sheep were also pretty well represented. We noticed the Merino, Dishley and other breeds.

The ploughing match was a scene of considerable interest. It took place at 9 o'clock, about one mile from the hall on Union Hill, from which there is a bird's eye view of the flourishing and pleasant town of Worcester, bounded on all sides by beautiful, and highly cultivated swells of land, presenting a landscape of indescribable richness, which was enlivened at this time by the large assemblage of people on the ground, and by the long irregular line in scattering groups which dotted the route from the village to the hill. The scene of action had been marked out and prepared beforehand, and a furrow thrown up on two sides of the field and stone walls on the other sides which were the boundary lines for the numerous spectators. The plot of ground was divided into lots of one eighth of an acre each, and each lot numbered. The competitors first drew lots for choice of ground, and then with their respective teams took their stations accordingly. There were 8 single and 9 double teams engaged in the match. At the word of command the teams started together. It was gratifying to notice that the oxen were managed by the drivers with much quietness, and with little use of the whip. The work was done in an admirable manner, evincing great skill in the ploughmen.

We thought it would require great discrimination and good judgment on the part of the committee to know how to decide who was entitled to the premium.

The hall was well filled with specimens of domestic manufactures, such as hearth rugs, carpets, counterpanes, and a hundred nameless, useful and fancy articles, the hardy work of the thrifty housewives and their daughters.

Here were to be seen also, fine lots of butter and cheese, big squashes and pumpkins; roban potatoes and other vegetables; agricultural implements, including a corn planter, which attracted much attention. The operator sits in a sort of gig and drives his horse over the field, and while he is taking an airing and smoking his pipe, (if he has a fancy for it,) he is planting his corn. There was also in the hall a highly finished barouche, manufactured in Worcester, and many other articles too numerous to mention.

At eleven o'clock a procession was formed at the Worcester House, which proceeded to the Calvinistic church to hear the address from the Rev. Henry Colman. The meeting was called to order by the Hon Levi Lincoln, the presiding officer of the day. He remarked that they were celebrating their 20th anniversary. After giving some account of the progress of the society and of the present exhibition, he adverted to the state of the funds of the society, and regretted to say, that in consequence of losses sustained, and the extra expense incurred by the erection of new pens for the cattle, the funds had been reduced from an amount something over \$9,000 to a sum less than \$8,000. He called upon the young men of the county to come forward and sustain the society by becoming members, and thereby increase the funds and impart new energy to the society. It appeared by the remarks made, that the young men had been rather backward in the performance of this duty, and were suffering their fathers to bear the heat and burden of the day, and as a necessary consequence, unless they came to the rescue, the society would soon be on the wane. We trust the appeal was not made in vain, and hope that before another anniversary day shall come round, every young man in the county who is in any way connected with agriculture will put his hand to the plough, and pledge himself not only to sustain the high reputation of the so-

ciety, but also endeavor to increase its usefulness a hundred fold.

Mr Lincoln regretted the prevailing disposition on the part of many young men, to be dissatisfied with N. England, and their desire to emigrate to the far west. He remarked that he had been placed in situations to know full well the trials of the New England emigrant in the west, and was well satisfied from what he had seen and from facts which have come before him, that in a great majority of cases, their expectations were far from being realized, and that numbers had awakened from their dreams of ease and plenty, and would gladly return to the good society, good institutions, and healthy climate of New England if it were in their power. He spoke so eloquently and so much to the point on this subject that we were persuaded that if any present had the emigration fever, they would at least consider the subject a little further before they bid adieu to the land of their pilgrim fathers.

The Rev. Mr May, of Leicester addressed the throne of grace. Mr Colman's address was listened to by a crowded audience, apparently with deep interest. As it will probably be published we will not mangle it, by attempting a sketch. From the meeting house the company proceeded to witness the trials of the strength of working oxen, which was tested by drawing loads of stone up rising ground, by backing and manœuvring in various ways; but owing to the great crowd, we did not get a chance to witness this part of the ceremonies.

At three o'clock a large number of gentlemen sat down to a bountiful dinner, which was provided in good style at the Worcester House. The festivities of the board were enlivened by sentiments and addresses from a number of distinguished guests.

But to conclude, we must say that we were highly gratified with the various exhibitions and performances of the day, and from what we witnessed, are well satisfied that a body of men so intelligent as the gentlemen who compose the Worcester Agricultural Society, will not suffer the cause of agriculture to languish, but that this chief corner-stone in the foundations of our national prosperity, will as far as they are concerned, be laid as strong as the hills which beautify the county they inhabit. J. B.

After the above was in type we received a better account of the cattle show at Worcester from Mr Colman than what we have written. We are sorry it was not received a few hours sooner, but as it is, we must omit the greater part of it, giving some extracts.

Speaking of the ploughing match he says,—“We cannot particularize, if we were so disposed, for we did not learn a name, which we can recall, but the work of the single teams on the same field was as good, as deeply ploughed and as well ploughed as any done by the double teams. The order of the field was perfect. The spectators were not suffered to come on to the work nor to break the line. This is a matter of particular importance, because oxen, especially not being blinded, are very liable in a crowded field to be disturbed as they come to the end of furrow by the spectators, who are apt to press to that point; and the ploughman is unable to bring out his furrow in a straight line, and to square his corners. Besides this the committees are left wholly unembarrassed in the discharge of their duties. So far as we could see, there was scarcely a loud word spoken on the field; there was no hallooing nor scolding, nor swearing, nor whipping. It was in no respect a race. It was not ploughing against time; and the work was executed in a fine manner.”

The exhibition of live stock embraced 377 entries. We should do no justice to account by any attempt to give what might be called an account of them; that would require much more time than was afforded us for the examination. The fat cattle were respectable but not extraordinary, with the exception of a fat cow from Barre, weighing 1500 lbs. We have rarely seen her equal. She was a cross of the Durham Short Horn; but how fed we received no information. There were some bulls of this

same stock that were very distinguishable; and by their deep briskets, their fine necks, their full quarters and their symmetrical forms, and, if we may be allowed an Hibernianism, their rounded points, rose very high in comparison with our native stock, which stood near them. The sheep likewise were beautiful specimens of the pure Dishley, of the native stock, and of the fine wooded rasses. The flat backs and round and barrelled forms of the Dishley attracted much attention. For autumn those sheep prove excellent crossed with our native breeds, in this way acquiring more hardiness than belongs to them in their pure state; and thus better recommending them to our labors, which are not yet such as to secure to highly improved animals all that carefulness and liberality in feeding which are absolutely requisite to keep them where they are.

Two yokes of twin steers were particularly noticeable, — a pair from the Hospital for the Linsue were among the most beautiful animals in color, marks, condition and form, which are ever seen. We certainly have never met with their superiors; we do not recollect their equals. The show of swine, fat hogs and breeding animals, of which there was a large variety and number, was pre-eminently excellent. We have no doubt that the intelligent committee on this subject will do ample justice to their extraordinary merits.

The Report of the Massachusetts Horticultural Society, for last week, is unavoidably omitted. It shall appear in our next.

BRIGHTON MARKET.—MONDAY, Oct. 15, 1838.
Reported for the New England Farmer.

At Market 1900 Beef Cattle, 800 Stores, 48 Sheep, and 550 Swine.

Prices.—*Beef Cattle*.—We quote first quality, \$7 50. Second quality, \$6 75 a \$7 00. Third quality, \$5 75 a \$6 75.

Barrelling Cattle.—We quote, Mess, \$6 75, No. 1, \$5 75 a \$6 00.

Stores.—Yearlings, \$9 a \$11. Two Year Old, \$18 a \$28. Three Year Old, \$22 a \$38.

Sheep.—Former prices hardly sustained. We quote lots at \$1 62, \$1 83, \$2 00, \$2 12, \$2 33, \$2 50, \$3 00, and \$3 25.

Swine.—Lots to peddle were taken at 7 1-4 a 7 1-2 for barrows, and 6 1-4 a 6 1-2 for sows. Selected old barrows, 7 1-2, sows 7. At retail, 7 a 8 1-2.

DUTCH BULBS.

Just received at New York from Rotterdam, and will open in a few days, our annual supply of splendid Dutch Bulbs, consisting of

- Double Red, Yellow, Blue and White Hyacinths,
- Single " " " " " "
- Single and Double Tulips.
- Crown Imperials, Double and Single, of sorts,
- English, Spanish and Persian Iris,
- Polyanthus Narcissus, of sorts,
- Ranunculus,
- Anemones,
- Fritillarias,
- Crocus, of sorts.

JOSEPH BRECK & CO.

Boston, Oct. 16, 1838.

RASPBERRY BUSHES.

For sale at the Charlestown Vineyard, fine plants of the following Raspberries, viz.

- Red Antwerp,
- White do.
- Baronet,
- Franconian, and
- Mason's Seedling.

Orders left with JOSEPH BRECK & CO. will meet with prompt attention. THOMAS MASON.
Charlestown, Oct. 10, 1838.

COUNTRY SEAT IN NEWTON, FOR SALE.

The subscriber offers for sale the house in which he now resides, with the Barn, Sheds, Garden and about 35 acres of land situated on Nonantum Hill, in Newton, 5 1-2 miles from the city. The garden occupies nearly two acres. It is stocked with a great variety of fruit trees, and about 10,000 Antwerp Raspberry Vines. The place may be seen and further particulars obtained on application at the premises.
LOT WHEELRIGHT.

July 16th.

PEAR TREES FOR SALE.

At the Pomological Garden, Salem, Mass., a good collection of Standard Pear Trees, all of which have been proved. They comprise the choicest of the old and new varieties. Also 5,000 superior Buckthorn Plants for hedges.
Salem Oct. 8, 1838. ROBERT MANNING.

LAYING OUT GARDENS AND ORNAMENTAL PLANTATIONS.

E. SVEENS begs leave to inform his friends and the public in general that he will attend the laying out gardens and ornamental plantations, and hopes by strict attention to business to merit the approbation of those who may be pleased to employ him.
All orders left with J. Breck & Co. Agricultural Store, No. 52 North Market Street, will be punctually attended to.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders to any amount, which will be promptly attended to.
Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston.
Sept. 20. NAIUM WARD.

FOR SALE.

Five acres of good Salt Marsh, in Quincy, or (Squantum so called).
Also, Four acres of Salt Marsh in Brighton.

Also, Several fall blood animals, cows and calves. Apply to A. Greenwood, on the Welles Farm, Dorchester, near Dr Codman's meeting house.
Sept. 12, 1838.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaqueth's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham. ISAAC PARKER.

NOTICE.

The subscriber offers for sale his real estate in Westford and Groton; consisting of his homestead, 35 acres, his farm, 17, one pasture, 17 acres, one do. 33 acres, one woodland, 13 acres, one do. 5 acres, and one do. 10 acres. For further particulars see his advertisement in the Lowell Journal, or inquire of the subscriber at his house, near the meeting houses and academy in Westford.
EPHRAIM ABBOTT.

FARM FOR SALE.

In Cambridge, about one mile from Mardock's Hotel on the West Cambridge road with a valuable stone ledge on the same; containing forty acres of good land with the buildings on the same. It will be sold at a bargain if applied for soon, as the present owner is about removing to the West. Apply to the subscriber on the premises.
Sept. 25. 3w AMMI C. TEEL.

FOR SALE.

The thorough bred Short Horned Durham Bull, Superior. Superior was calved in August, 1831. He was got by Frederick, and he by Wye Comet.
Dam, Yellow Rose, by Young Denton.
G. Dam, Arabella, (Imported,) by North Star.
G. G. Dam Aurora, " " Comet.
G. G. G. Dam " " Henry.
G. G. G. G. Dam " " Dan.
The above pedigree may be found in the English Herd Book.

He is a roan and perfectly gentle and docile; and his stock, which may be seen at the farm of the subscriber, will testify to his value. Price, \$250 Apply to C. N. Berent, Esq. near Albany, N. Y.; or to Wm. Augustus North, Mount Marie, Duncasburgh, N. Y.
October 3, 1837. 4w

MULBERRY TREES.

1500 Morus Multicaulis.
1000 White Mulberry.
For sale, the entire lot, or in small quantities. They are very superior, and being raised so far north, have the advantage over southern raised trees, for this State.
JAMES STEWART,
Indian Hill Farm, near Newburyport, Mass.
October 3, 1837. 3w

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dume, situated in Rochester, N. H. six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quarries of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to Joseph Barck & Co., No. 51 and 52 North Market Street, Boston.
August 15, 1838.

MISCELLANEOUS.

THE VANDOS HARVEST HYMN.

Father of mercies! God of Peace!
Being whose bounties never cease!
While to the Heavens, in grateful tones,
Ascend our mingled orisons,
Listen to these, the notes of praise,
Which we, a happy people, raise!

Our hamlet, sheltered by Thy care,
Abodes of peace and plenty are;
Our tillage by Thy Blessing yields
An hundred fold—the ripened fields
Of flowing grain—the hushed vine—
Are tokens of Thy Love Divine.

The cradled head of infancy
Oweth its tranquil rest to Thee—
Youth's doubtful step, man's farmer tread,
In years mature, by Thee are led—
Secure may trembling age, Oh Lord!
Lean on its staff, Thy Holy Word.

Teach us these blessings to improve,
Teach us to serve thee, teach to love—
Exalt our hearts, that we may see
The Giver of all Good, in Thee;
And he Thy Word our daily food,
Thy service, God, our greatest good.

Whether in youth, like early fruit,
Or in the serene and solemn suit
Of our autumnal age, like wheat
Ripened and for the reaper fit,
Thou cut us off, O God, may we
Gathered into Thy garner be!

From the Richmond County Mirror.
SUMMER'S GONE.

Jack Frost has been to work again among the forest leaves. Already his bold crimson and russet hues are peeping from among the strange deep green of summer. And—like the first gray hairs which stray intrudingly upon our ear-locks—the first shrunken leaves rustle past us with a sad foreboding story. They tell the melancholy tale of Nature's faded loveliness. The time is near at hand when we must stoically bow to the behest of Nature, and bid a short adieu to the green and sunny seasons of the year. To many this farewell will be the last—for the last time some of us now look out upon the green drapery of this beautiful earth, upon the structure of which the immaculate Creator has displayed so much of His power, his goodness, and inexhaustible benevolence. For the last time we watch the silver mountain-streams leaping from their unknown fastnesses, laving the mossy banks and swathing the long grass which dapples in their mimic eddies. The same stern hand whose iced thrall shall lock up their energies in its icy manacles, may also lay upon us its cold and stilly ruin! To many there may be sorrow in this contemplation. But to him whose ethereal mind springs naturally from mundane glories, and sees in heaven's pure arc a pleasing hope of those pure hopes and joys immortal which are to grace his future history, these beautiful changes mark the welcome approach of that day "when this mortal shall put on immortality, and this corruptible shall put on incorruption." Oh, what a bright picarian fount does bland Philosophy open to those whose knowledge-yearning souls are ever ready to drink in its rich nectar. And Poesy too—the fairy

offspring of the enchanted nymph—as she moves majestically over the earth, unseen by all but her worshippers, how can she swathe us with her heavenly spirit, and immerse us in her care-dispelling Lethe! Guided by her, we look with new eyes upon the varied panorama of Creation, and see in every lineament of Nature the peerless mechanism of a Power Supreme. With her twin sister, Philosophy, she floats on aerial pinions, and touches with a magic wand the golden gates of pure and undefiled religion. The narrow path, which but a few may find, is lighted by her presence with a noon-day glory, while the thousands who are debarred participation, are dazzled by the glowing splendor until their eyes are even darkened by the unbroken light.

In the providential changing of the seasons, we have the most convincing proofs of the wisdom of that Great Original, from whose plastic hands worlds without number mount into their spheres, as sparks spring upward from a rustic fire. While myriads of stars shine in the azure depths, with brighter lustre than the golden tiles which whilom glistened on the walls of Solomon's vain-glorious temple. But there is an indefinable line which prescribes the limits of philosophy, and beyond which her step-by-step advances cannot delve. Here it is where man's own knowledge defines its ignorance, and where his wondrous lore makes the discovery of his imbecility and weakness. At this point his giant powers mount just high enough to peep from the confine-walls of their enclosure beyond which all is inscrutable and dark. Man cannot know how mere a worm he is, until Philosophy holds up to him the mirror of creation, and even then, the infinity of his littleness shrinks to a point which the immortal soul within him cannot descend to contemplate. Thus it is, the divinity within him tells plainly of that high source which he may boast. The mighty mover of this great machine,

"Whose body Nature is—and God the soul!"

Here it is where Philosophy loses herself in her own depths, and reclines her exhausted form upon the altars of the "Great

—First-Last! pavilioned high, who sits
In darkness—from excessive splendor born—
By gods unseen, unless through lustre lost!"

From the Maine Farmer.

THE WEALTH OF A COUNTRY DEPENDS UPON THE FARMERS AND MECHANICS.

What is wealth? These things which are convenient and necessary to use, and which administer to our wants and our comforts. Money alone, cannot therefore be considered as wealth, because if the articles or things above mentioned are not to be had, or are not in existence, a man would be poor indeed, though he were loaded with gold and silver. If he were hungry and there was no bread to be bought, if he were shivering with cold and there were no garments made for sale, his gold would be but of little service. It is true, mankind, by a common consent, have agreed that gold and silver should be the signs or evidence of property,—or in other words, the *measure* of property; and he who has a certain amount of it, has evidence of so much wealth. He can exchange it for the very things or articles which do in fact constitute wealth.

Thus a man who has a hundred dollars in his pocket, has the *ticket*, as it were, to entitle him to enter into the possession of an hundred bushels of

corn, or a hundred yards of cloth, or a hundred acres of wild land, or a yoke of oxen, or a horse and wagon, as the case may be. But if these things do not exist, and he needs them, his *ticket* is of no more use, than if he had a ticket to go into a theatre, and it should have been burned down before he used it. The elements therefore of wealth consist in natural productions, brought together, changed and modified by the skill and labor of man; of the farmer and mechanic. Commerce, though necessary and honorable, is nothing more than the *moving* or *changing* of these productions from place to place. It has always appeared singular to us, that merchants should consider themselves, as too many, far too many of them do, above the farmers or mechanics, merely on account of their profession, when they are indeed only the *teamsters* to the others. They are the agents to transport their productions hither and thither, as calls may exist for them. But to return to the subject. If we are right in the position which we have taken, that wealth consists in natural productions changed and wrought upon by the labor of man, it follows that the country which possesses the most of the elements or materials to work upon, such as good soil, abundance of water power, forests of timber, quarries of different kinds of stones, mines, and beds of different kinds of minerals, &c., must have the most natural wealth. It then only requires the hand of industry and skill to put these materials into shape, and to put them together to form real substantial wealth. This is the duty of the farmer and mechanic. They are the second creators of wealth. They take the raw material as it came from the hands of the Almighty, and change it by their labor into the thousands and tens of thousands of different forms, which render it useful to man, which make it subservient to the wants and comforts of human life. The more industrious and skilful this class is, the more wealth will be accumulated in the country. Do farmers and mechanics consider these things rightly? Are they not too apt to think themselves as mere plodders and servants, rather than as second to the Great First Cause in the production and increase of wealth? And, indeed, is there not a false standard of respectability, too much in use in society, and are not the productive classes apt to measure themselves by it? This standard appears to be *idleness and a fine coat*; and consequently, the more idle a man can be, and the finer the dress, the more of a gentleman. Not so. Respectability should consist in an improved mind, and skilful and industrious hands. Moral qualifications being equal, he should have the most honor, who by the combination of the efforts of his mind and physical powers, has contributed more largely to the increase of those things which constitute wealth.

Such an one has done more for the amelioration of society, than a thousand unproductive *dandies*, who toil in the shade and wash in cologne. And society should bestow upon such a corresponding need of honor.

NEW ENGLAND FARMER AND GARDENER'S JOURNAL.

(For the New England Farmer.)

THE BEURRE CAPIAUMONT AND FREDERIC DE WURTEMBERG PEARS.

MR EDITOR,—Having been absent on a journey of some two or three weeks, to a distant State, a notice of the remarks of your respected correspondent, the Hon. Mr Lowell, on the report of the committee on fruits of the Mass. Hort. Society of the 8th ult. has necessarily been delayed.

In order to show the grounds on which the committee rest their opinion, that the *Beurre Capiamont* figured in the London Pomological Magazine, is not the true variety cultivated on the continent of Europe under that name, but the *Wurtemberg*, or rather the "*Frederic de Wurtemberg*," which is sometimes also called, perhaps improperly, the "*Roi de Wurtemberg*," I submit, first, the following extract from that work published in 1829, and accompanying the figure.

"The first specimens which were seen in this country, came to the Horticultural Society in 1820, from M. Parmentier of Enghien, and M. Dumortier Rutteau, of Tournay. They excited much admiration at the time, and measures were immediately taken to secure the variety for this country. Unfortunately, however, the cuttings which were sent over were so much mixed, or so carelessly labelled, that a very small proportion of them proved to be of the true kind. In their room we received the *Beurre Rance*, the *Colmar Janinette*, and even the *Napoleon*. The true kind has always been sold by Mr Richard Williams, of Turnham Green; and from trees procured from his nursery, and growing in the garden of the Horticultural Society, our raising was made."

It will be observed that this drawing, figured several years after the specimens of the fruit had been received, which excited so much admiration, was made not from fruit produced from the cuttings received from M. Parmentier and others, but from trees brought from the nursery of Mr Richard Williams. How Mr Williams obtained the true kind is not stated, but it is evident that the London Horticultural Society had no other means of testing the identity of this fruit than the authority of an English nurseryman, and we have the assertion of Mr Knight himself that at that time, he knew of no English nurseries to be trusted in regard to the new fruits, "that he feared there was too much confusion in all the large nurseries, &c."

It would not therefore have been an event at all surprising if the society had been led into an error by Mr Williams, as it will be seen by the following extract from the catalogue of the society published by Mr Robert Thompson in 1831, to what extent similar mistakes had occurred; he says, speaking of the omission of the abbreviations which distinguish the most important characters of the fruit, "In these cases no certain information is collected at the garden; owing either to the trees not having fruited, or to inaccuracies hav-

ing been discovered in the names of the plants received at the garden. These inaccuracies have taken place to an extent of which no one who has not personally inspected the progress of investigation, can form an idea, and have caused more embarrassment than all other causes whatsoever taken together."—So much for the possibility that an error may have been made at the garden of the Horticultural Society; but for this error, its late venerable and highly distinguished president could have been in no way responsible; from the nature of the case, he must have depended on others, or on those who had received the trees from Mr Williams, and he again on some one else, and so on, through a connection, which we have no means of knowing how multiform it may not have been, an error in any part of which would have been fatal to the truth of the variety. The conclusions arrived at from what is before stated may be said truly, to be only conjectural; they show, however, that there has been room for error, and we will now proceed with the evidence we have that there has been an error in the case of the *Beurre Capiamont*; and this we are the more anxious to do because we have received a rebuke from a quarter entitled to grave consideration, and our highest respect, and whether the rebuke be deserved or not, yet coming, as it does, from the early and constant patron of horticulture, and of our own society especially, we are quite sure was made in kindness and with a view to its benefit. We stand, therefore, in this matter, on our defence, only so far as to show that we had strong evidence for adopting the opinion expressed.

The term *miscalled* may certainly appear harsh, and if it had any particular personal allusion, would be so in fact; but it had none, it was inadvertently applied in the haste of a weekly report, and the meaning intended to be conveyed was simply "*what people at this time miscall*." We have no doubt that the description of the pear in the Pomological Magazine is a true one of that fruit sent to this country by Mr Knight, as the *Beurre Capiamont*; but the question now at issue is, whether the pear which is there figured and described, is that which it was intended to be or identical with the true *Beurre Capiamont* which was then, and now is, cultivated on the continent; if it be so, then indeed are we in error, but if otherwise, most assuredly the integrity of those through whose instrumentality the scions were obtained and so liberally distributed throughout our country, can in no way be impugned.

Soon after the *Capiamont*, sent by Mr Knight as such, came into bearing, some of the members of our Society (including Mr Manning and myself) received specimen trees of the *Capiamont* from other sources; from France and from Flanders, all bearing a like resemblance to each other, in the young wood and the leaf, but essentially different from the *Capiamont* sent by Mr Knight.

At a subsequent period, Mr Manning received from Messrs Buel & Wilson, a tree, among others, of the "*Roi de Wurtemberg*;" (believed to have

been received by them from the London Horticultural Society,) and being at Salem sometime afterwards, he called my attention to this tree, and we concluded from its appearance that it must prove to be identical with the *Capiamont* of Mr Knight; this tree has since produced fruit, which has been annually exhibited, and our predictions have been fulfilled.

In 1834 and 1835, we received scions also, of the "*Wurtemberg*," from Dr Van Mons, of Louvain, the wood and leaf exactly corresponding with the tree received from Messrs Buel & Wilson; these have also produced fruit, which has been exhibited by Mr Manning, and which proves to be the same as the *Capiamont* of Mr Knight. Dr Van Mons has stated the *Frederic de Wurtemberg* to be a fruit which was originated by himself (not by M. Capiamont) and his description coincides precisely with the *Capiamont* of Mr Knight, and also with that figured in the Pomological Magazine. Dr Van Mons says the *Wurtemberg* is a twice bearing variety, this also is in exact accordance with what we have seen.

In order, however, to satisfy ourselves, and to resolve all doubts on the subject, we sent, in 1834, to Mr Thompson of the garden of the London Horticultural Society, for scions of the *true Beurre Capiamont*; we also sent at the same time to Dr Van Mons for scions of the same fruit; they have been received from both sources, and they entirely correspond in appearance, both in leaf and wood, with those which have been before received from France and from Flanders as such, as well as with the tree which produced the fruit exhibited by Mr Ives as the *true Capiamont*, at our late annual exhibition, the same having been received by ourselves from France. It may also be observed, that the fruit exhibited by Mr Ives as the *true Capiamont*, corresponds with the account given by Mr Thompson in the last descriptive catalogue of the fruits which had been produced in the garden of the London Horticultural Society, up to the date of that work in 1831, and is as unlike to the *Capiamont* sent by Mr Knight, as is the tree and the leaf.

The *Beurre de Capiamont* is thus briefly described by Mr Thompson in the descriptive catalogue of 1831.—Of medium size and of ovate form, color brownish red next the sun; *beurre* and of first rate quality, a great bearer, withstands late spring frosts better than most others. Its season October.

We would also observe that in 1836 and 1837 we were visited by M. De Vael, from Flanders, the Secretary of the Horticultural Society of Antwerp, a gentleman who brought letters from Dr Van Mons to several members of our society, testifying to his high attainments as a naturalist, and especially in pomological researches; possessing himself a vast collection of fruit trees of different varieties;—at first sight he pronounced the *Capiamont* of Mr Knight to be the *Wurtemberg*.

We have indeed no good reasons for supposing that any one with a right understanding of the

business, could have an interest in multiplying names, because they may have "trees to sell," as none who raise trees for sale, would be likely to recommend a new kind of fruit which has not been satisfactorily proved with us, however highly recommended, *except only to amateurs and for trial*; it is in this way most of our new and finest varieties have been introduced and become known; and I doubt much whether twenty trees of the true Beurre Capiaumont have ever been recommended or sold in New England, and those only to amateurs and for trial; while thousands of the Wurtemberg have under another name been highly recommended and sold.

Every friend of horticulture must be obliged to Mr Lowell, for his friendly remarks, which having a tendency to elicit discussion have also an equal tendency to elicit the truth, in relation to the nomenclature of our fruits, and should error in any case be discovered, it is believed that to avoid confusion, it will be best rectified by a speedy resumption of the *true original names*; in the present case there seems to be no alternative, unless we give a new name to the fruit last received, which would only create farther confusion, and which we believe legitimately entitled to the name it now bears.

WILLIAM KENRICK.

Nonantum Hill, Newton, Oct. 12, 1838.

From the Franklin Farmer.

CHARCOAL FOR DISEASED LUNGS IN HOGS.

MR EDITOR,—As the rearing and fattening of hogs has become a business of great importance to the west, and especially to our own corn-growing state; and as new and terrible diseases have made their appearance within the last few years, among that class of our domestic animals, I, as a common sufferer with my brother farmers, have been trying to ascertain the cause of, and remedy for the one which I have suffered the most by, and which I shall call your attention more particularly to. It is admitted I believe by pathologists, that diseases may, and do change their type in the same latitude, and become more and more malignant as the population becomes more dense and the country becomes older; thus our own intermittent has degenerated into the more deadly typhus fever; thus that which we once called quinsy or swelling of the throat in swine, has now assumed a more malignant type, and requires a different treatment; the cause is the same, but the effect is not always instantaneous or accompanied by the same symptoms or results. I think it may be safely assumed that most of the diseases, if not all, that hogs are liable to are produced by sudden transitions from heat to cold; and as they do not, like most other animals, perspire through the pores of the skin over the whole surface of the body, but through small orifices on the legs and throat, which are constantly liable to obstruction, and especially in the winter season, when the animals in large numbers bed together, producing great heat and free perspiration for a short time, but from the restiveness of their nature they are often changing the position first assumed, all tending to clot the mediums of respiration and thus lay the foundation of disease and death by alternating between heat and cold through the winter. Ordinarily the weak of the herd are the first to die. This may be chargeable to their inability to change positions, subjecting them to the crushing weight

of the whole number in the bed; or their long subjection to the great heat engendered by the common mass, until they are called to partake of the morning food. This, as we have stated, formerly produced enlargement of the glands of the animal's neck, which often ended in inflammation and death. Now, the same cause produces a very different effect, and although it is still strangulation, yet the inflammation falls with its whole weight upon the lungs, and if both tubes of the organ are affected, death instantly ensues; if only one, the animal may live a long time, but never recovers unless the remedy that I shall presently suggest, or one equally potent, be applied. The symptoms where the attack is violent, are a seeming sense of suffocation, great indisposition to move, a crimson color, approaching to purple, all over the body, and if forced to move a few paces, the animal will pant as if worried by dogs in hot weather. If the attack is less violent they will take much more exercise with seemingly less pain, will throb in the flanks in much the same way that a horse will when exhausted by fatigue and hard usage, are generally inattentive to their company, are inclined to eat earth rather than their accustomed food; such generally live a long time but never recover. I proceed to point out the way to prevent the disease and to cure if taken in time. Do not suffer your hogs to herd together in large lots in cold weather; never suffer them to sleep in hollow trees; if you have sheds for them to sleep under, let them be set so low that they cannot in great numbers heap together; in dry hard freezing weather let them have some succulent food, such as apples, potatoes or turnips, but especially let them have plenty of salt and charcoal; this last is a cure for the disease above described if administered before they entirely refuse to eat. It is known to almost every one, that charcoal is a powerful antiseptic and absorbent, and that hogs will search for and eat it with eagerness, and especially in banks of leached ashes, and so they will unassociated with ashes, if at first you will break it up into small lumps and pour a little salt and water over it. I have tried the various means in common use, such as tar, antimony, sulphur, &c. and never had one to recover its health until I tried the charcoal, and I have every confidence that it will succeed with others as it has with me, and if it does, I shall be well paid for this communication, feeling as I do, that no man ought to live for himself alone.

W.

AGRICULTURE OF DUMFRIES-SHIRE.

The agriculture of Dumfries-shire may be considered as a *national* object. The lands which are devoted to farming, and whose rental is about 200,000*l.*, at twentyfive years' purchase, are worth five millions sterling; and the buildings have cost the land proprietors at two and a half years' rent, another half million. The farmers do not find it safe to enter on leases with less than about 5*l.* of capital and credit per arable acre in course of cultivation, which for 160,000 acres in the rotation fields, added to 10*s.* per acre for nearly three times as great an extent not in cultivation, would indicate in all a farming capital of about one million sterling, for the whole of Dumfries-shire, the property of the farmers themselves. Let this be added to the value of the lands and farm buildings, and it would seem that about six millions and a half sterling are embarked in the farming of this county.

The returns in rent are very moderate, surely, as above; but the *gross returns* ought to be very considerable,—three times the rent of lands in cultivation being thought by no means excessive to cover the whole outlay, risk and interest with moderate profits; and twice the rent of lands in pasturage, all as the gross returns of the land. Now, as the prices of these times can hardly be calculated above 4*l.* for the returns per English acre, or 5*l.* per Scottish acre under crops, and the lands in crop are not above twofifths of the whole fields, or cultivated lands, the other three-fifths being in grass,

64,000 acres in white and green crops, at 4*l.* per acre, would give as the total of *crops* yearly, 256,000

And *cattle*, having for some time returned little for the mere grass, and being also rather fewer in number than in 1812 though better grazed, the grass returns, of 30,000, at 1*l.* 10*s.* each, are, 45,000

Sheep are fully as numerous as in 1812, having partly the lower pastures now and the returns for two or three years have been improved, but still the mere pasturage returns of 200,000 sheep, at 7*s.* 6*d.* each, would exceed the average beyond three years, and are, 75,000

Pigs return little for mere grazing, certainly not above 1*l.* for each, which for 30,000 pigs would be, 30,000

The breeding of *horses* is chiefly to keep up the stock; and for *poultry, bees, &c.* the returns are small; but it may be only fair to state the whole at a sum equal to the gross returns from pigs being 30,000

And the total returns from *crops and pasturage* would thus be, 4436,000

A sum fully high stated, as is believed, on reviewing it; and these returns are becoming less and less yearly, instead of increasing, as they ought to do, so as to encourage improvement in arable land.—*Dr Singer, in the New Statistical Account Scotland.*

CATTLE SHOW AND FAIR.

On Wednesday and Thursday the third and fourth days of October, instant, the Berkshire Agricultural Society held its twentyeighth anniversary at Pittsfield. The rain which continued until o'clock in the morning of the first day, was the only unpleasant circumstance attending the Fair and this did not prevent the usual collection of animals, even from some of the most distant towns in the county. The field appropriated to the exhibition of cattle, sheep and swine, was the principal place of concourse; and it was here that good effects of this society were made again as former years, strikingly apparent. The exhibit of working cattle, particularly four year old and three year old steers, has never been equal before, either in number or quality. Indeed of neat cattle generally, we have never seen so great a variety together before. Besides native bred there were the Durham, the Devonshire and Ayrshire, with a variety of crosses. The Comtees were engaged most industriously during the afternoon in viewing and comparing the animals and in the evening in preparing their reports.

The reports of the committees will give the details in this department.

The Hall of domestic manufactures was also a place of great resort; and presented an interesting variety of the results of domestic and manufacturing industry. The afternoon of the day was delightfully pleasant. The whole scene was one of exceeding interest, to all who have the interest and honor of old Berkshire at heart. The vast concourse of our fellow citizens, all seemingly gratified with this opportunity of exchanging their congratulations, comparing the results of their agricultural experience, exhibiting their stock, viewing the stock of others, buying, selling, and exchanging, could not but be regarded with pleasure and patriotic feelings. Although this is the oldest agricultural society in the United States—although this is its twenty-eighth anniversary, yet the interest of our community in its annual Fairs, so far from flagging, is constantly and steadily increasing. It is our best; almost our only holiday; and the citizens of Berkshire will long continue to cherish it.—*Lenox Eagle.*

WHAT IS BOOK FARMING?—The editor of the Quarterly Journal answers the question as follows: "Book farming, we know, is not in favor with farmers, otherwise we should find admittance into every farmer's library, and every farmer [in Scotland] has a library. But although we know, and therefore admit, that no man can be made a farmer by book, we cannot admit that the best farmer cannot, may not, at times, find useful hints in a book. The best farmer cannot know every article of practice which is followed in every part of the country; and as such practices are discovered by what is called chance or accident, it is clear that the discovery cannot generally be made known until it is disseminated abroad. A farmer who travels, appreciates the information which he receives in conversation with farmers, and by observation of field labor. Such a farmer possesses advantages over him who always remains at home, that is, within the circle of his markets. Now the object of an agricultural book, and particularly of an agricultural periodical work, is, at stated times, to carry hints, suggestions or discoveries, important or unimportant, to the home of the farmer, that he who loves to stay at home may possess the advantages of him who at times travels abroad, and that he who travels abroad may compare what he has seen with what he reads, and decide which practice is best suited to his particular purpose; or perhaps when comparing the hints of others, he may himself discover a practice superior to them all. In this manner a good agricultural work is the means of disseminating through the country practices which would be confined to the district which gave them birth. Its principal aim should be to be a good work, that is, replete with suggestions of good sense, and with confirmations of experience. The collection and presentation of these desiderata, is attended with much trouble and expense, and unless the labor is appreciated and encouraged, it is impossible to use the means to collect the most valuable kind of information for presentation."

REMEDY FOR SHORT CROPS.—The excessive drought has so diminished the pasturage in some neighborhoods, as to render it necessary to resort to feeding stock with fodder, and if it should continue, many more will be under the necessity of

resorting to it. If so, or if the season for feeding should be much prolonged, which looks probable, economy and good management will become necessary, otherwise much suffering will result. In order as much as possible to avert this state of things, let every farmer cut the *hay, straw, and corn fodder* given to his stock, and wet or moisten it before it is fed. Much will be saved by this simple process, as will soon be discovered by making trial of it. An excellent farmer has been doing it for some weeks past with manifest advantage. Let all the grain fed to your stock be first *boiled or steamed*. It is much better for having the heat applied gradually, and for a long time; eight or ten hours is better than a shorter time; it will double the bulk of the grain, and from experiment, it is believed that one bushel of the cooked grain, goes as far as a bushel of the raw; if so, one half is saved by the process, abating labor and expense. If your boys should demur at the labor, or show by their looks or their mutterings, that they are too lazy to save a penny, hire a hand at once to attend to it properly, and turn them out to hunt pasture for themselves, and let them try the experiment of getting a living by growling and complaining, and despising industrious, economical habits. They may do for steam doctors, but they are not the stuff of which *thriving farmers* can be made.—*Furmer's Cabinet.*

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Oct. 13, 1838.

Pears.—Specimens of the following fine varieties were exhibited by Mr Downer. Belle et Bonne, a noble autumn fruit of large size and fine quality, appears identical with the Belle de Bruxelles; Cumberland, a native fruit, pear shaped, of good size and handsome, of fine flavor; Bezi Vact.

From Mr Pond, Burnet Pear, and Beurre Diez.

From Mr Manning, Pound Pear.

From Mr James Eustis of South Reading, a beautiful fruit, rather large and truncated in form, of a fine straw color, rather astringent, an ordinary fruit for the table, but must prove fine for baking.

Apples.—From Mr James Eustis of South Reading, Ben Apple, a large round fruit, covered with pale scarlet on a yellow ground; flavor first rate, and equal to the Baldwin. A winter variety, said to be a good bearer and evidently highly deserving of cultivation.

From Mr Manning, Sweet russet; also Murphy, a noble fruit and a native, of large size, striped with dark crimson, and covered on the tree with a profuse blue bloom; flavor fine relieved by a due proportion of acid; tree a good bearer. This fruit much resembles in appearance the Blue Pearmain.

By Mr Downer, Gravenstein, and Lyscom.

By Mr Luther Little, a red apple of medium size and good quality, from a tree in Marshfield over 200 years old, which was planted by Peregrine White, the first native white man of Massachusetts, and born on board the *Mayflower*.

Grapes.—Black Hamburg from Mr Thomas Mason of the Charlestown Vineyard.

From Mr J. L. L. F. Warren, Black Hamburg, of good quality, from out of door culture.

From Mr E. Weld of Roxbury, Catawba.

From Mr Pond, Isabella.

For the Committee,

WILLIAM KENRICK, *Chairman.*

Saturday, Oct. 20, 1838.

The Annual Meeting for the choice of officers was held at their room agreeably to notice given.

The committee appointed to collect, sort and count the votes, reported the following gentlemen as chosen:

President.

ELIJAH VOSE, Dorchester.

Vice Presidents.—Enoch Bartlett, Roxbury, Jonathan Winship, Brighton, M. P. Wilder, Boston, John Prince, Roxbury.

Treasurer.—Samuel Walker, Roxbury.

Corresponding Sec'y.—Robert Treat Paine, Boston.

Recording Secretary.—Ezra Weston, Jr., Boston.

Counsellors.—T. Lyman, Jr. Boston, Augustus Aspinwall, Brookline, Thomas Brewer, Roxbury, Henry A. Breed, Lynn, George W. Brimmer, Boston, Joseph S. Cabot, Salem, E. Hersey Derby, Salem, N. Morton Davis, Plymouth, David Haggerston, Watertown, Joseph G. Joy, Boston, William Kenrick, Newton, John Lemist, Roxbury, William Lincoln, Worcester, Thomas Lee, Brookline, Charles Lawrence, Salem, Benjamin Rodman, New Bedford, M. P. Sawyer, Boston, Charles Tappan, Boston, Aaron D. Williams, Roxbury, Jonathan Winship, Brighton, William Worthington, Dorchester, Thomas Whitmarsh, Northampton.

Professor of Botany and Vegetable Physiology.—Rev. John L. Russell.

Professor of Entomology.—T. W. Harris, M. D.
Professor of Horticultural Chemistry.—J. W. Webster, M. D.

STANDING COMMITTEES.

Committee on Fruits.

Wm. Kenrick, Chairman, Robert Manning, Sam'l Downer, Benjamin V. French, E. M. Richards, John A. Kenrick, John M. Ives, Salem, P. B. Hovey, Jr., L. P. Grosvenor, J. L. L. F. Warren, Samuel Pond, W. H. Cowen.

Committee on the Products of Kitchen Garden.

J. L. L. F. Warren, Samuel Pond, Aaron D. Williams, Rufus Howe, Ebenezer Crafts.

Committee on Flowers, Shrubs, &c.

S. Walker, Chairman, C. M. Hovey, J. Breck, S. Sweetser, D. Haggerston, S. R. Johnson, W. Carter, John Tagger.

Committee on the Library.

E. Vose, Chairman, R. T. Paine, W. Kenrick, E. Weston, Jr., C. M. Hovey, M. P. Wilder, Thomas Lee.

Committee on Synonyms of Fruit.

J. Lowell, Chairman, R. Manning, W. Kenrick, S. Downer.

Executive Committee.

E. Vose, Chairman, C. Newell, B. V. French, E. M. Richards, E. Bartlett.

Committee on Finance.

E. Vose, Chairman, B. V. French, L. P. Grosvenor.

Col. Wilder proposed the Abbe Berlese, of Paris, as Honorary Member—and M. J. Rudz, Jr. of Frankfort on Main, Germany, as corresponding member. Then adjourned two weeks.

E. WESTON, JR. *Rec. Sec.*

Sampson Washburn of East Bridgwater, Mass. raised this season from one pumpkin seed, (spontaneous growth,) 37 pumpkins—all fair. Whole weight 743 lbs. One weighed 30 lbs. Five grew so near together as to touch.

WHAT QUANTITY OF MANURE SHOULD BE APPLIED TO THE ACRE?

The answer to this question involves many considerations which preclude a definite reply, such as the condition of the land, the quality of the manure, and the kind of crop. Too much, as well as too little manure, may be applied. What would be beneficial for an autumn-ripening, or hoed crop, would be prejudicial to a small grain, or summer-ripening crop, and more particularly if the manure is applied in an unfermented state, and be withal a waste of fertilizing matter. Twenty tons to the acre would not be too much for corn, potatoes, ruta baga, &c., if applied broad-cast, and ploughed in; but if long manure, and applied in the drill, or hill, and a dry season should ensue, it might prove an injury; and if this quantity of long, or even short manure, were applied to the acre of small spring grain, it would probably cause a flush of straw, likely to be affected with rust, at the expense of the more valuable part—the grain. Dr Coventry, late professor of agriculture in the University of Edinburgh, whose business and study it was to collect data, and make correct deductions in this and other agricultural matters, was of the opinion, that from four to five tons are yearly requisite to keep up the fertility of a soil of the kind usually denominated spit, or totally rotted dung; and this supply he thinks a well managed farm may be made to produce. To show how this quantity may be obtained, and how it should be applied, we quote from Mr Youatt, the writer of *British Husbandry*.

"According to that calculation," says our author, "it must be observed, that the course of crops is supposed to consist—on light soils, of the alternate plan of corn and green crops, (see *New System of Husbandry*),—on clays which do not admit of that system, that the holding contain a proportionate quantity of grass land; and that the quantity of manure should be supplied not in small quantities annually, but in large ones, at intermediate distances of four, five, and six years. Light soils, in the common course of husbandry, rarely require the application of putrescent manure oftener than once in four years, and in all cases where the clover is allowed to stand two seasons, it may be deferred without disadvantage for another year. Heavy soils may run six years without it, provided that the land be laid one year in fallow, and that there be sufficient meadow to be reckoned at least one crop in the course. It being, however, clearly understood, that—whether on light or heavy land—nothing but grain, seeds and live stock is to be sold off the farm, unless replaced with an equal portion of purchased dung; that the whole of the green crops, the haulm of pulse, and the straw of corn, be used in the most economical manner; and that some of the live stock be either soiled or fattened upon oilcake, which plan, if carefully pursued on good soils, with capital sufficient to secure an abundant working and fattening stock of cattle, ought, under fair management, to furnish an adequate supply of dung for any of the usual courses of culture."

Having thus submitted to our readers all that occurs to us of importance on the subject of farm-yard manure, we shall here recapitulate a summary of the chief points which we deem particularly worthy of their consideration:

1. To bottom the farm-yard with furze, fern, (in Yankee dialect, brake,) dry haulm, (strubble, &c.) or any other loose refuse that takes the longest

time to dissolve; and over that to bed it deep with straw.

2. To occasionally remove the cribs of store cattle to different parts of the straw-yard, in order that their dung may be dropped, and their litter trodden, equally.

3. To spread the dung of other animals, when thrown into the yards, in equal layers over every part.

4. To remove the dung from the yard at least once, or oftener, during the winter, to the mizen.

5. To turn and mix all dung-hills, until the woody or fibrous texture of the matter contained in them, and the roots and seeds of weeds, be completely decomposed, and until they emit a foul putrid smell, by which time they reach their greatest degree of strength, and arrive at the state of spit-dung.

6. To keep the dung in an equal state of moisture, so as to prevent any portion of the heap from becoming fire-langed. If the fermentation be too rapid, heavy watering will abate the heat; but it will afterwards revive with increased force, unless the heap be either trodden firmly down or covered with mould to exclude the air.

7. To ferment the dung, if to be laid upon arable land during the autumn, in a much less degree than that to be applied before a spring sowing.

8. To lay a larger quantity on cold and wet lands than on those of a lighter nature, because the former require to be corrected by the warmth of the dung, while, on dry, sandy, and gravelly soils, the application of too much dung is apt to burn up the plants. Stiff land will also be loosened by the undecayed fibres of long dung, which although its putrefaction will thus be retarded, and its fertilizing power delayed, will yet ultimately afford nourishment.

9. To form composts with dung, or other animal and vegetable substances, and earth, for application to light soils.

10. To spread the manure upon the land, when carried to the field, with the least possible delay; and, if laid upon arable, to turn it immediately into the soil.

11. To preserve the drainage from stables and dung-hills in every possible way, and if not applied in a liquid state, to throw it again upon the mizen.

12. To try experiments, during a series of years, upon the same soils and crops, with equal quantities of dung, laid on fresh, and afterwards rotted; in order to ascertain the result of their application to the land. The whole quantity to be first weighed or measured, and then divided.

The fermentation of farm-yard manure is, in fact, a subject of far greater importance than is generally imagined, for on a due estimation of its value mainly depends the individual success, as well as the national prosperity of our agriculture. The experiments to which we point, cannot therefore, fail to come home to the interests of every man; they may be made without expense, and without any other trouble than the mere exercise of common observation and intelligence. Leaving, however, aside the discussion concerning the disputed worth of fresh or fermented—of long or short dung—let the farmer sedulously bend his attention to the accumulation of the utmost quantity that it may be in his power to procure. The manner and the time of using it, in either state, must however be governed by circumstances which may not always be within his control; and every judicious husbandman will rather accommodate himself to the

exigency of the case than adhere strictly to his own notions of what he conceives to be the best practice. In fine, whether favoring the one or the other side of the question, let him collect all he can, apply it carefully to his crops, and then trust—*to events, "let the land and the muck settle it."*

—*London Farmer's Magazine, Aug. 1838.*

ON THE CAUSES AND PREVENTION OF RUST OR MILDEW.

The Quarterly Journal of Agriculture, to which we are indebted for much valuable matter to fill our pages, has a lengthy article on smut, canker, and rust or mildew. Having published in our two last numbers, several articles on the causes and means of preventing smut, we shall now give so much of the article from the Quarterly, as is descriptive of the rust or mildew, the ascertained cause of the evil, with some suggestions for its prevention, omitting the speculative opinions which have prevailed on the subject, and their refutation by modern writers and experience.

DESCRIPTION OF RUST OR MILDEW.

"Rust first makes its appearance on the upper leaf, and then on the lower leaves and the stem, in the form of small white spots, scattered irregularly like spots made by rain on new cloth. These spots gradually increase in size and number, and assume a reddish tinge, and at length form a sort of dust-looking powder, of an ochre or orange yellow, little cohesive, and without smell or taste, and therefore very different from canker or smut. It stains the fingers yellow, as well as the clothes of those who walk among the affected corn.

"The dust-like substance of the rust originates beneath the outer bark or epidermis of the plant, which it raises up, renders thin, and at length cracks and bursts through. When examined by the microscope, it presents a congeries of egg-oblong bodies, some of which have projections almost like tadpoles or *pothecads*, though they are not animated.

"Wheat is attacked with the red rust at different periods of vegetation, but more particularly when in the ear. When the rust seizes young plants, they are said to suffer less than when they are more advanced, often recovering vigor before blooming; whereas at a later period they sustain irreparable damage, and crops which promise well are often in a short time rendered comparatively worthless. In this case the texture of the leaves is disintegrated, and presents only longitudinal fibres of a brown color, while the joints and the tubes of the straw between are blackened, as if they had been scorched by fire, the growth ceases, a portion of the ear becomes yellow, another portion remains green, and the grain shrivels up in the husk without attaining maturity.

"The evil, however, is rarely carried so far as this, and the yellow spots of rust become chocolate-brown or black, without disorganizing the portions of the plants where they occur; and the Abbe Tessier says he has seen, after heavy rains, the clothes of the reapers stained with this black substance of the rust as if they had been dipped in ink. But though the plants are not disorganized, the flow of the sap is interrupted, the ripening of the grain is prematurely hastened, and it is hence light, containing a small proportion of farina, while the straw is bad. Sometimes the rust only leaves a yellow powder on the husks and upper end of the

grains, taken by Fontana and others to be a different species.

"Sometimes rust prevails so extensively, that few fields escape; but for the most part it is observed in fields sheltered from the north winds by walls, hedges or woods, or where vegetation is very luxuriant, on account of fresh soil or abundant manuring. Sometimes one part of the field escapes while the other is attacked; sometimes the chief plants, and at other times the side shoots withering from them are affected; and sometimes rusty and sound plants grow from the same root."

OF THE INFLUENCE OF THE BARBERRY BUSH.

Although it is conceded, that the farmers of England, and on the continent, generally ascribe the rust, in a measure, to the infection which spreads from the barberry bush, and that this notion is sometimes strengthened from the rust appearing in patches and strips among the grain, as if it had been carried thither by the wind from the barberry bushes—and although this opinion was sustained by Sir Joseph Banks,—the writer nevertheless considers the theory as fallacious, and quotes an anonymous authority in saying, that the rust which is found on different trees and plants is altogether of distinct and separate species.

"Dutrochet's discovery of the mode of growth in *fungus*.—In a damp cellar where wine was kept, M. Dutrochet, one of the most original observers of the day, remarked, about two or three years ago, a white looking net-work of fibres, which previous botanists had described as a species of *crow-silk*, (*Byssus*.) Being struck with its peculiar manner of growth, he watched it with careful attention, and got M. Tupin, probably the best botanical draughtsman in Europe, to take drawings from it in every stage of its growth. The general result was, that the supposed *crow-silk* was not, as had been supposed, of the genus *Byssus* at all, but the genuine stems, hitherto known as such, of a mushroom, (*agaricus crispus*, Tupin) the mushroom itself being the fruit only, and not as hitherto believed, the whole plant. According to this view, then, it would be as correct to consider a bunch of grapes, with their fruit-stalk, a complete plant, as the fruited mushrooms, puff-balls, or puddock-scools, all these being but the fruits of plants generally growing under ground, in the form of small white or grey fibres of net-work, and termed improperly by gardeners, *spaven*, indicating that it is the seed of mushrooms, whereas it is the genuine plant.

"M. M. Dutrochet and Tupin, further discovered that the seeds, or, as they are termed by botanists, *sporules*, consisting of minute globular bodies, are contained in the cells of fungus fruit in prodigious numbers, and they succeeded in observing these germinate and produce young plants like their parent. There therefore cannot remain a doubt, that *funguses* are produced from seeds in the same way as all other vegetables, though these seeds or *sporules* are exceedingly smaller than those of green plants—being as subtle, Mr Fries remarks, sometimes as smoke.

"Contrary, then, to what takes place in regard to the eggs of insects, which are too heavy to be carried about by winds, and if they were lighter, are generally, when laid, glued to the substances destined for the food of the young, when hatched, the minute, light, subtle seeds of *funguses* and *mosses* are floated about in the air with the gentlest breeze, and in this way diffused over immense tracts of country, in numbers altogether countless. The discovery of M. Dutrochet is, therefore, of the

greatest interest in making us acquainted with the economy of Providence in the propagation of *fuogi*, hitherto altogether mysterious.

"What we term smut, canker and rust, are, according to this discovery of M. Dutrochet, only the fruit of particular *funguses*, the plants of which they are the fruits being hitherto undescribed and unknown, but which must be sought for in the form of delicate fibres, probably transparent, and probably difficult to see in the textures of the corn affected with those destructive parasites.

"It forms no objection to this view, that the fibres of these *funguses* have not been seen except partially by Bauer and Ad. Brongiart, in their microscopical researches, for M. Dutrochet further found, that when the fruit of the plant observed by him (*agaricus crispus*), sent up its foot-stalks, (*stipes*) it became partially detached from the main plant, and independent of it for its future nourishment, the fibres of the main plant indeed becoming exhausted of substance, and disappearing as in what were previously supposed to be the roots at the base of the fruit-stalk in the edible mushroom, which supposed roots are the fibres of the main plant, partly exhausted of their substance by the nourishment of the fruit."

The editor of the Quarterly here details some ingenious experiments of M. Fee, to ascertain the manner in which plants become affected by fungi, or the mode in which the *sporules* are propagated. M. Fee infers from the result of these experiments, that the seeds or *sporules* of the fungi are sucked up with the moisture of the soil, by the tips or spongioles of the root fibres.

ASCERTAINED CAUSE OF RUST OR MILDEW.

"The rust, and various sorts of what are termed mildew, are all caused by small fungi, such as the tuft-brand, (*Puccinia graminis*, Persoon; or *uredo fumentii*, Sowerby,) and the linedeband, (*uredo linearis*, Persoon; *u. largissemata*, Sowerby,) which do not differ so much in the injuries which they produce as in their mode of growth and appearance, as has been already described.

"The history of the red rust need not detain us, as it has been long well known from the very good account given of it by Sir Joseph Banks, with most admirable drawings, by M. Bauer. The opinion, however, which Sir Joseph seems to adopt is, not that the seeds of the rust fungus get into the corn plants by the tips of the roots, but by the pores on the leaves and stems, being carried there by the winds, and caused to adhere by the moisture of dew or rain. When once entered into the pores, he says—they germinate, and push their minute roots, no doubt, (though these have not yet been traced,) into the cellular texture beyond the bark, where they draw their nourishment by intercepting the sap that was intended by nature for the nutriment of the grain. The corn, of course, becomes shrivelled, in proportion as the fungi are more or less numerous on the plant; and as the kernel only is abstracted from the grain, while the cortical part remains undiminished, the proportion of bran in blighted corn is always reduced to the same degree as the corn is made light. Some of the last year will not yield a stone of flour for a sack of wheat."—*On blight in corn.*

PREVENTION OF RUST.

On this branch of the subject, we find little to copy, that, in our opinion, is worth the pains. The writer adopts the opinion, that the seeds or *sporules* of the fungi, smut, canker and mildew, are dissem-

inated in myriads over our fields—that these seeds are carried into the soil by the rain, and that they enter the plant by the tips of the roots. The prevention recommended is paring and burning, or copiously liming; the first of which he thinks will destroy wholly, and the other partially, the vital power of the fungi.

We dissent from the opinion of Fee, adopted by the Quarterly, that the seeds of the fungi enter the plant by the root, and are disposed to believe with Sir Joseph Banks, that the seeds of the rust-fungus get into the plant by the pores of the leaves and stem. And we will offer some reasons for this belief. 1. The prevalence of rust depends much upon the temperature and humidity of the season when it prevails. If the season is moist and hot, and the atmosphere calm, this disease most abounds. On the contrary, if it is cool and dry, and northern winds prevail, we see very little of it. 2. The prevalence of rust depends much on exposure and luxuriance of growth. If the field is much sheltered from drying winds, the air in a measure stagnant, or the growth of straw luxuriant, as on the site of dung heaps, the rust-fungus is pretty certain to appear; but it seldom shows itself in open exposures, where the growth of the straw is moderate, or has not been stimulated by recent or too abundant manures, except the season is hot and humid. Upon M. Fee's theory, all seasons and all soils would produce it alike, provided the soils were once impregnated with the seeds. Its appearance only in certain seasons and in certain locations, can readily be explained on Sir Joseph Banks' theory. In the seasons and locations in which rust is most prevalent, the atmosphere is comparatively light and stagnant, and the epidemics of the grain soft, spongy and moist. Now assuming what M. Fee asserts, and we have no reason to doubt his correctness, that the seeds of the rust-fungus are as subtle as smoke, they might readily be wafted by this light atmosphere to the leaves and stems of the grain, which would be in an excellent condition, under such circumstances, to receive and nurture them. But when the atmosphere is dry, and the air in brisk circulation, its specific gravity is too heavy for these seeds to float in it, and the leaves and stems of the grain are less fitted for its reception. When the atmosphere is light, smoke lingers upon the earth's surface; when it is dry and heavy, smoke immediately rises to the upper regions.

If our views are correct, liming, or even paring and burning, would effect little towards the prevention of rust and mildew. The best preventives, in our opinion, are, to apply the manure intended for wheat, to a previous hoed crop, that the heat of fermentation, which causes a strong and protracted growth of straw, may have subsided; and to sow upon dry grounds, or if flat and retentive, to lay the land in ridges, that all surplus water may readily drain off. These precautions, added to clean and thorough tillage, we think, will be as efficacious as paring and burning. Liming wheat lands, we have no doubt, is beneficial in many respects; but that it will prevent rust, we have no facts before us that will justify us in asserting.—*Cultivator.*

PRODIGIOUS.—A cow, the property of Mr F. Kent, of West Springfield, during sixty days, beginning June last, has given 1346 quarts of milk! averaging 22 1-2 quarts a day. Largest yield, 11 quarts in morning and 16 in the evening!

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, OCTOBER 24, 1838.

RURAL FESTIVAL AT BARRE, MASS.

The spirited farmers at Barre have been for several years past accustomed to hold a cattle show and exhibition of manufactures for that town. It was held this year on the 17th Oct., and was numerously attended, very few of the enterprising and intelligent farmers of that town being willing to absent themselves from so agreeable an occasion. Many farmers from the neighboring towns gladly availed themselves of the opportunity to cultivate the kind and friendly sympathies, and "to see how their neighbors were getting along."

The business of the day commenced with a ploughing match. The ground was marked out for five teams. One failed and four entered the list as competitors for the honor of success. The teams were all single; the oxen of superior character and well trained, and the work well done. The plough generally used here is Nourse's plough, of Worcester; and is designed to be an improvement on Wood's plough, which led the way in the great improvements in the construction of this most important implement, that have taken place within the last twenty years. The improvement understood to have been made by Nourse consists in lengthening the mould board. By this extension of the mould board the friction and of course the difficulty of draft is increased; but the movements of the plough are more steady, and the sward is intended to be more completely inverted and laid down. We do not believe, however, that the proper shape of the mould board is yet commonly reached among us, either as it regards lightness of draft or goodness of work. A good ploughman will often make good work with a very inferior plough; but much certainly depends on the construction of the implement. In regard to the ploughs used on this occasion, in our opinion they were too un-venx to work with the ease of draft which might be obtained; and their operation in such cases is to double the furrow in a sort of spiral form rather than to lay it flat, or place it at such an angle of inclination as might be desired. The workmanship of the ploughs, both the wood and iron parts are much to be commended. They were without a cutter or coulter, which in sward land especially, ought always to be employed. After the ploughing match the drawing match took place, which from not being appraised of it, we did not witness, but which we understood was well contested.

The show of working cattle was beautiful. They were numerous, well trained, and in excellent condition, though it was said that Barre might have produced four times the number, of equal excellence. The show of fat cattle was small; but some of them were capital. A yoke of oxen seven years old, fattened by Mr Daniel Bacon, one of the best farmers in the county of Worcester, and that is saying a good deal, were of remarkable excellence. They weighed upon the hoof 4390 lbs., and were of our native stock. Some valuable cows were presented;—one owned by Mr Ayres, of very ordinary appearance and now twelve years old, had given fifty pounds of milk per day. Two others presented by Mr Holden were of extraordinary beauty; but their produce was not stated. It was evident that the Devon blood largely predominated in them; and there were signs of the intermingling of the improved Durham in their origin. But nothing was known with certainty. The Barre farmers, whose main object is the dairy, raise more or less stock yearly; but as yet little attention has been paid to the improvement of the breeds. Several spoke of having

had a bull from Connecticut river, purchased some time since by a joint contribution; but his true character or pedigree were not known by any, to whom our inquiries were addressed. This is a deficiency among our farmers yet to be supplied. They are not familiar with the different breeds which exist or have been introduced among us; and in almost every case of attempt at improvement no record is kept, and the genealogy is soon lost in confusion. Of swine there were no samples presented of any note; but if any one desires to see good swine, let him go to the styes of some of the farmers in Barre, and he will be gratified with the sight of some as fine as New England can show. Let him go especially to the styes of Mr Daniel Bacon; rather an onomastic name, which if the poor things understood, we fear it would too much disturb the equanimity of their spirits, for them to thrive as they do; but they seem in this case to be wrapped up in a happy insensibility to every corroding care; and more extraordinary thrift and size and symmetry have never come under our observation. It is a little singular and shows only what may be done in the marvellous transmutations of material things that Barre should make such excellent beef or pork at pleasure.

After the show the farmers of Barre sat down, to the number of one hundred and thirty, to an elegant and excellent dinner at the tavern of Mr Wheelock, a hotel which we can cordially recommend to all travellers in pursuit of kind attentions and most comfortable accommodations. The dinner was succeeded by an address mainly on the subject of the dairy, by the commissioner of agricultural survey. Reports of the several committees on the various matters of exhibition were then given in a sportive humor, intermingled with many piquant sentiments from several gentlemen present. The occasion was one of unmingled gratification. Such holidays among the farmers cannot fail to excite a laudable and powerful competition in their art; and passed in this rational and agreeable manner, must exalt the character of the profession.

The association being wholly voluntary and unincorporated has no premiums to bestow; but we hope this deficiency will another year be supplied. No one of the Barre farmers, who attended the exhibition, would find it at all difficult to give a bushel of wheat, or two bushels of corn, or a good cheese to the advancement and encouragement of this great art, by which he lives, in his own town. In the benefit and pleasure which would at once be reflected back upon himself, he would find an ample compensation. Now let the farmers there be asked to levy annually this light tax upon themselves either in kind or in money, and a fund is at once formed to be distributed in premiums, which would quicken emulation, and give a vastly increased interest and value to their shows.

The exhibition of domestic or household manufactures, or dairy produce, or vegetable products, was extremely meagre. This ought to be otherwise; and we may express the hope that another year there will be an ample display of their rich domestic and household products in every form; and perhaps no town in the commonwealth from their own resources, could furnish a more beautiful or creditable exhibition. Farmers of Barre! go on; and lead off in the fine style in which you have begun.

H. C.

NORTHAMPTON CATTLE SHOW AND EXHIBITION OF DOMESTIC MANUFACTURES.

This occasion took place on the 11th and 12th of the present month. We regretted not being in season to see the show of cattle, many of which were removed from the pens before our arrival, but we were told that it was

quite respectable in quality, though not large in number. The exhibition of household manufactures, such as pieces of flannel and of dressed cloth blankets, quilts and counterpanes, carpeting, hearth rugs, hosiery, and a great variety of fabrics of a useful as well as an ornamental character, was beautiful and extremely creditable to the women of the county of old Hampshire. They constitute at the same time to the young men of industry and enterprise, the best recommendation, which they can ask for of the county as the place to apply for frugal, industrious, intelligent, and useful wives.

The second day was occupied with a ploughing match, an exhibition of horses, the usual address, and the announcement and distribution of premiums. Of these a full account will be given in the reports of the committees, which we shall publish as soon as received.

In the ploughing match seven teams were entered, five of which were two horse teams; the other two ox-teams, a single yoke each. The ploughing of six of the teams was excellent; and the committee, where all was so well done, found it extremely difficult to make the necessary discriminations. The ploughs used were of various patterns,—Howard's, Nourse's and Wright's. Though within twenty years, since the first ploughing match at Brighton, much has been gained in the construction of the plough and the mode of handling, there is still great room for improvement, before we reach that perfection of execution, to which the art of ploughing has arrived in England and Scotland. There young men are trained to the plough from their childhood, and no line can be drawn with more exactness than they strike out with the plough and without a driver. The direction of the furrow, its straightness, its width, its depth, and the mode of laying it, whether flat, or overlapping or at what angle it shall be set up, are with them all matters of the greatest precision. The finishing of their lands likewise is always executed with the utmost exactness. The construction of this great implement in agriculture so as to secure the best work with the greatest lightness of draft and the mode of executing this operation under all circumstances being of the greatest importance to husbandry, cannot receive too particular attention. To ploughing matches to the competition and inquiry there excited, we are mainly indebted for the improvements already made. Still greater than have been made are in prospect; and the introduction of the side hill plough with a changing mould board may be strongly recommended to farmers for common use on their level lands as saving much time in turning and the necessity of a dead furrow.

The day at Northampton, was lowery and rainy, any by the condition of the previous weather, the attendance of many farmers from the distant parts of the district was undoubtedly prevented. The occasion was one of much enjoyment and good fellowship.

H. C.

The editor of the Newburyport Herald says, that "Mr Colman, a tutor of the N. E. Farmer, has recently been on a tour through Maine, New Brunswick, Nova Scotia," &c. This will probably be news to Mr Colman as it was to us. He verily thought himself engaged in the agricultural survey, in the western part of this State and we believe he has been thus engaged since April last. The Herald has been led into an innocent mistake which we should not perhaps notice, were it not that we do not wish Mr Colman to be made chargeable with more than his own sins. Mr Colman has generally given us a weekly communication, for our editorial page, which have of late been signed by the initials of his name; but the care and arrangement of the paper has fallen upon the senior proprietor, who to clear H. C. from the responsibility of any inaccuracy of language and style in his own communications has signed his own initials. The

article from which extracts were republished in the Herald was written by J. B., and it was he who took the tour through the places mentioned.

RURAL FESTIVALS.—The annual rural festival of the farmers in Hardwicke took place on the 4th inst. That of the farmers in Petersham is appointed for today.

ERRATA.—In Mr Buckminster's address, published in our last, the 4,000 hills of turnips planted with the machine in 55 minutes, should be 15,000.

The repetition of the substance of the section on pressure grounds was caused by sending one page to the press that was intended to be suppressed.

We have a number of communications on hand which are unavoidably postponed until next week.

BRIGHTON MARKET.—**Monday, Oct. 22, 1838.**
Reported for the New England Farmer.

At Market 2000 Beef Cattle, 900 Stores, 5400 Sheep, and 750 Swine.

Prices.—Beef Cattle.—We quote to conform to last week, viz: First quality, \$7 50. Second quality, \$6 75 a \$7 00. Third quality, \$5 75 a \$6 25.

Barrelling Cattle.—Mess, \$6 75. No. 1, \$5 75 a \$6 00.

Stores.—Yearlings, \$9 a \$14. Two Year Old, \$13 a \$23. Three Year Old, \$22 a \$38.

Sheep.—We quote lots at \$1 62, \$1 88, \$2 00, \$2 25, \$2 33, \$2 62, \$3 88, and \$3 25.

Swine.—Lots to peddle were sold at 6-1-2 for sows, and 7-1-2 for barrows. At retail, 7 a 8-1-2.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northernly exposure, week ending October 21.

FRUIT AND ORNAMENTAL TREES.

The subscribers will be happy to receive orders for *Fruit*, and *Ornamental Trees*, *Shrubs*, &c. We shall be enabled to furnish at Nursery Prices, and at short notice, Trees and Shrubs of every description, and hope to give satisfaction to all who may be disposed to favor us with their orders.
Oct. 22. JOSEPH BRECK & CO.

EASTERN POTATOES.

100 Barrels of first rate Eastern Potatoes, for sale by Oct. 24. JOSEPH BRECK & CO.

CHINESE MORUS MULTICAULIS, &c.

At the LINNÆAN GARDEN, Flushing, N. York, 100,000 splendid trees of the genuine Chinese Morus Multicaulis, for sale at moderate prices, and also cuttings of the same. None of the humbug kinds have been cultivated at this establishment.

It is a large supply of the Canton, Moretior Alpine, Dandlo, Expansa, Broussa, Asiatic, and cuttings in any quantity. Priced catalogues will be sent to every applicant, but a personal application will be found by far the most satisfactory, and purchasers can then see these superior trees.

Also, Fruit and Ornamental Trees, Plants and Seeds of every kind, and an immense stock of Bulbous Roots, just arrived from Holland. W. M. PRINCE & SON.
Oct. 24. 4w

RASPBERRY BUSHES.

For sale at the Charlestown Vineyard, fine plants of the following Raspberries, viz.

- Red Aotwerp,
- White do.
- Barnet,
- Franconian, and
- Mason's Seedling.

Orders left with JOSEPH BRECK & CO. will meet with prompt attention. THOMAS MASON.
Charlestown, Oct. 10, 1838.

DUTCH BULBS.

Just received at New York from Rotterdam, and will be open in a few days, our annual supply of splendid Dutch Bulbs, consisting of
Double Red, Yellow, Blue and White Hyacinths,
Single " " " " " "
Single and Double Tulips,
Crown Imperials, Double and Single, of sorts,
English, Spanish and Persian Iris,
Polyanthus Narcissus, of sorts,
Ranunculus,
Anepones,
Fritillarias,
Crocus, of sorts.
Boston, Oct. 16, 1838. JOSEPH BRECK & CO.

LAYING OUT GARDENS AND ORNAMENTAL PLANTATIONS.

E. SAYERS begs leave to inform his friends and the public in general that he will attend the laying out gardens and ornamental plantations, and hopes by strict attention to business to merit the approbation of those who may be pleased to employ him.
Orders left with J. Breck & Co. Agricultural Store, No. 52 North Market Street, will be punctually attended to.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders to any amount, which will be promptly attended to.
Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston.
Sept. 20. NAIUM WARD.

FOR SALE.

Five acres of good Salt Marsh, in Quincy, or (Squantum so called.)
Also, Four acres of Salt Marsh in Brighton.
Also, Several full blood animals, cows and calves. Apply to A. Greenwood, on the Welles Farm, Dorchester, near Dr Codman's meeting house.
Sept. 12, 1838.

FOR SALE.

A two years old Bull of the Cream pot breed; from Mr Jaquet's stock at Ten Hill Farm, Charlestown. Cows of the above breed make the most butter of any stock in this country. Inquire of the subscriber near the factories in Waltham. ISAAC PARKER.

NOTICE.

The subscriber offers for sale his real estate in Westford and Groton; consisting of his homestead, 35 acres, his farm, 117, one pasture, 17 acres, one do. 33 acres, one wood-lot, 13 acres, one do. 5 acres, and one do. 10 acres. For further particulars see his advertisement in the Lowell Journal, or inquire of the subscriber at his house, near the meeting houses and academy in Westford.
EPHRAIM ABBOTT.

FOR SALE.

The thorough bred Short Horned Durham Bull, Superior. Superior was raised in August, 1831. He was got by Frederick, and he by Wye Comet.
Dam, Yellow Ross, by Young Denton.
G. Dam, Arabella, (imported,) by North Star.
G. G. Dam Aurora, " " Comet.
G. G. G. Dam " " Henry.
G. G. G. G. Dam " " Danby.
The above pedigree may be found in the English Herd Book.

He is a roan and perfectly gentle and docile; and his stock, which may be seen at the farm of the subscriber, will testify to his value. Price, \$250. Apply to C. N. Ement, Esq. near Albany, N. Y., or to Wm. Augustus North, Mount Marie, Duane'sburgh, N. Y.
October 3, 1837. 4w

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dime, situated in Rochester, N. H., six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quarries of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to JOSEPH BRECK & CO., No. 51 and 52 North Market Street, Boston.
August 15, 1838.

FARM FOR SALE.

An excellent farm, near the centre of Framingham is offered for sale, on liberal terms. Inquire at this office.
Aug. 22, 1838. 3m

EMPLOYMENT WANTED.

A Gardener out of employment would be happy to attend to orders for budding or gardening of any description. Apply at the New England Farmer Office.

PEAR TREES FOR SALE.

At the Pomological Garden, Salem, Mass., a good collection of Standard Pear Trees, all of which have been proved. They comprise the choicest of the old and new varieties. Also 5,000 superior Buckthorn Plants for hedges.
Salem Oct. 8, 1838. ROBERT MANNING.

MISCELLANEOUS.

(From the New York Mirror.)

NEW ENGLAND.

New England! dear New England!
My birth-place proud and free;
A traitor's curse be on my head,
When I am false to thee!
While rolls the bright Connecticut,
In silver to the sea—
While old Wachuset rears its head,
I will remember thee!

By every recollection dear,
By friendship's hallowed tie,
By scenes engraven on the heart,
By love that cannot die—
And by the sweet—the farewell kiss
Of dearest Rosalie,
New England—dear New England!
I will remember thee!

I may not climb thy misty hills,
At purple eve or morn,
Nor bind among the laughing girls
The yellow sheaves of corn.
I may not tread the crags that bear,
The thunder of the sea,
But by the bright autumnal sky,
I will remember thee!

Though in the far and sunny south,
The eyes of love may shine,
And music at the revel charm,
And beauty pour the wine,
I will not listen to the harp,
Nor join the revelry,
But in the fountain plunge my cup,
And drink a health to thee!

And when from weary wanderings,
At length I hasten back,
How blithely will I tread again,
The old familiar track.
And if my Rosalie be true;
(And false she cannot be.)
New England! in thy mountain streams,
I'll drink again to thee!

THE NOBILITY OF LABOR.

BY ORVILLE DEWEY.

So material do I deem this policy—the true nobility of labor I mean, that I would dwell on it a moment longer, and in a larger view. Why, then, in the great scale of things is labor ordained for us? Easily, had it so pleased the Great Ordainer, might it have been dispensed with. The world itself might have been a mighty machinery for the production of all that man wants.

The motion of the globe upon its axis might have been going forward without man's aid, houses might have risen like an exhalation,

"With the sound
Of dulcet symphonies and voices sweet,
Built like a temple;"

gorgeous furniture might have been placed in them, and soft couches and luxurious banquets spread, by hands unseen; and man clothed with fabrics of nature's weaving, rather than imperial purple, might have been sent to disport himself in those Elysian palaces. "Fair scene!" I imagine you are saying; "Fortunate for us had it been the scene ordained for human life!" But where, then, tell me,

had been human energy, perseverance, patience, virtue, heroism?

Cut off with one blow from the world; and mankind had sunk to a crowd of Asiatic voluptuaries. No, it had not been fortunate. Better that the earth be given to man as a dark mass, whereupon to labor. Better that rude and unsightly materials be provided in the ore-bed and in the forest for him to fashion to splendor and beauty. Better, I say, not because of that splendor and beauty, but because the act creating them is better than the things themselves; because exertion is nobler than enjoyment; because the laborer is greater and more worthy of honor than the idler.

I call upon those whom I address to stand up for the nobility of labor. It is Heaven's great ordinance for human improvement. Let not that great ordinance be broken down.

What do I say? It is broken down; and it has been broken down—for ages. Let it then be built up again; here, if anywhere, on these shores of a new world—a new civilization. But how, I may be asked, is it broken down? Do not men toil, it may be said? They do indeed toil, but they too generally do it because they must.

Many submit to it, as, in some sort, a degrading necessity; and they desire nothing so much on earth as escape from it. They fulfil the great law of labor in the letter, but break it by spirit. To some field of labor, mental or manual, every idler should hasten as a chosen coveted field of improvement.

But so he is not impelled to do, under the teachings of our imperfect civilization. On the contrary, he sits down, folds his hands, and blesses himself in idleness. This way of thinking is the heritage of the absurd and unjust feudal system, under which serfs labored, and gentlemen spent their lives in fighting and feasting. It is time that this opprobrium of toil were done away.

Ashamed to toil art thou? Ashamed of thy dingy workshop and dusty labor-field; of thy hard hand, seared with service more honorable than that of war, of thy soiled and weather-stained garments, on which mother nature has embroidered, mist, sun and rain, fire and steam her own heraldic honors? Ashamed of those tokens and titles, and envious of the flaunting robes of imbecile idleness and vanity? It is treason to nature, it is impiety to Heaven; it is breaking heaven's great ordinance. Toil, I repeat, toil, either of the brain, of the heart or of the hand, is the only true manhood, the only true nobility!

LOT'S WIFE.—Mr Colman, in his Agricultural Address last week, illustrated the folly of modern fashionable female education, by an anecdote. A young man who had for a long while remained in that useless state, designated by "a half pair of scissors," at last seriously determined he would procure him a wife. He got the "refusal" of one who was beautiful and fashionably accomplished and took her upon trial to his home. Soon learned that she knew nothing either how to darn a stocking or boil a potato or roast a bit of beef, he returned her to her father's house, as having been weighed in the balance and found wanting. A suit was commenced by the good lady, but the husband alleged that she was not "up to the sample," and of course the obligation to retain the commodity was not binding. The jury inflicted a fine of a few dollars, but he would have given a

fortune rather than not to be liberated from such an irksome engagement. "As well might the farmer have the original Venus de Medicis placed in his kitchen," said the orator, "as some of the modern fashionable women. Indeed," continued he, "it would be much better to have Lot's Wife standing there, for she might answer one useful purpose—she might *salt his bacon!*"—*Northampton Courier.*

BWARE OF LOCO-FOCO MATCHES.—A boy was bringing into our room some parcels of these matches, when a bunch, wrapped in a paper, slipped from his hand, and fell on the carpet; the friction occasioned by the fall instantly ignited the bundle. We doubt not but many recent fires have been caused the accidental ignition of these phosphorated matches. Every house-keeper should see that these matches are securely kept in metal or earthen, and apart from all combustible materials. Another modern improvement—the portable furnace—we doubt not, has led to immense losses by fire.—*Cultivator.*

FRUIT AND ORNAMENTAL TREES, MULBERRY-TREES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honey-suckles; Peonies, Dahlias and other Herbaceous Flowering Plants.

100,000 MORUS MULTICAULIS are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussa and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. D. BRECK, Commission Store, No. 132 Water Street, New York, M. S. PEWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston.

August 1, 1838.

WILLIAM KENRICK.

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more as may be wanted, of the most approved kinds—consisting of the best selected varieties now in use, for cultivation, feeding worms, and making silk;—being acclimated to this country, and adapted to either warm or cold climates, affording a rare opportunity for companies or individuals to be supplied, from the most extensive collection of mulberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and orders left with Messrs. I. B. Colt, Secretary of the Connecticut Silk Manufacturing Company, Hartford; Alonzo Wakeman, at the office of the American Institute, No. 157 Broadway, N. Y.; Thomas Lloyd, Jr. No. 236 Filbert street, Philadelphia; Pa.; Luther L. Cox, Baltimore, Md.; B. Snider, & Co. Savannah, Ga.; Bliss Jenkins, & Co. Mobile, Ala.; James Lyman, St. Louis, Mo.; Case and Judd, Columbus, O.; G. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass.

Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Mulberry Plantations.

Apply at the office of
D. STEBBINS,
Northampton, Aug 22, 1838.

THE NEW ENGLAND FARMER

Is published every Wednesday Evening, at \$3 per annum payable at the end of the year—but those who pay within sixty days from the time of subscribing are entitled to a deduction of 50 cents.

AGRICULTURAL.

BRIDGEWATER CATTLE SHOW.

PREMIUMS AWARDED—OCT. 10, 1838.

Articles of the Dairy.

The committee on articles of the Dairy, have attended to that subject and submit the following report. Contrary to their expectations, owing to the severe drought of the past season, the quantity of butter and cheese presented, far exceeded that of former years.

The quality also, as well as the quantity would not suffer in comparison with any heretofore presented. The butter and cheese were generally and almost without exception, of a superior quality. Your committee regret that it was not within their province to have distributed something where there were so many deserving.

After the most careful examination, they recommend that the premiums offered by the society be given as follows:

Butter.

Mrs Bethiah Bates, Bridg'r,	1st prem.	\$5 00
Mrs Hannah Crooker, do	2d do	3 00
Mr Dyer Robinson Jr. do	3d do	2 00

Cheese.

Mrs Olive S. Pratt, Bridg'r,	1st prem.	\$6 00
Mr Philip Brewster, Hanson,	2d do	4 00
Mrs Lydia Thompson, Middleboro',	3d do	3 00

For the Committee,

HOLMES SPRAGUE.

Cocoons.

Oliver B. Gurney, Abington,	No. 1	\$6 00
Abraham S. Brooks, Scituate,	No. 2	5 00
Deborah Brooks, do	No. 3	4 00
Thomas Cushman, Bridg'r,	No. 4	2 00

Wrought Silk.

Elizabeth S. Brooks, S. Scituate,	12 1-2 oz.	
sewing silk,		1 56
Mary Briggs, Plympton,	3 3-4 oz. 9d pr. oz.	47

Fancy Articles.

Joseph Clark, Middleboro' 1 pair covered stools,	75
Miss Julia Ann Kingman do, 1 cricket,	50
Fanny D. Kingman, do, 1 do	75
Benj. Hathaway, Plymouth, lot of neck stocks	3 00
Lydia Kingman, Middleboro', 1 wrought muslin cape,	75
Abraham S. Washburn, Bridg'r, 1 do do	25
Deborah L. Hale, do 1 do do	50
Susan L. Revere, do 1 do do	75
Abraham A. Loring, Hingham, 1 do double do	1 50
Luce Whitman, E. Bridg'r 1 do do do	1 00
Deborah W. Thompson, Halifax, 1 lace cape,	25
Abraham Barker, Pembroke, 1 thread collar,	50
Abraham G. Jackson, Plymouth, 1 muslin do	25
" " do 1 do cape,	50
Anna Jacobs, Hanover, 1 do do	50
Annah W. Bassett, Bridg'r, 1 collar, muslin,	50
Luce Whitman, E. Bridg'r, 1 wrought lace cap,	1 00
Artha J. Allen, Pembroke, 1 thread cap,	50

Charity W. Washburn, Bridg'r, 1 linen cap,	25
Lucinda Keith, E. Bridg'r, 1 lamp mat,	50
Abigail Keith, do 1 do do	50
Sarah Hooker, Bridg'r 1 do do	25
Lois F. Dean, Middleboro', 1 pair do	50
Deborah P. Thompson, Halifax, 1 pair do	25
Baker & Lincoln, Hingham, lot of bell rope, fringe tassels, &c.	5 00
Susan L. Revere, Bridgewater, 1 pair wrought cuffs,	25
Matilda Peterson, Duxbury, 1 stool cover,	1 00
Elizabeth Bates, Bridg'r, 1 do do	75
Mrs Wilkes Wood, Middleboro', 1 pair do do	50
Hannah Backus, Middleboro', 12 yds wrought lace,	1 00
Louisa S. Jackson, Plymouth, 1 pair fancy cotton hose,	50
Mrs Nathl. Reed, Middleboro', 1 do do	75
Calvin Pettee, Middleboro', 1 11-straw bonnet,	2 00
Calvine B. Peckins, do 1 do do	1 00
Mrs Wm P. Cutter, Bridg'r, 1 drawn brown silk do	2 00
Emeline Bassett, do 1 Dustable straw do	3 00
Phebe Bassett, do 1 do do	2 50
S. S. Lovell, do 1 do do	2 00
H. M. McLaughlin, E. Bridg'r, 1 fancy do do	1 00
Mary Hayward, Plympton, 1 lace scarf,	75
Mrs Albert Smith, N. Bridg'r, sample shell work	50
" " do 1 picture wro't artificial flowers,	1 00
Mrs Sabine, Bridg'r, 1 pair children's wro't shoes,	25
Geo. H. Brown, E. Bridg'r, samples of gold printing,	3 00
Emeline Bassett, Bridg'r, 1 thread reticule,	75
Mrs Hannah Boyd, do 1 wro't bead bag,	1 00
Sally Perkins, N. Bridg'r 1 do seed do	50
Mrs Diana Munro, Bridg'r, 1 child's frock,	2 00
E. M. Wilper do 1 sampler,	25
Sally Perkins, N. Bridg'r 1 bead chain,	75
All which is respectfully submitted,	
NAHUM STETSON, Chairman.	

Working Oxen.

Warren Hackett, 1st prem,	\$10 00
Martin Leonard, 2d,	8 00
Col. Abram Washburn, 3d do	6 00

Steers.

Thomas J. Howard, 1st prem.	\$6 00
Ebenezer Pratt, 2d do	4 00

Your committee likewise recommend awarding one volume New England Farmer to each of the following gentlemen, Benjamin Hobart, Philander Wood and Spencer Leonard.

WILLIAM DUNBAR, Chairman.

Ploughing.

The committee appointed on ploughing had fourteen teams entered for the competition. Thirteen appeared at the appointed hour and performed their service to the very great satisfaction of your committee. Your committee feel sorry that they are not better enabled to satisfy them for their services;

for certain it is, with so many competitors, and so few premiums offered, very few can receive large premiums. Your committee, after mature deliberation, have unanimously agreed on the following awards:

The first premium of ten dollars, they have awarded to Martin Leonard, 2d, of Bridg'r—Labor performed in 19 minutes.

The second premium of eight dollars they have awarded to James Howard, of W. Bridg'r—Labor performed in 18 minutes.

The third premium of five dollars they have awarded to Bela Mitchell, of Bridg'r—Labor performed in 19 minutes.

The fourth premium of three dollars they have awarded to Van R. Swift, of Bridg'r—Labor performed in 20 1-2 minutes.

They also award to Theron Ames, of N. Bridg'r, one volume of the Complete Farmer.

To Benj. Hobart, one volume of the Complete Farmer.

To Newton Mitchell, one volume of do.

To Philander Wood, one volume of do.

All which is respectfully submitted.

ABRAM WASHBURN, 2d, Chairman.

Inventions.

Your committee on inventions have attended to the duty assigned them and beg leave to make the following report, viz—

William Turner, Bridgewater, for a pair of improved boot clamps,	\$1 00
Calvin Washburn, Bridgewater, velocipede,	1 00
Do do model common carriage,	50
Do do improved panel door,	50
Asaph Holmes, Kingston, drilling machine,	1 00
Col. Samuel Leonard, Bridgewater, spark extinguisher for locomotives,	3 00
Hathaway & Tucker, Bridg'r, horse power and thrashing machine,	2 00
George C. Elliot, East Bridgewater, highly finished carryall,	5 00

Your committee are aware that they have awarded small sums for some articles of inventions and improvements exhibited, still we endeavor to do justice to ourselves and the society.

We flatter ourselves that we have awarded sufficient sums to encourage further improvement.

SOLOMON HAYWARD, Chairman.

Stock.

The committee on stock have attended the duties assigned them, and make the following report, viz;

The pens have been filled with fine cattle of every description although our mowing fields and pastures wore a gloomy aspect for a part of the past season, but their appearances have changed and a smile is seen on the countenances of our farmers and they have presented fat oxen, fine milch cows, and other young thrifty and fine stock.

And we award to our farmers the following premiums offered by the society, viz:

West Bridgewater, best fat ox,	1st prem, \$10 00
Joshua Bates, Bridg'r 2d do	2d do 8 00

Van R. Swift, Bridg'r	3d fat ox	3d prem.	6 00
Joshua Bates, do	4th do	4th do	4 00
Dyer Robinson, do	best milch cow	1st prem.	10 00
Seth Pratt, do	2d	2d do	6 00
Zenas Crooker, do	3d	3d do	4 00
Gad Robinson, do	best heifer,	1st do	5 00
David Snow, do	2d	2d do	3 00
Abm Washburn, 2d,	do best bull,	1st do	4 00
Salmon Keith, do	2d	2d do	2 00
Alb. Reed, 2d, Abington,	best do calf,	1st do	3 00
Horatio Keith, Bridg'r,	2d	2d do	2 00
Paul Revere, do	best heifer calf,	1st do	3 00
Joseph Copeland, do	2d	2d do	2 00

D. OLDHAM, Chairman.

Improvements.

In this county there are extensive tracts of waste land. The growth of useful herbage or wood has in most cases been obstructed by redundant water. Some expensive operations are necessary in the renovation of these lands. But when the work is once accomplished, we acquire some of the most productive and enduring fields under our cultivation. Waste lands early employed the attention of the Trustees of this Society; various projects in different periods have been formed to induce our farmers to lessen the borders of barrenness. Sometimes prospective premiums have been offered for the renovation of the greatest quantity of waste land in a given number of years; sometimes annual premiums for the best crops produced on reclaimed lands. Something of embarrassment and difficulty attended the award of those premiums, from the vague statements of claimants and the consequent uncertainty in the minds of the Trustees concerning the original state of the land, and the amount of labor that had been performed. With the purpose of avoiding such difficulties, premiums were this year offered for the greatest efforts in reducing waste land in a single season to a condition to receive the seed of useful plants. It was required of claimants to make entries early enough for the committee to view the land before their operations commenced. One entry only was made. A member of your committee viewed the land, which presented many formidable enemies to the health and growth of useful plants. The owner seemed then to have a stout heart, an unsuspecting confidence, of conquest; but from some cause has entirely failed, and the enemies to a useful vegetation are now standing there with countenances of apparent triumph and defiance. Your committee perceive nothing in the terms of these offers demanding alteration, we recommend the continuance of them and hope future claimants will not suffer their promises to exceed performances.

For the cultivation of mulberry trees, (Morus Multicaulis,) we award the first premium of \$10 to Dr Lemuel W. Briggs, Jr. of Middleborough. The second premium of \$5 to Mr Franklin Ames, of West Bridgewater. Dr Briggs exhibited eleven hundred and thirty trees raised from cuttings. Mr Ames three hundred and seventy-nine chiefly from cuttings. Dr Briggs has a large nursery of white mulberry trees planted in 1837; these come not within the offers of the present year, but in consideration of the exertions he has made, we recommend a gratuity of three volumes of the N. E. Farmer.

White mulberry trees seem to be falling into neglect in the county. It is supposed, we think erroneously, that these trees cannot endure the severity of our winters. The supposition is proba-

bly founded on the failure of experiments injudiciously conducted.

Nurseries, we believe, have often been sowed in much richer soils than those into which the trees were afterwards transplanted. This is contrary to all approved rules of nursery men. Forcing the growth of young trees, it is easy to perceive increases the danger of their destruction by frost. Experimenters should not be governed implicitly by the language of seed venders, which may quite as often be dictated by personal interest as practical knowledge. They should proceed cautiously and make theories for themselves in the progress. Where full grown trees are desired we at present think this variety preferable to any other; the Morus Multicaulis we consider very important for annual propagation and use.

A few years since there was something of excitement on the subject of raising mulberry trees. Many extensive nurseries were planted from which few results are now visible. The excitement has in a great measure ceased, and we fear, as often happens, that things are left in a worse state than before. It is now manifestly difficult to induce efforts. We have this year offered liberal premiums for preparations for nurseries; none of which are claimed.

In past years premiums have been offered for building the greatest quantities of good stone wall. This year it was judged expedient to encourage no competitions on the subject, but give reward to every man who should build one hundred rods and an increased sum for every additional hundred rods. Some members of the board while they approved the principle of this arrangement fear the consequence would be too great a drain on the treasury.

No inconvenience of this kind is realized the present year. We propose to give some reward to four persons for building wall and yet not pay quite as much money as we used to appropriate to the object in two premiums. Mr Dion Bryant of Bridgewater, is entitled to \$21,90 having built 207 1-2 rods of wall. The actual improvement in this case is not confined to the erection of so much substantial fence; some beautiful fields are cleared of the obstacles to an easy cultivation, where the sons of sons may labor with pleasure to the latest generation.

Paul Hathaway, Esq. of Middleborough, is entitled to \$9 having laid one hundred rods. Mr H. has made important improvements in fields by the removal of rocks; but the pressure of his business probably, occasioned his dropping into stone holes some too valuable materials for such a purpose. Compost manure will not produce much immediate effect when deposited two or three feet below the surface.

Mr Ebenezer Shaw of Middleborough, has built an hundred rods of wall and is entitled to \$9. Mr S. has recently engaged in the business of cultivation, is laboring on what farmers call hard land; a good beginning is made. Mr S. seems to possess all the innocent zeal of a new proselyte; perseverance will give success.

Capt. Solomon Howard of West Bridgewater, is entitled to \$9, having built 116 rods. Mr H.'s wall appeared to be a sufficient security against the inroads of cattle. It is good fence, but in a part of it there is more of zigzag than the eyes of the committee could follow with much pleasure. There might have been reasons for short turns not manifest to us, strong reasons, however, are necessary to justify them.

We were first among agricultural societies in offering premiums for stone wall, we may yet be standing alone in the thing; if we be, there is no occasion for us to blush in the position. The money we have paid has been returned to the community in more than two fold proportion. The subject is growing every year more important, we would bestow due attention, not shrinking from singularity when sure that we are useful.

We have the satisfaction of reporting an increased attention to the business of composting manure, the great instrument in the farmer's success and wealth. The committee are sometimes charged with admitting substances of little efficacy into the composition of manure. There is truth in these charges, but we suppose no just censure. We act in the belief that anything, whether animal or vegetable substances, can be mixed with soils in cultivation in a manner to increase the growth of plants. The same result can also be attained in the judicious mixture of different soils. We do not regard it so much our province in the discharge of this duty to determine what constitutes the richest compost manure, as we do to ascertain the comparative value of what has been made among the competitors. We would encourage renewed zeal in good works by awards in justice and liberality. We award the five premiums for compost manure, to the persons whose names follow. The first to Capt. Salmon Howard of West Bridgewater second to Benjamin Hobart, Esq. Abington; third to Paul Hathaway, Esq., Middleborough; fourth to Mr Nahm Snell, W. Bridgewater, and the fifth to Rev Freeman P. Howland, of Hanson. We also recommend the addition of one volume of the N. E. Farmer to each of these premiums.

We recommend that a gratuity of eight dollars be given Mr Chelsias Howard of Hanson, for his exertions in composting manure. The largest number of loads made by any competitor this year is 798, and the smallest about 350. Mr Hobar used lime to some extent, and Mr Howard made a considerable quantity of ashes with swamp turf but the other competitors have performed little more than to collect and mix materials found on their own farms. We believe almost any farm can be made productive in the employment of such means. Not to the extent of some more expensive applications, yet as productive as a prudent and wise policy would in many cases justify. Farmers situated at a distance from any considerable market town, would not be ultimately successful, they should engage extensively in the purchase of the richest manures, which must be conveyed to their farms from a distance of twenty or forty miles. Nor should we recommend immediate extensive engagement in all the operations discovered in science to accelerate the efficacy of substance, which we apply to enrich fields. The time has not come, it may never, when in this country we can profitably adopt the process and improvement no doubt it may in some places be justly called, o M. Jauffret in producing the fermentation and digestion of vegetables in casks to fertilize our fields. Prudence will not lead us to great market places in pursuit of the bones of cattle, the most effective among manures; it will rather lead to the exercise of living bones in the collection of things located near us, which though not immediately so effective will in the issue prove far more profitable. Field liberally dressed with pulverized bones, the French man's Poudrette, or the Spaniard's favorite Guano may for a time look far more fruitful than those

ressed with less active manures, still deep digging is the most certain road to agricultural success. And here, sir, we ask permission to remark that the lessons given us by those who are investigating and analyzing the substances that compose our earth, showing as far as the progress of science extends the natural influence of them on plants, are received by some aspirants to agricultural knowledge with most extravagant and absurd expectations. When the chemist directs attention to an article which he believes forms the chief food of plants, then all their thoughts and exertions concentrate in a single point about which, like former honey diggers they think there is magic, and if the instrument be once pointed in right direction the treasure is forever secure without much additional labor. Science will never fulfil any such expectation, it would prove our curse if it should. The developments of science may greatly assist and animate us in agricultural pursuits; but the man who believes he is qualified by discoveries made to define accurately all that enters into the nourishment of plants or stimulates their appetites ought to be regarded as having embraced only a moonshine theory. If scientific men could tell us with certainty all that constitutes the food and stimulants of plants, if they could show the exact proportions which would contribute to their greatest vigor and perfection; then, why could not our physicians tell us the precise effect of every sort of food we take on the animal system, and direct to such apportionment of it that we might live even beyond the age of ancient patriarchs? The physician's skill or the lessons we take from him, could never secure our health without observation and the exercise of care and prudence on our part. We can never become good practical farmers merely by taking lessons from the philosopher and chemist, these lessons are a good foundation on which to build a theory, but to the purposes of practical success, it cannot be established without continued observation, inquiry and reflection.

MORRILL ALLEN, *Chairman.*

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Oct. 20, 1838.

From S. Walker, Esq., Swan's Egg Pear (Cox o. 36.) We believe this to be the true Swan's egg of the English Gardens, and entirely distinct on the Egg Pear of Duhamel.

From Mr John M. Ives, Salem, Capiaumont Pear from a tree planted out this spring, handsome and good.

From Mr E. M. Richards, Dedham, Orange and ear Shaped Quinces; also fine Peaches, name unknown, from a tree imported from France.

From R. Manning, Salem, Fourcroy, Figs of Apples and Minot Pears, Drap d'or Apples (Cox o. 20.) also a specimen of Seedling Apples, from garden in South Salem, beautiful and good.

From Hon. Judge Heard, Forelle, Beurre Diel, and St Michaels Pears. The specimen of the Forelle was large and handsome, and it may yet in this country attain the high reputation it has acquired in Germany of a first rate fruit.

From E. Vose, Esq., a very fine specimen of Duchess de Angouleme Pear, weighing eighteen ounces.

From William Oliver, Esq., a Green Flesh Winter Melon, taken from a vine in Granada, 64 days old, and represented to keep in good condition

till March; the flavor was found to be very delicious, equal to the best of our Summer Melons.

Also specimens of Grapes from an unknown source.

For the Committee,
ROBERT MANNING.

VEGETABLES.

Saturday, Oct. 27, 1838.

Dr J. C. Howard, Woodlands, Brookline, presented some fine specimens of Brillie's White Giant, and Salmon colored Celery. These specimens were decidedly the best we have seen the present season. For the Committee,

S. WALKER.

CULTURE OF BULBOUS FLOWER ROOTS,

HYACINTHS, TULIPS, NARCISSUS, ETC.

The proper soil for bulbs, in general, is a light rich soil, mixed with a considerable portion of fine sea sand; and the compost generally used, is one third fine sand, one sixth rich loam, one third cow dung, and one sixth leaves of trees. The two last to be well rotted, and at least two years old; with this mixture, the beds are formed two feet deep, at least, and raised four or six inches above the level of the garden, to turn off rain. The proper time of planting in beds, is in the months of October and November, though it may answer by the first of December—provided the ground remains sufficiently open.

HYACINTHS

May be set six inches apart from each other, and each bulb placed in fine sea sand and covered with it four inches deep. After the bed is thus planted, cover the whole carefully with earth four inches. When the winter is fairly set in, (say from the 1st to the 10th of December,) then cover with leaves, straw, or sea-weed, four or six inches deep, which should be removed early in the spring; a part of it, perhaps as early as the 20th of February, and the remainder during March. *With too much protection, the bulbs draw up weak and pale, and are materially injured.* During their bloom, it will be proper to support the bells by small sticks, and protect them from heavy rains and the sun. The flower stems should be cut off as soon as they have faded, and the beds left exposed until the leaves are nearly dried, when the bulbs should be taken up, the leaves cut off half an inch from the top of the bulbs, and then replaced (sideways) with the fibres on, and covered with earth, there to dry gradually for a month; when they are to be taken up, cleaned from the earth and fibres, and each bulb wrapped in a separate paper in a dry place, and frequently aired, or to be packed in dry sand.

When wanted for the parlor, they should be planted in September, (if to blow early in the winter) in deep narrow pots, six inches in diameter at the top, and about one third deeper than common flower pots. The soil the same as before mentioned, and the bulb to be just covered by it. They should not be watered from the top, but the pots should stand, twice a week, in saucers filled with water. Let them have as much air and sun as possible, and not suffer them to feel the direct influence of the fire—for heat forces the stem out before the bells have time to form and acquire vigor and beauty. When the flowers begin to open, give as much water as the earth will imbibes.

To preserve these bulbs, they should, as soon as the bloom is over, be turned out of the pot with

fibres and earth, and put in a prepared bed in the garden, to be treated afterwards as those growing in open ground. By this mode the bulbs will not be materially injured, and will blow well the second year. Whereas those grown on glasses or forced, are seldom good for anything afterwards.

SINGLE HYACINTHS are preferable to most double ones for early flowering in winter; being two or three weeks sooner in bloom. Their colors are more brilliant, and the bells more numerous than the double.

TULIPS are hardier than the hyacinth, and in open ground may be planted four inches apart, covered two or three inches with earth.

THE POLYANTHUS NARCISSUS should be planted six inches deep, and eight inches apart, and carefully protected from frost, being the most tender of the bulbs. Unless taken up after bloom, it will grow in the autumn and suffer during winter.

Depth and distances.—Hyacinths, amaryllis, mar-tagon, and other lilies, and peonies, should be planted at the depth of four inches; crown imperial, and polyanthus narcissus, five inches; tulips, double narcissus, jonquilles, colchicums and snow-flakes, three inches; bulbous irises, crocuses, arums, small fritellarias, tiger flowers, gladiolus, and snow-drops, two inches; ranunculuses, anemones, oxalis, and dog's-tooth violets, one inch; always measuring from the top of the bulbs. The rows should be about ten inches apart, and the roots be placed from four to six inches apart, in the rows, according to their size.

Method to bloom Hyacinths and other bulbs in the winter season, in pots or glasses.—For this purpose, single hyacinths, and such as are designated earliest among the double, are to be preferred. Single hyacinths are generally held in less estimation than double ones; their colors, however, are more vivid, and their bells, though smaller, are more numerous. Some of the finer sorts are exquisitely beautiful; they are preferable for flowering in winter to most of the double ones, as they bloom two or three weeks earlier, and are very sweet scented. Roman narcissus, double jonquilles, polyanthus narcissus, double narcissus, and crocuses, also make a fine appearance in the parlor during the winter. It is a remarkable circumstance of the crocus, that it keeps its petals expanded during a tolerable bright candle or lamp light, in the same way as it does during the light of the sun. If the candle be removed, the crocuses close their petals, as they do in the garden when a cloud obscures the sun; and when the artificial light is restored, they open again, as they do with the return of the direct solar rays.

Hyacinths intended for glasses should be placed in them about the middle of November, the glasses being previously filled with pure water, so that the bottom of the bulb may just touch the water; then place them for the first ten days in a dark room, to promote the shooting of the roots, after which expose them to the light and sun as much as possible. They will blow, however, without any sun; but the colors of the flowers will be inferior. The water should be changed as it becomes impure; draw the roots entirely out of the glasses, rinse off the fibres in clean water, and the glasses well washed inside; care should be taken not to suffer the water to freeze, as it not only bursts the glasses, but often causes the fibres to decay. Whether the water be hard or soft is of no great consequence; but soft or rain water is considered preferable, but it must be perfectly clear. Forced bulbs are seldom good for anything afterwards.

SICKNESS IN THE WEST.

The editor of the Bangor Whig, now travelling in the West, writes—

I cannot say I am so well pleased with what I have seen in the western country as I anticipated, but I am but ill qualified to judge as yet. One thing is certain, this part of the country, if it ever arrives at the greatness predicted, must do so through the deprivations and sufferings of the present generation. The present settlers are working hard for posterity—will posterity reward them? The common comforts and conveniences of life are given up,—people merely stay, dragging out an existence; toiling and sweating for the improvement of a country which it will take years to bring to a state of civilization, if one may so term it. The cities of the west are comfortable compared to the interior settlements, but even those are at present miserable places for men to live in, but yet they are inhabited. Chicago, for instance, on Lake Michigan, is below the level of the water in some places, and no where above it. No cellars can be dug because of water. Here lurk bilious and intermittent fevers and agues.

The past summer, throughout the whole country, as you are aware, has been remarkable for its intense heat, and great drought—through the west this has been the case in a most extraordinary degree. The consequences are now being experienced, and they are indeed awful. A wide spread pestilence extending from the Ohio to the Far West, is sweeping many to their graves, and causing an immensity of suffering. Places have been deserted, and the cattle turned in the unreaped fields. Whole towns have been sick—six or eight patients to a family—none have escaped, far and near this disease has stricken the weak and the strong. It is a bilious fever, not very fatal it is true, but exceedingly distressing. I have scarcely seen a good looking countenance since I left Detroit. This fever is natural to this new country, and always prevails during the latter part of the summer in some places, and to some degree, but it has never before made the sick tremble, and the well man turn pale. The fever will undoubtedly stop as soon as cold weather approaches.

WHAT HAVE THE STATES SEVERALLY DONE TO ENCOURAGE AGRICULTURE?

"Grains of sand the mountains make."

Maine, with a population less than 400,000, last year gave \$76,000 to her citizens engaged in agriculture, out of her public treasury, as a bounty on wheat.

A bill was recently introduced into the Legislature of New York, appropriating \$20,000 for the promotion of agriculture and the household arts. This bill proposes a premium of \$500 for the discovery of an efficient remedy for the grain worm, an insect now doing much damage to the wheat crops in the north-eastern states—the formation of a museum containing complete sets of mineralogical and geological specimens—premiums for improved agricultural implements, and superior crops—and last, though not least, it authorizes the State Board of Agriculture, which it creates, to procure as many copies of the "Cultivator" and "Monthly Genesee Farmer," as there are common school districts in the State, and furnish one copy of each to each school district, to be used as occasional class books.

Indiana has established a scientific and agricultural college.

Georgia passed an act at the last session of her Legislature, to "Incorporate the Board of Agriculture and Rural Economy, of the State of Georgia."

Massachusetts has undertaken an agricultural survey of the State; and a proposition was recently submitted to her Legislature, to give a bounty on wheat.* This State has given a bounty on silk produced by her citizens.

The Legislature of Maryland, a few weeks since, had a proposition before it to establish a *pattern farm* and agricultural schools.

Kentucky is organizing a state board of agriculture, or state society.

The Legislature of Michigan lately had the subject of establishing state and county agricultural societies before it.

Maine gives a bounty of 5 cents on each pound of cocoons raised in the state, and 50 cents for each pound of silk reeled in the State

Connecticut gives a bounty of \$1 for each 100 mulberry trees of five years growth, and 50 cents on each pound of reeled silk, the growth of the State.

Vermont gives a bounty on silk, of 10 cents on each pound grown in the State.

Pennsylvania gives a bounty of 20 cents on each pound of cocoons, and 50 cents on each pound of reeled silk, the growth of the State.

The Congress of the United States propose to give the President the power to lease any unappropriated lots in the District of Columbia, for the term of ten years, for the encouragement of the cultivation of the sugar beet, and the production of silk.

Should this policy be carried out by each State, our citizens will not long continue to eat foreign bread, and our country will regain her usual prosperity. This is our remedy for the *pressure—encouragement production.*—*Journal of Productive Industry.*

For the New England Farmer.

ROHAN POTATO.

Ma BRECK,—

Dear Sir,—I intended to have written to you some weeks since respecting my *rohan potato*, but have been waiting to gather the crop first, that I might state more confidently as to quantity and quality. The very dry hot summer will greatly curtail the quantity; they have been growing finely however, since the first of Sept. up to the 7th of this month, when the frost killed the vines. They now bid fair to produce a middling crop and of very fine quality. I have not yet dug them up. I was taught at the expense of one fourth of my small crop last year, that to prevent their loss in weight and to develop their fine farinaceous properties, they must be left in the ground as long as the season will permit. The frost kept off a week or two later than usual; with us, which has proved very favorable to our late crops. This potato has fully proved its hardness and capacity to resist the effects of our hot summers and usual droughts, much better than six other varieties which I cultivated this season. Their extraordinary productiveness is now sufficiently established; but the unfavorable impression that has been given the public respecting their quality as a table potato, is still prevalent,

* This proposition was not only submitted, but was accepted, and a law passed accordingly.—*Courier.*

and their scarcity and high price as yet, have prevented their merits in this respect being fully tested, by comparison with our other fine varieties. I have now cultivated them for the last three seasons and an perfectly confident they will fully sustain the character given of them by Prince Rohan, in every respect.

I should be much pleased to hear the result of any experiments in the cultivation of this potato in your part of the country. I have not learned as yet the result of any field culture of this potato for this season; a few experiments in garden soil and cultivation, (which to be sure, is not a fair test of their field produce on a larger scale,) have been sufficiently satisfactory. Two gentlemen of this neighborhood have produced the one from 1-2 lbs. planted the 10th day of May, in fine garden soil, was taken up the 9th of this month, and weighed 9 1/2 lbs. The other gentleman produced from 1 lb. dug up some days since, and weighed 93 1/2 lbs. I can give no accurate account of my own production of them, having planted them in five different locations and different soils, at different dates of planting; the soil nothing more than middling good soil, sward ground, and some part of it moderately manured, planted in rows 4 feet one way and 2 feet apart in the row, and ploughed but one way,—I believe I should have succeeded better to have planted 4 feet apart each way, and cross ploughed. Yours, respectfully,

JOHN A. THOMPSON.

Catskill, N. Y., Oct. 16, 1838.

ROHAN POTATO.—At the meeting of the Hampshire, Hampden and Franklin Agricultural Society the last year, the presiding officer of the Society the Hon. Wm. Clark, Jr. was presented by the Commissioner of Agricultural Survey with a Rohan potato. From that potato Mr Clark raised a great amount, and sent a bushel to the meeting house for distribution after the address. Mr C. C. Nichols formerly of Boston, but now of Northampton, and occupied in cultivating a small farm in this beautiful town with excellent judgment and success, from three pecks of this potato obtained eighteen bushels of a large size.

Mr Roswell Hubbard of Hadley, from the planting last spring of four pounds of the Rohan potato, obtained 1173 lbs.—that is 293 for 1. This potato will prove a most valuable gift to the country. The great fear is that our farmers with their negligent habits in this matter will soon suffer them to become mixed and degenerated.

It has been supposed they were not valuable for the table. Some of which we ate yesterday were excellent. They did not quite equal a pink eye or a foxite raised on a mountain soil; but they were among the fine third in the scale of excellence and when placed in the most favorable locations may be expected to be greatly improved in quality.

II. C.

We receive daily the most flattering accounts of the produce of the Rohan potato, and think it will prove a valuable acquisition. The Hon. Enos Sibley of Bradford informed us a few days since that from four pounds purchased of us last spring consisting of nine potatoes, he has dug enough to fill a lime cask heaping full. We suppose they will weigh at least 240 lbs., which is 60 for one planted, and this without any extra care, and when the potato crop is, generally, almost a failure.

J. B.

For the New England Farmer.

ON WHEAT.

Norfolk, Ct., Oct. 15, 1838.

MESSRS J. BRECK & Co.—

SIRS,—In your New England Farmer of 10th inst. I have read a communication signed "J. B." giving a glowing description of the farm of Mr B. V. French, of Braintree. My object in this notice of it, is on account of that portion of it relating to his ill success in his *wheat crop*, (which would rather lead the public to believe *our soil* or climate was not congenial to its culture,) you state that he gave a liberal supply of *lime and other manure*, and that having given a liberal allowance of 22 lbs. clover seed per acre on the *same land*, he had a great crop of that grass. Now my good sir, is not this very thing telling us the cause of loss of his wheat crop? It must have been literally smothered, there being no possible chance for air to pass through; it must of course become blighted. And from your statement also of the land being made *very rich*, the wheat would be inclined to produce *much straw* in proportion to the head or grain.

I know many of our best farmers disapprove of sowing much clover seed on rich lands, as the soil becomes inclined to that grass—and indeed I have in my mind one highly qualified by practical as well as *book* knowledge who only recommends two or three pounds of clover seed per acre, with other seeds; my own rule has been eight pounds with half a bushel of timothy or herds grass seed.

It is well known to those who read English publications, that their course is to sow wheat alone, and in very many instances by *drill*, having the rows 3 to 6 inches apart, so as to give a free circulation of air through it while growing, to prevent its rust or blighting.

As I am a strong advocate for giving wheat a fair trial in our State, I wish all the light possible on its culture, may be elicited, and hope to see many statements in print of its *successful* cultivation—and also where and how it has *failed*—fully believing that a liberal use of *lime* is very necessary.

Yours, &c. P.

REMARKS.—If the failure of Mr French's wheat crop had been a solitary case, it might, perhaps, have been attributed to the clover; but it was not so; his neighbors generally, had the same ill success. We know of one gentleman in another town about five miles from Boston, who tried eight or ten different experiments in his wheat field of four or five acres. Part was sowed without grass seed, and some with, and different sections of the field were dressed with different sorts of compost and manure. The Siberian, Italian and Eastern spring wheat were all tried—but in every experiment there was a failure nearly or quite as bad as Mr French's. Of the different varieties of wheat sowed, the Eastern was decidedly the best. But to return to French's field; he has informed us since, that a small part only of his field was manured, at the time of sowing; the other part was in excellent order, having been well manured the year previous, and that he could not perceive any difference between the two different sections;—the ground was well limed. At the time the wheat blasted the clover had not made much progress, and we can hardly believe that it was the cause of the blight. We have made considerable enquiry respecting the wheat crop, and we are sorry to state that we have

not yet heard of a good crop near Boston, although the accounts from the interior are much more flattering; and we have seen within twenty or thirty miles, fields that were good. We have no doubt, but what wheat can be profitably cultivated throughout our State generally, and shall be glad to be acquainted, through the Farmer, of any facts which may have a tendency to throw light upon the subject of the prevention of blight, which has the present year disappointed the hopes of many.

Eight pounds of clover and one half bushel of herds grass we should suppose about equal to 22 lbs. of clover seed alone.

J. B.

(For the New England Farmer.)

POTATO BLOSSOMS.

MR BRECK,—I am aware you are acquainted that the potato is the most productive and useful vegetable in Nova Scotia;—the climate and soil of this province being extremely favorable to its cultivation, much more so than our sister provinces of New Brunswick and Prince Edward Island.

On the receipt of your valuable paper of 25th July last, containing an article on "Potato Blossoms," I was induced to try the experiment, whether plucking off the flower before any balls were formed, would increase, or diminish its productiveness. It may not be improper to preface my remarks, that for several years past, there has been a decrease in our seed, which has subjected the potato to the *dry rot*, and it has been recommended in the report made by the Agricultural Society lately formed here, and by the most skillful agriculturalists, that the most effectual remedy that can be adopted to eradicate it, "*is to pluck the potato whole*;" but as it is impossible to persuade every one to adhere to this principle, we shall, I fear, be still subject to it. The potato I selected for the experiment was the white kidney (early sort) grown from the apple by the late John Young, Esq., and of course planted *whole*. The following are the particulars and the result. I selected two rows in my field along side of each other, 30 feet long, each planted at the same time, the same manure, and the same seed—distance potato from potato 10 inches. When I received your paper, the blossoms had just opened. One row I plucked off the blossoms, and on the other I suffered the flower to exist. I dug them yesterday, and the product was as follows:

The row on which the blossoms remained produced 61 lbs. potatoes.

The row from which I plucked the blossoms, produced 71 lbs. potatoes, not so numerous as the former, but much *larger*, so that it appears the latter has yielded an increase of *one sixth*—and of better quality.

Like yourself, I do not pretend to understand the philosophy of it, but of the accuracy of the foregoing statement you may rely upon, but let us remember, that the laws of nature are not yet, nor ever will be thoroughly understood,—the common place opinion however here is, that by taking off the blossom, it throws the strength of the plant to the root, and they justify this opinion, by reference to the lopping off the branches of a young tree, which causes it to spread, and throw out more bush at the bottom.

If this experiment, made upon a small scale, yet applicable to a general principle, can elicit any useful information to the farmer I shall be much gratified. I am not without hope some of your

correspondents on your side of the water, have made the same trial, and I wait with much anxiety to learn, through the medium of your paper, the results in your climate. Yours, &c.

E. BROWN.

Halifax, N. Scotia, 11th Oct. 1838.

From the Con. Courant.

THE ROHAN POTATO.—On the 15th of April last, through the kindness of a friend, Alexander Thompson, Esq. of Catskill, the subscriber received a few small tubers of this variety of the potato, the average weight of which was a fraction less than five ounces each. I carefully divided twenty of them by cutting them into pieces so as to leave two sets or eyes, on each piece, amounting in the whole to 279 pieces, and weighing a little less than half an ounce each.

These I planted on the 27th of April in hills, four feet asunder, each way, placing one piece only in each hill.

On the 9th inst. the crop was gathered. The product as measured in a half bushel, I found to be twenty bushels and a half, being a fraction over a bushel to each tuber planted. The average weight of a few of the most productive hills was eight pounds ten ounces—the largest single tuber which I weighed, 2 lbs. 13 oz. During the past season the extremely hot weather and severity of the drought in this section of the county, have, in the opinion of the farmers in my neighborhood, lessened the potato crop from one third to one half, on the product in ordinary seasons. It is reasonable to suppose that the same causes have had a like operation upon the Rohan potato.

From the small *practical* acquaintance I have yet had with the cultivation of this variety, I feel a diffidence in expressing an opinion on the best mode of its cultivation. I will therefore only state briefly the method in which I proceeded in this small experiment. Long or baru-yard manure was spread upon the surface of the ground and turned in with the plough—furrows 10 or 12 inches deep—seed planted deep, covered with 4 inches of earth—in hoeing, very little accumulation of earth upon the hill.

On opening the hills I found the tubers thickly clustered together—occupying little if any more space than if placed in a half-bushel measure. This circumstance has induced me to believe that a space of three feet between the hills would be amply sufficient, and would secure as great a growth in each, as if planted four feet apart. I should also think it advisable to plant in each hill two pieces with two sets on each piece, placing them six inches apart from each other.

SAMUEL WOODRUFF.

Windsor, Oct. 13, 1838.

REAPING MACHINE.—There is exhibited at the New York Fair a mowing machine worked by horses, which cut and clips the grain like shears, and is really a most ingenious plan, and can mow ten or fifteen acres per day. It is the invention of William and Thomas Schuble, of Hagerstown, Maryland.

The proprietors of the Liverpool lines of packets will hereafter charge twentyfive cents for each letter sent by their ships, between New York and Liverpool.

**NEW ENGLAND FARMER,
AND GARDENER'S JOURNAL.**

BOSTON, WEDNESDAY, OCTOBER 31, 1838.

AGRICULTURAL SOCIETIES AND CATTLE SHOWS.

The cattle shows and exhibitions of manufactures in our State having closed for the season, we propose now to say a few words, of their utility, and the modes of managing them; and to suggest such measures as in our opinion would increase the advantages of our agricultural societies, and render their influence more effectual to agricultural enterprise and improvement.

We have not at hand the means of ascertaining with precision the dates in the case; but, as well as we can recollect, the first cattle show in the United States was held about twenty-four years since, under the spirited exertions of some intelligent gentlemen at Pittsfield, Mass., at the head of whom was Elkanah Watson, Esq., then of that town. The Berkshire Agricultural Society took the lead in the case, and a ploughing match was connected with their cattle show. This intelligent and highly enterprising society have continued their cattle show and exhibitions from that time to the present, with unabated zeal; and with beneficial effects of a decided and permanent character upon the agriculture of that district. Perhaps no better evidence of this can be given than in the fact, that the interest taken in this institution by the farmers of Berkshire universally was never stronger than at this time; and the exhibitions of the society, as we have been informed, were never more numerous attended nor better sustained than the current year.

The Massachusetts Agricultural Society, instituted as early as the year 1791, soon followed the lead of the Berkshire Society; and for more than twenty years, with the exception of three or four intermissions, held cattle shows and exhibitions of domestic manufactures at Brighton, open to the competition of farmers from every part of the commonwealth. Here too ploughing and drawing matches were held, which, by the liberality of their premiums, brought competitors oftentimes from a distance of fifty miles. These shows were held and managed under the direction and personal superintendence of gentlemen of the highest standing in professional and political life; and went off with spirit and effect.

These movements were soon followed by the formation of county societies in the several counties of Essex, Worcester, Middlesex, Hampshire, Hampden, and Franklin, and Bristol and Plymouth. These societies were encouraged by liberal grants from the Legislature, giving to every agricultural society, formed in a county containing not less than 25,000 inhabitants, for every thousand dollars, which they should raise and permanently invest for the benefit of that society, the interest of which should be yearly appropriated to purposes of agricultural improvement, the annual sum of two hundred dollars, to be applied in premiums under the direction of the Trustees of the society; provided however, that in no case should any society receive annually more than six hundred dollars. Under these provisions a sum of upwards of four thousand dollars has been yearly given by the State to these different societies to be disbursed in agricultural premiums. This being added to the amount furnished by their own funds had formed a considerable aggregate: the sums actually offered by the Mass. Agricultural Society in premiums the current year exceeding in amount twelve hundred dollars. These county societies are now all of them in the practice of holding cattle shows and exhibitions in their respective counties. We have had the pleasure of attending as many of these as

was practicable. As far as our observation extends, the bounty of the State could not have been applied to a more worthy object, nor with more success as concerns the public wealth, and the general improvement. The agricultural improvements in the State within the last twenty-five years have been immense. The plough itself has become a new instrument, in form, in lightness of draft, in ease in handling, in ease of repairs, in the execution of its work, and in the neatness of its construction. The potato hoe, the drill seed sower, the seed harrow, the cultivator, the roller, the cradle, the horse rake, the corn planter, the threshing machine, the double-mould board plough, the side hill plough, owe their origin and general diffusion to agricultural societies and agricultural publications. The introduction of new seeds, of most valuable fruits, of excellent esculent vegetables, of improved varieties of Indian corn, wheat, barley, and oats, this likewise is to be attributed in a great measure to the same source. The introduction likewise and diffusion of improved breeds of live stock, of the fine-wooled sheep, the long-wooled sheep, the mutton breeds, the several improved varieties of swine, the beef and dairy stock, the Devon, the Holderness, the Alderney, the Ayrshire, the Improved Durham Short Horns, and of horses of an improved kind for the saddle and for draft, are all more or less to be ascribed to the spirit of public enterprise and improvement awakened and kept alive by these agricultural societies, exhibitions, and publications. It is indeed impossible to estimate by any exact measure what has been effected in the short space of a quarter of a century; but it meets the observing and experienced eye everywhere in the improved and well furnished houses, ornamental fences and embellishments, smooth and well-cultivated fields, commodious barns, substantial wagons and carriages, which are to be found every where in profusion among our agricultural population. It is important to keep this spirit of enterprise and public improvement awake and active; to press the steam to the utmost limits of safety; "to speed the plough;" and to relax no efforts to advance the cause of agricultural improvement; to diffuse agricultural intelligence; to raise the character and the profession of the farmer; and thus to extend the power and means, and quicken the spirit and enterprise by which the treasures of the earth shall be developed, the fund of human subsistence become constantly enlarged; and the comforts and reasonable luxuries of life diffused among all without stint.

The agricultural societies hold the power of doing immense good; and, as the gentlemen who have the direction of the funds of these societies have no private views to answer, but are laboring in the most disinterested manner, solely for the public good, we know them too well to fear giving offence by any suggestions, which have no other object than the public good; and which will not be submitted without a perfect respect for their public spirit and superior judgment.

We have the highest opinion of the utility of cattle shows, ploughing matches and the exhibition of agricultural products and household manufactures. They excite an emulation, which engenders no bitterness of feeling, and which prompts to the most spirited improvements. They gratify a laudable ambition to exhibit to others, what we have accomplished. They extend the knowledge of what has been done far beyond what it could be by any other means. They are the only opportunities which many farmers enjoy of seeing samples of the improved stock in the country; and of comparing it with what they have themselves. They bring farmers together to interchange friendly sympathies, and to communicate their mutual experiences. They bring men of different professions and conditions together, the professional, the

literary, the commercial, the manufacturing and the agricultural on common ground, and where no jarings of religious or political party ought to intermingle; where those, who labor with the head are made to feel their dependence on those, who labor with the hand; and those who labor with the hands recognize their obligations to science, to commerce, and to the mechanic arts, and find their own profession exalted and their self-respect increased by this unstrained and mutual intercourse. These cattle shows have been the means of inducing the importation of all the valuable animals, which have been brought into our State through the liberality of gentlemen of large capital and large minds, in order to improve the stock of domestic animals in our own State. Especially, they keep the great subject of agriculture before the public mind in the light of its intrinsic, permanent, and universal importance. The well-known custom of the Emperor of China at the return of every spring, to show his respect for the cultivators of the earth and thus honoring their great art by holding the plough himself in the presence of the dignitaries of the realm and of assembled thousands of his subjects, is well known. Its favorable influence upon the agricultural classes may easily be inferred; and our cattle shows, bringing together as they do gentlemen of all professions, have the same beneficial effects.

It has been therefore to us matter of much regret that the Massachusetts Society has now for two or three years suspended its annual and accustomed show at Brighton. We know that it is attended with great labor to the gentlemen of the Board of Trustees, to get up and superintend a matter so foreign to their accustomed pursuits and habits; perhaps it is a labor we ought not to ask of them; but we believe that sixty or a hundred dollars would furnish them three or five practical men, who would gladly take all the drudgery of the management off their hands and get it up and carry it through in a manner honorable to the board and entirely satisfactory to the public. We know the labor is considerable, and in such case ought to be compensated; and we do not know how some portion of their funds could be more properly applied.

H. C.

**MASSACHUSETTS AGRICULTURAL SOCIETY
PREMIUMS.**

It is matter of just surprise that the magnificent premiums offered by this society for the advancement of agriculture should excite so little attention, and be so little known throughout the State. They offer the present year in four premiums for the best cultivated farms in the Commonwealth, the large amount of six hundred dollars; and yet we think we may safely say that nine tenths of the farmers in the State have never heard of it. This must in some measure be their own fault, perhaps, in not taking an agricultural paper; for the prospectus of premiums offered was published at large we know in the New England Farmer, and we believe in other agricultural papers in the State; and copies of this prospectus were distributed among the members of the Legislature, and sent to every postmaster. The Agricultural Commissioner likewise, though having no agency whatever in the proceedings of the society, has distributed a great many in various parts of the State. Premiums are likewise offered, one of a hundred dollars, two of fifty dollars, and one of thirty for the best butter and cheese presented to the society by the first of December in Boston. The samples of cheese and butter for the highest premiums must amount to 300 lbs.—for the lower premiums 100 lbs. As we understand the proposals, competition for these dairy premiums is not limited to Massachusetts. The entries must be made with Benj. Guild, Esq., Boston; and auctioneers will be furnished for the sale of the produce offered whether successful or not in the competition for premiums. The butter and cheese presented on such occasions have always commanded high prices. The premiums are certainly sufficient to be an excess; and the competition it is to be hoped will be much more extended than heretofore.

BRIGHTON MARKET.—MONDAY, Oct. 29, 1838
Reported for the New England Farmer.

At Market 1650 Beef Cattle, 1100 Steers, 4700 Sheep, and 2550 Swine.

Prices.—Beef Cattle.—Our last week's quotations were fully sustained. We quote the same, viz: First quality, \$7 50. Second quality, \$6 75 a \$7 00. Third quality, \$5 75 a \$6 25.

Barrelling Cattle.—Mess, \$6 75. No. 1, \$5 75 a \$6 00.

Stores.—We continue our former quotations, viz: Yearlings, \$9 a \$14. Two Year Old, \$18 a \$28. Three Year Old, \$24 a \$38.

Sheep.—Dull and former prices hardly sustained. We quote Loo at \$1 54, \$1 88, \$1 92, \$2 12, \$2 37, \$2 75, \$3 00, and \$3 25.

Swine.—Lots to peddle were sold at 6-1-4 a 6-1-2 for sows and 7-1-4 a 7-1-2 for barrows. At retail, 7 a 8-1-2. A few hundred swine unsold.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded Northernly exposure, week ending October 25.

Saturday,	27	32	50	48 N.
Sunday,	28	34	52	40 N. E.

Tulips, Ranunculuses, Anemones, Auriculas, Carnations, Picotees, Pinks, and Geraniums.

II. GROOM, of Watworth, near Loudon, England, by appointment Florist in Her Majesty Queen Victoria, begs respectfully to call the attention of his friends and the admirers of flowers in America generally, to his extensive collection of the above flowers, which from his having been very successful in their cultivation this season he can offer at very moderate prices. He would particularly recommend to those persons about commencing the growth of the Tulip (which in England is becoming very fashionable) the under collection of bulbs, as it is by far the cheapest mode of purchasing them.

Tulips arranged in beds with their names.
First Class.
A bed of 30 rows containing 210 bulbs including several of the newest varieties, - - - - - £15
A bed of 15 rows, - - - - - £21
A bed of 60 rows, - - - - - 25 guineas
Second Class.
A bed of 30 rows including many fine sorts, - - - - - £10
A bed of 40 rows do - - - - - £14
A bed of 60 rows do - - - - - £17 10s
Tulips not arranged.
100 Superfine sorts, with their names from - - - - - £7 7s to £13
Superfine mixtures, from - - - - - 7s 6d to 21s
Ranunculuses.
100 Superfine sorts, with their names from £3 3s to £5 5s
Superfine mixtures, from - - - - - 5s to 21s per 100
Anemones.
100 Superfine sorts with their names, - - - - - £3 10s
Superfine double mixtures from - - - - - 10s 6d to 21s per 100
Auriculas.
25 Superfine sorts with their names, - - - - - £13 6d
Catalogues with the prices of the other articles may be had on application.
Orders received by
JOSEPH BRECK & CO.

JOSEPH BRECK & CO.
Boston, Oct. 16, 1838.

BONE MANURE.
The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders to any amount, which will be promptly attended to.
Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No 52 North Market Street, Boston.
Sept. 20. NAUM WARD.

NOTICE.
The subscriber offers for sale his real estate in Westford and Grotton; consisting of his homestead, 35 acres, his farm, 117, one pasture, 17 acres, one do. 33 acres, one wood-lot, 13 acres, one do. 5 acres, and one do. 10 acres. For further particulars see his advertisement in the Lowell Journal, or inquire of the subscriber at his house, near the meeting houses and academy in Westford.
EPHRAIM ABBOTT.

FARM FOR SALE.
That large and beautiful farm, late residence of the Hon. Judge Dame, situated in Rochester, N. H. six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quarries of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to JOSEPH BRECK & Co., No 51 and 52 North Market Street, Boston.
August 15, 1838.

AUTUMN SONNETS.

THE HARVEST MOON.

Mild were her beams, and light her graceful horn,
 When first her slender crescent hung on high!—
 —Now, like the breaking of another morn,
 She bathes in silver light the eastern sky.
 They say with hastening step at set of sun,
 She comes, the autumn harvest home, to light,
 And when our woods, and hills, and streams have won
 Her beaming eye, she lingers o'er the sight.
 How doth her beauty sink upon the heart!—
 —Waking the thoughts we cannot breathe in words,
 O'er which our saddened spirits brood apart,
 And sigh to break their chains, and soar like birds.
 Strange that the beauty of her gentle beams
 Should make us sad, as when we wake from pleasant dreams!

A SUMMER DAY IN AUTUMN.

A warm, bright, sunny day, like one of those
 That thrilled our hearts, when earth was gay with flowers,
 And leaves were fresh in all the forest bowers!—
 —The fragrant summer lingers, ere she goes
 From her green haunts, beside the cooling brook,
 With a sad beauty, like the last fond look
 Of one we love. The melancholy sky,
 The fading leaves—the withering grass—the dim,
 And hazy light, have to the gazer's eye,
 A mournful charm; and hark! the funeral hymn
 Of the last summer day is on the breeze,
 Mocking the brightness of the tinted trees,
 And gently o'er the earth, with dying swell,
 The lingering zephyr sighs its last farewell! **

YOUNG MECHANICS.

There is no class of the community upon whom the future welfare of the country more essentially depends than upon the rising generation of young mechanics. If they are intelligent, sober, industrious, and consequently independent, able and accustomed to judge for themselves, and governed, in their conduct, by an enlightened view of their own best interests; if they are men of this sort, the mechanics and especially the young mechanics, will form the strongest bulwark of our free institutions, and the best hope of the Republic.

If, on the other hand, they are ignorant, idle, dissolute, and consequently poor, and dependent upon those who are willing to trust them—if our mechanics should unhappily become such a class, (of which, thank God, there is but little danger,) they would soon be converted into the mere tools of a few rich and artful men, who, having first stripped them of every sense of self respect, and every feeling proper to virtuous citizens, would use them as passive instruments for promoting their own ambitious objects, and for the enactment of laws which are beneficial to nobody but the artful few with whom they originate.

It is as true of the mechanical arts as of any other profession, that "knowledge is power," and we earnestly recommend to the attention of our friends among the young mechanics, the following excellent "hints," copied from the Buffalo Journal:—*National Intelligencer*.

HINTS TO YOUNG MECHANICS.—The first object of a mechanic, as it should be that of every one, is to become thoroughly acquainted with his particular business or calling. We are too apt to learn

our trade or profession by halves—to practise it by halves—and hence are compelled to live by halves—die by inches.

Study and labor to excel your competitors, and then you will not fail to command the patronage of the most discerning and liberal paymasters. There is a great variety of highly useful knowledge which appertains to every branch of business, that may be acquired by a course of judicious reading. This knowledge, well digested and systematized, constitutes the science of every occupation. Thus, if you are a carpenter, the science of architecture should be studied with profound attention; if a ship-builder, the science of navigation and hydrostatics, and that combination of them which will give the largest capacity to a vessel with the least resistance from the water, and the greatest safety in time of danger from the elements. If you are a mechanist or mill-wright, the mechanic powers should be well understood; and if the machinery is to be propelled by steam or water, you should study the science of hydraulics, and should have a perfect knowledge of the chemical combination of heat and water, both in its latent and active state, and understand how it happens that a quart of water converted into steam, which, by a thermometer, is no hotter than boiling water, yet will bring a gallon of water up to the same temperature. If you are a hatter, a dyer, a painter, or a tanner, there is no study so useful as chemistry.

The fact was known a quarter of a century to chemists that gum shellac was insoluble in water before any hatter ever used it to make waterproof hats. The whole art of giving beautiful and durable colors to different bodies depends entirely upon the chemical affinity of such bodies for the coloring-material, and the affinity of this latter for the different colored rays of light.

We speak understandingly when we say that the *tanners* and the public in the United States lose millions annually from the lack of scientific knowledge how best to combine vegetable *tannin* with animal *gelatin*, which is the chemical process of making leather—call it by what other names you please.

There is a vast amount of knowledge which is now completely useless that ought to be brought home to the understanding of every operative in this Republic. We love industry and respect all who practise it. But labor without study is like a body without a soul. Cultivate and enrich the mind with all useful knowledge, and rest assured that an intelligent understanding will teach the hands how to earn dollars when the ignorant earn only cents.

EXTRAORDINARY YIELD.—From the farm of Abram Bennett, of Saratoga County, N. Y., has been raised this season, a large Chinese Squash, measuring in circumference, 6 feet 5 in., weighing 155 lbs. This is one of six raised from a *single seed*, the whole weighing 714 lbs. From *two seeds*, Mr Bennett actually has raised the weight of 1177 lbs. Beat this who can? This squash may be seen at the store of Smith & Wood, 237 River street.

LARGE SQUASH, AT UNDERHILL & HALL'S.—	
	ft. in.
Length,	2 3
Diameter,	2 5
Circumference, (longitudinal),	8 1-2
do (latitudinal),	7
Weight,	236 lbs. 3 oz.

The above was raised by John Hall, (milkman,) on the Hoyle farm, in the south part of the city, from seed brought from France, by Mr Cushman. The seed planted nearly three weeks later than the proper time.

GREAT CURIOSITY.—Lieut. Comdt. Sturgis, of the Revenue Cutter Hamilton, showed us, this morning, a *hoe*, which was found completely embedded in a stuck of live oak timber, of Georgia growth, intended for the ship Republic, built last year, at Wareham, by Capt. David Nye, and now sailing out of the port of New York. The timber measured 15 inches square, and the hoe was discovered by one of the shipbuilders cutting into it with an axe.—*Trans.*

The editor of the *Vevay Times* says, unless some of his subscribers send him some oats he shall again have to feed his horse upon exchange papers.

FRUIT AND ORNAMENTAL TREES, MULBERRYES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honeysuckles; Pæonies, Dahlias and other Herbaceous Flowering Plants.

100,000 MORUS MULBICATUS are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussa and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to E. D. BACCK, Commission Store, No. 132 Water Street, New York, or S. PEWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston. August 1, 1838. WILLIAM KENRICK.

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more as may be wanted, of the most approved kinds—consisting of the best selected varieties now in use, for cultivation, feeding worms, and making silk;—being acclimated to this country, and adapted to either warm or cold climates, affording a rare opportunity for companies or individuals to be supplied from the most extensive collection of mulberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and orders left with Messrs. I. B. Colt, Secretary of the Connecticut Silk Manufacturing Company, Hartford; Alonzo Wakeman at the office of the American Institute, No. 157 Broadway, N. Y.; Thomas Lloyd, Jr., No. 236 Filbert street, Philadelphia, Pa.; Luther L. Cox, Baltimore, Md.; B. Snider, & Co. Savannah, Ga.; Bliss Jenkins, & Co. Mobile, Al.; James Lyman, St. Louis, Mo.; Case and Judd, Columbus, O.; G. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass.

Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Mulberry Plantations.

Apply at the office of Northampton, Aug 22, 1838.

AGRICULTURAL.

BERKSHIRE AGRICULTURAL SOCIETY. CATTLE SHOW AND FAIR.

On Wednesday and Thursday, the 3d and 4th days of October instant, the Berkshire Agricultural Society held its 28th anniversary in Pittsfield. The rain, which continued until 11 o'clock in the morning of the first day, was the only unpleasant circumstance attending the Fair; and this did not prevent the usual collection of animals, even from some of the most distant towns in the county. The field appropriated to the exhibition of cattle, sheep, and swine, was one of the principal places of concourse; and it was here that the good effects of this society were again as in former years, strikingly apparent. The exhibition of working cattle, particularly four-year-old oxen and three-year-old steers, has never been equalled before, either in number or quality. Indeed, of the neat cattle generally, we have never seen so great a variety together before. Besides our own native breeds, there were the Durham, the Devonshire and the Ayrshire, with a variety of crosses. The committees were engaged most industriously during the afternoon in viewing and comparing the animals; and in the evening in preparing their reports. The reports of the committees will give the details in this department.

The hall of domestic manufactures was also a place of great resort, and presented an interesting variety of results of the domestic and manufacturing industry. The afternoon of the day was delightfully pleasant. The whole scene was one of exceeding interest, to all who have the interests and honor of old Berkshire at heart. The vast concourse of our fellow citizens, all seemingly gratified with this opportunity of exchanging their congratulations, comparing the results of their agricultural experience; exhibiting their stock, viewing the stock of others, buying, selling, and exchanging, could not but be regarded with pleasure and patriotic feelings. Although this is the oldest agricultural society in the United States—although this is its 28th anniversary, yet the interest of our community in its annual Fairs, so far from flagging, is constantly and steadily increasing. It is our best; almost our only holiday; and the citizens of Berkshire will long continue to cherish it.

The second day was one of the most mild and beautiful days of this remarkable season. The exhibition of this day opened with the Ploughing Match, on the farm of Mr. James Foot. The field prepared for the spectators, adjoining the ploughing field was occupied by thousands of both sexes and all ages; all animated by the morning air; the pleasant ride, and the excitement of the rural strife.

Before 11 o'clock, the vast concourse had returned to the village; and the procession, under the direction of Col. Weston, Chief Marshal, and eleven assistant Marshals, escorted by the "Berkshire

Greys," under the command of Capt. West, was on its way to the meeting house.

The prayers were offered by the Rev. Dr. Shephard. The sacred music was performed by the "Hastings and Mason Musical Association," led by Mr. M. S. Wilson. To those who are acquainted with the zeal, spirit and perseverance, with which this Association has been conducted, it is needless to speak of the character of their performance. The citizens of this county have just reason to be proud of this Association, and its public exhibitions.

The annual address was delivered by the President of the Society, the Hon. Lester Filley. It was plain, practical, full of instruction, containing many striking and eloquent passages. After the address, the reports of the committees were read by the Secretary; and the premiums delivered to the successful competitors by the Treasurer.

The society dined on the first day at Brown's Coffee House, and on the second at Warriner and Russel's Hotel; and the entertainments on both days, were of the most satisfactory kind.

The most perfect order and regularity was preserved throughout all the exercises of the second day, and for this, much credit is due to the Marshal and his assistants, as well as to the escort.

The following gentlemen were chosen officers of the society for the ensuing year: viz:

LESTER FILLEY, President.
WILLIAM WILLIAMS, } Vice President.
CLEMENT HARRISON, }
SAMUEL D. COLT, Treasurer.
JULIUS ROCKWELL, Cor. & Rec. Sec'y.

Grenville D. Weston	} Com. on Agriculture.
Roderick Norton	
Jay Shears	
Levi Goodrich	} Com. on Animals.
John M. Hulbert	
Jason Newton	
Thomas B. Strong	} Com. on Manufactures.
Justus Tower	
David Carson	
Edward A. Newton	} Com. on Accounts.
Calvin Martin	
Thomas Twining	
Calvin Martin, Auditor.	

A resolution was unanimously adopted, presenting the thanks of the society to the President, for his address, and requesting a copy for the press; and Moses A. Lee, Samuel D. Colt and Henry W. Bishop, were appointed a committee to communicate the same.

On motion of E. A. Newton, Esq., a resolution was adopted authorizing the Executive Committee, to offer Premiums on the 1st, 2d, and 3d best thirty yoke of working oxen from any one town.

Mr L. Chandler Ball, of Hoosic, N. Y., was elected an Honorary Member of the society. The fine stock exhibited by this gentleman, will be found noticed in the appropriate report.

REPORTS.

On Agriculture.

The Committee on Agriculture have performed the duties assigned them and respectfully report:

That the return of this anniversary furnishes abundant reason for grateful thanks to the "Author of all Good," for his merciful dispensations to us in the events of this year. This section of the country has been favored with a long and warm season and seasonable showers, while other parts have suffered from severe droughts, rarely if ever experienced, and the committee would congratulate their fellow citizens upon the bountiful harvests of the fruits of the earth as the reward of their industry. This county is at present enjoying the sunshine of prosperity. Not only is the husbandman blest with an abundant supply, but our mechanics and manufacturers cease to complain of the "distress of the times." And the busy hum of machinery again is heard—all its activity and cheerfulness.

The agriculture of Berkshire is rapidly advancing—keeping pace with the improvements in the best agricultural districts in the country—showing conclusively that the spirit of inquiry is abroad among our farmers, and carrying them to prosperity and wealth. Although much has been done in the way of improvement, yet it is undeniably true that much remains to be done. It would be unnecessary and of little avail to particularize deficiencies—the committee rely much more on the means of information which is within the reach of every farmer, by the reading of agricultural journals, and the opportunity afforded at the end of each agricultural season by the assemblage of our most intelligent and successful agriculturists, and by an interchange of opinions and detailed accounts of the experiments they have made. The committee fully believe that the agriculture of the county has received great benefit from the efforts of this society, and would be much more promoted, should the farmers generally give it their undivided support.

The committee believe that the premiums offered by the society on Summer Rye and Flax do not lead to any useful result—the former being at the best a poor crop and the latter will not be generally cultivated by our farmers—and they venture to recommend that the society cease to offer premiums on those crops and increase the amount offered for productions more in the spirit of improvement.

The committee viewed 114 crops entered for premium, most of which displayed good husbandry in the cultivation. Winter Rye was unusually large and well filled, and every field of it viewed was good enough for a premium crop. Corn was abundant and there were a great many competitors for the prizes. It required the utmost scrutiny in fixing on the successful applicants. Without trespassing further on the time of the society, the committee award the premiums as follows:

To Edwin Shears of Sheffield, for the best 2 acres of winter wheat,

2d best do. to Oren Curtis of Sheffield, \$5
 3d best do. to John L. Cooper of do. 3
 To Eldad Post of Lenox, for the the best two acres of summer wheat, 7
 2d best do. to James D. Colt of Pittsfield, 5
 3d best do. to George Goodrich, of do. 3
 4th best do. to Chester K. Lamplire of Lanesborough, 2
 To Samuul Lewis of Great Barrington, for the best two acres of winter rye, 7
 2d best do. to Eli Ensign of Sheffield, 5
 3d best do. to Phillip Merrell of Pittsfield, 4
 To Enos Smith of Stockbridge, for a good piece of rye, 3
 To Newton Kasson of N. Marlboro', do. do. 3
 To Prentice Cmonck of Great Barrington, do. 3
 The committee also viewed several other excellent pieces of rye, showing the very best of cultivation, and regret that they could not have extended to the owners the bounty of the society. Several of these pieces the committee take pleasure in naming, viz: that of Sewell Sergeant of Stockbridge; Dickinson Graves of Lee; Francis Whiting of Great Barrington; J. B. Bush of Sheffield; Russell Griffin of Richmond; George Butler of Lenox.
 To Levi Hyde of Great Barrington, for the best two acres of spring rye, 6
 2d best do. to Nelson Shepard of Sheffield, 4
 To Nathan Chapin of Richmond, for the best two acres of oats, 6
 2d best do. to Jeremiah Shears of Sheffield, 5
 To Richard Coman of Pittsfield, for a good piece of peas, 4
 To Morgan Lewis of West Stockbridge, for the best two acres of Barley, 6
 2d best do. to Seymour Wilcox, Lanesborough, 5
 To Clement J. Harrison of Adams, for the best two acres of corn, 6
 2d best do. to Leonard Tuttle of Sheffield, 3
 3d best do. to Jonathan Andrews, of Richmond 3
 To Henry Warden of do. a reserved premium 3
 To Justus Tower of Williamstown, do. do. 3
 To Joseph Tucker of Lenox, do. do. 3
 To Josiah A. Hulbut of G. Barrington, do. 3
 To Crocker Thatcher of Lee, for the best 1-2 acre of ruta bagas, 5
 2d best do. to Oren J. Farnum, of Lanesborough, 4
 3d best do. to Wm. Weller of Pittsfield, 3
 To Levi Goodrich of do. for the best acre of potatoes, 6
 2d best do. to Solomon L. Russell of do. 4
 3d best do. to Moses Spur of Sheffield, 3
 To Edward Sexton of Stockbridge, for the best 1-2 acre of carrots, 5
 2d best do. to Samuel D. Colt of Pittsfield, 4
 To Thomas B. Strong of do. for the best variety of choice fruit trees, 6
 The committee, from a sense of duty and pleasure, refer the fact that Mrs Amanda Burt of Great Barrington, widow of the late Rev. Sylvester Burt, sowed in the month of May, 1838, 3-4 of an ounce of mulberry seed on 3 rods of ground in her garden, from which she has raised 5000 trees of uncommon growth, being generally about six feet high, and believing that she merits the approbation of the society, do award her a premium of 4
 All of which is respectfully submitted.

THOS. F. PLUNKET, *Chairman.*

On Animals.

The committee on the first division of Domestic Animals have attended to the duty assigned them and report as follows:
 For the best stock of cattle, to Titus Parker 2d, of Pittsfield, \$7
 2d best do. to Asa Perry of Richmond, 6
 For the best pair of fat oxen, to Wm. A. Royce of Lanesborough, 8
 2d best do. to Hezekiah Porter of Dalton, 6
 3d best do. to Calvin Rood of Sheffield, 5
 For the best yoke of working oxen, to Jay Shears of Sheffield, 8
 2d best do. to Silas Lester of G. Barrington, 6
 3d best do. to Jonah A. Hulbut of do. 5
 4th best do. to Luther Sears, Jr. of Lenox, 4
 For the best yoke of four year old oxen, to David Smith of Dalton, 8
 2d best do. to Saml. Lewis of G. Barrington, 6
 3d best do. to Frederick Jones, of Stockbridge, 5
 4th best do. to Levi Laird of G. Barrington, 4
 For the best pair of three year old steers, to Isaac Avery of G. Barrington, 7
 2d best do. to George O. Peck of Lenox, 5
 3d best do. to Norman Loomis of Otis, 5
 4th best do. to John Sears Lenox, 4
 To Ethan James of Pittsfield, for two pair of very fine three year old steers, a reserved premium of 4
 For the best pair of two year old steers, to Wm. W. Ward of Pittsfield, 6
 2d best do. to Erastus Dewey of Lenox, 5
 3d best do. to Oreo J. Farnum, of Lanesboro', 4
 The committee examined 21 pairs of three year old steers entered for premium, all of which were superior animals, and were considered equal if not superior to any cattle of that age ever before exhibited in Berkshire. The working cattle generally, but especially the three and four year olds, bear honorable testimony to the judgment and good management of their owners.
 The committee regret that the limited sum at their disposal prevented them from awarding premiums where there was real merit.
 Respectfully submitted,
 LEVI GOODRICH, *Chairman.*
 The committee appointed to view and award premiums upon the second division of Animals have discharged the duty assigned them, and beg leave respectfully to submit their report:
 That the animals coming under their official notice were unusually fine, in quality and condition. That it was with difficulty that they could come to the following determination as to the animals entitled to the premiums.
 Upon cows the committee awarded to Crocker Thatcher of Lee, the 1st premium, \$8
 2d do. to Saml. Lewis of G. Barrington, 6
 3d do. to James Foot of Pittsfield, 5
 Upon two year old heifers, having had calves, to Edwin Shears, Sheffield, 1st p. 5
 2d do. to Ethan James of Pittsfield, 4
 On bulls, to Asa Perry, Richmond, 1st pr. 8
 2d do. to John M. Hurlbut, G. Barrington, 8
 3d do. to Henry A. Robbins of Pittsfield, 4
 On two year old heifers not having had calves, to James Foot of Pittsfield, 1st pr. 4
 2d do. to Erastus Rowley of Richmond, 4
 On yearling Heifers, to Erastus Rowley of do. 4
 1st premium, 3
 2d do. to Jay Shears of Sheffield, 3
 3d do. to Edward A. Newton of Pittsfield, 2

On yearling Steers, to Asa Cone of Richmond, 5
 1st premium, 5
 2d do. to Abram Race of West Stockbridge, 4
 All which is respectfully submitted.
 JOHN M. HURLBUT, *Chairman.*
 The committee appointed to examine and report upon the animals comprised in the third division—consisting of sheep and swine—respectfully report:
 They have awarded the following premiums:
 For the best buck, to Walter Tracy of Hinsdale, \$6
 2d best do. to Seymour Wilcox, Lanesboro', 5
 3d best do. to Edson Sexton of Stockbridge, 4
 For the best 5 ewes, to Thomas F. Plunkett of Pittsfield, 6
 2d best do. to Robert Colt of do. 5
 3d best do. to Elias Warden of Richmond, 4
 For the best 5 fat weathers, to William A. Royce of Lanesborough, 5
 2d best do. to Silas Clark of Washington, 4
 For the best boar, to Solomon P. Fitch of Pittsfield, 5
 2d best do. to Henry W. Bishop of Lenox, 4
 For the best sow to Lyman Warriner of Pittsfield, 5
 2d best do. to Levi Childs of do. 4
 The exhibition of swine undoubtedly excelled any previous Fair. The number of swine was unusually large, and it was exceedingly difficult for the committee to decide between them. This kind of stock has very greatly improved within the last few years in this county. The committee being limited as to the number of their premiums were unable to give premiums in some instances where they were deserved—and they would particularly notice a boar and sow of Mr Daniel Stearns, and a pair of Mr Henry Root, both of Pittsfield.
 The committee also noticed with great pleasure, some swine sent for exhibition by Mr Caleb N. Bament of the Three Hill Farm, Albany, N. York. They consisted of a pair of pigs, one week short of five months old, of the genuine Berkshire breed. Also two sows, a cross of the Neapolitan and improved China breeds, seven months old. These are of greater length than the China or Mocho breeds; compact and deep bodies; small and short legs; small head and ears; very docile and quiet; their hair and skin very thin, and no bristles. They appear to be easy and quick feeders. The committee recommend an extra premium of \$5 to Mr B. upon these swine, as a testimony of the grateful feelings which this society entertain toward him for his exertions in improving the breeds of swine, and for his public spirit in sending them so great a distance for exhibition at the Berkshire Cattle Show and Fair.
 All which is respectfully submitted.
 J. NEWTON, *Chairman.*
 The committee on Stock exhibited, but not included in the premium list, have attended to the duty assigned and beg leave to subject the following report:
 The number of calves exhibited were unusually large, and they were superior (in the opinion of your committee) both in size and symmetry, to those shown on any former occasion. This fact furnishes the best evidence that our farmers are awake to the subject of improvement of their stock. Your committee regret that they are not authorized to award premiums on this department of animals.

Among the calves exhibited the committee cannot refrain from expressing the admiration of the following:—One 12 months old, owned by Charles S. Thatcher of Lee—a brindled calf, 5 months old, owned by Ebenezer Axtel, of South Adams—one 5 months old exhibited by Levi Butler of Lenox—one two months old, owned by Asa Cone of Richmond—another exhibited by Gustavus Dunham of Richmond, and last though not least, a beautiful bull calf (called *The Westminster*) owned and exhibited by Henry Colt of Pittsfield. This calf is from a cow imported by E. A. Newton, Esq., and was much admired for his size, color and beautiful symmetry.

Mr Eldad Post of Lenox exhibited his stock of cattle consisting of 21 head. They are mostly selected from our native stock, but would do great credit to any farmer in Berkshire.

The number of animals exhibited, but not owned in the county, was unusually large and added much to the interest of the exhibition. Your committee would express their warmest acknowledgments to those gentlemen whose zeal in the good cause has led them to make such sacrifice for our gratification, and they deeply regret that the funds of the society will not allow them to award premiums out of the county except in rare cases and of small amount. Your committee first examined a stock of cattle owned by L. Chandler Ball, Esq., of Hoosic, N. Y. The stock consisted of 3 two year old heifers and 2 calves, pure thorough bred Durham. These animals need only be seen to be admired. They are the most perfect specimens of their kind your committee have ever seen. One of the calves is 7 and the other 5 months old, and their aggregate weight is 1180 pounds.

Mr Ball is determined not to be outdone in the breeding and rearing of fine cattle, and if this society will import a few head of well-selected stock, he offers to subscribe \$1000 for the same laudable object. Your committee have awarded to L. Chandler Ball, Esq., for his stock of short horned Durham cattle, a special premium of 6 dollars.

A Holderness and Devonshire bull was exhibited by John Wilcox of Canaan, N. Y. This animal was much admired.

Mr Dunn of Albany, whose animals have so frequently added interest to our annual fairs, exhibited to us 4 Bakewell or Leicester bucks, of superior size and beauty. The aggregate weight of two of them is 640 lbs.

Your committee are also gratified at the exhibition of a lot of Durham heifers and Berkshire Neapolitan and China pigs, owned by C. N. Bement, Esq., of Albany. Austin Harman, Jr. of Bennington, Vt. exhibited a Durham bull, 18 months old, of great beauty—his weight is 1300 pounds. The committee would also notice the fine Ayrshire bull, the property of Mass. Agrl. Society, which has been in the care and keeping, during the past season, of this society. Great hopes are entertained from crosses from this stock. It is also expected that arrangements can be made by which this animal may remain in this county for another year.

All of which is respectfully submitted.

M. A. LEE, Chairman.
(To be continued.)

NO MISTAKE.—Bend the first and third fingers of the left hand—and commencing with March at the thumb, count on—the bent fingers will indicate months which contain only 30 days.

(For the New England Farmer.)

CAPIAUMONT AND FREDERICK DE WUR- TEMBERG.

MR EDITOR,—If Mr Kenrick had left his *facts* to speak for themselves, I should never again have troubled the public press; but anxious to show how poor Mr Knight was led to commit this blunder of sending the Frederick of Wurtemberg for the Capiaumont, Mr Kenrick has made assumptions which are erroneous, and furnished evidence to show that Mr Knight's name was the correct one, as I shall endeavor to prove by Mr Kenrick's own evidence. The assumption is this, that one Richard Williams procured the *Frederick of Wurtemberg*, and sold it to the Horticultural Society of London, for the Capiaumont. That they raised it, and ignorantly sent it to the Pomological Magazine, for the Capiaumont, though their officers had long before seen, examined, and tasted the true Capiaumont from Belgium—that Mr Knight's tree was from this corrupted source, though Mr Kenrick acquit him of blame.

Now this statement has but one defect, and that is, that it is not true. This I shall prove from Mr Kenrick's evidence beyond any controversy. The London Horticultural Society first received the true Capiaumont from two distinguished Belgians, M. Parmatier of Eughien, and M. Dunalier of Louvain, in the fall of 1820. I say the true Capiaumont, because M. Parmatier, one of them, did not know the Frederick of Wurtemberg at that time, nor four years afterwards, when he printed his catalogue, though he knew the Capiaumont, and M. Duhortia's pear must have been the same, or the Society would have noticed it.

The London Society were so pleased with the pear, that they ordered it from Belgium. This could not be before the following spring, which was 1821. I assume that they could not have had the pear in their garden from Williams at that time, or they would not have sent for it. This requires no argument. They received three scions (at least) for the Capiaumont, because they produced three different pears, all false. These trees could not all have borne fruit under two years, and while it was doubtful, they would not purchase of Williams, because they had better and higher authority. This brings us to the fall of 1823, before they could possibly know that all their Belgian scions had proved false. I admit then that in the spring of 1824 they bought of Richard Williams their Capiaumont. Now in the spring of 1824 Mr Knight's Capiaumont was growing on Nonantum Hill, the seat of Wm. Kenrick, Esq., and in 1823, it was growing on my place, nay more, it was three years old from the graft, when it came. Of course it was grafted at Downton Castle in the spring of 1820, six months before the Horticultural Society of London received the first specimen of the Capiaumont direct from two eminent Belgian cultivators. This I call mathematical proof that Mr Knight's tree did not descend from the Horticultural spurious one, as is imprudently and unwisely insinuated.

The spurious one (as Mr Kenrick deems it) was the true one. The pair painted in the Pomological Magazine, was the true Capiaumont, as I shall now show. Two high authorities in Belgium sent the fruit of the true Capiaumont to the London Society; their Officers, who were, then, eminent botanists, pomologists, and draughtsmen, examined these pears, and tasted them. They then bought the Capiaumont of Williams. It bore fruit in their

garden. They must have known, whether it was the same pear they received from Parmatier and Dumortia. They decided that it was, and sent it to the editors of the Pomological Magazine to be published for the light and instruction of the British public—was there ever so complete a chain of proof? Suppose Col. Carr, of Philadelphia, had sent the Petre Pear to our Society—they committed it to Messrs. Downer, Kenrick and Manning—they examined it and tasted it, and sent to Col. Carr for scions—they come, bear fruit, and these gentlemen examine the new fruit and decide it to be the same—would not they smile in derision and scorn, if a man should tell them that they had mistaken the *Seckle* for the *Petre*? Yet this is precisely what Mr Kenrick asks us to believe. No, it is too absurd to reject such irresistible evidence as this, because two, or even ten gentlemen have been deceived, (a very common case,) in their importations from Belgium.

Against such a mass of conclusive proof, that the Capiaumont of Mr Knight and of the Pomological Magazine are French. Nothing but receiving scions from M. Capiaumont himself, from the original tree will suffice. It is next to impossible that Tuma and Sabine, the secretaries of the Society, should not have known whether Williams' pear was the same they had received from Parmatier. One word more, and I quit this topic never to resume it, let what will be said. I prove that Mr Knight had this pear in 1820, probably in 1818. Can Mr Kenrick show that the Frederick of Wurtemberg then existed? I need not spend words to show that Mr Knight could not have sent me a pear which had no being!! This is not a frivolous or captious objection, for M. Parmatier was requested in 1824 to make a list of all the pears he then knew. He did, and the London Society voted him their gold medal of the value of ten guineas for it.

In that list the Roi de Wurtemberg and the Frederick of Wurtemberg are not found. If that pear had existed six years before, it is strange that Parmatier who lives only one half a day's ride from Brussels, Mons, and Louvain, had not seen it in 1824. I have done—and the readers will rejoice at it. I participate their delight.

JOHN LOWELL.

Broomley Vale, Oct. 20, 1838.

Massachusetts Horticultural Society. EXHIBITION OF FRUITS.

Saturday, Oct. 27, 1838.

Pears.—From Robert Manning, Salem, *Brugmansbire*; middle size, skin russet brown, good quality.

From Joel Burnett, Southboro, *Burnett*; large size, excellent quality.

Apples.—From Peter Fay, Southboro, a handsome large red apple, name not known.

From R. Manning, black apple, beautiful specimen.

Quinces.—A fine sample of Portugal Quince, weighing 16 oz., from Jos. Baleh, Roxbury.

For the Committee,

L. P. GROSVENOR.

THANKSGIVING.—The Governors of Maine and New Hampshire have appointed Thursday the 29th instant to be observed as a day of Public Thanksgiving and Prayer in their respective States.

WORCESTER AGRICULTURAL SOCIETY.
REPORT ON SWINE.

William Lincoln of Worcester; Samuel Mixter of New Braintree; Joseph Davis of Northborough; Rufus Bullock of Royalston; James Draper of Spencer.

The past, present, and possibly (?) future members of the senate, house of representatives, judiciary, and militia of Massachusetts, enjoying the distinguished, but unmerited honor of being appointed "*Judges of Swine*," came, this morning, fresh from the people, to form a *Supreme Court of Hogs*. Deprived of the countenance of the councillor of the commonwealth, first of their body, their records must be entered up, as the term was kept, without his advice and consent. The vacancy occasioned by his absence was too great to be supplied. Lamenting the want of counsel, they publish the reports of all the cases adjudged and decided by them, with the journal of their doings.

The commission issued under the great hand and seal of the society, conferring their honors, (which should be annexed hereunto, and marked A. NO. 1) commanded the judges to take their seats on the bench at the room of the *selectmen* of Worcester, at eight o'clock precisely. Good men are so rare on earth, that it may be presumed the place of their meeting was made thus *select*, from regard to their joint and several legislative, legal, and military capacity. It was not only *select*, but *exclusive*: although "*no admittance*" was not inscribed on the entrance, a closed and bolted door conveyed a gentle hint to that effect, and prevented the enjoyment of the room or company of the chosen municipal officers. Compelled to adjourn, they emigrated eastward. Decent respect for the opinions of men, induced them to imitate the example of other tribunals of the United States, by doubting of something. Having convened in the *ninth* instead of the *eighth* part of the day, it was easy to find occasion for debate on the soundness of their own constitution. Eight o'clock had waived itself, and there was satisfactory evidence of a general custom of the country to postpone all engagements for an hour at least; wherefore it was considered that the course of time must be overruled. Out of the frying pan of one difficulty, the way was clear into the fire of another. Standing in the area, beneath the sky, and between the pens, unsheltered by the roof of the hall of local jurisdiction, precedents were abundant where courts of inferior dignity had held that one place was another, and it was determined, the absent justice not concurring, that the judges would be out of place nowhere. No officer appeared to bear the sword of justice, without her scales before them, and no person was ready to cry for them. Unattended and in procession, they cast themselves, like pearls before the swine.

The hogs had been in a meeting too, and one more numerous and respectable has rarely gathered in this age of meetings. The cold clouds of autumn looked darkly down on eightyseven of the best swine of the county, assembled in their regular, annual convention; and eightyseven swine looked brightly up at the heavens ready to burst into tears, making an exchange of cheerful for chilling glances, without discount.

Massachusetts is a glorious Commonwealth. Her renown heretofore has been wreathed with the valor of her warriors, the wisdom of her statesmen, and the worth of her citizens. If, hereafter, in the

vicissitudes of human affairs, patriotism shall grow faint, and public and private virtue become impaired, the fame of our own beloved State may rest secure on the greatness of her pigs; and the lustre of her people, if unhappily it grow dim, be rekindled by the solid excellence of the inmates of the pens.

The town of Worcester has always been unrivalled for boars. They were now, as heretofore, more intense than in any other part of the ample territory of a county extending between independent States.

The boar of Messrs. J. G. & D. H. Perry, speckled, but not striped, had proportions as exquisite as those of a fifteen gallon jug, in which no evil spirit had ever entered. "Born and distinguished" at home, to him was awarded the first premium of five dollars. The second premium of three dollars, was awarded to Mr Israel Whitney of Worcester, for an animal that was entire, and was finely formed as if his frame had been raised by the rule and square in days' works, and not constructed by contract. Mr Edward Curtis of Worcester, exhibited a pig, whose sire was a native of New York, and who traced his lineage back almost to Kinderhook. He trod so closely in the paths of his illustrious competitors as to be considered worthy of the recommendation that a gratuity of two dollars should be bestowed, the testimonial of affectionate regard. The pig of Mr Aaron Howe, unlike the western citizen, who was not raised but grew up, was raised by hand, and had grown into a fine specimen of domestic industry and skill in pork manufacture. The individual owned by Mr Samuel Harrington of Worcester, of tender years, and less robust figure than his neighbors, gave evidence of a genius for future usefulness, which if cultivated and developed, may make him the head of large families of hopeful offspring through coming generations.

In approaching the pleasant society of females, the loveliness of form and feature sometimes leads admiration away from the handsomeness of doings to the grace of beings. The incorruptibility of the court permitted no such seduction. The sow of Messrs. J. G. & D. H. Perry appeared before them with ten "sweet pledges" of maternal affection, frolicking merrily, and taking the young responsibility of feeding plentifully. The venerable matron, mother of the decimal family of suckers, who played over and around her, of the greatest boar of the festival, and of another troop of chubby, white haired children, was thrice blessed in being worthy of the first premium of five dollars. The second premium was awarded to Mr Aaron Howe of Worcester, for a sow, beginning life by acquiring the rudiments of good breeding in Holden, and subsequently gaining settlement in Worcester.

The "weaned pigs, not less than four in number," prescribed by the laws of the society, counted twentyone. All of them were very nearly best. Six presented by Mr Nathaniel Dodge of Sutton, round, plump, and white, of the Whiting breed, were worthiest among the worthy of the premium of six dollars. Close behind them came those of Mr Aaron Goodale of West Boylston, deserving the premium of four dollars. In the long procession of the virtues of the pigs, half a dozen of those of Mr Nathaniel B. Flagg of Shrewsbury, weighed in the balance with their competitors, were found so abounding that it is recommended to bestow on the proprietor a gratuity of two dollars. As the mother of the nursery of J. G. & D. H. Perry had received a premium for proficiency in the multiplication table, and her son had received equal favor

for declining to study or adopt the principles of Malthus and Miss Martineau, against population, it was concluded that the swine of these gentlemen deserved a reward in better currency than gold, silver, or irredeemable paper—in the circulating medium of praise.

Artemas Ward, Esq., who keeps the faithful history of the titles of our farms, permitted the name of an animal to be entered on the secretary's day book, and suffered judgment to be rendered for default of appearance. Among all the good deeds of the excellent register of the county, there is but this one instance, standing solitary and alone, where he ever did injustice to any living being. Depriving his pig of an opportunity to present himself on such occasions, and to show his merits, is an omission which even repentance cannot now supply.

The excellence of the State Lunatic Hospital is known wherever the name of the best charity of our government has been heard. Its works in pork were exhibited in three splendid editions; an octavo set which had been kept five months; four thick quartos, six months and ten days old, and a series of gigantic folio volumes of fat. The swine belonging to the institution appeared to be perfectly rational, and of sound sense, and clear memory. Eight of them, in one vast brood, gave examples of the results of good treatment, a ton and a half in weight. They resembled independent sub-treasury depositaries. When they stood, they lied; for they could not stand; they could scarcely sit; if they endeavored to place themselves upright in one direction, by an easy transition, they revolved into another equally perpendicular. There were no objects bearing comparison with their huge dimensions, except the vegetables transplanted from Wethersfield, celebrated in Morse's Geography, as the paradise of beauty and of onions, by Dr Woodward, whose unrivalled skill not only restores to the disordered and enfeebled mind its healthful action and vigor, but gives to the earth he cultivates, new powers of production. While the mouths of one committee have watered at the prospect of the living barrels of food in the pens, the eyes of another have doubtless been moistened in contemplating the odoriferous roots which have graced the hall.

It is gratifying to know the patriotic spirit which animated the vast delegation of swine from the hospital. With a promptitude worthy of all approbation, they took measures to reach their appointed place the day before the fair. How the journey was performed is not known; to have rolled over the distance would have been the easiest mode of locomotion for shapes as deep as broad, and broad as long. Loosening the green earth around, on their arrival, they stretched themselves on its feathery pillow to rest. The chairman, moved with deep anxiety for their repose, viewed them by a lantern at midnight, when they slept in the silver beams of the moon, like small mountains covered with snow. The music of their dreams floated as softly on the air as the melodies of Mr Frank Johnson's celebrated band, which has poured its sweet notes of hand on the ears of Queen Victoria. Nothing could alloy such happiness except the sad deprivation of the privilege of becoming members of the Society and participating in its agreeable exercises. It has always been difficult to conceive how one pig could look another in the face without laughing from reflected enjoyment. These creatures had no faces to look at—the chief extremity.

absorbed by the body, was only distinguishable from the termination which follows in the footsteps of its predecessor, by a delicate, white projection, appearing as the representative of its absent constituent, the snout.

Unhappily the commonwealth is not a citizen of the county of Worcester. Although worthy of being admitted to the freedom of our community, she cannot at present claim a premium for her children. It is recommended that the sum of two dollars, which, if possible, would have been awarded to her, should be presented to Mr Mirick M. Chaffin, the attendant of her hogs, by whose care they have been made to resemble elephants in miniature, with their trunks packed up.

The race recently introduced, whereby hangs no temperance tale, the Dedham breed, producing by its bite the dreadful horror of cold water, was entirely invisible. Lithographic representations rode on the rails of the pens. Whether the striped pig would have been examined had he been present, it is unnecessary to determine, as no opportunity was offered to consider its form or spirit.

One of the most lively writers of American sketches, in whose hands charcoal marks white, exclaims, "I wish I was a pig; there's some sense in being a pig that's fat; pigs are decent behaved people and good citizens, though they have no votes." No considerate spectator of the calm content and philosophical repose of the inmates of the pens could refuse to respond with heartfelt sincerity to such reasonable wish and opinions. Pigs do not buy lands, nor build houses, nor pay taxes, nor have bills left with an attorney for collection, nor subject themselves to the caprice of any court except that of the judges of swine. They are not abused for owning bank shares, nor obliged to borrow money to support those who denounce them. They never burst their boilers, nor have messengers sent under an assignment process to confiscate their estates to defray the costs of settling them. Pigs are above being politicians. No hog of respectability was ever heard to express an opinion on the sub-treasury system, or to commit himself in relation to the vexed question of the license laws. Nor has it ever been known, that a pig has reserved the aspiration for happiness already quoted, by praying that he might be a man. There is no comparison between pigdom and manhood.

All which, in behalf of the pigs, and of the absent counsellor, and present senators, representatives, justices, officers, and soldiers of the committee, is respectfully submitted.

WILLIAM LINCOLN, *Chairman.*

LUCERNE AND SAINTFOIN.

BY MR TOWERS.

Lucerne is the plant of plants! yet its merits, though undeniable, are but imperfectly understood. It is a native of England, belongs to the seventeenth class, fourth order of Linnæus, (*Diadelphica decandria*) and the natural order *Leguminosæ*. It is a member of the genus or family *Medicago*, medick, distinguished by having ten stamens, one of them distinct from the other nine. One seed vessel, a *legume* or pod, spirally twisted or sickle-shaped, (*papilionaceous*.) One plant (*M. Sativa*) grows to the height of two feet or more; but the stems are upright and firm, the foliage ternate, of a rich lively green, the leaflets saw-cut at their edges, the flowers are produced during June or July, in spikes, and are of a full violet blue. I extract the follow-

ing from "London's Encyclopedia of Gardening," partly to prove the great antiquity of the culture, but particularly to show the fallacy of the concluding observations, and thereby evince the worth of the plant.

"It is highly extolled by Roman writers; it is also of unknown antiquity in old Spain, Italy, and the south of France; is much grown in Persia and Peru, and mown in both countries all the year round. It is mentioned by Hartib, Blythe, and other early writers, and was tried by Lisle, but it excited little attention till after the publication of Hart's essays in 1757."

"But though it has been so much extolled, it has yet found no great reception in this country. If any good reason can be given for this, it is that lucerne is a less hardy plant than red clover, requires three or four years before it comes to its full growth, and is for these and other reasons ill adapted to enter into general rotation."

I have grown lucerne during four or five years, and previously I had witnessed its great success and extensive culture in the Isle of Thanet, Kent; there it is a *sine qua non*, because it affects chalky districts, and sends down its wiry elongated roots deep into the interstices of the chalk. It succeeds perfectly in sound loams, and therein appears to me to require little manure. *Hardy it is*—and as to tardiness, though the plant may acquire strength, and improve during four years, the fact is beyond controversy, that if sown in drills about the third week of March, and the spaces between the rows (from nine to twelve inches) kept clean by the hoe for the first three or four months, the young plants, if favored by a mild spring and genial showers, will advance with so much vigor and rapidity, that a first cutting over with the scythe can be made in June or July, and three other cuttings will follow in pretty regular succession, between the latter period and the first of November.

Seasons will of course vary; soils and other auxiliaries may be more or less favorable; but that which I have stated has occurred; it is the result of my own experience and practice. I have during five seasons witnessed the abundance of green food, which is produced by a plot of young plants, the supply being ample for a cow, even within four months after the sowing of the seed. I am thus authorized to refute, upon the evidence of facts, the charges contained in the concluding paragraph of the quotation. In cutting for a cow it will always be advisable to take the plant when it is tender and juicy, and such it will be when about a foot high. I have thus cut my plot over six times after the first year, but they who leave the plants to grow two feet high will find the stems rigid, fibrous, and less juicy; and that what they gain in bulk will be lost in time and quality.

As to the trouble in managing an established crop, it is really nothing. Though I allow it is good to hoe twice during the summer, as the plot is mown, piece by piece, yet *one general fork-digging* at that period of early spring, when the plants exhibit the first symptom of growth, so as to remove every weed and loosen the surface of the soil, will be amply sufficient to secure the safety and full development of the herb. Upon the whole, lucerne is a plant of the utmost value; for if the seed be good, the ground rich and in heart, and rendered deep in the first instance by a thorough trenching, the young plants start into lively growth, attain strength in the shortest possible time, and yield a bulk of luxuriant herbage that cannot be

surpassed. If the plant require four years to attain its maximum of power, it is still a giant even from its infancy, advancing from strength to strength.

Well might the writer of a recent agricultural report (of Norfolk if I mistake not) recently exclaim, "What a plant lucerne!" I re-echo this introductory "note of admiration," and will unhesitatingly assert, that if abundance, permanent and unailing, particularly in shallow soils upon chalk-rock, be the object of the farmer, he will attain it by the cultivation of lucerne. The rotation must be improved by it, as in point of product it will yield double the bulk of grass from an old sedgey meadow.

The soil which is most favorably to the perfect growth of lucerne is worthy of consideration. Chalk is what it affects, and therefore we find it most generally cultivated in Kent, those parts of the southern coast wherein the sub-soil is a chalk-rock. But my fine plot grows in a rich, deep, and rather sandy loam; the subsoil is indeed chalky or marly, but at a considerable depth. It was prepared by taking off the turf, trenching to the extent of three spits, and placing the turfs, their grassy surface downward, at the bottom of each trench. Upon these reversed turfs a sprinkling of common salt was given, and the earth was returned into the trench, with the precaution to keep the heavier and inferior soil below the fine black earth of the surface. Due preparation affords a rich and permanent pasture for the wandering roots; and my piece of hardly one-third of an acre, has been so undeviatingly productive, with little subsequent manuring, that in a showery season, we have found in cutting over the end where we began ready for the scythe again before the mowing was completed. Lucerne is known to produce much milk, perhaps more than any other of the artificial grasses (*Leguminosæ*;) but some complain that it communicates an austere or bitter flavor. I doubt the fact; but would always recommend that it be given quite fresh to a cow, particularly at an early period after calving. If the required quantity be cut over night, it will be fit for the stall by ten o'clock of the following morning; and again, the afternoon meal should be exposed to the sun for two or three hours before it is used.

A well prepared field, if kept clean by the forking, will remain productive for more than ten years; but as a change of crop always promotes abundance, it would be advisable to prepare a successional plot every six years.

The grass and weeds raised by the fork, and raked up with the small quantity of earth, adhering to the roots, if salted and sprinkled with quicklime and placed in a heap, will form a most excellent manure for the lucerne. The cuttings *here* are usually over by the end of October; the herb then becomes, as it were, torpid, and whatever manure is applied should be given as a top-dressing during the winter's state of repose. The surface must not be disturbed at that season, nor till the herb begins to grow, then, as I have before said, the fork-digging will effect all that is absolutely indispensable; it will turn in the remaining manure, remove the encroaching weeds, and open the soil, burying a fresh surface into contact with the advancing rootlets. The experience of one or two seasons, under commonly favorable auspices, will verify all that I have asserted.

Somewhat resembling lucerne in character and habits is the French grass or Saintfoin (*Hedysarum Onobrychis*), a lovely flowering plant, rich in her-

bage, and also a native of Britain. The grand object of agriculture ought to be the renewal of soils, and the adaptation of crops; and as science advances, and its sons become more influential, these objects will be attained. — *Quarterly Journal of Agriculture.*

NEW ENGLAND FARMER,
AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, NOVEMBER 7, 1838.

AGRICULTURAL SOCIETIES AND CATTLE SHOWS.
NO. 11.

We are of opinion, most decidedly, that in no case should less than two days be devoted to a cattle show and ploughing match. This is as little time as can be taken for the proper and satisfactory discharge of the duties and business of the occasion. Everything is performed in an inconvenient, hurried, and unsatisfactory manner when all the business is crowded into one day. The ploughing match, the drawing match, the inspection of the various pens, the examination of the household manufactures, the address and services at the church, the awards of the committees, the dinner and its accompaniments, the reading of the reports and the announcement of premiums, all compressed into one short day in October, renders everything unsatisfactory to all who feel an interest in the true objects of the exhibition. We have been repeatedly engaged on committees at such times; and we know that it has been impossible to do anything, or see anything excepting what was particularly submitted to the committee on which we were placed; and know how unpleasant it has been to be compelled to report in a hurried manner on the subject submitted. In such cases, likewise, we could have no comfort in hearing the address, which indeed it often happened we could get no time to attend; no pleasure in the dinner because, perhaps, our report was not made up; and as to any conversation with friends from a distance, this was utterly out of the question. The reports in such cases are of necessity in general extremely meager; the committees are compelled to make up their award after the most partial examination; and the unsuccessful competitors are often with very good reason dissatisfied. Indeed such examinations and reports are many times a mere farce rather than the performance of an important and responsible duty.

Not less than two whole days then, should be devoted to this occasion. If matters are properly arranged and managed, two days cannot be better spent. Let the cattle be in the pens at nine o'clock of the first day; and the committees, who should be previously appointed, proceed uninterruptedly to the performance of their duties. Let the domestic manufactures and dairy produce, and agricultural implements be ready for inspection, and let no persons be admitted to the rooms until the committees have made their examination. Let none of the cattle be removed until four o'clock in the afternoon, so that every person, desirous of doing it, may have a full opportunity for inspection. Let the public dinner take place at two o'clock of the first day; and let it be the occasion for pleasant humor and friendly intercourse; and for the utterance of sentiments, which will be sufficiently exhilarating without the aid of heavy potations of wine to give them force; and let the occasion be devoted to speeches and discussions immediately connected with the business of the day. If need be let gentlemen be selected for this express purpose and subjects of address be given them, for which they may come prepared. The dinner

should not be expensive. If wine is dispensed with, fifty or seventy-five cents will furnish as good a dinner as ought to be desired; and as to those who want wine, let them call for it and pay for it. The price of the dinner should be such that no respectable farmer should feel that he cannot afford the expense. In the evening let the farmers come together at some common place of meeting, and organizing themselves by the choice of a moderator, let them proceed to discuss matters of an agricultural nature, or listen to the relation of important experiments of those who have any such to communicate.

Let the second day be devoted to the ploughing match, the public religious services, the address, the reading of the reports of the committees, which they will then have had ample time to prepare in a full and satisfactory manner, and to the public awarding of the premiums to the successful candidates. Let the public services of the second day be closed with another public dinner of the same description as the dinner of the former day; and let it afford an occasion for the suggestion of any new subjects of premiums, or any measures for advancing the objects of the association. There is no occasion for, nor any advantage in, any sort of extravagance in such case. A gentleman may dine any day at the best hotels in our cities, at a table furnished with the greatest elegance and abundance and with all the luxuries of the season, for fifty cents; and it can be equally well done in the country. At several of the cattle show dinners which we have attended, no wine was furnished, and none drank, but we saw no want of good humor and hilarity. In this matter we would leave it to every gentleman to do as he pleased and to call, on his own private account, for what he desires. If the old proverb be true, that when "wine is in wit is out," we think gentlemen who are likely to meet on such an occasion, would have no difficulty in discovering that wit might be in, though wine should be out.

We wish another thing likewise, and this, in the interior, where farmers come from a considerable distance would be particularly desirable, that suitable and comfortable provision should be made for such of the farmer's wives and daughters as might see fit to avail themselves of it. We do not mean without expense to them; but as things are now managed they are often most uncomfortably situated, and can scarcely find a resting place. Since gentlemen have given up their bacchanalian revels on such occasions, and there would be nothing to offend their delicacy, if there were room, they might be invited to come to the public table. They themselves ought to be encouraged to become competitors in their line for the premiums of the society; and their presence in such cases so far from being a hindrance to any rational and manly pleasure would serve only to heighten the gratification.

There is another circumstance, which we know from observation, would add greatly to the interest of the occasion. The practice prevails in the Berkshire Society of awarding all the premiums above a dollar in some durable form, in a spoon, a set of spoons, a ladle, a cream-pot of silver plate, or other useful articles, and of bestowing it in public on the second day of the show. After the reports are read and the awards announced, the successful competitors are called for and the premium gained is publicly handed to them. The premiums in this form are spread upon the table in front of the pulpit, and this passing them along by the marshals creates naturally an intense interest among all parties. If the successful competitor be for example, some excellent dairy woman, who has secured a premium upon her butter and cheese, her husband finds a new motive to honor her and show himself deserving of her esteem; and, if some young woman is called up, who has shown her superiority and

cleverness in the use of the needle, or the fabrics of the loom, in her carpeting, or her blankets, or her hosiery, then the industrious and sober young man knows where to apply to get a *helpmeet* for him.

This is not all. The article so honorably gained is carried home as a permanent trophy. It is brought out on great occasions, and is always shown to visitors with an honest and laudable pride. It stands as a perpetual memorial of past success, and presents a new stimulus to future exertions. It goes down as an heir-loom in the family. Children receive it as a precious legacy, and it inspires in them a noble ambition of like honors. But when premiums are paid in money and settled with the Treasurer in private, they are frequently spent as soon as received, and, like most money which comes in the form of a gift, it is oftentimes spent for what is useless; the successful competitors themselves soon forget their own success; and its little good effect of the premiums come to others compared with what might be obtained from them. In every case of premium we are of opinion that some durable memorial should be given, though where the premium exceeded a certain amount, say five or ten dollars, some portion of it might be given in money to be applied and used at the pleasure of the receiver. I. C.

RURAL FESTIVAL AT PETERSHAM, MASS.

The intelligent and spirited farmers of Petersham, Worcester county, held a Cattle Show and Festival on the 24th Oct. The weather was unpropitious as the rain fell abundantly and without cessation though the whole day. But in spite of every inconvenience a large number of people and cattle were assembled; and the ploughing match and drawing match were contested with much spirit and skill.

158 yoke of fine oxen and steers, all belonging to the town, were exhibited; and most of them of superior quality and condition. One yoke of oxen weighed 4270 lbs—these were of native stock—and one yoke of two year old steers of the strong mixture of the Improved Durham Short Horn, possibly of unmixed blood, weighed 2571 lbs. One bull of mixed blood, one year old last spring weighed 1010 lbs. One handsome pair of steers of native stock, 4 years old, weighed 2305 lbs. One pair of oxen 3720 lbs. One cow 1325. One cow 1250 lbs. The ploughing match was contested by eight single yoke ox teams.

After the surveys were made by the committees and the ploughing and drawing matches were closed, an abundant and handsome dinner was given at Foster's Tavern where one hundred and thirty plates were all occupied. After dinner an address was delivered by the Commissioner of Agricultural Survey, mainly on the character and condition of our present breeds of neat stock, and the introduction of the improved breeds; topics in which the farmers of Petersham, a stock-raising town, were particularly interested. The day was spent in innocent hilarity. Many good sentiments, abounding with wit and humor were thrown out; the reports of the committees afforded much entertainment; and the farmers separated gratified by the interchange of kind feelings with each other; a spirit of agricultural enterprise was excited and nourished, and a new spur was given to agricultural improvement. I. C.

SMALL POTATOES AND FEW IN A HILL.

We are receiving from day to day accounts from different quarters, of large productions, heavy crops, and great yields; one man exhibits a mammoth squash of huge dimensions, another a wonderful cabbage, a third boasts of a pumpkin so large that two men can hardly turn it

over with crow-bars, and a fourth raises Rohan potatoes at the rate of 300 for 1.

We will now record a remarkable yield of potatoes, the facts of which came under our own observation, and names can be given if necessary. 400 hills of potatoes yielded a little short of one bushel, and many of them were nearly the size of pigeon's eggs. Beat this, who can?

BRIGHTON MARKET. — MONDAY, NOV 5, 1838.

Reported for the New England Farmer.
At Market 2100 Beef Cattle, 500 Stores, 4000 Sheep, and 1400 Swine.

Prices — Beef Cattle.—The prices obtained for a few weeks were hardly sustained. We quote First quality, \$7 28, second quality, \$6 50 a \$7 00. Third quality, \$5 50 a \$6 00.

Barrelling Cattle.—“Dull” and former prices not sustained. We quote Mess, \$6 50 a \$6 75. No. 1, \$5 50 a \$5 75.

Stores—Former prices were not sustained, probably occasioned by the storm. We quote without much alteration, viz. Two Year Old, \$13 a \$18. Three Year Old, \$14 a \$18.

Sheep.—Lots were taken at \$1 58, \$1 71, \$1 83, \$2 00, \$2 17, \$2 37, \$2 75, \$3 00, and \$3 25.

Swine.—Lots to peddle were sold at 6 1-4 for sows and 7 1-4 for barrows. At retail from 7 to 8 1-2.

THERMOMETRICAL.

Reported for the New England Farmer.
Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded ortherly exposure, week ending November 4.

BULB GLASSES,

A good assortment, consisting of white and blue plain Hydraulic Glasses; white and blue painted do.; plain glass of zes do.; ground glass, painted and plain, do. of various zes and patterns.
Crocus Glasses, plain white, for sale at the N. E. Agricultural Warehouse and Seed Store.
Nov. 7. JOSEPH BRECK & CO.

ROHAN POTATOES.

Orders will be received for Rohan Potatoes by JOSEPH BRECK & Co. or communication may be directed to JOHN A. HOUSTON, Catskill, N. Y. who has them for sale.
Boston, Nov. 7, 1838.

RASPBERRY BUSHES.

The subscribers offer for sale, 5000 Red and White Antwerp, and Franconia Raspberry Bushes of good strong growth.
JOSEPH BRECK & CO.

WHEAT FARMS FOR SALE IN WESTERN NEW YORK.

In the counties of Monroe, Orleans, Genesee and Erie—varying in quantity from 50 to 300 acres each—under a good state of cultivation and improvement, with suitable buildings, fences, &c., watered with durable streams, and most of them are well on the ground. Five or eight years credit can be given, if wanted, on the whole principal sum, with annual interest. These farms are situated in the midst of a rich agricultural district, unsurpassed in the richness and productivity of its soil, lying on the banks of the Erie canal, and in the vicinity of Rochester, Lockport and Buffalo, affording at all times a ready and sure market for all the article produce, which at present prices amply reward the husbandman, and enables him with a few crops to pay the first cost of his lands. A favorable opportunity is here presented to the enterprising farmer who would wish to obtain good farm on liberal credit, with sufficient means to secure payment of one third of the purchase money. Letters (post paid) promptly attended to.
JOHN C. NASH.
Rochester, N. Y. Oct. 18, 1838.

EASTERN POTATOES.

100 Barrels of first rate Eastern Potatoes, for sale by Oct. 24. JOSEPH BRECK & CO.

RASPBERRY BUSHES.

For sale at the Charlestown Vineyard, fine plants of the following Raspberries, viz.
Red Antwerp,
White do.
Barnet,
Franconia, and
Mason's Seedling.
Orders left with JOSEPH BRECK & CO. will meet with prompt attention. THOMAS MASON.
Charlestown, Oct. 10, 1838.

DUCH BULBS.

Just received from Rotterdam, our annual supply of splendid Dutch Bulbs, consisting of
Double Red, Yellow, Blue and White Hyacinths,
Single “ “ “ “ “ “ “ “
“ “ “ “ “ “ “ “
Single and Double Tulips,
Crown Imperials, Double and Single, of sorts,
English, Spanish and Persian Iris,
Polyanthus Narcissus, of sorts,
Ranunculus,
Anemones,
Fritillarias,
Crocus, of sorts.
JOSEPH BRECK & CO.
Boston, Oct. 16, 1838.

FRUIT AND ORNAMENTAL TREES.

The subscribers will be happy to receive orders for Fruit and Ornamental Trees, Shrubs, &c. We shall be enabled to furnish at Nursery Prices, and at short notice, Trees and Shrubs of every description, and hope to give satisfaction to all who may be disposed to favor us with their orders.
Oct. 22. JOSEPH BRECK & CO.

CHINESE MORUS MULTICAULIS, &c.

At the LINNEAN GARDEN, Flushing, N. York, 100,000 splendid trees of the genuine Chinese Morus Multicaulis, for sale at moderate prices, and also cuttings of the same. A number of the humbug kinds have been cultivated at this establishment.

Also, a large supply of the Canton, Moretiorum Alpina, Dandolo, Expansa, Broussa, Asiatic, and cuttings in any quantity. Priced catalogues will be sent to every applicant, but a personal application will be found by the most satisfactory, and purchasers can then see these superior trees.

Also, Fruit and Ornamental Trees, Plants and Seeds of every kind and an immense stock of Bulbous Roots, just arrived from Holland. W.M. PRINCE & SON.
Oct. 24. 4w

PEAR, PLUM, GRAPE VINES, &c.

1000 Pear Trees of the most approved kinds;
1000 Plum Trees, of the most approved kinds and extra size—many of them have borne the past season;
500 Quince Trees;
3000 Isabella and Catawba Grape Vines, from 5 to 15 feet high, most of them have borne fruit—Black Hamburg, Sweet-water, Pond's Seedling;
30,000 Giant Asparagus Roots;
5000 Wilmot's Early Rhubarb or Pie Plant, lately introduced.
Also—a good assortment of Gooseberries, Roses, &c. of different kinds.
All orders left at this office, or with the subscriber at Cambridgeport, will meet with immediate attention.
SAMUEL POND,
Cambridgeport, Mass.

NOTICE.

The subscriber offers for sale his real estate in Westford and Groton; consisting of his homestead, 35 acres, his farm, 117, one pasture, 17 acres, one do. 33 acres, one woodland, 13 acres, one do. 5 acres, and one do. 10 acres. For further particulars see his advertisement in the Lowell Journal, or inquire of the subscriber at his house, near the meeting-houses and academy in Westford.
EPHRAIM ABBOTT.

FARM FOR SALE.

That large and beautiful farm, late residence of the Hon. Judge Dame, situated in Rochester, N. H. six miles from the village of Dover, and four miles from Great Falls. Said farm contains upwards of 300 acres of land and a large and well finished two story house, with barns and other out-buildings in good repair. About 150 acres are covered with hard and pine wood, besides a good portion of heavy timber. There are also on the premises large quarries of the most desirable granite. Any person desirous of purchasing may learn further particulars on application to JOSEPH BRECK & CO. No. 51 and 52 North Market Street, Boston.
August 15, 1838.

FOR SALE.

Five acres of good Salt Marsh, in Quincy, or (Squatoun so called).
Also, Four acres of Salt Marsh in Brighton.
Also, Several full blood animals, cows and calves. Apply to A. Greenwood, on the Welles Farm, Dorchester, near Dr Cotman's meeting-house.
Sept. 12, 1838.

FARM FOR SALE.

An excellent farm, near the centre of Framingham is offered for sale, on liberal terms. Inquire at this office.
Aug. 22, 1838. 3m

EMPLOYMENT WANTED.

A Gardener out of employment would be happy to attend to orders for hudding or gardening of any description. Apply at the New England Farmer Office.

PEAR TREES FOR SALE.

At the Pomological Garden, Salem, Mass., a good collection of Standard Pear Trees, all of which have been proved. They comprise the choicest of the old and new varieties. Also 5,000 superior Buckthorn Plants for hedges.
Salem Oct. 8, 1838. ROBERT MANNING.

MISCELLANEOUS.

TO MY WIFE.

My heart elings fondly unto thee,
My well-beloved wife,
Without thy smiles, how could I bear
The checkered ills of life?

Thou art my sun to cheer the way
In disappointment's hour;
My sweet support and gentle stay,
When storms of sorrow lower.

The cares that sink my spirits low—
The gloomy fears that rise—
Are all forgot amid the joys
Thy constant love supplies.

When other friends forsake, I know
There's confidence in one,
Whose true, unchanging, faithful heart
I daily lean upon.

If sickness come, thy constant watch
Will be around my bed—
And thy soft hands will gently wipe
The cold drops from my head.

Oh, who would pass this vale of tears
Without a friend so dear?—
Whose presence every moment cheers—
Brings peace and comfort near.

PAINTING ROOFS.—An article in the last N. E. Farmer which gives several useful compositions for covering the roofs of buildings, says, notwithstanding, "We believe there is no great economy in spending much upon roofs for paint." We beg leave to differ somewhat from this opinion, having no doubt that it is good economy to keep the roofs of buildings well painted; and if we neglect to paint buildings it is from want of time and money to set out right, rather than from a conviction that painting is not good economy.

The Rev. Mr Perry's meeting-house in Bradford, was built in 1790, the shingles then laid and painted, are on row, and we should hesitate to exchange them for those of any other public building in town, though the others are mostly new. The roof was painted after the shingles were laid, and has been painted we believe, twice since. The paint is the common Spanish Brown, and oil; which we are inclined to think by this experiment, and by the tenacity with which it adheres to many ancient farm houses, is quite as good as any. There is not half the advantage in painting shingles in courses as they are laid, as many have imagined. The shingles suffer little underneath, by what water goes through the joints; it is that part of the shingle which is fully exposed to the sun and rain, that wears out first; and that part of the shingle which lays immediately under the joint of the next course, is frequently sound and bright when the exposed part is quite decayed. The late Moses Parker, Esq. of Bradford, who died last year, at 81 years of age, and was for at least 60 years, more engaged in the erection and repair of buildings, than any other person in this vicinity, and whose long life gave him ample opportunity to make observations, and whose genius and habits distinguished him as an economist, was entirely satisfied of the utility of

painting roofs, and nearly every one of more than twenty buildings owned by him at his decease, are covered with red paint. This was not a mere notion of his, for which he gave direction, without further care, his own hands were always engaged in his alterations and repairs of his numerous tenements, which was his principal business for the last 20 years, even to the last day of his life—and his opinion is entitled to great weight. His buildings were always painted after the shingles were all laid.—*Haverhill Gazette.*

HOME.—No man of sensibility, after battling with the perplexities of the out door world, but retires with a feeling of refreshment to his happy fireside; he hears with joy the lips of the cherub urehin that climbs upon his knee, to tell him some wonderful tale about nothing, or feels with delight the soft breath of some young daughter, whose downy, peach-like cheek is glowing close to his own. I am neither a husband nor a father, but I can easily fancy the feeling of supreme pleasure which either must experience. Let us survey the world of business: "What go we out for to see?" the reed of ambition shaken by the breath of the multitude; and cold hearted traders and brokers, traffickers and over-reachers, anxious each to circumvent, and turn to his purse the golden tide in which all would dabble. Look at the homes of most of those. There the wife, waits for her husband; and while she feels that anxiety for his presence, which may be called the hunger of the heart, she feeds her spirit with the memory of his smile, or perhaps looks with fondness upon the pledges of his affection as they stand like olive branches around his table.—*Poughkeepsie Telegraph.*

All mankind are interested in promoting the peace and advancing the intelligence of the people. None can be interested in its disorganization but those who seek temporary elevation on its prejudice and its passion. That man is the worst enemy that society can have who seeks to array one class against another. It matters not what his motive may be, the consequences must be blighting to the best good of human society. In our land there is no royal road to fame. The way is open to all. The brightest intellect that ever adorned the age, burst from the shackles of abject poverty; the richest man of our country was once a poor Welsh boy who wandered from the green hills of his father's cottage, and sought employ in a merchant's counting-house. The poorest boy in our Republic may go up to the high places by unweary industry, perseverance and economy.—*Philad. Gazette.*

UNDER BEDS.—Would you have good under beds, constituted of materials that will endure? Then give up the old notion of filling them with straw, which soon becomes worn down to chaff, and requires replenishing once or twice a year,—and, if you have not corn of your own, go to some neighbor's husking, and preserve the inner husks of the corn for this purpose. The outer husks are a little too stiff; but the inner ones are soft and elastic when dried, and when you have obtained enough of them to fill the bed sack, dismiss all trouble about that bed for years,—for it will probably last as long as you live. It is quite an object for a family to have all their beds filled in this manner.

ONE WAY TO EMPTY A CART.—An honest son of Erin lately arrived at Baltimore, was employed to drive a dirt cart. Not being an adept in the art and mystery of hauling dirt, he was woefully perplexed when he wished to empty the cart, and after as much manœuvring to get it into proper position, as would have sufficed to move a seventy-four, he marched up to the horse's head, seized the bridle with a powerful grasp! and sang out with a hearty good will—"rare up, rare up!" calculating, we suppose, that the horse would elevate himself far enough to empty the cart!

The New York corner's inquests tell another horrid story of the miseries of intemperance. Two children awaked at midnight, and found their mother dead and cold between them! the result of continued intemperate habits. There are in this Babel daily scenes, sights, and current stories, which make one sick at heart of city life.

FRUIT AND ORNAMENTAL TREES, MULBERRIES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Peaches, Apples, Plums, Penches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grapes, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Flowering Suckies; Pæonies, Dahlias and other Herbaceous Flowering Plants.

100,000 MORUS MULTICAULIS are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussa and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, an application to B. D. BRECK Commission Store, No. 132 Water Street, New York, M. S. POWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nomanum Hill, Newton, near Boston. August 1, 1838. WILLIAM KENRICK.

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more may be wanted, of the most approved kinds—consisting of the best selected varieties now in use, for cultivation, feeding worms, and making silk,—being acclimated to this country and adapted to either warm or cold climates, affording rare opportunity for companies or individuals to be supplied from the most extensive collection of mulberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and order left with Messrs. I. B. Colt, Secretary of the Connecticut Silk Manufacturing Company, Hartford; Alonzo Wakeman, N. Y.; Thomas Lloyd, Jr. No. 336 Filbert street, Philadelphia, Pa.; Luther I. Cox, Baltimore, Md.; B. Snider, Jr. Co. Savannah, Ga.; Bliss Jenkins, & Co. Mobile, Al.; James Lyman, St. Louis, Mo.; Case and Judd, Columbus, O.; G. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass.

Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Mulberry Plantations. Apply at the office of D. STEBBINS, Northampton, Aug 22, 1838.

THE NEW ENGLAND FARMER

Is published every Wednesday Evening, at \$3 per annum payable at the end of the year—but those who pay with sixty days from the time of subscribing are entitled to a deduction of 50 cents.

AGRICULTURAL.

BERKSHIRE AGRICULTURAL SOCIETY.

CATTLE SHOW AND FAIR.

(Continued.)

ON THE PLOUGHING MATCH.

The committee on the Ploughing Match, having discharged the duties assigned them, respectfully report :

That they have had the pleasure of witnessing the perfect work of well formed instruments in skilful hands—all that good ploughs, held by adroit ploughmen, could be expected to perform. The plough is the most ancient and useful of the implements of agriculture. Good ploughing is the basis of good husbandry. Two thousand years ago, Cato, who wrote upon agriculture, said, that the best enture of land was *good ploughing*—the second best—ploughing in the *ordinary way*. Manuring is set down as of less importance. Before the time of the Grecian king Augeas,—the proprietor of the far-famed Augean Stables, and who, as Pliny says, was the inventor of manure—ploughing was regarded as the capital operation on the farm, and the tallest and most athletic youth were selected and trained for ploughmen. Less attention, however, was anciently given to the construction of the plough, than the important purposes of its application would seem to require. The plough of the ancient Egyptians, as sculptured upon the image of Osiris, who first taught them agriculture, was a simple pick like tool, an implement, which might answer its purposes very well upon the light alluvial of the Nile. It is quite uncertain whether any part of it was iron. It is clear however, that the Israelites, who were taught agriculture in Egypt, used iron shares, for in the reign of Saul, it is said, "there was no smith found throughout all the land of Israel, but all the Israelites went to the Philistines, to sharpen every man his share and his coulter." In the time of the Romans the plough had been much improved. They had several kinds with coulters and with and without mould boards. Varro mentions one with two mould boards, used in ridging—and Virgil describes one with a mould board, used both for ridging and covering seed. It is probable, therefore, that the ploughs used by that people in the time of the Republic were of convenient structure. The fashion of the common plough, now used in Castile, is as old as the time of Cincinnatus. The ancient improvements in the construction of this important farming utensil do not appear to be known, even now, in all parts of Europe. Loudon, in treating upon the present state of agriculture in Poland, says, "We have seen lands ploughed by one cow, tied by the horns to the trunk of a young fir tree—one of the roots shaped and acting as a share, and the other serving the ploughman as a handle." In our own country, since the introduction of cast iron ploughs, much attention has been given to their proper construction. They are formed upon various models, adapted to different soils, and suited to different purposes.

Still ploughmen are by no means agreed which upon the whole, is the best—each has its advantages, and each may be superior to the other in certain soils and for certain uses. It would seem to your committee wise enough, if it be not already done, to ascertain the true principles of construction applicable to all ploughs, for whatever use designed—having reference to the line and weight of draught, the depth and width of furrow, and the angle at which the furrow slice should be left. The improved Scotch plough, not yet introduced among us, is regarded by competent judges as embracing most of the attributes of a perfect instrument. Whether it will prove better upon our lands, and for our purposes, than those now in use, experiment will determine, and it is worthy of a full and careful trial. The attention of farmers is particularly directed to the subject, because if there can be no good husbandry without good ploughing, there can be no good ploughing without good ploughs. The teams as usual in the competition of the Ploughing Match, were pressed beyond their ordinary speed. To perfect execution much depends upon the rate of progressive motion. It should not be so quick that the ploughman cannot give the necessary attention to his work, nor so slow that no motion is imparted to the furrow slice. Cattle move at a pace moderately active, with as much ease as at a sluggish one. They never should be suffered to become dull; if they are so, the ploughman is in fault, for they oftener conform to his pace, than he to theirs. There were brought upon the field seven ox teams and five horse teams. All have wrought well—several with great skill and dexterity. The committee have been perplexed in their efforts to determine the comparative merits of the competitors. It is hard to say which of several have won the prize, when all reach the goal at the same instant. They award as follows:

First premium on ox teams, to Titus Parker,	
2d, of Pittsfield,	\$7
2d do. to Thomas Warner of Pittsfield,	6
3d do. to Joseph Foot of do.	5
4th do. to Justin Griswold of Lenox,	4
5th do. to Wm. A. Sears of Pittsfield,	3
First premiums on horse teams to Roswell Hubbard of Pittsfield,	6
2d do. to Levi Goodrich of Pittsfield,	5
3d do. to Wm. Bradley of Lanesboro'	4

All of which is respectfully submitted.

H. W. BISHOP, *Chairman.*

AGRICULTURAL IMPLEMENTS, ETC.

The committee on Agricultural Implements and specimens of machinery report:

The present is an age signally characterized for improvements and inventions, many of which manifest much more of ingenuity than practical utility. To combine the several qualities of strength, durability and labor saving should be the great desideratum sought to be accomplished. The greatest possible simplicity is also desirable. Many inventions which at first view may be considered beneficial are ultimately rendered useless, or nearly so,

by their complexity. Your committee are happy to say that although there was not as full an exhibition of improvements as has been witnessed on former occasions, yet those presented evidently displayed such degree of practical utility as to render them worthy of public attention and approbation. Your committee award

To S. H. Bushnell of Sheffield, for the best drill barrow,	\$4
2d best do. to Allen C. Metcalf of Lenox,	3
To Chauncey Sears of do. for the best grain cradle,	3
2d best do. to Elias Parker of Pittsfield,	2
To E. W. Shepherd of Northampton, for an improved fanning mill,	5
To A. Clark of Richmond, for a beautiful sample pitchfork,	1

Your committee noticed with pleasure a splendid set of bench tools, exhibited by Messrs. J. & W. Webb of Pittsfield. Also some very handsome rail road axletrees, exhibited by the Messrs. Wells' of Otis, which, on the morning of the day of exhibition, were in the rough state of pig iron, and were manufactured at their bloomery and in the hall of exhibition before noon of the same day. They award them

All of which is respectfully submitted.

THOS. P. PLUNKETT, *Chairman.*

ON BUTTER AND CHEESE.

The committee on butter and cheese have attended to the duty assigned them and report:

That the quantity of each exhibited at this anniversary was unusually small, and the quality of the latter, with the exception of one cheese, quite inferior: and they had scruples as to the propriety of awarding any premium for this article. One lot of old cheese might, perhaps, have been pronounced good, had it not been so overcharged with rennet as to be very distasteful; a fault, to some extent, they noticed in some of the other lots. The number of lots exhibited was only five.

The butter was very good. There were only three lots. The one to which they have awarded the highest premium would have been creditable to any dairy, in any market.

The committee beg leave to suggest whether it may not be advisable for the society to increase its premiums on these two most important articles hereafter, and require greater quantities to be exhibited in order to obtain them; the demand for both is daily increasing, as well for home use as for exportation, and the increasing facilities for transportation to distant markets makes increased attention to their production more and more desirable and necessary.

They award the society's first premium on butter to Levi Childs of Pittsfield,	\$6
2d do. to Henry Root of do.	5
3d do. to Wm. Bradley of Lanesboro',	3
1st premium on cheese to Edwin Shears of Sheffield,	6

2d do. to Erastus R. Adams of Sandisfield, 5
3d do. to Humphrey Anthony of Adams, 3
EDWARD A. NEWTON, *Chairman*.

ON MANUFACTURES.

The committee on household Manufactures beg leave to report;

That they have performed the duties assigned them on this Agricultural Anniversary with great satisfaction. Many articles of domestic manufacture, yielding proofs of industry and active ingenuity, have been spread before them in rich array, competing for that excellence which is deserving of reward. Rich products of the card and spinning wheel, substantial fabrics of the loom, tasteful ornaments of the frame and needle, have come with a beauty of coloring and fineness of texture unrivalled, to show what the industry and taste of the frugal housewife can effect. No little credit is due to the ladies of Berkshire for having, from the very commencement of your society, so well sustained their parts in its public exhibitions. To them is due here, as ever in the sphere where they move, the meed of praise of having been unrivalled by the other sex.

Your committee cannot but hope that this part of the annual exhibitions of your society will ever receive that encouragement it deserves. In this, they believe, is to be found that germ of life which has so long sustained it. All which encourages the industry of the farmer's domestic circle must be invaluable, for it is his home which makes him what he is. The sound of the wheel and the vigorous strokes of the loom, commingling with the cheerful song and the contented smile, have always made his fireside the green spot of his life. The thought of it nerves his arm, and cheers his heart in the toils of the day. And in homes like his are the strong holds of virtue and independence. If our cities foster the growth of pomp or the elements of discord—if the rich prairies of the west populate with a speculating and immoral community, if crowds of foreign emigrants threaten to sow broad-cast over our land the seeds of evil—from these peaceful farm houses will go forth a spirit, pure as the air of our own mountains, to cherish and preserve and invigorate the liberties we love. The committee have awarded the following premiums:

On woollen fulled cloth, to Miss Jane Farnum of Lanesboro', 1st premium, \$6
2d do. to Miss Mary D. Parks of Dalton, 4
3d do. to Mrs Sophronia C. Tillotson, 3
4th do. to Mrs Ann Coman of Cheshire, 3
On white flannel, to Miss Julia Comstock of South Adams, 1st premium, 3
2d do. to Miss Nancy Tracy of Hinesdale, 3
3d do. to Mrs Sarah F. Bishop of Lenox, 3
4th do. to Mrs Emily Washburn of do. 2
On woollen and cotton sheeting, to Mrs Jerusha Clark of Pittsfield, 1st premium, 3
2d do. to Mrs N. Brown of Cheshire, 2
On woollen blankets, to Mrs Lucy Buck of Lanesboro', 1st premium, 3
2d do. to Mrs Hannah Bradley of do. 2
An extra premium on a pair of plaid blankets, very fine color, to Miss Harriet Churchill of Pittsfield, 2
On coverlids, best, to Mrs Mary Jones of Stockbridge, 2
On carpeting, to Mrs Hannah Bradley of Lanesborough, 1st premium, 4
2d do. to Miss Rebecca Shears of Sheffield, 3

3d do to Mrs Charlotte Callender, Pittsfield, 2
Very little stair carpeting was offered, and upon this your committee made no award.
On hearth rug, to Miss Laura Washburn of Lenox, 1st premium, 2
2d do. not awarded.
On linen sheeting, to Mrs Prudence Cook of Lenox, 1st premium, 4
2d do. to Miss Sarah Sturgess, Lanesboro', 2
No linen shirting offered,
On linen diaper, to Mrs Mehitabel Huntington of Becket, 1st premium, 4
2d do. to Mrs Hannah Wilcox, Stockbridge, 3
An extra premium to Mrs Julia Carter of do. 2
On women's wollen stockings, to Miss Rowenna Cook, Richmond, 1st premium, 2
2d do. to Miss Betsy Cook of do. 1
On a pair of plain unbleached linen stockings, to Miss Sally Curtis of Lanesboro', 1
On thread hose, to Miss Eliza Kendall of Richmond, 1st premium, 2
2d do. to Mrs Mehitabel Dewey of Lenox, 1
On men's woollen hose, to Mrs Agnes Buel of Pittsfield, 1st premium, 2
2d do. to Mrs Almira Sears of Lenox, 1
An extra premium to Elizabeth Durant of Hinesdale, aged 86, 1
2d do. to Mrs Prudence Foot of Pittsfield, aged 90. 1

We can but speak in recommendation of the industry of these two aged ladies. Certainly we mean to disrespect when we say that their contending so successfully for premiums at so advanced an age has reminded us strongly of the old song:

"She lived to the age of an hundred and ten,
And died by a fall from a cherry-tree then,
What a frisky old girl!"

And though we would deprecate so unfortunate an end to their useful lives, yet we heartily wish they may attain the full age of their brisk prototype.

On woollen yarn to Miss Hannah M. Tracy of Pittsfield, 1st premium, 2
2d do. to Miss Melissa Sherwood of Williamstown, 1
On sewing silk, to Miss Emily Sherwood of do. 1st premium, 1
2d do. to Miss Julia Ann Fitch of Lenox, 1
Silk manufacture, to Mrs Mariette Sands of Pittsfield, 1st premium, 2
2d do. to Miss E. Sherwood, Williamstown, 1
Straw bonnet, to Miss Abigail Francis of Hinesdale, 2
4 To Miss Nancy Tracy of Hinesdale and Miss Julia Briggs of Stockbridge the committee award \$1 each for lace veils; and to Mrs Armanda Washburn of Lenox and Mrs Sarah Sturgess of Lanesboro', \$1 each for Highland shawls, 4
Your committee remark a great deficiency in the selection, arrangement and firmness of colors in almost all the articles presented; in some instances have declined awarding premiums to the otherwise best articles for this reason.

Extra Premiums.

For finely finished satinets, to the Messrs. Ball, Bassett & Co. of Lee, 2
For cassimeres, to the Messrs Russells' of G. Barrington, 2
For some beautiful letter paper, of good texture

and exquisite surface, to Messrs. Sturgess, Phillips & Allen of Lee, 2
For a bed spread, to Miss Eliza Wood of Pittsfield, 1
2 For do. to Mrs Grace P. Bliss, Stockbridge, 1
For flannel, to Miss Betsey D. Tracy of Hinesdale, 2
For a white bed spread, to Mrs Rebecca Barrett of Lenox, 1
For a well finished trunk, to James M. Noble of Pittsfield, 1
4 For well made otter caps, to C. B. Platt of Pittsfield, 1
2 For 3 pairs linen stockings, to Mrs Hannah Wilcox of do. 1
2 For stocking yarn, to Miss Melissa Sherwood of Williamstown, 1
Several linen table cloths, exhibiting great taste and industry, were presented, but not for premium, by Mrs Franklin Root of Pittsfield.
Your committee have seldom seen more elegant specimens of satin embroidery than were presented by Mrs E. P. Day of Pittsfield, wrought for the Young Ladies' Benevolent Society.
All which is respectfully submitted.

N. S. DODGE, *Chairman*.

For the New England Farmer.

MR EDITOR,—Perhaps there never has been a season in this country that presented fairer prospects to the farmer than the last summer. Everything of the vegetable kingdom appeared to be in its glory; and if the growing herbage could have had the power of utterance and of song, we should have literally heard the welkin ring with its music. Plenty showed her fat and ruddy cheeks all around, and smiles were common currency. But the severe droughts sadly changed the scene, and there came a fear upon us that the yielding of the earth would scarcely repay the "labors of the workmen." It was foolish thus to anticipate troubles; the event has shown that the fruits of the earth have not been withheld from us, and there is plenty for our comfort and for our joy. The potato crop is, indeed, considerably cut off, nevertheless, by economy we shall be able to supply our necessities at least. There is a growing fondness here for farming, which I am happy to witness, and husbandmen have increased in the country by reason of the times, and this is one cause why the fields of grain have been more plenteous than for years heretofore. We are indebted to Providence for the prosperous growth of our crops most assuredly; but certainly there is an increased attention to agriculture by the people; the old method is done away, of following the footsteps of our fathers; husbandmen read and think, as well as work, and therefore their labor is more judiciously laid out, and comes to better account, than formerly. I think it a duty here to say, that the N. E. Farmer, and other periodicals, have been in a very great degree instrumental in bringing about a happy change.

Permit me to ask—what has become of your sweet melodist, *Agricola*? We hope the minstrel has not laid aside his pipe entirely. There is reason to sing now; no season is without its charm; and could he but know how he delights the country swains and lasses with his harmonious numbers, I am sure he would sing on. We do, verily, hope that he will vouchsafe to resume his lute again. *The Farmer's Daughter*, by the same author, I pre-

is sung by all our country damsels far and near, and the little mimic verse of the *Thrush*, is in the mouth of every urchin. H. Y.
Worcester County, Nov. 1832.

From the Practical Farmer.

CLEANING NEAT CATTLE.

The following we translated, and we would invite the attention of farmers to the subject. Our German correspondent is the right kind of a man. He gives his notions well confirmed by experience.—*Editor*.

Xenia, Ohio, June 14th, 1838.

Μα ΕΔΙΘΩΡ.—Allow me through the "Farmer," to say a word to my fellow farmers on, what seems to me, an important subject. In this country, you will seldom find a curry-comb and hand brush in the cow-stable; but I consider them indispensable in the cow-stable, as in the horse-stable. Why farmers do not curry and brush their cows, I know not, unless it be that they think cleanliness is not so necessary to the cow as to the horse.

But if we will, for a moment, consider the evils arising from this neglect, the importance of keeping cows clean must strike every reflecting mind. It is well known that no animal, neither horse nor cow, can be healthy; unless the *insensible perspiration goes on regularly*, and this can never be going on if cows are kept in a dirty stable, and no pains taken to rub off carefully the dirt or matter which obstructs the vessels or pores of the skin.

Wherever cows are regularly curried and rubbed, they are invariably stronger, and in a healthy condition; not liable to *cutaneous* and other diseases; and from experience I know they yield more milk, and that too of a better quality—a cleaner milk, richer cream and sweeter butter, necessarily follows.

I make it a practice to curry my cows once a day very carefully—I never suffer any dung to stick to their coats—it looks bad and injures the cows. This useful animal does not deserve such *dirty treatment*. Give them litter sufficient, and remove the dung regularly, and this part is accomplished.

Many of our farmers seem to think that in order to have healthy and good cows, you need only feed them with a sufficiency of food; however, I am fully convinced from experience, that cows may be well supplied with food, still they will not be as profitable as they would be if kept perfectly clean, and free from all kind of dirt and matter obstructing perspiration, as above stated; besides this, if cows are kept perfectly clean, they will thrive upon a less quantity of food.

Cows are often subject to have swollen teats and udders, as well as other excrescences. These may be prevented if the parts be occasionally washed with warm water. The udder and teats should be carefully washed immediately before the cow is milked. It has been well said by Lodon: "Go to the cow stall—take with you cold water and a sponge, and wash each cow's udder clean before milking; douse the udder with cold water, winter and summer, as it braces and repels heat."

Yours, DAVID HEYMACKER.

MANURE.

Feed your plants and they will feed you.

It is a subject of much regret that more vigilance and care is not taken by many farmers to increase

the quantity of their manure. It is the very base of their prosperity; without it little can be achieved that is important or valuable; with it, everything can be accomplished that is within their reach. By the use of lime applied to grass lands, and great care in bringing all decomposable articles into the dung heap, the quantity on some farms has been doubled in seven years. After it has been obtained it requires a little skill and judgment to preserve its most valuable parts from being drenched and washed away by frequent rains; for although it is not best to keep it too dry, yet it is much more frequently suffered to become so often wetted with drenching rains as to wash away the most nutritious portions of it. Dung that has remained under open sheds where it was but partially exposed to the elements, has been found to be much richer in quality than that which was entirely exposed to the rain. In some situations, much is lost by water running through barn yards during heavy showers, and in some cases they are perfect quagmires for half the year, rendering it disagreeable, if not dangerous to approach a stable door. This state of things constitutes an absolute nuisance, and ought to be provided against by every farmer who has a proper sense of propriety, and a due regard to the female members of his family, who are obliged, twice a day, to trudge through wet and filth to milk the cows.

The autumn is the proper season for making suitable footways to stable doors, and other arrangements for preserving the manure to be made during the approaching winter from loss by washing, and to protect it from being filtered by rains till it loses its most valuable component parts. A shrewd old gentleman of Montgomery county, estimates the importance of a farmer by the number of loads of manure he makes annually. A fifty load farmer is rather a small article; one of a hundred loads stands a little stiffer; one of one hundred and fifty loads holds up his head pretty well and begins to be quite respectable; and the two hundred, two hundred and fifty, and three hundred load farmers are entitled to have the word Mr as a prefix to their names, and the letters Esq. placed after it. These are the solid yeomanry, in his estimation; the men of substance and stamina, out of which, in his opinion; any useful article can be manufactured, even up to a Congressman or Governor. Whether he is altogether right in his way of estimating farmers, we must leave others to judge; but one thing is pretty certain, that it is a good thing for every farmer to have an abundance of manure to furnish nutriment to his crops, and this he won't be likely to obtain unless he is very industrious and manages well.—*Farmer's Cabinet*.

SMOKING WITH SULPHUR.

In England the fumigation of plants with sulphur, to destroy plant lice, aphides, the turnip fly, insects on trees, where the top could be covered or exposed to the suffocating fumes, has been for some time, practised with great success. To most animals and insects the fumes of sulphur are almost instantly fatal. The *rationale* appears to be this. The smoke of sulphur immediately combines with water when brought in contact with it; and in this way, by combining the smoke of sulphur in leaden chambers with water that covers the floor, and is frequently agitated, the sulphuric acid of commerce is formed. Thus when the fumes of sulphur are brought in contact with the moist surface of the

lungs, or breathing vessels of animals or insects, sulphurous acid is usually generated, and the lungs refusing to act under such circumstances, suffocation is produced. Of this, any one can easily satisfy himself by experiment.

Taking the hint from these facts, it was proposed to attempt the suffocation or destruction of the wheat fly or grain worm by fumigation on its first appearance, and we are happy to learn it has been tried the present season with entire success. It is stated in the *Amsterdam paper*, (a Journal on the Mohawk in Montgomery county,) that a farmer in Herkimer has preserved a large wheat crop from the worm the past season, by using brimstone in fumigation liberally, while all around him who did not adopt this preventive, had their crops seriously injured or destroyed. The brimstone was prepared by melting, and in thin strips of old woollen cloth were dipped. These fixed on sticks, and fixed in different parts of the field, were set on fire, generally at evening. The matches were given in the greatest numbers to the windward side of the fields, and the offensive and destructive smoke of course driven over every part, proving fatal to the insects that inhale the gas. About 100 pounds of brimstone were used to 100 bushels of sowing, and the preservation was complete; thus proving, in this instance at least, a remedy equally cheap and efficacious.—*Genesee Farmer*.

HOGS BETTER COAXED THAN DRIVEN.—Several of our good citizens residing about the foot of Delancy street, and the neighborhood, have for some weeks past missed a great number of their pigs; and setting their wits to work, have ascertained that they have been taken on board the Eastern coasters—not by force, but by the free will and consent of the porkers themselves. The plan was to lay a trail of grain down the wharf, and when at high water the vessel's deck was level with the wharf, the trail was extended on board across a plank. The unsuspecting grunners of course took the bait—but were no sooner on deck than they were seized and thrust below the hatches. It was ascertained, that two schooners, which sailed last week, had on board each some seven or eight fine hogs, which had been decoyed on board in this manner. On Thursday, Mr George Bell of Delancy street, missing several of his pigs, obtained the aid of Officer Foster, went on board of the schooner Eliza Ann, of Machias, and on searching the hold, found, nicely stowed away among some flour barrels, four of these animals, which he identified as his property. The pigs were liberated, and the matter settled, by the captain's prompt payment of all necessary expenses incurred in the search.—*N. Y. Express*.

BENEVOLENCE.—The late Archbishop of Bordeaux was remarkable for his tolerance and enlightened benevolence. The following anecdote will not be read without interest. "My lord," said a person to him one day, "here is a poor woman come to ask charity; what do you wish to do for her?" "How old is she?" "Seventy." "Is she in great distress?" "She says so." "She must be relieved; give her twentyfive francs." "Twentyfive francs, my lord, is too much, especially as she is a Jewess." "A Jewess?—" "Yes my lord." "Oh, that makes a great difference. Give her fifty francs, then, and thank her for coming."

PRESERVATION OF THE POTATO.

One can form something of an estimate how extensively the potato enters into use as an article of food among the American people, from the complaints we hear from all parts of the country, or at least with very few exceptions, of the partial failure of that crop the present season. We frequently hear people when instituting a comparison between that root and bread, declare they would sooner part with their wheat bread, than with their potato; and these are not the poorer classes, but respectable wealthy people. Now, though we do not carry our affection to this esculent as far as this, yet we are "free to acknowledge" that a good potato is a good thing, and an inferior one, the worst of bad things. An unripe or defective potato, is one of the most indigestible and unwholesome kinds of aliments that can be taken into the stomach, if indeed there is any aliment about it all; and from the specimens we have seen at numerous tables this year, we have no doubt that many of the cases of illness that have been charged upon hot weather, bad water, malaria, and a variety of other things, are justly due to the swallowing potatoes as hard and as heavy, as well as about the size of ounce balls.

The potato, in its original uncultivated state, is decidedly poisonous; and whenever it is used in an imperfect or unripe state, the result is not widely different now. Owing most likely to the hot dry weather, potatoes, this year, are generally of an inferior quality, and hence more pains and care should be taken in selecting those intended for food, and greater attention paid to preserving them, than in years like the last, when among thousands of bushels there was scarcely a defective one. Ireland, on the other side of the Atlantic, and Nova Scotia on this side, are the most celebrated for the excellence of their potatoes, and both have a temperature comparatively low, and an atmosphere moist and humid. If such a climate and temperature is required for the perfection of this root, will not the hot weather we have had the present year, account most satisfactorily for its little value, and also show why its growth is impossible in our more southern states, or still nearer the equinox.

Potatoes almost instinctively shun the light and air. These things so indispensable to the perfection of many other things, are most injurious to the potato, and the grand secret of its preservation lies in the most perfect exclusion of these elements but active agents. To perceive the difference between roots exposed, and those secluded, we have only to take one which has grown partially above ground, and one that has ripened in its proper place. The one will be green on the exterior, hard, heavy, and bitter in the interior, while the other will be of the natural color, farinaceous, and fine flavored. Farmers should take lessons from these facts, and conform their practice to the teachings of nature. In England and Scotland, where most serious complaints have arisen from the failures of the planted tubers, it is acknowledged by all, that roots which are allowed to remain in the ground during the winter never fail of vegetating, and that those secured by pitting are more likely to succeed than those put into cellars, and thus partially exposed to light and air.

The most common method of preserving potatoes is to put them into bins in the cellar, where they are left without any covering or other preparation, and used as wanted. It is also customary to get in as little dirt with them as possible, and one standard of good farming has been the clean

state of a farmer's potatoes when deposited in his cellar. For the reasons given above, and from our own experience, we think both these modes of securing potatoes, or preparing them, erroneous. If put into bins, they should be covered as closely as possible from light and air; and if there is dirt enough thrown into the bin to completely fill all the interstices between them, so much the better for the roots. It has been recommended by some potato growers, and the practice is founded in reason, to line the sides of the bins with turf, the lower sides placed inwards, and when the bin was filled, to cover it closely in the same way, and with the same material.

Owing to the severity of our winters, potatoes cannot be allowed to remain where they grow; else their meanness and freshness, would be much increased by allowing those that are to be used the coming season to remain where they are till the spring opens. Since this cannot be, the method of preservation that approaches the nearest to this will be found the best, and this method doubtless is pitting, or as most of our farmers term it, burying in holes in the field. In burying in this way care should be taken not to put too many in a pit, or in other words, not make the heaps too large. Twenty or twentyfive bushels is quite enough; and some prefer even a smaller number. The cone should be regular so as to be covered equally. The covering of straw and earth first put on should not be too thick, as otherwise the roots will heat, and be injured; but at the latest period allowable, the thickness of the covering should be increased so as effectually to prevent freezing. In covering potatoes in the fall, it should be remembered that the great object of the first covering, is simply to exclude air and light, and preserve them from rain or unfavorable weather, and the last covering is the one to be relied on as a defence against the frost. If the roots are dug and pitted immediately without unnecessary exposure, and if the ground and the process of covering is properly selected and performed, the potatoes will come out in the spring, in excellent order, rather improved than deteriorated by their winter's keeping.

Farmers who are in the habit of making their pork from potatoes, or feeding them extensively to their stock, will undoubtedly see the propriety from the present high prices, of sorting their roots more carefully than they have hitherto done, in order to sell, or preserve, as many as possible. The apprehended scarcity of this root will also prompt to this course; and should induce all to adopt the best and most effectual measures to preserve through the winter uninjured, or, if possible, improved, this root on which so many rely for sustenance.—*Genesee Farmer.*

From the Cultivator.

THE VERMONT BEE-HIVE.

Hon. JESSE BUEL,—

Sir—In my communication, which appeared in the Cultivator, May last, relating to the construction of a *bee-house* and *bee management*, I recommended my mode of growing honey, in preference to the old mode of managing bees, where it was designed to facilitate their cultivation among those who would pay but little attention to them, dislike the task of living, and render them more safe from the destruction of the moth and other casualties, than the ordinary method by which bees are generally kept.

In all cases where it is convenient and desirable to the owners of bees to devote their attention, live them where they swarm, and those who wish to realize a profit from this insect, by forwarding yearly a quantity of honey to market, I do freely, and consider it no more than justice due my neighbor, Mr John M. Weeks, and the community at large, recommend the Vermont bee-hive, which is considered the best in use by a majority of the apiarists of this state, and is coming into general use in most of the states in the Union.

This *hive* was invented and patented by John M. Weeks, Esq. of Salisbury, Vermont, who has from youth devoted a portion of his time studying their nature, and most assiduously for the last eight or ten years, in observing their habits and demonstrating facts; the result of which no doubt is opening a new era in bee management, from which the public must derive a great benefit.

He is considered the first apiarist in this state, and it is a matter of doubt whether there is one in these United States that has investigated the subject, and made so many discoveries respecting the nature and habits of this instinctive little insect, as Mr Weeks, who has been at several thousand dollars expense, in time, in experimenting, publishing books, illustrating facts, &c. &c.

When on a visit at his residence, a few weeks since, I could not but feel deeply interested in his illustration of facts, as exhibited to us by means of *full observing hives*, (glass, covered with wood,) neat and elegant as any parlor furniture; the chambers filled with the most pleasing and admirably constructed drawers of glass, and drawers filled and filling with beautiful honey, without bread, or any thing unpleasant in its appearance. These drawers are taken out and sent to market at any season of the year. He informed us that he usually obtained from his old stocks, from twenty to thirty pounds of honey in these drawers annually, and from his earliest young swarms, thirty pounds and over, without robbing them of their winter stores. The Vermont hive affords an easy and safe method of preserving the lives of the bees through the winter, without destroying any. He showed us a *feeder*, and the manner of using it. Through the means of this, the bees may be fed on low priced or sale honey. We noticed several healthy stocks, which he informed us were wintered entirely on Havana honey, and have yielded several boxes of clover honey this summer. We were also informed that the principal part of bee management depends on a knowledge of the natural habits of the queen and her influence; and no apiarist can at all times be sure to succeed in their cultivation, unless he has a thorough knowledge in managing them.

He also instructed us in his art of compelling the bees to make and keep on hand extra queens; how they may be divided into separate colonies when they have become too numerous, without swarming.

He showed us how the bees would transfer themselves when the age of their combs rendered it necessary, by a little aid of their owner, and urges, by many arguments, that bees should never be compelled to leave one tenement and take another.

We observed in one hive, that he had killed the queen and confined her therein. In this experiment, Mr Weeks is about to demonstrate several important facts, viz: That there is no monarchical government in a hive of bees, nor domineering power in a queen; though the queen may be dead

bees will continue to work as well, provided carcass be present; and that no young bees be raised without a queen; the old bees never breed, &c. These experiments Mr Weeks intends to publish, and their results; therefore I can say, that it is an interesting system, which affords an agreeable amusement, a comfort and profit. He advances his opinion, that bees are susceptible of a high state of cultivation; that they will never flee to the woods and mountains, unless neglected by their owner, or through a deficiency knowing how they must be managed; and that they had not lost a swarm by flight to the woods in fifteen years. One reason of the bees deserting for better quarters is, when the rays of the sun directly exhausts the air in the hive of its vitality. Mr W. sells the common coarse wood swarms of honey, in Boston, at from thirtyfour to fiftytwo cents per pound, by the quantity; and for the best glass and mahogany boxes, he receives a higher price.

Mr Aaron Barns, of Rutland, states, that ten of his swarms in the Vermont hive, produced, last season, \$75 worth of extra honey.

Mr Week's last edition of books on the management of bees, have all been ordered, but another edition will probably be published the ensuing winter. He is ever ready to congratulate all those who may call on him—such as parties of pleasure, amusement, and profit, and none can leave without a taste of his bread and choice honey; in addition a pleasing course of lectures on the natures and habits of the honey bee, and other insects, which is very entertaining, instructive and useful.

Respectfully yours,

SOLOMON W. JEWETT.

Weybridge, Vt. August, 1838.

PATRONAGE TO AGRICULTURE.

Goshen, August 27, 1838.

ESSE BUEL, Esq.—

Dear Sir—If you think the following will observe the cause of agriculture, you can give it place in your valuable journal. It has always seemed surprising to me, that this country, which is so productive in the fruits of the earth, should have received in its agricultural department so little aid from its rulers. While patronage is extended with a liberal hand to the various mechanical arts, and improvements in machinery anxiously sought after, the parent art, upon which all others depend for their support, is neglected. I know that is the fault, in some measure, rests upon the people themselves; but something should be done to elevate the standard of agriculture. The ancients took much more interest in the cultivation of the soil, than is manifested at the present time. The artists and manufacturers had not attained their present state of perfection, and it was only by the tilling of the soil that the greater portion of the inhabitants were enabled to procure a subsistence. But their kings and princes, orators and great men, united in hurrying the science to such a pitch of perfection as has not been seen since. A great many excellent treatises were composed upon the subject of which we ought much to regret the loss. The kings of Egypt were famous for their skill in husbandry, and for the improvement they caused to be made in that country. They caused drains to be

made to convey the water of the Nile to the dry and arid tracts not usually irrigated in the annual overflow of that river. Of such utility were these improvements, combined with the fertilizing properties of the water brought from the Nile, that the country of Egypt, consisting of only 6,000 square miles, comprised, as we are told by Pliny, a population of 20,000,000 souls. This amazing fertility, although caused principally by the Nile, could not have benefited the Egyptians in a very great degree, without the kindly aid and instruction of their rulers. Cicero, also, one of the first orators of Rome, devoted much of his time to agricultural pursuits. He composed many valuable works. Virgil also has immortalized himself in his *Bucolics*. But perhaps of all the kings recorded in history, Hiero, king of Syracuse, in Sicily, stands first as a patron of husbandry. He came in possession of the throne at the age of thirty, and found the country convulsed with seditions and corrupted by luxury. He soon succeeded in placing agriculture in honor among his subjects, who, whether high or low, rich or poor, applied themselves diligently to cultivating the soil. The consequence was, that in a few years the inhabitants of Sicily, a small speck in the Mediterranean, who were in the habit of importing nearly all their grain from the continent, had now a large surplus for exportation. This brought the wealth of the surrounding country into their own, and then into the pockets of the farmers. By means of these wise regulations, he also kept an infinite number of hands busy, which might otherwise have been employed to the detriment of the state. This is a policy which should (and it cannot be too often repeated) be the peculiar care of a wise and prudent government, but it is often sadly neglected. Hiero's laws were so excellent in this respect, as well as others, that sometime afterwards, when the island became a Roman province, the inhabitants were allowed to be governed by their own laws, the Romans not being able to substitute anything better in their room.

And why, permit me to ask, may not the example of Hiero be imitated in this country? It is from the Legislatures of the several states that we must look for encouragement, in a government constituted as ours is. They have begun to awake, and have done something, as is the case in regard to Maine, Massachusetts, Kentucky and Pennsylvania. But much still remains to be done.

The condition of agriculture at present, is somewhat analogous to that of our common schools. Something should be done to give the useful science of agriculture its proper respect in the minds of men. Education and agriculture should go hand in hand. All improvements in the one should be met by improvements in the other. The power and influence of the general assembly, are acknowledged by many to be necessary in advancing the character and promoting the usefulness of common schools. Why should not that power and influence be exerted in forwarding the usefulness of agriculture, upon which so much depends, and in which so many are concerned? That august assembly, the senate of Rome, did not think it beneath them to bring this art to perfection, and why should the legislature of this country neglect so important a source of revenue? In the hope, dear sir, that this may not be altogether out of place, I remain your obedient servant.

CHARLES STRONG.

From the Baltimore Patriot.

CRUELTY TO ANIMALS.

"A righteous man," says Solomon, "regardeth the life of his beast," and it may be added that he regards his *comfort* also. I have often been surprised and pained, at what appears to be an unmerciful regardlessness of the comfort and health of their animals; particularly their colts and horned cattle; in not providing them with shelter, in the winter season. These animals are around a stack, at a distance from any shelter; or around a barn, where there is none, except protection by the sides of the barn, from the direct force of the wind; these too, night and day, through storms of rain and snow, and whether the thermometer is above freezing or below zero, and in severe cold weather, standing shivering, and curling up with evident signs of discomfort and suffering. Now I would not ask a farmer to build a house, with parlors in it, and stoves to warm his animals, and with floors carpeted, and windows curtained, and feather-beds for them to sleep upon. No such thing; with all my sympathy for their neglect and suffering. But this I would say—give them at least cow-houses, and so far as practicable, stables, or what shall shut them up from storms and wind.

Another thing. I often see barns and cow-houses, which are the mere ghosts of such things; shingles off, boards off, or so far apart that they are very little shelter from the cold; a door lying on the side, edgewise before the place where it ought to be hung, bona fide, upon hinges, and capable of being shut. Now here are slovenliness and cruelty, both together; very fit company for each other too.

I heard a man, telling how much his cattle suffered through one of our late winters because the winter came on suddenly, and before he had covered his barn. "Thinks I to, myself," (and I am sorry now I did not say it, as well as think it,)—"Why, man alive! why didn't you snatch every day that came—after the first onset of winter. Go to bed and sleep quietly night after night, with your cattle and colts shivering under the fences, and exposed to rain, snow, and hail, for the want of a little enterprise and bravery of the cold! Shame upon you! Has a beast no sensation of cold, think you?"

Cruelty of this sort, is bad economy. Animals that shiver with cold, and tremble from weather during winter, will be lean and feeble in the spring.

For two reasons, ay! three—should a man who would be considered a good farmer, afford a good shelter to his animals, in the winter; to wit: for *economy's* sake; for *mercy's* sake; and for *conscience's* sake.

A FRIEND TO HORSES AND CATTLE.

The damage to the crops, &c. on the Tar river and its tributary streams in North Carolina by the storm of the 28th of Sept., has been estimated at three millions of dollars.

An idle fellow, complaining of his hard lot, said he was born the last day of the year, the last day of the month, the last day of the week; and he had always been behind hand. He believed it would have been fifty dollars in his pocket if he had not been born at all.

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, NOVEMBER 14, 1838.

AGRICULTURAL SOCIETIES AND PREMIUMS.

No. III.

The amount of money offered and disbursed in premiums annually by the different agricultural societies in the State is very large. We have not at hand the means of ascertaining this amount with exactness, but it considerably exceeds five thousand dollars. The premiums offered, according to their published list, by the Massachusetts Society amount to 2090 dollars; by the Worcester Society to 669 dollars; by the Hampshire, Hampden, and Franklin Society to 631 dollars; probably the amounts offered in premiums by the Berkshire, Middlesex, Essex, and Plymouth Societies do not fall short of six hundred dollars each;—supposing this to be the precise sum, the sum total would be 5750 dollars. It probably exceeds this amount; and a disbursement of this amount for this object is in a high degree creditable both to public and private liberality; and ought to be productive of much and immediate and obvious advantage. That this has been the case we know. We have already adduced evidence of it. That proof might easily be extended; and it meets the intelligent and candid mind, wherever it directs its inquiries. But we are anxious that this good should be increased; that these premiums should create more attention; and kindle everywhere a more spirited emulation. Massachusetts with her rocky soil, and her inhospitable climate, has the honor of having done more for the encouragement of agriculture, with the exception of the wheat bounty paid last year in Maine, than all the other States put together. In this matter she has acted with a sound discretion and has done herself honor. Her proffered bounties on silk, beet-sugar, and wheat, will, we have no doubt, largely increase the debt, which her own citizens, and the whole community owe to her munificence. She has already reaped the greatest advantages from her liberality; and the seed, which she has bountifully sown promises a more abundant and enduring harvest.

The Massachusetts Society has this year offered six hundred dollars in four premiums, for the best cultivated farms. It is now several years since such premiums were first proposed; but they have never until this year been raised to so liberal an amount. The Essex Society has offered liberal premiums for the same object for years. The Middlesex Society has done the same. So also we believe has the Plymouth Society. The competition for these premiums has not been so spirited as was to have been expected. This has in a degree arisen from the proposals of the State Society not being so extensively known as it should be. This has not been the fault of that society; but of the persons to whom the prospectus has been sent or entrusted, not having taken pains to circulate or publish them. Copies have been always distributed among the members of the General Court; and sent to every postmaster in the State; but there is a culpable indifference or want of public spirit somewhere by which the patriotic views of the society have failed of being seconded. In the next place there is a diffidence on the part of many of our best farmers, which makes them reluctant to enter the competition. They are unwilling to present their farms as pattern farms, and to come into comparison with others. Many whose agriculture and husbandry are highly creditable to them, keep no account whatever of their expenses or products, no minutes of any agricultural experiment or operation, which they perform; and never know the *when*, or the *how*, or the *how much*, or the *wherefore*, of anything in which they are concerned. In this important particular we cannot

but hope for alteration and improvement. If the agricultural survey of the Commonwealth now in progress results in no other good, we believe it will confer a benefit vastly more than a compensation for its labor and expense, in inducing farmers to keep accounts of their husbandry, to study exactness in all their operations and experiments, and to know how they stand and where they stand. To this object the attention of the Commissioner has been particularly directed; and the blank form of a Farm Report, which he has distributed among the farmers, wherever he has been, strongly attracts their attention to this subject; and shows those, who are little accustomed to making up accounts, how it may be accomplished with ease. Another objection to entering their farms has been in the fact that few or no farms in the State combine that universal variety of husbandry, which the requisitions of the Society seem to imply. With the exception of raising such variety, and in such quantity, of articles as the immediate wants of the family render necessary, or in the vicinity of market-towns as the demands of such markets require, our husbandry is as it should be, comparatively single in its objects, and accommodated to the nature or condition of the soil, and the localities of the farm as it respects tillage, manure, climate, and market. This renders it impossible for the generality of farmers to come into the competition under present arrangements, with the hope of success. Should the premiums of this character be continued by the Massachusetts Society we would respectfully suggest for their consideration a different form of presenting them. We begin by saying that we think them too large, and that no premium should exceed one hundred dollars. This is more matter of judgment; and we understand well the motive which induced the Trustees to make them as liberal as they have done, in hopes, by strongly tempting the cupidity of our farmers, to induce them to do, what they had heretofore found it so difficult to induce them to do, enter their farms for premium. But we believe it has not hitherto been that the premiums were not liberal enough that the farmers have been kept back from the competition. By reducing the size and enlarging the number of the premiums, competitors feeling that they had a greater chance of success, would be more numerous. Six hundred dollars divided into six, eight, ten or even twelve premiums, would be deemed an ample compensation and honor, by any successful competitor among the farmers, for any pains he may be at in keeping and presenting an exact account of his husbandry to the Trustees; or for any skill or industry, which he may display in the cultivation or management of his farm. Gentlemen accustomed only to deal in thousands, tens of thousands and hundreds of thousands can have but imperfect notions of the estimate in which a plain working farmer would hold the sum of fifty or a hundred dollars, to be obtained as a gratuity or premium. Their acquisitions are usually the result of small and minute earnings and savings; and the obtaining of fifty or a hundred dollars in a single sum without actual hard labor, is a thing, which does not even present itself in their golden dreams, if at any time the poor fellows are not too tired to have any such dreams.

In the next place we think it would be expedient to distribute these premiums somewhat in this form. A premium should be given for example on the best sheep farm. The number of sheep kept should not be less than —, and the account required by the Board should embrace their whole history and management; their kind; the quality of their wool; the amount of wool to a fleece; their cost of keep; their feed; the kinds of feed; the quantity required in any given number; the value of hay, straw, Indian meal, oil meal, potatoes, turnips, carrots, cabbages; the number pastured on an acre; the value of pasturage; the average number of lambs

raised to any number of ewes, or any mixed flock; the number of bucks required to a flock; the time of lambing; the mode of managing sheep at the time of lambing; the comparative value of ewes and wethers; the utility of salting or withholding salt from sheep; the age to which sheep may be advantageously kept; the time of shearing; the mode of washing sheep; the mode of preparing the fleece for market; the loss in weight, if any which the fleece suffers from keeping; comparisons of profits or advantages among the different breeds; the results of crossing with different breeds; the raising early lambs for market; the fattening of wethers for market; the most eligible condition, age, modes of feeding, and kinds of feed; the proper construction of sheep pens, racks, mangers, coits, houses; the comparative advantage or disadvantages of housing or exposing sheep; the ordinary diseases and accidents to which sheep are liable and the remedies or preventives; and many other particulars, which are important, and would naturally suggest themselves to any practical inquirer.

The next subject of premium might be for example Dairy farms, whether of butter or cheese, and this likewise should embrace its entire management. The number of cows should not be less than —. The competitor should be required to state their number; age; breed whether raised or not by himself; mode of raising calves; feed of cows; pasturage; value of land for pasturage; number of acres required for a cow; winter feed; hay; corn-fodder; vegetables; such as turnips, carrots, parsnips, pumpkins; Indian, rye, or oil meal their quantities and comparative value from actual trial and observation; cost of feed; pounds of hay or vegetables consumed in any given time; trials of cooked or uncooked feed; of simple or mixed; cut or long feed; time of milking; mode of milking; management of milk setting of milk for cheese; mode of preparing and keeping rennet; of breaking and draining curd; of pressing best form of press; time the cheese is kept in press coloring cheese; anointing cheese; capping or covering, cheese with cloth; quantity of milk required for a pound of cheese; mode of sending cheese to market; loss in weight by keeping; value of whey for swine; butter from whey; quantity obtained and uses to which applied number of swine kept compared with number of cows number of hands required in milking a given number of cows; female help required, and cost of such help in making and managing the cheese. So likewise in regard to a butter dairy, it should embrace every important particular in the management of the stock or the manufacture of the produce—as for example, in addition to the above as far as they are applicable to butter, all the particulars should be required as to the mode of salting the milk; the kind of pans, whether earthen, wood, or metal; whether the milk be scalded or not; how long allowed to stand before it is skimmed; whether butter be made from milk or cream, and comparative advantages of using either; temperature of the cream when churned; usual time of churning; kind of churn; cream how kept; milk room or cellar; deep or shallow pans, and which most eligible; advantages of putting water in milk when set, if any; of freezing milk, if any; butter, how worked when taken from the churn; salt used; quantity and kind; modes of preparing butter for market; of packing butter for keeping; trials of the butter; qualities of the milk of different cows, by a lactometer or by weight; quantities of milk or butter made by individual cows; quantity of milk or cream required for a pound of butter; and in all cases of application for a dairy premium samples of butter and cheese; and of a wool premium at least a whole fleece properly done up to be sent for the inspection of the Board.

MISCELLANEOUS.

THE AMERICAN BOY.

"Father, look up and see that flag
How gracefully it flies;
Those pretty stripes—they seem to be
A rainbow in the skies."
It is your country's flag, my son,
And proudly drinks the light,
O'er ocean's wave—in foreign climes,
A symbol of our night.

"Father—what fearful noise is that,
Like thundering of the clouds?
Why do the people wave their hats,
And rush along in crowds!"
It is the voice of cannonry,
The glad shouts of the free,
This is the day to memory dear—
'Tis Freedom's Jubilee.

"I wish that I was now a man,
I'd fire my cannon too,
And cheer as loudly as the rest—
But, Father, why don't you?"
I'm getting old and weak—but still
My heart is big with joy;
I've witnessed many a day like this—
Shout ye aloud, my boy.

"Hurrah! ye for Freedom's Jubilee!
God bless our native land:
And may I live to hold the sword
Of freedom in my hand!"
Well done, my boy—grow up and love
The land that gave you birth;
A home where Freedom loves to dwell,
Is paradise on earth.

From the Cleveland Herald and Gazette.

THE LAKE FISHERIES.

Few persons except those engaged in or connected with the business, are aware of the extent of the Lake fisheries. They are a source of production which ought not to be overlooked, in estimating the resources of the country bordering upon the Lakes. There are no published statistics of this trade, so far as we know, nor any records, from which the quantities of fish put up for market can be accurately estimated. Estimates only can be given, and these may be more or less correct, according to the accuracy of the information on which they are based.

Lake fish form a staple article of provisions at all the Lake ports. The principal kinds are White fish and Mackinaw trout. The latter, a delicious fish, resembles the Salmon trout, and are possibly the same. They vary in size, from five pounds or under, to fifty or sixty pounds weight. Besides these, there are pike, pickerel, and different kinds of bass: the *cisquet* or *cisquetel* of Lake Superior, a fine fish, like the mackerel in appearance and flavor, but larger; and the *muscalonge*, also a delicious fish, weighing sometimes fifty or sixty pounds. The *cisquet* is scarcely known in market, as they are caught only in Lake Superior, and few have been put up. The *muscalonge* is not, in Lake Erie at least, caught in very large quantities, and is generally sold fresh. There may be other kinds of fish, but those named are the chief, and the most valuable.

Very few white fish are taken in Lake Erie, and we believe no trout. Pike, pickerel, and bass are taken in abundance about the islands in the upper part of the lake, and in the Maumee bay and river. These are salted in considerable quantities. In Detroit river the same kinds are found as in Lake Erie, and white fish are caught to some extent.

In Lakes Huron and Michigan, and the straits of Mackinaw, trout, white fish, and other kinds are caught in abundance. The Thunder Bay Islands, a group near Thunder Bay, in Lake Huron, the Beaver, Fox, and Manitou islands, near the foot of Lake Michigan, and Twin rivers, on the western shore, are the principal fisheries of those two lakes. Fish are caught, however, at other places in the lakes. They are also caught in the vicinity of Mackinaw in abundance; about the small islands in the straits, and at Point St Ignace.

It is supposed that these fish might be taken in Green Bay. A year or two since, some persons caught a very large quantity of trout at Sturgeon Bay in winter, fishing with a hook through the ice. They piled up their fish, intending to carry them, frozen, to Navarino, to be salted; but a sudden thaw spoiled the speculation.

In St Mary's river, at and below the Sault, the same kinds of fish are caught in plenty; but Lake Superior furnishes not only the largest and finest flavored, but the greatest abundance of fish. Until within two or three years, the fisheries of that lake have been unimproved, if not unknown; and it is supposed that they are now not half explored. Immense quantities have been taken upon Lake Superior for two or three years past; it is said that these are mostly caught about the group of islands known as the "Twelve Apostles," near the head of the lake. But little is known about this however, as the trade of Superior is, in fact, monopolised by the American Fur Company and the Hudson Bay Company. There is no mode of going up this lake except in vessels of one of these companies; and the American Fur Company does not permit adventurers a passage in its vessels.

Two schooners have been heretofore employed upon Lake Superior; one belonging to each of these companies. A new one was built the last spring by the American Fur Company, so that there are now three. When the canal around the Sault de St Marie shall be finished, it is likely there will be a rush of competition for the business of Lake Superior. Whether the expectation of those who are sanguine will be realized, as to the extent and value of the trade thus to be opened, time will determine. Furs are growing scarce upon the shore, it is said; fish are abundant, and whether there are minerals upon the shore worth digging for, is disputed. But when that ship canal is completed, Lake Superior, and the country around it, will be minutely explored, and its resources, whatever they may be, ascertained.

But to return to fish; a gentleman who has good means of judging, estimates the quantity put up for market upon the lakes in 1837 at 12,000 barrels, and of these he judges 7000 barrels were brought from Lake Superior. At nine dollars the barrel, which may be taken as a fair price, the whole would amount to \$108,000.

The same gentleman estimates the proportion of trout caught in Superior at one-fourth of the whole; the rest chiefly white fish. In the other lakes he thinks the proportion of trout to white fish not so

large. These two kinds usually bear about the same price.

The total quantity, we should guess, was not over-estimated. According to the collector's returns, there were 4,082 barrels of Lake fish set down the Ohio canal from this place in 1836, at 6,244 barrels in 1837.

If any contemporary upon the Lake has had means, we shall be glad to see a fuller and more minute account of the fisheries than this—which is such as our imperfect information on the subject enables us to give.

ANECDOTE.—A colored servant happening to hear a clergyman complaining to his master of the insufficiency of his salary, thought the minister was complaining of the drought and scarcity of vegetables, ran to the garden and conveyed to the chaise of the minister a large quantity of celery. After the worthy guest had gone, the negro came in and said, "Massa, I guess Mr _____ got sary enough now; I cram his big empty box full."

FRUIT AND ORNAMENTAL TREES, MALBERRY TREES, &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pear Apples, Plums, Peaches, Cherries, Quince Gooseberries, Raspberries, Currants, Strawberries, Gray Vines, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrub Roses, Honeyuckles; Pæonies, Dahlias and other Herbaceous Flowering Plants.

100,000 MORUS MULTICAULIS are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussas and other varieties.

Malberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and orders promptly executed, on application to E. D. Bacon Commission Store, No. 132 Water Street, New York, N. Y.; PEWELL, Seed Store, No. 7 Arch Street, Philadelphia, or the subscriber, Nonantum Hill, Newton, near Boston. August 4, 1838. WILLIAM KENRICK.

MALBERRY TREES.

200,000 Genuine Malberry Trees, and as many more as may be wanted, of the most approved kinds—consisting of the best selected varieties now in use, for cultivation, feeding worms, and making silk;—being acclimated to this country and adapted to either warm or cold climates, affording rare opportunity for companies or individuals to be supplied from the most extensive collection of malberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and order left with Messrs. I. B. Colt, Secretary of the Connecticut Silk Manufacturing Company, Hartford; Alonzo Wakeman at the office of the American Institute, No. 157 Broadway, N. Y.; Thomas Lloyd, Jr. No. 236 Filbert street, Philadelphia, Pa.; Luther L. Cox, Baltimore, Md.; B. Snider, E. Co. Savannah, Ga.; Bliss Jenkins, & Co. Mobile, Al.; James Lyman, St. Louis, Mo.; Cass and Judd, Columbus, O.; G. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass. Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Malberry Plantations. Apply at the office of D. STEBBINS, Northampton, Aug 22, 1838.

AGRICULTURAL.

(From the Farmer's Register.)

ACTUAL STATE OF SILK CULTURE

IN THE NORTH, AND REMARKS ON ITS EXTENSION
IN THE SOUTH.

To the Editor of the Farmer's Register.

Some years past, I have been endeavoring to collect all the information that was accessible on the subject of the silk culture, with the view of engaging in it as soon as opportunity should offer. And during the past summer I made a visit to some of the northern states, for the purpose of more fully satisfying myself, by personal observation; and to see with my own eyes what was doing there, that might justify the glowing accounts that were published in the agricultural papers. It is now my intention to give, in as fair and impartial a manner as I am capable of doing, the results of my observations; interspersed with such remarks and reflections as they have suggested.

In these times, when so much is done for effect, and when every new enterprise is ushered before the public with so much pomp and circumstance, it is natural that the sanguine should be easily led astray, and come readily to indulge in all the extravagances which characterize the projectors of novel schemes. In regard to silk-culture, though I am perfectly convinced that it will be both practicable, and profitable, and that its introduction into this country will become, or ought to become, a general thing at no very distant day; yet considering the progress that has been actually made, and the little that has been accomplished, the wildest calculations have been made of its profits; theory has run far ahead of practice; and very few of those who make such extravagant boastings have tested its real advantages by experiment.

Some years ago, when the subject was first agitated with so much earnestness, a number of incorporated companies with large capitals were established in the eastern states. The most of these have now an existence only in name. Some of the most prominent of them, by attempting too much, and by combining the manufacture with the production of silk, have entirely sunk their means. Others have failed to make any dividends, through the incompetency of agents, or in consequence of the high salaries that were allowed them. Others again, and perhaps all, in a measure, have transferred their zeal from the legitimate object of their establishment, to the tempting allurement held out by the high prices of mulberry trees; and not one, so far as my information extends, has done anything towards extending the knowledge of the silk-culture amongst the people at large, or made any attempts to introduce improvements in the management of the worms, and in the art of reeling and preparing silk. In the excess of their early zeal, the natural order of things was reversed. Lands were provided, buildings and fixtures erected, be-

fore there was any food for the sustenance of the worm. Having begun at the wrong end, and been then diverted by other considerations from carrying out the original object of their design, they have failed to answer the purposes contemplated by their formation.

Whoever therefore, depending on the ostentatious parade with which silk companies have been introduced to the admiring gaze of the readers of silk and agricultural papers, visits New England or elsewhere, with the expectation of seeing the silk culture carried on by them, and of deriving the necessary information from them for his own guidance, cannot fail to be disappointed. He must go to private individuals for instruction; he must get access into families, engaged in feeding worms, and observe their practices and management. It is amongst them only that anything has been done, or from whom anything can be reasonably expected. The silk business, in its present state of infancy, will not justify a large outlay, with a view to carrying it on to advantage. And especially is it necessary to consult economy in those places where the white mulberry is depended on as food for the worms. There is not, at present, skill enough in the country to justify the employment of agents, except under the immediate control of the person interested, to superintend the feeding of a large number of worms. When the business shall have been perfected in families, and the process of making silk shall have become generally understood, so that given means may be relied on to effect given results, operations may be extended to a larger scale with greater prospect of success.

At Northampton I expected to see greater progress made in the silk culture than at any other place in the United States. It has claimed for itself the merit of being the pioneer in the great work. For years the Northampton paper has been applauding the efforts that have been making to introduce and extend it. We were led to believe that it was the head-quarters of the silk business—the fountain from which instruction was to flow like a stream, to gladden and enrich the whole country. A great silk company, styled *par excellence*, the "New York Silk Company," was established there at an early date—a large capital was subscribed—a farm of several hundred acres was purchased at a great price—upwards of one hundred acres were planted in mulberries of one kind or other—a large factory was erected at considerable expense—and there the work terminated. The farm is now offered for sale; and the operations of the company are to be confined in future to the factory. Not a pound of silk, as far as I was informed, has ever been produced by the company. Glowing accounts have also been given of a silk company at Norwich, in Connecticut. Before leaving Virginia, I had been advised to take that place in my route, and was informed that silk would be produced there this year, not by pounds, or by hundreds of pounds, but by thousands! During the time I remained in New England, I made diligent inquiries about Norwich, and could not learn that

anything was in progress there that would interest or interest a visitor. These examples are given as a fair illustration of what has been performed by incorporated companies. At Northampton, however, we are promised better things for the future; and something has been done during the past season, both in the village and in the neighborhood, in the way of feeding worms. I saw one cocoonery, in which perhaps fifty thousand worms had just completed their labors; and another, erected on a large scale, in which nearly a million of eggs were in the act of being hatched. But there was a great scarcity of food; and liberal prices had to be offered to the owners of such plantations as were situated in the vicinity of the village, for whatever amount of foliage they could supply. So great has been the trade at Northampton, in mulberry trees, that out of the hundreds of thousands of seedlings which have been grown there within the last few years, the number of those planted expressly for feeding worms is very inconsiderable. Perhaps no place has dealt more largely in the article; and the practice of selling off so close as to leave none for feeding worms, has been the subject of considerable censure. A reformation has been promised in this respect; and I was assured by a prominent and enterprising culturist that he was determined hereafter to retain the greater part of his trees for permanent plantations on his own grounds. Should he devote his energies to the silk culture, I know of none whose intelligence and qualifications are better calculated to insure success.

It is not my intention to charge either individuals or associations with a design to delude the public. On the contrary, I have no doubt that most of them were influenced by as correct motives, in advocating the adoption of the silk-culture, as generally govern the actions of men, willing to instruct others and promote their interests at the same time that they can do it with advantage to themselves. Neither do I believe that the silk culture is intended or expected to turn out a mere delusion. If companies have failed, individuals have been eminently successful, in a smaller way, it is true, but on a scale large enough to prove that the culture is both practicable and advantageous. A number of instances might be adduced to establish the fact that worms may be fed in this country, and carried through their various ages in perfect health; that the climate is admirably adapted to their welfare; and that silk of the best quality may be readily produced. The reason, therefore, that so little actual progress has been made, considering the much that has been said and written, and the great degree of public attention and even excitement that has been elicited in its behalf, is to be found in causes sufficiently obvious, and which have already been adverted to. The wonderful demand for the *morus multicaulis* and other valuable species of the mulberry, renders the cultivation of these plants the most profitable agricultural occupation that ever was followed in this country. A greater profit is to be derived from a few acres of land under this

culture, than from large fields of wheat or corn, or even cotton or tobacco. As long as men will consult their interests, it is not to be supposed that the slow and tedious process of rearing silk-worms and reeling silk, however profitable it may be, compared with most other agricultural pursuits, will be prosecuted with full vigor, while the profit to be derived from the sale of the plant which constitutes the food of the worm, transcends in value that of the silk to be derived from it. While the demand for the mulberry continues to be extensive, and the prices high, it will be idle to expect that silk will be produced in large quantities. But in a few years, when the country comes to be well stocked, and the prices decline so much that sales can with difficulty be effected, a new state of things may be anticipated. There will then be no other resource but to appropriate the mulberry to its legitimate use; the community at large will be compelled by the force of circumstances to engage in the culture of silk, and we may then expect to see the business extensively flourish. In the mean time, the experiments that are making will lead to improvements in the management of the worm; every year will be adding something to the stock of knowledge, and contributing to ultimate success. The mulberry will shortly be in the possession of every family, or readily accessible to all; and no longer, as at present, capable of being monopolized by speculators, who having no interest in the establishment of the silk culture farther than to supply the plants, and never intending to follow it as a branch of industry, are intent only on deriving a heavy profit from them.

I am not one of those that object to seeing the mulberry sell at fair prices. If there was no demand for them, all attempts to extend the silk culture would fail. But I do object to making the mulberry culture and the silk culture two distinct branches of business; and, above all, to the practice which many persons follow, of calling themselves *silk-culturists*, when they are only speculators in the plants, or growers of them for the market. None talk more largely of the benefits of making this a silk-growing country—none discourse more eloquently on the advantages to be derived from adopting the culture—while the main object is to create a demand for their trees. The press teems with "silk-growers' guides," and other publications, from the fertile pens of mulberry growers, demonstrating in glowing language the enormous profits of the silk culture. It would be desirable if public opinion could be brought to bear upon such persons, and compel them—a reasonable compulsion it would be—to appropriate some of their profits to the construction of eoconeries, in order to prove to those whom they are persuading to purchase, that silk may be profitably produced; and give them ocular demonstration that their trees are worth what is demanded for them. By this mode, the sale of trees might not be diminished; it would probably be promoted; but at the same time, every person would purchase with a knowledge of what he was doing; and the trees would fall into the hands of those who would endeavor to convert a portion of them into silk. Had this system been pursued, and light shed amongst the people, even the present high prices for the mulberry might not be above their value; at any rates, the demand would not be a fictitious one. It is in truth a most valuable plant, if the silk culture is practicable, and deserving of higher appreciation, from the fact that it is reproduced with so much facility.

Although the actual cost and labor of propagation are inconsiderable, yet its intrinsic merits so far surpass those of any other mulberry, that for an outlay of five dollars, a stock of plants may be obtained, in four or five years, capable of sustaining millions of worms. It would therefore be better to give even a dollar a piece for a few plants, than to give a dollar a thousand for the old white mulberry, which would only be fit to feed from, at six years of age, with a scanty supply of foliage, and difficult to gather, even then.

It is generally considered that the *multicaulis* is the most valuable mulberry in the country. In the southern states, and as far north as to New York, and even in some parts of New England, it flourishes with great luxuriance; and the roots, and even branches for the most part, will withstand the winters without material injury. But for the more northern portions of the United States, it is extremely doubtful whether it can ever be cultivated to advantage. It is certain that in the neighborhoods of Albany and Northampton, its growth is stunted; but local causes exist to render those places colder than any others in the same parallel of latitude. The soil for a considerable distance round them is so light and sandy, that it parts rapidly with its heat whenever the rays of the sun are withdrawn or excluded. For the northern and eastern states, however, there are other species of the mulberry more hardy than the *multicaulis*, of a rapid and vigorous growth, and furnishing leaves of a large size and in great abundance. Distinguished cultivators there have their particular favorites. The Alpine was introduced and is patronized by Saml. Whitmarsh, the Canton by Dr. Sieb- bins, and the Brussa by some gentlemen of Albany.* At Northampton, there is such a confusion of names, that persons residing at a distance have very little idea of what their mulberries really are. Instead of being designated in such a manner as to be readily distinguished from all others, the specific term of "*multicaulis*" is applied to species entirely distinct, as well from each other as from the *multicaulis* proper. Thus the Alpine is called the "*morus multicaulis Alpinense*;" and the Canton, the "*Canton multicaulis*." Both the Alpine and Canton have sufficient merits of their own to enable them to stand without any extrinsic aid; and the appropriation of terms to which a definite idea has been long attached, is calculated to mislead and produce a false impression. The Alpine is only known as having been brought from the foot of the Alps, where it was called the "*Chinese mulberry*," and is the same kind for which, under this cognomen, the gentleman that introduced it was made the object of so much obloquy a few years ago. The odium that was cast on him then, was, as I am now convinced, very undeserved. The merits of the controversy turned on a name; and that name appears to have been inadvertently adopted, or rather continued in conformity with the designation of the species in Italy, and not with the intention of passing it off as the genuine *multicaulis*. The effect, however, has been to impair his usefulness ever since.

If the silk culture has not advanced with the rapid strides, in the states where it received its first impulse, which were predicted of it; yet it has made some progress in other places, where it has

been recently introduced. A much larger number of worms has been fed during the past season than has ever been fed in one year before; and complete success, as far as I had the opportunity of observing or ascertaining, attended the management of them. In New Jersey, Pennsylvania and Delaware, and on the Eastern Shore of Maryland, much more has been done than in any other parts of the country. A considerable stimulus has been given to the business, in some of those states, by the liberal bounties upon silk produced within their respective limits. A large proportion of the late crop of cocoons was reserved for eggs for another year; and even now the demand for eggs is almost as great as that for mulberries. The experience of this year has satisfactorily proved that even from trees, the growth of cuttings and layers planted in the spring, worms may be advantageously fed the ensuing summer. It is only necessary to retard the hatching of the eggs by placing them in an ice-house, which should be done before the warm weather in the spring comes on. By this means, they have been kept till midsummer. Under any circumstances, the hatching may very properly be delayed till the early part of June, which is probably as soon as worms should be brought out even in Virginia. The cold, wet weather of May, which is frequently a disastrous period to the young worms, is thereby avoided; and the natural time of hatching is only postponed about three weeks. Whether they can, for a number of years, consistently with the health of the insects, be prevented from hatching until the latter part of July, may be regarded as doubtful. The practice is so contrary to nature, that it will not be at all surprising if the effect should prove unfavorable. Neither would any necessity exist for it, if the culturist would reserve a small number of standard trees or roots, and make use of the two-crop worm for his second and third crops.

I have no information which would enable me to state with precision the quantity of silk that may be produced from an acre of ground. During the past season, one gentleman in New Jersey obtained from the sixteenth of an acre, a product at the rate of 56 pounds per acre, from trees of the first year's growth. Had the trees been a year older, the quantity of silk would no doubt have been fully doubled; and might have been still further increased by successive crops. The cocoons of this year were almost invariably firm and heavy; and I heard of no worms that fed longer than twenty-eight or twenty-nine days; the usual period of their lives being thirty-five days. This abridgment of the ordinary term of their existence, is to be ascribed to the high temperature of the summer; for we know that, under different circumstances, it is sometimes prolonged to forty days. The past season, hot and dry as it was, appears to have been very favorable to the health of the worms. I heard, on respectable authority, that a culturist in Delaware had fed 150,000 with a loss of not more than twenty. Among all that I saw, some of which were a good deal crowded, I observed no symptoms of disease, and heard of none prevailing elsewhere. One or two facts that came within my knowledge, showed that much care is requisite in the treatment of eggs when the hatching is to be postponed. It is acknowledged by all, that it is important to keep them dry; and to guard against the least admission of moisture, some persons put them in bottles and seal them air tight. Whenever the eggs remain in this condition for any length of time, their vital

* Charles Rhind, Esq., formerly minister at Constantinople, introduced the Brussa mulberry.

ny destroyed; while others of the same parcels, but treated with less care, hatched without loss.

Without intending to make any invidious comparison, and premising that there were many places where the silk culture was said to be thriving, which I did not visit, I have no hesitation in saying that there was more doing at Burlington, New Jersey, considering how recently the business has been started there, than at any other place which came under my observation. A considerable number of persons were engaged in feeding worms as well as in raising trees. A few extensive cocooneries had been erected, one of which was large enough to accommodate about a million of worms; and several others from one to two or three hundred thousand. The soil in the vicinity of Burlington, is light and sandy, and well adapted to the growth of the multicaulis. Indeed the greater part of New Jersey is admirably suited to the purpose; and the business is so rapidly spreading, that in a few years, that state will probably be much in advance of any other. Within a few years the improvements in the construction of cocooneries, have contributed greatly to the facility of feeding worms. The plan of those at Burlington, struck me as being rather superior to any I saw elsewhere. The necessity of handling the worms is entirely dispensed with by the use of hurdles of net-work; at the same time that the cleansing of the shelves and the removal of the litter are more easily effected. When it is time to change them, another hurdle is laid on the one containing the worms, and fresh leaves are sprinkled over it, which are always cut up by running them through a cylindrical cutting box. In a few hours, the worms attracted by the fresh leaves, get on the upper hurdle, when the lower one, containing the litter, is removed. In this manner, a large number of worms may be cleansed in a day, by providing extra hurdles. A better fixture for the accommodation of the worms in spinning, has been latterly introduced. On the lower side of the shelf immediately above, which is not more than twelve or fourteen inches distant, strips or lathes, about two inches wide and three inches from each other, are fastened at right angles to the range of shelves, to which the worms mount by very simple ladders, and spin their balls along the junction of the strips and floor. This mode adds greatly to the convenience of gathering the cocoons, and the floss is removed from them free of the litter which attends the use of brush or dried leaves. A room thirty feet wide, will admit of four ranges of shelves, three feet wide, leaving an aisle, between each range, and also between the outer ranges and the walls, of three and a half feet. The number of shelves in each range will be in proportion to the pitch of the room; say six shelves for a room, nine or ten feet high. Each hurdle is three by four feet, and will accommodate a thousand full-grown worms. On this plan, a room of a hundred feet in length by thirty feet in width, with a pitch of nine or ten feet, will accommodate, without crowding, about half a million of worms at a time. But in a cocoonery, near Frankford, in Pennsylvania, which was not of much more than half these dimensions, six or seven hundred thousand worms were fed in June last, which spun well. They were, however, evidently too much crowded, as was shown by the small size of the cocoons; and had not the season been of the most favorable character, the whole brood would have been in danger of being swept off by an epidemic. In a small room at New Haven, in a house occupied by

a Frenchman, which did not exceed ten feet square, he had successfully fed forty thousand worms, without the appearance of any disease amongst them. I saw a number of the cocoons, which were large and firm.

Many persons have amused themselves, and the public too, by making calculations of the great profits of the silk culture. It may be no difficult matter to state with tolerable certainty how many good cocoons will yield a pound of silk; but I think an error has been frequently committed by estimating the product *per acre*. Of mulberry leaves, as well as everything else, the crop will be very variable, and depend on the quality of the land. If worms can be preserved exempt from disease, and good cocoons can be obtained from them, the number that an acre of ground will support, at the usual prices of land in our country, is a matter of very subordinate interest. It is only important when land is worth from one hundred to three hundred dollars per acre. When the value does not exceed five or ten dollars, as is the case with most of our lands, it is better to estimate the profits of the culture by the number of worms that may be fed, than by the quantity of land that it will require to supply them.

While so much is doing in some of the states to the north of us, for the advancement of the silk-culture, scarcely anything has yet been attempted in Virginia. The attention, however, of some individuals, has been directed to the subject; and an interesting experiment in feeding worms has recently been detailed in the "Farmers' Register," by a gentleman of Brunswick. A very large cocoonery has been fitted up at Fredericksburg, which will probably be filled with worms next year. Other gentlemen are making arrangements to enter upon the culture. During the ensuing season, it is hoped that interesting results, may be established by various persons. But, unfortunately, almost every tree grown in Virginia and North Carolina, with the exception of those retained to propagate from another year, has been bought up, and will be taken to Pennsylvania or New Jersey. The Virginia and Carolina trees have a decided superiority in the northern markets, and are sought after with avidity; a fact of which the cultivators here are perhaps ignorant. Southern trees are mostly produced from cuttings, while those of northern growth are raised from what are called *layers*—that is to say, a whole plant, both root and stem, is laid horizontally in a furrow, and covered over with earth. The young shoots sprout up so thickly that they make a spindling growth. Plants from cutting, on the contrary, having more distance, throw out a number of side branches, and furnish a much greater supply of wood, which, besides that it is better matured by our southern sun, adds considerably to the market value. It would be desirable to know what number of trees have been grown in these two states during the present season. It will probably not fall much short of half a million; and next year, the number will no doubt be two or three times as many. But as long as we send them abroad, we are doing nothing towards the advancement of the silk-culture in our own state. And if there be any state in the union that would be more benefited by the introduction of this culture, allowing it to be, as is contended, both practicable and profitable, or whose soil and climate are better adapted to it, or where it can be prosecuted with greater economy in reference to labor, I should be at a loss to point it out. We occupy that position

in regard to climate, which is too far north to admit of ours being a planting state; and too much to the south to be a first rate grain-growing or grass-growing country. We have extensive tracts of impoverished land in which the mulberry will flourish without difficulty, and where nothing else will grow. Our dry and long continued summers are eminently favorable to the health and prosperity even of successive crops of the silk-worm. We have in almost every family a number of unprofitable hands, either too young or too old to be put to constant employment; and the more intelligent portion of our colored population, remarkable as they are for their tractableness and powers of imitation, would soon learn to conduct all the operations of the cocoonery with neatness and skill.

Many of the states to the north of us have encouraged the introduction of the silk culture by legislative bounties; and I am convinced the wisdom of this policy will be justified in due course of time. If from causes already pointed out, but little has yet been accomplished in the production of the article thus encouraged, yet the ground-work has been laid, and the superstructure will be erected upon it. The seed has been sown, which will produce, some ten, some twenty, and some possibly a hundred-fold. It will, however, necessarily be a work of time. It may be another generation, and yet another perhaps, before, before it is established on a durable basis. But with a climate like ours, and with a species of mulberry superior to any hitherto known, the energies of the Anglo-Saxon race will eventually command success. The mental resources, the quickness of perception, the determined perseverance, which constitute the distinguishing attributes of this people, will enable them to triumph over every difficulty, and achieve all but impossibilities.

T. S. PLEASANTS.

Goochland, Sept. 15.

From the N. Y. Commercial Advertiser.

IMPORTANT TO FARMERS.

I think, Messrs. Printers, that we have had enough in all conscience of puffing and blowing about family Ravels, *Tree* play actors, men singers, and women singers, Italian fiddlers, and rope dancers, live elephants and monkeys. (By-the-by it is a very prevalent opinion at Cow Bay, Cow Neck, Oyster Bay and Hallet's Cove, that if all those drones were turned out to fell trees, grub up brush and hoe corn, we would not need to import peas-meal and rye-flour from Germany—things which feed the sense of sight only.) Now we, some of your clod-hopping subscribers, think ourselves entitled to half a column of your paper to speak of things which feed the taste, and give nourishment to the body corporate.

Mr Jefferson says the man who makes three blades of grass grow where only one grew before, is more the friend of man than he who conquers kingdoms. I think if Mr J. had always preached such sound doctrine, he would have been the greatest philosopher of the age. Seeing, then, that this proposition about the grass is self-evident fact, what think you should be done to the man who makes three ears of corn grow where only one grew before? inasmuch as grass feeds the horse, and corn the man. But to come to the point at once:

Some three years ago a merchant in New York, while emptying a box of tea, observed therein a few grains of corn. Concluding that corn from China must be something new under our sun, he had them planted, so they grew and multiplied. Last spring, I received from a worthy friend, a portion of said corn—it's a new variety—so I gave it the name of China's fall prolific, or tree corn; as it strikes off in two, three, and frequently four branches, in appearance like a small tree, and produces an ear at the head of each branch, whereas the common corn shoots out the ear from the side of the stalk; it grows from eight to ten feet high, produces an abundance of fodder, and is a large white flint twelve rows long, and ears from ten to fourteen inches long. I counted six hundred and sixty grains on the ear; it was planted on the 10th of May, and had ears fit to boil on the 10th of July. Its produce was curtailed by the long drought, but notwithstanding I counted two thousand one hundred and twenty grains, the product of one stalk: being an increase of two thousand and one. The Dutton (which is an excellent corn) planted on the same day, on the same field, and received the same quantity of manure, cross ploughed and hoeing, did not produce one half. The patch about two hundred hills, was examined by many respectable farmers, who all pronounced it something new, and something superior.

The corn may be had of G. C. Thorburn, New York, and at the store of Wm. Thorburn of Albany, price 25 cents per ear; the net profits to be given to some of the charitable institutions in New York and Albany. Now, if there is a farmer between Maine and the Rocky Mountains who would rather pay 25 cents for two gills of brandy, than to buy one ear of this corn, which will plant 100 hills—I say, if there is a man, he ought to be fed on nothing but suppan and buttermilk as long as his little soul and big carcass will hang together. A stalk, having the ears on, to show the manner of growth, may be seen at the above stores.

Every printer in Kings, Queens, Duchess, Orange, and Albany counties, who is fond of Jennie cake—for if my informant speaks true, it took its name from a southern lass by the name of Jennie Dawson, who was famous for manufacturing this delicious article; but that at a meeting of the Bachelor's Club, Jennie was voted out and Johnny put in her place—I only hope that some of those chaps who were concerned in an affair so ungentlemanly may never taste one of these new made cakes, when anointed with fresh butter—will please insert as much of this long winded story as they see fit; and every printer who has children, who ere long may be orphans, will please insert the whole, and place it to the credit of the widow and the fatherless—he who is their Judge will register the thing in Heaven, as Uncle Toby says.

GRANT THORBURN.

Hallet's Cove, Sept. 24, 1883.

REMARKS.—We have sown of this corn for sale at the New England Farmer office, but as we know no more about it than what is contained in the above statement, every purchaser must take it on his own responsibility. J. B.

MIDDLESEX AGRICULTURAL SOCIETY.

The Committee on Farms, Orchards, &c., ask leave to report. That they have been called on to visit ten farms in different parts of the county, and that they have visited the same. That they were much

gratified to witness the improvements made and in progress on all of them, and particularly on their low grounds and peat swamps, many of which are easily converted into the most valuable mowing lands, and will well repay the expense of reclaiming them. On most of these farms good stone wall is the only fence relied on to secure the crops.

As your committee are restricted to four premiums, and as some of the farms now offered have already obtained premiums from this Society, and have been noticed in their reports, none will be here particularly named, but those which we select as best entitled to your bounty.

We visited the farm of Mr Zaccheus Reed, containing 80 acres of improved land, and 100 acres of wood land, lying in the town of Westford. Mr Reed must have toiled without ceasing, to convert a soil by nature so rough and forbidding, into a fruitful field. Within a few years he has turned ten acres of useless swamp land to good English mowing. He has 800 apple trees which he has raised from the seed and which he has since ingrafted. Sells on an average, 100 barrels of apples—keeps 25 head of cattle—30 sheep and two horses—raises this year by estimation, 50 bushels of barley, 50 do. of rye, and 800 bushels of potatoes. He has built 300 rods of stone wall six feet wide on the average. It was built this width to dispose of the surplus rocks on the farm.

We think Mr Reed is entitled to the society's first premium of \$25.00

Mr Caleb Wetherbee, of Marlborough, has a farm of 210 acres cleared land, and 100 acres of wood land. Keeps generally 40 head of cattle. Fatted last year 14 hogs and ten pigs, and made 2200 wt. of butter. Sells usually 60 or 70 barrels of apples. Mr Wetherbee sells but little hay. Keeps a fine lot of cows on hilly land made good by nature for pasturage. And the refuse of his dairy enables him to rear his swine at little expense, and at present prices of pork he finds it profitable business.

He carts much soil into his hog and cow yards to absorb the liquid manure, and has made a very good use of a part of this as a top dressing for his low lands which he is draining and rapidly bringing in to produce English hay. We recommend him as entitled to the society's second premium of \$20.00

Wm. Buckminster, of Framingham, has a farm of about 200 acres—fenced principally with stone wall. Within two years he has built 90 rods of wall, and has removed the former fence back, so as to leave the highway two rods and a half and three rods, the former width. His is a stock farm, and he raises but little grain on old ground—has sold 500 dollars worth of hay in a year, and 400 dollars worth of beef. This year he estimated that he has raised 200 bushels of rye on ten acres of land which he has newly cleared and is bringing into pasturage. He buys no manure, but enriches his lands by ploughing in green crops, this is done chiefly in autumn, turning in the after growth of grass, and thus loses no crop by the fallow process. By ploughing his orchards at this season and sowing them down immediately to grass he avoids the unprofitable course of raising grain or potatoes among his apple trees, and leaves the soil lighter about the roots, and improves the trees much less than he would do in planting, sowing, &c.

One orchard of five acres is now very full of fair fruit and produces three fold more than it has

formerly done, in consequence of his ploughing among his trees.

As he raises no grain on old ground for sale, and keeps from 30 to 40 head of cattle to consume his coarse hay, he calculates that he is annually enriching his lands and bringing them to produce larger quantities of grass and hay—his chief object of culture. He is yearly converting his poorest low lands into English mowing.

He has more than an acre of Ruta Baga that was planted the last day of June. The plants look finely.

We think him entitled to your third premium of \$15.00

Mr Stephen Howe, of Marlborough, has a farm of 30 acres; most of it high land. It abounds in rocks which he has been diligently putting up into a wall. He has subdued and brought under good cultivation a large portion of his farm; cuts 30 tons of hay, with which he can keep 20 cows in winter; he makes on an average, 70 barrels of cider, does most of his work himself, even the building of his large walls. His buildings appear in good order, and his farm seems to be well cultivated.

We think him entitled to your fourth premium of \$12.00

Your committee have examined the orchard of Eli Rice, Esq., President of the society. It contains a large number of trees, 154 in a thrifty condition; all of them ingrafted. Some have been standing several years, others but recently set. The trimming of these trees has been performed more judiciously than in most other orchards under our notice.

We recommend this orchard as entitled to the society's first premium of \$15.00

Mr Moses Sweetser, of South Reading, has a very pretty orchard of 94 trees; they are set in perfect rows—are of very uniform size, and have been very carefully attended to. Mr Sweetser mows this orchard excepting about eight feet square about each tree which has been dug and kept light. We think he has trimmed off rather too much of the tops and thus retards the growth.

We recommend to him the society's second premium of \$12.00

Mr Asa Parker of Acton, has an apple orchard of 125 trees in one lot, and 47 in another lot; the latter in low ground and much more subject to the frosts than those on the hill. Mr Parker has well cultivated the land about the trees, and they are thrifty, but he has committed an error in grafting his trees about five feet from the ground, first where the limbs begin to spread and there two scions are often left to grow on one stock, and he will find the winds will trim for him those handsome shoots that he was loth to cut off when small, and will leave him by and by, only half the top of his trees.

We recommend him as deserving your third premium of \$8.00

Mr Martin Rice, of Marlborough, has been at the trouble of planting 3500 or 4000 of the white mulberry trees. Under your premium list, we think he is to be considered the claimant for the first premium of \$15.00

Mr Sylvanus Howe, of Townsend, is the only other individual who has made it known to us that he also has planted a mulberry orchard. For his care and trouble, without much prospect of imme-

mediate gain, we think he deserves your second premium of \$10.00

By order of the committee,
JOHN H. LORING.

WINTER WORK.

The labors of summer and of harvest being finished, it may not be inappropriate to inquire, what shall be the work for Winter?

Fall's last month, and winter's three, with their short days and long evenings—how shall the farmer improve their moments of day and evening to his best profit and entertainment? We would say, let him *bestir* himself in his business during the day, and in the evening, cultivate the intellectual soil, the mind. Let him enjoy the fruit of his summer labor and industry by the social fire side, and treasure up a know edge which shall guide him in his duties as a citizen, and direct him in a better application of his labor so as to secure an increased product with less expense. The farmer is truly privileged above his co-equals of other classes, in the particular of having his evenings to himself, as a time of leisure from his toilsome labor, affording an opportunity of mental cultivation and social happiness, which the envied may envy. Improve it, we say—be glad in your abundance, and be wise in your gladness. And permit us here, to suggest that in this opportunity for the attainment of knowledge, you do not neglect the knowledge of your own occupation—the science of agriculture. Every one should give his chief attention to his own calling; it should be his highest ambition, to excel in that—to elevate it and render it honorable, and thus to be honored in it. But we will leave the merry evening, and turn to the work of the day.

The last month of Autumn, is not a month of idleness. The farmer must be active to prepare for winter. All the buildings intended as an asylum for man or for beast from the chill blasts of winter, should be made tight so as to exclude his cold breath. Cattle when kept warm, do not require near the quantity of food that they do if exposed to the inclemencies of the season. A warm house is half a wood-pile.

The cellar too, should be made secure from that old thief, Jack Frost—and everything we would wish to secure from his clutches should be *seasonably* deposited there just one day *before* the first freeze. Lastly, a word for the poor bawling cattle, and we will retreat into winter quarters. Do not let them suffer and starve and pine for want of food. What they do not obtain from the fields sufficient fully to keep them in flesh, supply from the barn. It is poor economy to *pinch* cattle at any season, but the poorest to commence winter by half starving them.

Winter—to the slothful, who have not made preparation, cold, dull, unwelcome winter; to the diligent, with their full garners, tight and convenient buildings, and a "rousing wood-pile" of dry wood, joyous, merry, welcome winter,—“this too, is not a season for idleness; a term which precludes the idea of enjoyment, but its active hours are pleasant and useful to the farmer; it is peculiarly the season of his intellectual culture. But we will defer a specification of its appropriate work, as “there is time for that yet” (a bad phrase) meanwhile suggesting that the Cheshire Farmer will expect to greet you at your winter evening fireside.—*Cheshire Farmer.*

For the New England Farmer.

BLIGHT IN PEAR TREES,

AND REMARKS ON PLUMS.

JOSEPH BRECK, Esq.—

Sir—I have taken the N. E. Farmer from the last eight years, the Albany Cultivator from its commencement, and frequently see the Genesee Farmer and other agricultural papers, and have read all the various articles on the fire blight. From my own experience, I am satisfied that not one of the various writers knows anything about it. Whenever our medical men shall discover the cause and cure for the Asiatic cholera, then, and not till then, I fear, will our horticulturists learn the cause and cure of the blight. I have whittled many limbs into fine shavings, dug up a number of trees, examined the roots and shavings as closely as possible with a good glass, and am fully satisfied that it is not caused by any insect. One of my trees, in the fall of 1837, produced 10 bushels of pears; this season blossomed full; soon after the fruit was formed, was attacked on the body about four feet from the ground; a strip around the body of the tree about 10 or 12 inches wide, was entirely killed in three or four days, whilst every limb was vigorous and healthy. The bark of the body of the tree was coarse and rough. Could that have been done by an insect? I had 50 trees, 25 of which were killed, from the seedlings of two years up to those of 30 years standing. I had the Easter Beurree, Bartlett, Passe Colmar, St. Michael, Seckle, down to the most worthless seedling. The disease pays no attention to age, location or quality of fruit. My soil is a sandy loam; a number of the trees stood in the kitchen garden and have been cultivated for 25 years; others stood in the fruit garden which has been in sward for a number of years; one tree stands within a few feet of a spring strongly impregnated with iron, and the soil in the immediate neighborhood contains iron ore, which I should suppose would answer as well as to hang old iron on the limbs of the tree. A Seckle pear tree had 40 or 50 pears of a very large size ripened well; about two weeks before they were ripe the tree was attacked within two feet of the ground; although the tree was apparently healthy and vigorous above the wound, the flavor of the fruit was strongly affected by it. Could this have been caused by the effect of the sun upon unripened wood? The disease has been known in this section of country about six years; it commenced on my trees this season, about the 20th of May, when the trees were in full blossom, and continued till the first of September. The months of April and May were remarkably cold and wet, the summer hot and dry.

The apple trees and the quince are affected by the disease, but not to the extent of the pear. As to some experiments that I made on plums, see N. England Farmer, Vol. 15. No. 31. Not one of them answered any good purpose.

Dr J. P. Kirkland, a gentleman who has had probably more experience than any other man west of the Allegany mountains, says (in a report to the Legislature of Ohio) he knows from experience, that hogs, whenever they can have ready access to the tree to eat the premature falling fruit, and root and rub around the tree, is an effectual remedy.

A gentleman at my house a few months since, says that he has a plum orchard which for a number of years used to be loaded with fruit, the plums commenced falling soon after they were formed, and continued to fall during the whole season; that

scarce any ever ripened; ten years ago he converted it into a hog-pen and since has never failed to have plums in abundance.

If any gentlemen will call at my house in Euclid and examine my pear trees and is not fully convinced that the disease is an epidemic, I will give him a plain farmer's dinner.

Respectfully yours, &c.

Euclid, Nov. 4, 1838.

M. L.

Since writing the above article, I saw a notice in your paper of an extraordinary cow exhibited at the Worcester Cattle Show, weighing 1560 lbs. I had cow during the summer and fall of 1837: gave a large quantity of milk, was kept with my other stock, ate nothing but grass, had been dry only two weeks; that weighed 1574 lbs. Had she been fattened like some of the Connecticut River cattle, she must have weighed 2000 lbs.; she is said to be of the full blood Durham Short Horns.

(For the New England Farmer.)

We send you a copy of a letter we have just addressed to the editor of the Wisconsin Culturist, which you are at liberty to insert in your paper.

Yours respectfully,

WM. PRINCE & SON.

Flushing, Nov. 9, 1838.

Wm. P. Prouffit, Esq., Editor Wisconsin Culturist.

DEAR SIR,—We have perused a letter in your paper from Lucius B. Allyn, Esq. accompanied by an editorial comment, which, without proper explanation, is calculated to mislead the public. It appears that Mr Allyn received seeds from Dr Stebbins of Northampton, Mass. which he deems to be the *morus multicaulis*, and from which he states he has raised 30 to 40,000 trees. We have simply to say that there never has been one ounce of genuine *morus multicaulis* seed sold in the Union, and that all the trees raised from seeds *professionally* of the *morus multicaulis* have proved to be none other than an improved variety of the white mulberry, with much larger leaves than the white mulberry, but possessing no resemblance or affinity to the genuine *morus multicaulis*. All such applications of the term “*Multicaulis*,” meaning *many stalks from one root*, are totally improper, and any such terms as *Alpine Multicaulis*, or *Canton Multicaulis* are delusive. The *Alpine* is the *Moretti* Mulberry of France, and was originated there from seed, and is *not known* in China, and all efforts to import the genuine *multicaulis* from China have as yet proved abortive, and there exists no proof whatever that it is to be found there, although in all probability it is, but at some locality not yet ascertained. The genuine *multicaulis* was brought from the Philippine Islands to France, and was first imported into America by ourselves. It is time these errors should be put a stop to, as thousands of dollars have been already lost by persons cultivating and propagating the wrong tree. The seed from Dr Stebbins no doubt produces valuable trees; but let them be called by their *true name*, and not by one totally distinct, and the use of which may mislead people at a distance, although here it cannot. In the whole town of Northampton there were not 50,000 trees of the genuine *morus multicaulis* raised the present season, but they have there many other fine varieties in abundance. Yours respectfully,

WM. PRINCE & SON.

Linnæan Garden and Nurseries, Flushing, Nov. 8, 1838. }

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, NOVEMBER 21, 1838.

AGRICULTURAL SOCIETIES AND PREMIUMS. No. IV.

In pointing out subjects of premium we have spoken of the qualifications and conditions under which they should be presented. The objects of bestowing premiums are two;—first by the value or honor of the reward promised to excite an ambition and attempt to ascertain what is practicable; what can be attained or accomplished by art, or skill, or industry, or perseverance. The second is to ascertain how it may be done; in what manner improvements of any kind or of a particular kind may be effected, so that the knowledge may be diffused for the general benefit. The second object, it is apparent, is the important point; but then it is as obvious that the promotion of the former object is the direct and most certain means of accomplishing the latter. We cannot too frequently revert to the great truth that in agriculture experiment is the great teacher; and we must distrust all theories, which are not based upon, or fully confirmed by actual facts, experience or observation. It is a great point therefore, to induce intelligent men to make experiments and observations in the settlement of doubtful points, or the ascertainment of new truths; and we may lawfully do this by appeals to their cupidity, or ambition, or vanity. When the public, however, have paid for the experiment, then are they entitled to know fully the mode of operating; and an indispensable condition in all cases of awarding the premium should be a full, exact, and detailed statement of the manner in which an experiment has been conducted or any truth found out.

Little advantage, in our opinion, comes from the premiums bestowed on live stock compared with what might be derived from them. Animals, for example, are often rewarded with premiums, whose owners have recently purchased them; and for the sole and express purpose of obtaining the premium, without any regard whatever to the great point, whether an actual improvement in the breed has been effected; what is the origin and history of this improvement; how long it has been in progress; and by what means it has been brought about. Milch cows are often made the subjects of premium when nothing is known of them excepting what appears at the time of exhibition, unless, perhaps, you get from the claimant some such definite replies as these:—if you ask him, for example, how much milk his cow gives, he will answer, "she gives a pail full froth and all,"—and if you inquire what is the quality of her milk, probably you will get some such reply as that "her milk looks very yellow and our folks sell some butter besides what we use in the family;" and if you inquire, how she is fed, "why she goes in a pasture with other cattle in summer; and in winter we give her some hay and coarse fodder, and so much of the wash of the house as we don't want for the pigs; and this ain't a great deal, for sometimes we keep a good many pigs and sometimes not so many;" and then too she runs with the other cows, and we never keep her milk separate." And this is a fair specimen of the exact and definite manner in which some claimants think proper to commend their cows for premiums; and more than that, this is all that is sometimes demanded by the committee in order to award a premium, unless it be that they occasionally get the oral certificate of some kind neighbor, that "he does not know exactly but he has seen neighbor such a one's cow, and she carries a pretty considerable bag, and he has 'hearn soy,' that she gives a good deal of milk." Now we need not say that when

premiums are bestowed on such ground as this or anything like it, it is a mere squandering of money and the true objects of such premiums are entirely lost sight of.

We admit that much good comes from the mere exhibition of a fine animal. It is important to show farmers what can be done by showing them what actually has been done. Farmers in general, it must be admitted, are a race of men rather slow of belief with respect to anything different from that to which they have been accustomed. Living oftentimes in comparatively insular situations, having little intercourse with the world, and being little familiar with anything more than the daily routine of their own circumscribed operations, they know little of what is going on in other parts of the country; and the verbal testimony of the most intelligent and fair men, will make but small impression on the obduracy of their unbelief, unless the matter is demonstrated to their senses. This excessive and unreasonable incredulity is in some degree yielding to that intelligent curiosity and spirit of inquiry, which is so generally awakened by the wide diffusion of agricultural knowledge and information through the many periodicals with which the country seems destined to be inundated; and yet there are some men who appear determined to keep their eyes and ears hermetically sealed; and who have not yet arrived even at the first great truth of the Copernican system, that the earth revolves round the sun. With respect to such men it is impossible to convince them that any improvement can be effected in the race of domestic animals beyond their own half-fed and half-grown stock, unless you can place them directly in the pen along side one of your beautiful, sleek, mahogany Devons, or one of your magnificent improved Durhams. Then, and then only will truth triumph over obstinacy, ignorance and prejudice.

But this is of little importance compared with informing the intelligent class of farmers, bent upon improvement, and every day becoming more numerous, how such improvements in their live stock can be effected. When therefore, a premium is proposed for live stock, unless it be for live stock brought into the country from abroad, the claimant should be the raiser of the animal; he should be able to give its pedigree, and the manner in which from its birth it has been fed and kept; its weight, and its actual gain per year or month; and in what particulars, if any, other than those which are obvious to every observer, he thinks the animal excels, or any improvement has been effected. If a milch cow, for example, is offered for premium, the claimant should be required to state her age, her parentage, the qualities on the side of the dam for milk or butter, if they can be ascertained; the race by which she was sired; the mode of rearing her; the time of coming in with her first calf; the number of calves she has had; how her calves have proved, if they have reached an age to have been tried; her milk—its amount in any twenty-four hours or week, or month, in pounds or in cubic measure, and whether ale or beer measure; the amount of cheese made from her, or the amount of butter in any given time or from any given quantity of milk or cream, and precisely her mode of being fed during this time; and how long she remains in milk. On these and other particulars exact information should be sought and required. So likewise in regard to a bull presented for premium, his history and pedigree should be required; and if of an age to be ascertained, the character of his stock should be known; their growth, their thriftiness, their feeding or their milking qualities.

It may be objected that we cannot expect such exactness from our farmers; and that the amount of premiums offered is not sufficient to compensate for the trouble and expense of keeping or of making out such accounts.

We cannot tell what can be done until we have made the attempt. Our farmers have all of them intelligence enough to see the importance of such exactness, and the great advantages which would result from it; and although it might be difficult or impossible to accomplish in this matter all we could wish, we can gradually approach it; and every approach towards it would conduce essentially to the general improvement. If the amount of premium be not sufficient to indemnify the expense and trouble, reduce the number of premiums and make the amount sufficient. If necessary have two classes of premiums— one for the exhibition of valuable or fine animals while the premiums shall be merely sufficient to cover the actual expenses of bringing the animals to the place of exhibition; and trust to the love of approbation, or the spirit of competition, or motives of public good to induce farmers to bring out their fine animals; and let there be another class of premiums sufficiently large to reward any intelligent and well directed, and persevering exertions to effect a permanent and substantial improvement in the breed, which shall be demonstrated by the exhibition of the actual results of such efforts.

This is a matter of great moment to the farming interest. Improvements in the breed of animals, thought to a certain extent as practicable as improvements in anything else are not to be effected but by intelligence and exact exertions continued for a length of time. Many years have been consumed and great expenses have been incurred by the intelligent stock raisers in Great Britain in bringing their noble races of animals to the degree of perfection to which they have already attained. In Massachusetts little has yet been accomplished. We have had many fine animals among us; but few of our farmers have with any care availed themselves of the advantages, which have been within their reach. Many of them after one or two crosses have through indolence or indifference, allowed everything to run into confusion. We have taken no pains, comparatively, in the improvement of our own native stock, which is of a character, under careful management, to furnish a basis for distinguished excellence. The butcher is allowed to select, at his pleasure, our best calf or our best lamb, and our cows and our sheep may go just where they please to get another. We will indulge the confident hope that an era of improvement will presently dawn upon us; and farmers at last see in this matter their true interest.

H. C.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Nov. 12th and 17th, 1838.

Apples.—From S. Downer, Pomme de Neige, Brussels Pippin, Flushing Spitzberg, American Nonsuch.

From R. Manning, Kilmah Hill; Been, Fall Harvey.

From Rev. H. Ramsdell from Thompson, Connecticut, Chandler, Nichols' winter sweet, Pomme Royale, Randall's red sweet, Reddick, Red Pumpkin Sweet.

Pears.—From W. Kenrick, Napoleon, Duchess d'Angouleme.

From E. Vose, Passe Colmar, Napoleon, Lewis, Wilkinson, Duchesse d'Angouleme, (very large and fine, weight of largest 16 3-4 oz.)

From R. Manning, Beurre Duval, Newton Vergalieu.

From S. Downer, Catilae, Bezi Vaet.

From N. Clapp, Lewis.

From Geo. Brown, Haste.

Grapes.—From M. P. Sawyer, Arwingsburg, and a kind unknown.

For the Committee,

L. P. GROSVENOR.

BRIGHTON MARKET.—MONDAY, NOV. 19, 1838.

Reported for the New England Farmer.

At Market 1050 Beef Cattle, 425 Stores, 5800 Sheep, and 1800 Swine.

Prices.—Beef Cattle.—Sales were not brisk, and the price of the two last weeks were hardly supported. We shall quote without much alteration. First quality, \$7 38. Second quality, \$6 50 a \$7 00. Third quality, \$5 50 a \$6 00.

Barrelling Cattle.—Mess, \$6 50 a \$6 75. No. 1, \$5 50 a \$5 75.

Stores.—"Dull." Two Year Old, \$16 a \$27. Three Year Old, \$24 a \$35.

Sheep.—"Dull." Lots at \$1 50, \$1 75, \$1 88 \$2 12, \$2 38, \$2 62, \$2 75, \$2 92, and \$3 25.

Swine.—A large proportion of the sales were at 6 for sows and 7 for barrows. Several lots were sold for something less. At retail 6 1-2 a 8. Several lots unsold.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded Northern exposure, week ending November 18.

NOVEMBER, 1838.	7 A.M.	12 M.	1 P.M.	Wind.
Monday,	12	48	52	S.
Tuesday,	13	50	54	S. E.
Wednesday,	14	42	56	S. W.

Friday,	16	38	52	34
Saturday,	17	30	48	40
Sunday,	18	28	40	36

PEAR, PLUM, GRAPE VINES, &C.

1000 Pear Trees of the most approved kinds;
1000 Plum Trees, of the most approved kinds and extra size—many of them have borne the past season;

500 Quince Trees;
3000 Isabella and Catawba Grape Vines, from 6 to 15 feet high, most of them have borne fruit—Black Hamburg, Sweet-water, Pond's Seedling;

30,000 Giant Asparagus Roots;
5000 Wilmot's Early Rhubarb or Pie Plant, lately introduced;

Also—a good assortment of Gooseberries, Roses, &c. of different kinds.

All orders left at this office, or with the subscriber at Cambridge-port, will meet with immediate attention.

SAMUEL POND,
Cambridge-port, Mass.

BULB GLASSES,

A good assortment, consisting of white and blue plain Hyacinth Glasses; white and blue painted do.; plain glass of sizes do.; ground glass, painted and plain, do. of various sizes and patterns.

Crocus Glasses, plain white for sale at the N. E. Agricultural Warehouse and Seed Store.

JOSEPH BRECK & CO.

NOTICE.

A person now in the Nursery business, on a limited scale, who has peculiar advantages for its extension, not possessed by any other individual in this country, wishes to connect himself with some person who can furnish a small capital sufficient to make the business both pleasant and profitable. Inquire at the office of the N. E. Farmer.

Nov. 21, 1838.

MULBERRY TREES.

200,000 Genuine Mulberry Trees, and as many more as may be wanted, of the most approved kinds—consisting of the best selected varieties now in use, for cultivation, feeding worms, and making silk—being acclimated to this country, and adapted to either warm or cold climates, affording a rare opportunity for companies or individuals to be supplied, from the most extensive collection of mulberry trees ever seen in any village within the United States.

Autumn is decidedly the best time for removal, and orders left with Messrs. I. B. Colt, Secretary of the Connecticut Silk Manufacturing Company, Hartford; Alonzo Wakeman, at the office of the American Institute, No. 157 Broadway, N. Y.; Thomas Lloyd, Jr. No. 26 Filbert street, Philadelphia; Pa.; Luther L. Cox, Baltimore, Md.; B. Snider, & Co. Savannah, Ga.; Bliss Jenkins, & Co. Mobile, Al.; James Lyman, St. Louis, Mo.; Case and Judd, Columbus, O.; G. Harwood, Rochester, N. Y.; and the publishers of this advertisement, or with the subscriber, in Northampton, Mass.

Orders left with the above gentlemen will be promptly attended to, and each will be furnished with samples of the foliage.

Several valuable farms may be had with or without Mulberry Plantations.

Apply at the office of D. STEBBINS,
Northampton, Aug 22, 1838.

PREMIUMS FOR BUTTER AND CHEESE.

The Trustees of the Massachusetts Society for promoting Agriculture, give notice, that they will award their premiums, for Butter and Cheese, to be exhibited in December next, at the Central Hall, over the Quincy Market, in Boston, which has been kindly granted to them, for that purpose, by Mr H R. KENDALL. The premiums are as follows, viz:

For the best lot, in tubs, pots, or firkins, not less than 300 pounds, \$100 00
For the next best, not less than 300 pounds, 50 00
For the best, less than 300 pounds, and not less than 100 pounds, 30 00
For the best lot of Cheese, not less than one year old, and not less in quantity than 300 pounds, 50 00
For the best lot of Cheese less than one year old and not less in quantity than 300 pounds, 40 00

The claimant on the several premiums on Butter, must state in writing, the following particulars, viz:—the number of cows kept on his farm; his mode of keeping; the treatment of the milk and cream before churning; the mode of churning, winter and summer; the measures adopted to express the butter milk; the quantity and sort of salt employed, whether saltpetre, or any other substance has been used in the process; the best time for churning and keeping Butter in hot weather, and the best mode of preserving it, in and through the summer and winter, and in what vessels.

The claimants for the several premiums on Cheese, must state the mode of making the same, and the following particulars, viz:—the number of cows kept; whether the cheese is made from the proceeds of one, two or more milkings; whether any addition is made of cream; the quantity and sort of salt used and the quantity of rennet; the mode of pressure, and the treatment of the Cheese afterwards.

Farmed in the several States are invited to compete for the premiums at the exhibition in December.

Claims for the premiums must be made in writing, addressed to BENJAMIN GUILD, Esq. Boston, post paid, on or before the 1st of December next; and the parcels deposited before Tuesday the 4th, at the place above designated, on which day, at 10 o'clock, before noon, the committee will proceed to examine the lots offered for premium, and none will be admitted after that hour.

The premiums will be awarded at the same place on Wednesday the 5th.

Each lot must be numbered but not marked, and any public or known mark must be completely concealed, nor must the competitors be present; in default of either of these requisitions, the claimant will not be entitled to premium.

It is particularly recommended to the competitors, that the Butter be put up in the nicest manner.

There will be a public auction after the examination by the Committee, and those who desire to sell, will have an opportunity without any charge for auctioneer's fees, but the government duty must be paid by the owners of the butter and cheese. After the premium has been awarded, all the articles submitted must be taken care of by their respective owners, the Committee having no further control or responsibility in regard to them. The Committee will be at liberty to withhold from the auction sale, any parcels either of butter or cheese, which they may have reason to suppose, from the ordinary quality of the same, or other circumstances, may have been sent merely for sale.

DUTCH BULBS.

Just received from Rotterdam, our annual supply of splendid Dutch Bulbs, consisting of
Double Red, Yellow, Blue and White Hyacinths,
Single " " " " " " " "
Single and Double Tulips,
Crown Imperials, Double and Single, of sorts,
English, Spanish and Persian Iris,
Polyanthus Narcissus, of sorts,
Ranunculus,
Anemones,
Fritillaries,
Crocus, of sorts.

JOSEPH BRECK & CO.

Boston, Oct. 16, 1838.

FOR SALE.

Five acres of good Salt Marsh, in Quincy, or (Squantum so called).
Also, Four acres of Salt Marsh in Brighton.
Also, Several full blood animals, cows and calves. Apply to A. Greenwood, on the Welles Farm, Dorchester, near Dr Codman's meeting house.

Sept. 12, 1838.

ROMAN POTATOES.

Orders will be received for Roman Potatoes by JOSEPH BRECK & Co. or communication may be directed to JONAS A. THOMPSON, Catskill, N. Y. who has them for sale.
Boston, Nov. 7, 1838.

RASPBERRY BUSHES.

The subscribers offer for sale, 5000 Red and White Antwerp, and Franconia Raspberry, Bushes of good strong growth.

PEAR TREES FOR SALE.

At the Pomological Garden, Salem, Mass., a good collection of Standard Pear Trees, all of which have been proved. They comprise the choicest of the old and new varieties. Also 5,000 superior Buckthorn Plants for hedges.
Salem Oct. 8, 1838. ROBERT MANNING.

MISCELLANEOUS.

BRITISH CORN MARKET.—A late number of the London Standard has the following table, showing the nature of the seasons in Great Britain since 1790, and the annual average prices of wheat in each of the seasons. The object of its publication by the London editor is to show that the highest prices of grain have generally marked the seasons of the greatest commercial prosperity, and also to prove the greatly improved condition of the manufacturing population under the operation of the Corn Laws.

Years.	Nature of the Seasons.	Per Quarter.	Wheat s. d.
1790	Peace, and favorable seasons,	{	53 3
1791			47 3
1792			42 0
1793	War, but favorable season,	{	57 10
1794	Deficiency of the crop,	{	51 0
1795			73 0
1796			76 6

1836	Above an average,	{	48 6
1837	Under an average,	{	55 10

THE OWL.—The owl tribe, from the size of the head, though owing to the superabundance of feathers with which it is surrounded, and the peculiar

manner in which they are placed, the head appears larger than it really is, would reasonably be supposed to possess more than an ordinary degree of sagacity;—but, as, from the construction of their eyes, they are unable to distinguish objects in the broad daylight, and their manners and habits thus becoming altogether nocturnal, their sagacity has seldom been put to the test. When a boy, I took a young owl, the barn or common white owl, from a nest, and kept it for eighteen months. Perceiving that it was anxious to hide itself from human gaze during the day, I formed a hole for it, a yard in length, of bricks, where it passed the day, but from which as night approached, it sallied forth, displaying much activity and fierceness. It would come when called, even in the day-time; if called, it would approach the mouth of its hole and seize a piece of meat, with which it would instantly retreat, and it uniformly evinced a disposition to avoid the broad glare of day. It was amusing in its way; at dusk, it would strike a mouse, a bird, or a piece of meat, out of my hand with much dexterity; and I have no doubt, that it was susceptible of education much in the same way as a hawk, could the requisite instruction have been imparted in the dusk of the evening or during the night. This bird frequently rambled to a considerable distance in the twilight, but always returned to his day retreat. His fate was melancholy; two of my school-fellows, one of whom was the late earl of Huntingdon, contrived to purloin him, and after tying him upon the back of a duck, placed this ill-assorted pair in a pond. I did not witness this mischievous exhibition; but, it seems, the duck, not liking the involuntary companion, no sooner got into the water than it dived, carrying the unfortunate owl under the water with it. On coming to the surface, the night-bird loudly testified its dislike to immersion by that peculiarly dismal noise for which these birds are remarkable, called *hooting!* Down went the duck again, and so the cruel business was continued until the duck became completely exhausted, when it and the owl drowned.—*Physiological Observations.*

DUTIES PERFORMED BY A GOOD FARMER.

Every duty faithfully performed hath its reward.

The approach of winter always induces the thoughtful, and careful and industrious farmer to look about him to see that he is prepared to meet so boisterous and inclement a season of the year in the best possible manner. His windows, his doors, and the roofs of his building, are all examined, and if necessary, made tight and secure. His barn and stables are looked to and put in good order. His sheep, and hogs and poultry have all comfortable, dry lodgings prepared for them in due season, for he knows that no animals can thrive and do well, that is not well housed, and well fed, and every way made clean and comfortable. His potatoes, his sugar beets, his turnips and all his winter fruits and vegetables are well secured against frost, and placed in such positions that ready access can be had to them when necessary, without subjecting them to danger of injury by exposure to the weather. His fuel is so arranged and prepared for current use that his family can procure it without any unnecessary exposure to the rude blasts of winter. His fields and meadows are kept closed during the winter and early part of spring; so that animals may not be permitted to ramble over them

and injure his grounds. His barn yard is so arranged that his cattle never leave it during the period of winter feeding, by which means he saves all their manure for the nourishment of his crops. His implements of husbandry and food are all carefully housed and arranged in good order, so that they can be had when wanted for use. His garden, in which not a weed has been permitted to perfect and scatter its seed during the autumn, is thrown up into ridges about eighteen inches high, and separated only by trenches extending from end to end of the beds; this he knows exposes the soil to the meliorating influence of the frost, destroys the grubs and worms which seek refuge during the winter, deep in the ground, and induces the ground moles to seek out for dryer and warmer lodgings elsewhere. By this plan of ridging his garden in the fall, as soon as the frost is out in the spring, his beds are dry and warm, and admit of being levelled and worked at once, long before flat, wet ground can with propriety be moved by the spade; this enables his family to have a supply of garden vegetables several weeks earlier than those who have less intelligence or industry; the deeper tith and more thorough pulverization of the soil, also increases the growth of his plants, and enables them the better to protect themselves against the contingencies of either very dry or very wet seasons.—*Farmer's Cabinet.*

WHEAT FARMS FOR SALE IN WESTERN NEW YORK.

In the counties of Monroe, Orleans, Genesee and Erie—varying in quantity from 50 to 300 acres each—under a good state of cultivation and improvement, with suitable buildings, fences, &c., watered with durable streams, and most of them have wheat on the ground. Five or eight years credit can be given, if wanted, on the whole principal sum, with annual interest. These farms are situated in the midst of a rich agricultural district, unsurpassed in the richness and productivity of its soil, lying on the banks of the Erie canal, and in the vicinity of Rochester, Lockport and Buffalo, all of which are at all times a ready and sure market for all the articles of produce, which at present prices, amply reward the husbandman, and enables him with a few crops to pay the first cost of his lands. A favorable opportunity is here presented to the enterprising farmer who would wish to obtain a good farm on liberal credit, with sufficient means to secure the payment of one third of the purchase money. Letters (post paid) promptly attended to.

JOHN C. NASH.

Rochester, N. Y. Oct. 18, 1838.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders to any amount, which will be promptly attended to.

Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston.

Sept. 20. NATHAN WARD.

FRUIT AND ORNAMENTAL TREES

The subscribers will be happy to receive orders for *Fruit and Ornamental Trees, Shrubs, &c.* We shall be enabled to furnish at Nursery Prices, and at short notice, Trees and Shrubs of every description, and hope to give satisfaction to all who may be disposed to favor us with their orders.

WORCESTER SOCIETY.

EXTRACTS FROM REPORTS.

The committee on "all other manufactures than those of leather and of wool, or of which wool is component part"—Report,

That the number of articles submitted to their examination, as exhibited for premiums, or for the purpose of increasing the interest of our Fair, is much smaller than has been usual in past years. That they are not aware that the ingenuity and skill manifested in the manufacture, or the excellence of the material used, is less than heretofore. The variety, in proportion to the number of articles, can hardly, at any time, have been exceeded. The committee were called to estimate the worth and rarity of many articles, better fitted for fairy finers than theirs. There were coverlets, of such warmth and excellence, that even single blessedness might be comfortable under them; tiny socks, fit and warm, which fairy feet might wear when coming under the cold moon of our frosty nights; which, should the fairies not claim them, might be worn by those odd things call "sweet pledges," to do not honestly belong to single blessedness; there were hats of palm leaf and of silk, and bonnets of grass and of straw, for the head, a silk veil, and wrought collars for the face and neck and beauty; stockings and socks of cotton and linen, and the nether limbs of those whom they might fit, though the shape of some of them was such that it is doubtful whether any one will confess their use; there were crickets for weary feet, a screen to save the fair complexion from a fiery flush—pieces of flowers—of little love birds and their nests of little dogs looking wondrous sleepy or wise—of naughty boys robbing birds' nests—and of a forlorn wail, mourning over all. There were wires to take cards, cards to carry cattle, beautiful and ingenious implements of husbandry, and (though no necklaces for a sow,) gilded hames that dumb beasts, as well as men, may be proud of as a collar. The committee gazed, admired, wondered, decided, and directed such an account to be given of others as now follows.

Seven woven coverlets were offered, but as some of them were partly of wool, it was apprehended there might be a conflict of jurisdiction between the two committees on manufactures; happily, however, the peace principle prevailed, and the latter committee magnanimously relinquished their claim. A cotton counterpane, or Marseilles quilt, was decidedly the best, equalling the best imported, and the committee award for it the premium of \$5, Miss Sarah K. Shepherd, of Worcester. Only two bonnets were offered—the one made by Mrs Sally Leland, of Grafton, "from grass gathered around the dwelling house," was a beautiful article, of which any lady might, as reasonably, be proud to be the maker, or the wearer, as any bonnet whatever. The premium of \$5 is awarded to Mrs Leland.

A black lace veil of fine silk, wrought with much taste by Mrs Roxanna Stone, of East Brookfield, they thought deserving a gratuity of \$2.

A Highland plaid woollen shawl, made by Miss Ruth B. Wheeler, of Lancaster, and another by Miss Lydia W. Estabrook, of Princeton, were each deemed worthy of a gratuity of \$1.

Very excellent wire, Nos. 30, 31, 32, and 33, from the manufactory of Ichabod Washburn, of Worcester, was noticed with praise, as were copper wire cards, bearing the stamp of "C. O. Read, Worcester"—and iron wire cards bearing the stamp of "No. 10, Whittemore's Patent, 1. Washburn."

A barouche made by Albert Tolman, with a harness by William Leggate, both of Worcester, were examined and admired as excellent specimens of mechanical skill in that branch of business.

A corn planter and seed sower, by S. Wood, if not too complicated, will allow farmers to take rides for pleasure while planting their fields. It is certainly an ingenious article.

Boynnton's straw cutter, exhibited by Alvin Allen, of Worcester, is said to be the best article of the kind now known, and the committee thought it might be so.

A cheese press, by which cheese is so cruelly treated, as to be made to squeeze itself, was also exhibited—the inventor or exhibitor was not known to the committee.

Messrs. Ruggles, Nurse & Mason, deserve the thanks of the society, for the exhibition of several machines calculated to save the labor and more perfectly perform the work of the farmer and the gardener. They exhibited "a vegetable cutter," to prepare food for cattle, by the labor of one man, at the rate of a bushel per minute, price \$10—"A seed sower," or "drill barrow," for the field, and another for the garden, each of undoubted excellence, price of the one \$15, of the other \$3 50—"A grindstone turned by treadle and crank, with anti-friction rollers—and a Nourse's plough, somewhat improved, and very perfectly made. Each of these machines and implements deserves the particular examination of every cultivator of the soil.

By order of the Committee,

A. D. FOSTER.

Worcester, Oct. 10, 1838.

The committee on Fat Cattle and Milch Cows regret that they cannot speak of the stock submitted to their examination, with that exultation and liberal praise which other parts of the large and interesting exhibition of this day will excite in other committees. It is too obvious that the fat oxen now adjudged to be entitled to premiums, as the best, would be unsuccessful competitors with the fat cattle of former years. The causes of this comparative inferiority are the deficient supply of beef, which has hurried into our neat market, at uniform high prices, everything that "hath horns and hoofs," and the shortness of the pastures, occasioned by the drought of the last summer, and the high price of corn and potatoes.

As it is not a new predicament for Yankee far-

mers to be obliged to do the best with the stock which they have, the committee have had no trouble in adjudging the premiums among the animals submitted to them, which were valuable, though not such prodigies of fatness as we have seen.

It is stated that all the oxen offered for premium were fed with grass and pumpkins, and had no meal.

The committee award to Joshua Eveleth, of Princeton, for his fat ox, 4 1-2 years old, weighing 1711 lbs. the first premium of \$20,00

To Timothy P. Moore, of Worcester, for his fat ox, 6 years old, weighing 1790 lbs., the second premium of \$15,00

To Benjamin N. Child, of Worcester, for his fat ox, 7 years old, weighing 1890 lbs. the third premium of \$10,00

Mr Adam Harrington, of Shrewsbury, offered a yoke of oxen 4 1-2 years old, weighing 1775 lbs. and 1770 lbs. which deserve commendation for noble size and beauty of form, but they lacked the requisite of fatness.

Mr T. P. Moore, of Worcester, in addition to the fat ox for which a premium is awarded, presented three other fat oxen.

The committee viewed with much admiration, a well formed and very fat cow, weighing 1500 lbs. offered for exhibition by Mr Moses H. Felton, of Barre.

There was no more difficulty than in the celebrated choice of Hobson, in selecting the Milch Cow which should be distinguished by a premium, as but one was offered with the requisite certificate of merit. It is to be regretted that our farmers will not take the trouble to prepare themselves for competition in this most important department of the show. And it may be observed that the attention and labor of ascertaining the qualities of their cows as to milk, will bring its own reward in the improvement of their own stock, in addition to the good resulting to the individuals and to the public at these exhibitions. In many farm yards in the county, cows might be discovered which give milk that will make little or no butter, while the cows are bought at as high prices and kept with the same expense as the most profitable animal.

Our Commonwealth did itself honor in the exhibition of six milch cows of fine figure and in excellent flesh, from the State Lunatic Hospital. While the literature of the day and common observation prove that hunger, voluntary as well as involuntary, will not only break down stone walls, but commit many other excesses of word and deed, the success of this noble institution demonstrates that liberal feeding and every provision for contentment and satisfaction have wondrous power to give quietness and steadiness of mind. And the rotund forms and placid tempers of these stately animals show, that though they confine themselves to vegetable diet, they are no Grahamites in grazing, and though they "wax fat" like Jeshurun of old, they have no disposition to kick.

Respectfully submitted by order of the committee.
S. SALSBURY, Chairman.

The committee on working oxen have very much to regret that there was any misunderstanding in regard to the precise time when the drawing should take place—they stood some time at their posts anxious for the trial of strength and docility of that noble animal, the ox, and with patience waiting the tenderness of his driver, when they were informed "the time had not come," and they like some other tribes were soon dispersed. On their return they were at once struck by the appearance of a wondrous concourse of people:

"And saw every Yankee full of mettle
Swarm forth like bees at sound of kettle
Not Rome, when Tarquin rap'd Lucretia
Saw wilder mustering of militia"

The committee without further preface, would ask leave to report their award of the society's premiums as follows, namely:

To Leonard Wheelock of Grafton, for the best pair of working oxen, the first premium of \$12.00
To Isaac Hathaway of Sutton, the 2d premium of \$10.00
To John Newton of Milbury, the 3d premium of \$8.00
To Stephen Marsh, Jr., of Sutton, 4th premium of \$5.00

The committee regret their inability to bestow premiums to other individuals who offered and tried beautiful oxen—they were cattle that will do honor to any farm, town, or county. But while speaking in high commendation of the oxen, they hope to give no offence to their owners, if in the language of the Orator of the day, they say that "whipping is a gratuity," and if it is "received in humility," it is oftentimes misplaced.

A pair of oxen presented for exhibition by Henry Putnam acquitted themselves handsomely, as also did a fine pair which are under the care of Dr Woodward of the State Lunatic Hospital. The committee were much gratified with the appearance of a team of five yokes of young cattle belonging to Reuben Wheelock of Sutton—they were well matched for size and color, and under perfect command, and they recommend to him a gratuity of ten dollars.

The chairman, on his own responsibility, will say that the committee were able to decide all questions of right without appealing to the chair.

All which is humbly submitted.

THOMAS W. WARD, *Chairman.*

(From the Farmer Cabinet.)

SUBDIVIDING A FARM PROPERLY, &c.

It a matter of no small importance, and it requires much skill and judgment to lay off a farm properly into fields and inclosures so as to realize the greatest possible advantage by it, in regard to convenient access, equal size of inclosures, and convenience in watering of stock. The saving of fencing is also a matter of considerable consequence, both as it regards the expense in the first instance, as well as that occasioned by subsequent repairs.

Fields for cultivation should be rectangular, and the nearer they approach to a square, the less fence they require. The inclosures intended for a regular rotation of crops should be as near the same size as practicable, and the number of acres in each field should be accurately ascertained, and a register kept of it. The importance of having the fields to contain each a known number of acres, is

of much consequence in manuring, liming, plastering, and in sowing grain and grass seeds, and also in determining the amount of produce per acre, as well as enabling a farmer to judge correctly of the amount of labor bestowed on a given space of ground. All of these matters are too often *guessed* at, and sometimes the guessing is so coarse as to lead both the proprietor and his friends into great errors of judgment. Fields being of equal dimensions, require the same amount of labor each year, in tilling them, produce as near as human means can effect it, the same amount of products, and give the ability to distribute the manure with an equal hand over the whole farm.

Although many farms are beautifully laid off into fields so as to attain the objects above stated in an admirable manner; yet there are many others, so cut up as not to indicate much intelligent design in its accomplishment, either in respect to convenience, or the due apportionment of the respective inclosures. Where this is the case a system should at once be adopted, the tendency of which would be in a few years to regulate and correct it. There is something so incongruous in one year cultivating a large field and the next a small one, that it cannot be duly appreciated, except by one who has made trial of it; for one season your force is not adequate to your work, and the next it is superior to it. It is continual up and down hill work, and the larger fields suffer for want of an adequate supply of manure, and sometimes from insalubrious culture.

Thorough culture always ranks first in agriculture; *manure* next, and then follows good crops and prosperity, which maketh the heart of the farmer glad, and stimulates him to renewed exertions in promoting the fertility of the soil, and by that means increasing the sum total of animal existence and enjoyment.

When fields are elevated above neighbors' grounds, heavy rains carry the finest, richest particles of the soil on to them, but this kind of trespass has not often been found to destroy good neighborhood; if it should unfortunately do so, a small gutter made near the line fence or a few stones judiciously arranged under, near, or against it, will generally correct the evil, and no doubt promote the interest of the more elevated farmer, by keeping within his own enclosures the food which his own crops may be the more luxuriant for partaking of. Those who have had the benefits of the washings of their neighbors' fields, can form some estimate of its importance, for

"What is one friend's loss is another's gain."

AGRICOLA.

For the New England Farmer.

WASH NOT TO BE USED FOR PEAR TREES.

In conversation, a few days since, with one of the most intelligent farmers in the Commonwealth, in speaking of the use of potash and water as a wash for apple trees, he cautioned me against the using that wash for *pear trees*;—for the want of this information, I have lost within the last few years, several valuable pear trees, and was not aware till now of the cause. Hoping that others may profit by the above hint, I have communicated it for your paper.

One word on the use of the grafting composition (composed of wax, rosin and tallow,) instead of

clay. Three years since I had several apple trees grafted, using the composition; the grafts did well for one season, since which almost every stock has died, at least that portion which came in contact with the composition—neither is mine a solitary instance; I have known whole orchards injured or put back a year or two by the use of the above composition. X.

GRASS AND GRASS SEED.

A farmer never thrives unless he raises abundant crops of grass; for grass and hay feed stock, and stock makes manure, and with plenty of manure, grain and every other agricultural product is easily brought into existence, but without manure, which is the food of all plants, farming would soon come to a full stop; as well might we expect a mill to grind without water, or a watch to keep time without a mainspring, as for grass and grain to grow and thrive without being furnished with food. I have never yet known a prime good farmer that did not pay especial attention to raising the greatest possible quantity of grass, and I have never known one that did so, but what was more than amply remunerated for his expense and trouble. It is painful to see within twenty miles of Philadelphia, Indian or wood grass still maintaining its original position in some fields and meadows, when lime that can be so easily procured would soon destroy it and supply its place with something alike creditable and profitable to the cultivator of the soil. Grass seed should always be sowed evenly and in quantities to coat the surface with a sufficient number of plants to exclude weeds; there should be no room left for *unbidden guests* to seat themselves. Red clover, which should always be one of the grasses sown, on account of its large product, tap-root, and the fine condition in which it leaves the soil, weighs from 60 to 64 lbs. a bushel, and a bushel will sow from six to eight acres. The seed of timothy being small, one peck to the acre is sufficient. Orchard grass seed being clumpy and light, should be applied at the rate of from one to two bushels per acre, and herds grass or red top as it is sometimes called, one bushel to the acre. There should always be at least two, if not three of these kinds of seed sown together to insure a good crop, so that if one partially fails, the others may furnish a supply of plants. The loss or failure of a crop of grass is too serious an affair to run any risk about that can possibly be avoided; therefore sow plenty of different kinds on the same ground, and if you don't raise your own seed, be careful of whom you buy, lest you get an impure or damaged article, for

Cheap seed is always dearest in the end.

AGRICOLA.

N. B. Orchard grass is said to have stood the late severe drought the best, and timothy to have suffered the most by it of any of the artificial grasses; but it is perhaps yet too early to form a decisive opinion on this subject.—*Farmer's Cabinet.*

ORNAMENTAL TREES.—The time is at hand when those who are desirous of transplanting ornamental trees should be up and doing. We rejoice that the public taste in relation to this matter has undergone a great improvement within a few years, and that shady forest trees are now considered a useful and ornamental addition to a beautiful vil-

lage. We copy the following hints in relation to transplanting trees from one of our exchange papers:

"Be careful not to transplant before the leaves have fallen—as soon after as you please.

The trees should be taken from open ground. If taken from the dense forest, they will not bear the exposure.

Select trees of second growth; they have better tops and better roots than the first. Transplant the tree entire. The leaves are the lungs of the tree, and affect its growth as much as the roots. The frequent practice of lopping off the top is very bad.

Be sure and get all the roots. Remember the small fibres are what absorb nourishment for the tree. Strip off these, and the main body of the tree becomes only a contrivance to hold the tree up. Do not expose the roots to sun and air longer than absolutely necessary. Let them carry with them as much of the old soil as they can hold on to.

In setting out the trees, be careful to make the hole so large that the roots shall not be crowded; neither let them be crowded together, for then they will decay.

Throw upon the roots at first fine strong mould, never any manure; then throw on water, and shake the tree till the mud has filled up all the interstices between the roots. After the ground is somewhat dry, fill up the hole and tread down the earth. Never leave a tree so that water can stand over its roots."—*Worcester Spy*.

(From the Farmer's Cabinet.)

RECIPE FOR CURING PORK AND HAMS.—As soon as the pork becomes cool I cut and sort it taking great care to have the tubs perfectly sweet and clean. In cutting, I take out all the spare ribs, and make pickled pork of all the side between the ham and the shoulders; cutting it into pieces of suitable size for family use. I trim the hams and shoulders well. I cover the bottom of the tub with rock salt, and then put in a layer of pork, nicely packed, then cover this layer with salt, and so on, until the tub is filled. I use rock salt and very bountifully. In six or eight days make a pickle of salt and cold water, as strong as possible, and cover the pork previously salted with it. It will then keep for use for years if your choice.

In preparing the hams and shoulders, I weigh several, to come at the probable weight of the whole. They are packed with care, in suitable tubs. My process is to sprinkle some coarse salt at the bottom; then pack in the hams and shoulders finally, side by side, being careful not to put the back of one flat on the top of another. The spaces are filled up with chimes, blocks and jowls. To about every 300 weight of meat I take thirty pounds of rock salt, one pound of saltpetre, and fourteen lbs. brown sugar, or half a gallon of good molasses (generally the latter.) Take as much pure water as will cover the meat, put in a clean vessel, add the above articles, boil it, removing the scum as it rises, and when no more rises set it to cool, after which pour it on the meat until it is covered 3 or 4 inches.

If the hams are small, weighing from 12 to 15 pounds, let them remain in pickle five weeks—if from 15 to 25, six weeks—if from 25 to 45, seven weeks. When you remove them for the purpose of smoking, put them in clean cold water for two

or three hours. If there is too much salt or saltpetre adhering to the surface of the hams, the water will take it off. The smoke should be made of clean green hickory. A fire should be built only in dry weather. And when the meat has acquired a yellow tinge, not red or black, they are removed, and hung up in a dark place where they are not disturbed by flies or vermin.

DAVID COMFORT.

(For the New England Farmer.)

ROHAN POTATO.

Mr. JOSEPH BRECK,—

Dear Sir—Agreeably to your request, I give you the result of my observation and experience in regard to the Rohan potato, which I have grown for three years. For the table I consider it only second rate, compared with the Chenango; in all other respects I think that it is destined to hold a very conspicuous rank, and consequently to be extensively cultivated.

I am not aware that for productiveness it has any competitor. In the year 1836 I had four potatoes sent me from France. The product from these the present year was nineteen bushels; the largest weighed a pound and a half; they were grown in a field with other varieties, and no extraordinary pains bestowed upon them, either in relation to the culture or the quantity or quality of the manure. Coarse stable manure was used, a fork full to each hill. The land was of middling good quality, a part of it quite dry, and the crops suffered severely from the long drought. They should be planted early, by the 1st of May; if not convenient to plant by that time, I should recommend burying them in a warm place to accelerate their sprouting, which was the course I pursued the present year; or if they could be put into a hot-bed and sprouted it would probably be a better way; they should, however, be planted out before the sprouts become so long as to be in danger of breaking off in removing them. I have not cut them for planting excepting the first year. In 1837 in consequence of illness I did not have an opportunity of giving them a fair trial, not being able to give my personal attention to them. They were planted in rows and dropped three or four inches apart in the row on the north side of a high fence without any manure excepting some ditch mud. The product was only a bushel and a half, and none of them grew very large. I think it would be better to cut the large ones especially till they become more plenty. I have no doubt I should have raised a number of bushels more had I adopted that method, notwithstanding, from the causes above mentioned, the last years produce was small.

It is said, and I believe with truth, that the large ones are never hollow, whereas the large potatoes of other varieties are.

They are harvested with great facility, one man dug 12 bushels in 4 1-2 hours; the proportion of small ones was less than one bushel in nine, and they would hardly have been considered *small* the present year for any other variety.

I will mention only one more good quality which entitles it to consideration, viz., its being very solid, more so, I think, than any other variety which attains so large a size that I am acquainted with.

Respectfully yours,

E. M. RICHARDS.

Dedham, Nov. 8, 1838.

REMARKS.—In addition to what Mr Richards has stated respecting the Rohan potato we would state our experience and lay before our readers the result of our own experiment this year. From the statements made by a number of individuals, who had a few pounds of us in the spring, we were in hopes to have given a more flattering account of this potato than we are enabled to do. The produce has not been so great as we expected; but in comparison with other varieties it has done well. The St Helena and other varieties planted, have not paid the expense of digging, and with the same cultivation which was bestowed upon the Rohan. We are of opinion that we did not get two bushels for one planted. We planted 59 lbs. of the Rohan potatoes in hills, four feet by three apart, and manured with good coarse manure. The potatoes were cut in small pieces of two or three eyes each and three pieces planted in a hill. No extra pains were taken with them. The produce was 790 lbs. Considering the complete failure of every other variety of potato on the place, we think the result upon the whole, a good one, although we fondly anticipated a crop of 40 or 50 bushels. We have had them cooked in a variety of ways; we cannot say they were very fine; as good, perhaps, as any other sort of our own raising this year; but then it should be known that we have not had even a St Helena or any other potato that was fit for the table, the produce of our farm, the present season. We believe it will prove a valuable potato for stock, but not for the table.

J. B.

GREAT GOOSEBERRIES.

We copy the following notices of great gooseberries from that amusing and instructive work, "The Doctor," volume fifth, or the last that has been published:

"Lancashire is the county in which the gooseberry has been the most cultivated; there is a gooseberry book annually printed at Manchester; and the Manchester newspapers in recording the death of a person, and saying that he bore a severe illness with Christian fortitude and resignation, and that he was much esteemed among the class of gooseberry growers. A harmless class they must needs be deemed; but, even in growing gooseberries emulation may be carried too far. The Royal Sovereign grown in 1794, by George Cook of Ashton, weighed 17 pennyweights 18 grains, and was thought a royal gooseberry at that day. But, the growth of gooseberries has kept pace with the march of intellect. In 1830 the largest gooseberry was shown at Stockport. It weighed 32 pennyweights, 13 grains, and was named the Teazer. The largest red one was the Roaring Lion, or 31 pennyweights, 13 grains, and was shown at Nantwich. They have been grown as large as pigeon's eggs. But the fruit is not improved by the forced culture that increases its size. The gooseberry growers, who show for the annual prizes offered, thin the fruit so as to have but two or three berries on a branch: even then the prizes are not always gained by fair dealing; they contrive to support a small cup of water under each of these, so that the fruit for some weeks rests in water that covers about a fourth part, a process they call sucking the gooseberry."

The food of plants is neither more nor less than the principle of which they themselves are composed.

THE GRAIN WORM.

We give it up. Desirous as we have been to believe, or rather to hope, that the grain worm ceased to injure the berry of the wheat as soon as it became hard, and that consequently, the idea of its eating after the grain was harvested was erroneous, facts have convinced us that the worm does not cease to feed on the kernel until its transformation or its death. Some of these facts and our experiments we shall mention here. We have before alluded to confining some worms with wheat in a glass vial. They were so confined a month, when the wheat was examined and some of the kernels had been plainly eaten, but most of the worms were dead. The vial with its contents was again put away for fifteen days, and then examined. The worms were dead, but that they feed to the last is evident from the kernels now lying before us, some of them nearly half devoured, while others have been but just commenced upon. Every kernel was selected singly and perfectly sound, for the experiment. The fact therefore is undeniable, that the worm does feed on the ripened berry. We have also since harvest selected ears of wheat in the field, containing the worm, and which bore evident traces of having the kernels fed upon since maturing; and ears taken from the mow, containing worms, have not unfrequently kernels exhibiting the same appearance. Some of these worms we enclosed in a vial of flour. After being in it a month, the contents were examined, and every one was found dead; a conclusive proof that they are different from the weevil or the common flour worm, with which some have confounded them.

We have this summer been making some observations on the fly that produces the worm, and its method of operating; but fortunately for us, our opportunities for noticing the fly were not as favorable as last year, as they were much fewer in number on the wheat. After much attention to the matter, we are inclined to the opinion that there are at least two varieties of the fly that infest wheat, both belonging to the genus *Cecidomyia* of Letercille, the *Tipula* of Linnaeus. This is not improbable, when it is recollected there are a great number of known species of this insect; upwards of thirty having been found in England alone. One of these species, a reddish or changeable green fly, we have detected depositing its young on wheat, and on some kinds of ripe berries, as the common blackberry. It is furnished with an ovipositor that folds under its belly; and is used for penetrating beneath the chaff of the wheat. The o'her would seem from description to be the *Cecidomyia palustris* of Wilson, its white halteres, and flesh-red abdomen with a retractile ovipositor, corresponding exactly with his delineation. This we think is the common insect, the parent of the worm most commonly found in wheat, barley or oats, (we have seen the fly in all) and which is so destructive at the present time. The appearance of the worms themselves would indicate a parentage not in all cases the same, and we have observed that part of them attach themselves to any object with which they come in contact, and if disturbed secure themselves from falling by a thread, like the worms found in clover heads sometimes, which indeed this kind of the worms very much resemble.

Some difference of opinion exists among observers, whether the product of the fly is oviparous or viviparous; whether an egg is deposited which produces the worm, or whether the worm, already

vivified in the body of the parent, is placed on the kernel. As examples of young produced in both these ways, we may refer to the Genus *Musca* of Linn. of which, one species, the *Musca vomitoria*, or green fly, deposits an egg, from which the maggot is produced, while the *Musca carnaria* deposits its living larvæ, (the young having been hatched in the body of the mother) on any place deemed suitable for their residence. In the first case the egg, after the escape of the larvæ, always remains; in the latter case none is ever seen. In repeated examinations with an excellent microscope, we have never been able to detect the least appearance of a covering from which the larvæ had escaped; and though ears of wheat have been examined on which the fly was caught in the act of depositing its egg or young, the product was always living, and though exceedingly minute, able to move and crawl. The legitimate inference, therefore, would seem to be, that the worm is viviparous, or deposited in the living state by the parent. The fact is of some importance in determining the best means of effecting their destruction, as lime water or the fumes of brimstone, while they would produce no effect on an egg, would be fatal to the young larvæ; and it was regretted that the question could be determined no more satisfactorily.

Some observers of the habits of the wheat or grain worm, have contended that the young larvæ did not penetrate the kernel of the grain, but produced the injury by pressure of the grain, and an abstraction of the juices necessary to bring it to perfection. The latter is the case, but the abstraction is clearly made by the perforation of the kernels. In examining infested ears of wheat, after carefully removing the coverings of the berry, a small whitish spot may be seen on the grain. Submitting this to the microscope, it will be seen that the whitish mass is the small particles of exuvie thrown out around the insect, in the centre of which a small opening may be discovered most generally occupied by the head of the larvæ, which is thus occupied in feeding on the milk of the berry, and deriving his subsistence at the expense of the grain. Those who have examined green peas, when the pod and pea was occupied by the larvæ of the pea bug, can have a good idea of the appearance of a wheat kernel in the earliest stages of the attack of the wheat worm. That the worm does from the first penetrate the berry, and feed on its vital juices cannot admit of a doubt.

The propriety of threshing wheat as soon as harvested, when infested by the worm, is obvious; since, as after the berry becomes hard, the worm is at large in the chaff, and threshing and cleaning frees the wheat or other grain from their presence and their rapacity. Personal observation and inquiry in almost every county of the Western District of this state since the past harvest, has shown us that the worm has spread over the whole of it with the exception of a small part of the southern tier of counties. There we were assured the worm had not yet been seen, and the same exemption is enjoyed in the northern counties of Pennsylvania; while the great wheat growing counties of that state, to the south, have this year been greatly infested. That the grain worm is destined to overrun the country seems clear; how seriously, or for how long a time its presence is to be felt, time alone can determine.—*Genesee Farmer.*

Thinking.—Those who don't think correctly will not be likely to act well.

SOILING CATTLE.

The above is the term applied to the system of feeding animals with green feed during the summer; the animals being kept in stable, and the food cut and fed to them there, instead of allowing them to gather it for themselves, in the field. Von Thaer, the great Prussian agriculturist, in relating the experience of Baron Bulow on this subject, lays down the following as incontrovertible facts:

1. A spot of ground, which when pastured would yield only sufficient food for one head, will abundantly maintain four when left in the stable.
2. Soiling affords at least double the quantity of manure from the same number of cattle; for the best summer manure is produced in the stable, and carried to the fields at the most proper periods of its fermentation; whereas when dropped on the pasture or meadow, and exposed to the action of the air and sun, its power is much wasted.
3. Cows that are accustomed to soiling, will yield much more milk, when kept in this manner, and fattening cattle will increase much faster in weight.
4. They are less subject to accidents and diseases.—They are protected from the flies that torment them in the fields during the warm weather, and they do not suffer from the heat of summer.

Experiments in this country have been made which in the main establish the above positions of Von Thaer. The only serious objection that we have heard, is the labor required during the summer season, when work is in great request in the field and difficult to be procured at any price. Men can however, be hired for this labor if necessary, as well as for any other; and the policy of doing so rests on the mere question of profit and loss. If as Sinclair states, 33 head of cattle were soiled or 17 1-2 acres from the 20th of May to the first of October, when the same cattle would have required at least 50 acres in pasture, it is clear that the use of the 33 acres saved by soiling, at the lowest rates would have paid for far more extra labor than would have been required independent of the superior advantages of the system. One man would have taken care of the 33 head of cattle without difficulty; and the extra crops that might be grown on the 33 acres saved by the process, must be inferior indeed, not to compensate the labor of half a dozen men for five months. The experience of the Hon Josiah Quincy fully establishes these facts and inferences in regard to the benefit of soiling.

During the past years, as appears from a paper in the N. E. Farmer, Mr Holt, a gentleman of East Haddam in Connecticut, sensible of the advantages of the soiling system, but experiencing some difficulty in finding a proper succession of food, especially the latter part of the season, followed the example of a farmer near New London in sowing corn broad cast to be cut when wanted. The following he has given as the result of his experiment.

On the 15th of June, 1836, about 16 square rods of ground, which had been well manured, and well ploughed, were sown broad cast with horse tooth (ground seed or southern corn) at the rate of four bushels of seed to the acre. The seed was then lightly ploughed in with a small horse plough, after which the ground was rolled and harrowed. On the 10th of August following he began to cut upon the green crop of corn stalks, on the above described ground. The stalks which grew from the 16 rods of ground, afforded forage for a horse from the 19th of August to the 8th of October,

and also the principal part of the food of a cow from the 5th of September to the 8th of October; making 50 days keeping for the horse and 33 for the cow. On the 5th of September when this corn was 5 to 8 feet high, but had not eared or tasselled out, the produce of one square rod was cut up, and while green, it weighed 375 lbs. This was at the rate of 30 tons to the acre. This 375 lbs. was dried, and on the 27th of October weighed 86 1-4 lbs. which is at the rate of 13,200 lbs., or about 7 tons to the acre. The advantages of sowing the horse tooth corn, instead of some of the smaller sorts, are, the horse tooth being a taller kind, makes a much greater amount of fodder. An acre of corn sown this way on good ground, would probably afford green forage for 30 cows a month, or for 8 horses for the same length of time.

Such is the substance of Mr Holt's paper, and it seems to point out a mode in which Cobbett's project of keeping a cow, to an acre the year round, can be realised. Perhaps there is no food more grateful or healthful to the ox, or the horse, than that of the leaves or stalks of corn, when secured at the proper time, and in a careful manner. The quantity of nutritive matter the stalks contain, even under the present injudicious mode of treating it, is very great, and if cut and steamed as it should be, would add most materially to the means of feeding; and every one who has travelled at the south knows the avidity with which the northern as well as the southern horse feeds on corn leaf fodder. We would add here, that in our opinion, much of the relief, not to say cure, experienced by horses on the north subject to the heaves, when taken to the south arises from substituting the clean grateful corn leaf as food, in the room of the too frequently mouldy, and always dusty hay of the north. In a season of drouth like the past, an acre of two of corn like Mr Holt's sown broad cast, and of good growth, would have been a most material aid in supplying the many half starved cattle and horses that were to be seen even in our fertile Western New York with the most nourishing food; and if not wanted for that purpose in the summer, being cut and dried, would make a supply of inter food far greater and more valuable than could be obtained in a dry state in any other way.

The system of soiling, it is evident, requires rich lands to grow the food; and it is clear, there is no method so well calculated as this to keep lands rich. We think it might be made a most profitable part of our mode of farming on our rich rain growing farms, by enabling us to keep great quantities of stock than we are now able to do; thus securing at once, greater sources of comfort and profit, and the most effectual means of retaining the fertility of our soil.—*Genesee Farmer.*

(From the Farmer's Cabinet.)

THE STRAWBERRY AND GRAPE.

It is a matter of importance to farmers who attend market regularly with butter, poultry, and other productions of their farms, to turn their attention more than most of them do, to raising fruit of the most valuable kinds for sale in the market, as well as for home consumption. Attention to fruit trees, enriches an agreeable pastime to the younger members of the family, and produces *home attachments* which are important to be inculcated in youth of both sexes, and at the same time may become a source of considerable profit to an industrious, intelligent family. A good strawberry bed occupies

but little room, and requires but little time to keep it in good and productive order, which the pleasure derived from so agreeable and wholesome a fruit would repay four fold—but if it should be extended a little beyond the wants of the family circle, and their friends, would become a source of considerable income. I have seen a strawberry bed, not half the size of a common kitchen garden, which produced to its worthy owner more than five hundred dollars a year clear profit; a sum much greater than is realized on an average from more than half the farms in Pennsylvania, of 100 acres and better.

The grape is also a fruit much sought after in our markets, occupies but little room, requires but little labor, and meets with a ready sale at good prices, and furnishes an agreeable, cooling, refreshing relish in a family. The more delicate kinds of foreign grapes are too uncertain to justify their cultivation in our climate unless under peculiar circumstances; but the Isabella and Catawba, and the Elsenborough are all hardy, native grapes, and can be raised with certainty of success in any part of the country.

There are other valuable kinds of grapes that stand our climate and do well, but those named are readily procured, are well known, and the fruit much esteemed. A gardener near the city, who has been referred to in the last number of the Cabinet as eminently successful in the prosecution of his profession, informed me that a few years since, a friend gave him a few of the Isabella vines, which he planted on an arbor near his dwelling, and that last season after giving away several hundred weight to his friends and customers, and amply supplying his family circle, he sold six hundred and sixty pounds at ten cents per pound, producing \$66.

A worthy gentleman residing at Camden, New Jersey, causes to be sent to the Philadelphia market several thousand weight annually, of the Isabella and Catawba grapes which are sold at from 10 to 12 cents per pound. The Elsenborough grape is small, but it is perhaps the best native grape we have; vast quantities of them are raised by the gardeners and private citizens of the ancient and honorable city of Burlington, and the exhibitions of the Horticultural Society annually display quantities of the finest specimens of this most delicious and valuable native fruit.

I bring into view the strawberry and grape only, each of which is raised with less expense and trouble than the potato, and is much more profitable to the producer; but there are many other descriptions of fruit equally worthy the attention of the attention of farmers and perhaps equally profitable; the raising of which is shamefully neglected, but which is sincerely hoped will soon claim the attention of all worthy cultivators of the soil, for the profit to be derived from it, for the purpose of cultivating habits of industry and *home pleasures* as well as the public good.

"They shall plant vineyards, and eat the fruit of them."
WEST.

CULTURE OF ONIONS.

The town of Wethersfield (Conn.) has long been famous for the large quantities of onions which are annually raised and exported to the West Indies and the southern states. It has been superstitiously supposed there is something in the soil of Wethersfield peculiarly adapted to the culture of onions;

and this whim has no doubt discouraged many from attempting the cultivation of this valuable root, in other sections of the country, equally favorable to its growth. It is true the soil of Wethersfield is a rich gravelly and sandy loam, well adapted to horticultural purposes; but the success of its inhabitants in the culture of onions, is attributable in a much greater degree, to a particular virtue in the fingers of its females, than any peculiar properties in its soil.

The business of raising onions in Wethersfield, is reduced to a perfect system. The following is the method of cultivation. Early in the spring the land is manured by ploughing in fine manure from the stable or barn-yard, in the proportion of about ten loads to the acre. That of neat cattle is preferred, as that of horses is considered of too heating a nature. After the manure is ploughed in, the land is well harrowed and laid out into beds five feet wide. The beds are laid out by turning a furrow towards them each way. This raises the beds above the aisles and gives an opportunity for the water to run off should there be occasion for it. They are then raked with an iron-tooth, or common Jay-rake, and the aisles suffered to remain as left by the plough. Thus prepared, the beds are ready to receive the seeds.

As early as the season will admit, the seed is sown in the following manner. A rake, with teeth a foot apart, is drawn crosswise of the beds, for the purpose of making drills for the reception of the seed. The seed is then sowed in the drill, with the thumb and fingers, and covered with the hand. From ten to twelve pounds of seed is put upon an acre. After the plants come up they are kept free of weeds, which generally require four weedings. A hoe of a suitable width to pass between the rows, is used in weeding, which saves much labor. When ripe they are pulled and the tops cut off with a knife. A sufficient length of top is left to tie them to the straw in roping. They are then roped, or bunched in ropes or bunches of 3 1-2 pounds, as required by the law of the state. An ordinary crop is from 6000 to 8000 ropes to the acre. The quantity annually raised in the town, is estimated from 1,000,000 to 1,500,000 ropes, which are sold at an average price of \$2 a hundred, amounting to from \$20,000 to \$30,000.

Most of the labor in raising onions in Wethersfield, is performed by females. The cultivation of an acre requires from fifty to sixty days' labor of a female, whose wages, including board, is about fortytwo cents a day. Though many of the young ladies of Wethersfield spend a portion of their time in onion gardens; yet in personal beauty, education and politeness, they are not excelled by females of far less industrious habits.—*Connecticut paper.*

TOP DRESSING.—Nature always manures the soil by the top dressings, the rains carrying down the decomposed solution to the roots of plants; can man do better than to imitate and assist in her operations for his benefit?—*Farmer's Cabinet.*

Family conversation.—Sensible, judicious conversation in the family circle, exercises an important and salutary influence in forming the minds, and regulating the opinions of children and young people, and should be resorted to as the most efficient means of regulating their future movements in life.—*Id.*

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, NOVEMBER 28, 1838.

AGRICULTURAL SOCIETIES AND PREMIUMS.

No. V.

We have spoken of the conditions, which in our opinion, should be prescribed in regard to a dairy or a sheep farm. Another class of farms embraces particularly the raising of stock. In some parts of the state, cold and mountainous and wholly inaccessible to the plough, this or the raising of wool are the only objects to which the farmer, with any hope of advantage can direct his attention. The towns of Mount Washington at the south western extremity of the state, and of Florida, Clarksburg, Monroe and others at the north-western part, are of this description, and others differently situated would come under the same description. Perhaps it is seldom to be expected that farmers placed in these inhospitable locations would become competitors for the premiums of the societies, yet they should have the opportunity, if they desired to avail themselves of it; and farmers placed in more favorable situations, who by pursuing the same system of husbandry succeeded in obtaining them, by giving a full and detailed account of their success and improvements, would confer the highest advantage upon those mountain stock raisers by showing them, where the best stock is raised, and how it may be obtained and improved, and thus enabling them to make the best use of the restricted means afforded by their situation.

It has been questioned by many persons, whether Massachusetts can ever be with advantage, or to any extent, a stock-raising state. Compared with the Western States, whose boundless prairies give them an unlimited range of pasturage, and compared with those parts of the country, where the ground is not locked up for any length of time by an inexorable frost, nor wrapped up for four and five months in an unbroken covering of snow, her advantages seem very limited indeed. Yet in spite of all these hardships and restrictions Massachusetts may raise twenty, we are almost ready to say fifty times as much live stock, we speak of neat cattle particularly, to advantage; and, at such prices as the farmers have had to pay the present season, to a great profit. An increase of the supply would of course reduce the price; but by putting into requisition all the means of sustaining stock, which our farmers afford, and many of which are neglected, and by extending our means by the cultivation of vegetable crops, the increased amount of stock raised without a proportionate increase of expense would afford the farmer a bountiful return.

It must at the same time be remembered that little attention has been paid among us to the improvement of our breeds by judicious selection and crossing; and that the introduction or rearing, or improvement of a race adapted to our particular means and situation, would prove a great benefit to the agricultural community.

We should deem a stock-raising farm an object worthy of a specific premium of the Massachusetts Society or of other societies in the state. It is not easy to state with great precision the conditions on which such a premium should be granted or claimed, but the claimant should be required to produce the evidence of judicious and sufficiently long continued attempts at improvement and their successful results. The number of animals should be prescribed; their sex and age; whether bulls, cows, oxen, steers, heifers or calves; the objects attempted to be accomplished, whether it be the raising of an improved stock for labor, beef, or milk; the history of the animals from whom the stock is derived; the mode of raising the

calves; the time when the heifers come in; and the best time for the purpose ascertained by observation and experience, as far as it can be determined; the time and mode of breaking and training animals to the yoke; the time of coming to maturity for beef; the mode of feeding, if fed in the stall; the average cost of raising an animal, giving fully the quantity of hay consumed in any given time by an animal, and the kind and age of the animal; the number of acres required for the pasturage of an animal; and the value of hay and of land used for pasturage; and the comparative value of the breed or kind of animals thus raised in reference to other known breeds. In the same class of premiums might be included likewise the stall-feeding of cattle for beef; the kind of animal; the age; the mode of feeding; the live weight when put up; the gain per week, or month; the feed consumed or required per day or week; the mode of its preparation; experiments upon cooked or uncooked food; upon grain, or meal, or esculent vegetables; the value of an animal when put up to be fattened; his value when fattened; and in fine a full and detailed history of the whole matter of breeding, raising, and fattening stock.

Another important subject of premium should be a tillage farm. This should embrace the whole subject of cultivation; the nature of the soils; the manures used and how applied; the crops raised; the mode of ploughing; the plough used; a comparison of fall and spring ploughing; the time and manner of planting; quantity and preparation of seed; the after-cultivation; the harvesting; the mode of saving and using the stover, stalks, or straw; the getting out of the grain and its preparation for market; the whole cost of the crop, and its marketable value.

Let another subject of premium be that of mixed husbandry, whether on a large or small scale. This is the kind of farming on which premiums are now offered; and the conditions prescribed by the society are already so full and pertinent that it might be difficult to improve the form of them.

Another class of premiums might include particularly market farms; or farms cultivated so near to a quick market that the produce is at once disposed of in the form of milk, or vegetables, or fruits. These farms are numerous and highly productive; and it would be interesting and useful to the agricultural community to know their management and modes of cultivation, especially in the forwarding of vegetables and the cultivation of the finer kinds of fruits. It might be difficult to obtain this information, as few perhaps, would be found willing to go into a full detail of their farming. To obviate this objection, however, it should not perhaps be required of them to give an account of their actual sales and expenditures; but only of the amounts produced; and the yield per acre; with the modes of manuring and culture.

We have gone thus fully into this subject of premiums certainly not with any view of dictating to the gentlemen to whom it properly belongs to bestow these funds; and whose honest and earnest desire to render them most useful and effectual, we properly appreciate; but in the hope that our suggestions, if they avail to no other ends, may at least lead to the inquiry, whether the modes of their present appropriation are the most eligible, or others may be discovered of greater efficiency and utility.

As there are few things which attract more attention or are read with more interest by the agricultural community than a full and detailed account of an enterprising and intelligent farmer's own personal experience and operations, so there is no farm in which valuable information can be communicated so intelligibly, or more usefully. Every encouragement should be given the farmers to come forward with these details. Small experiments, tried by common farmers and within the means of

the most humble, may be equally decisive in respect to many important matters as experiments on the most extended scale; and, as we have often had occasion to remark, experiments, which fail, may as often be useful in determining what can or cannot be done as experiments which succeed. What is mainly important at the trial, the operation, and the results, patiently, exactly, fully, and intelligibly observed and recorded. H. C.

THE WEATHER.

Since the first part of October more rain has fallen than is perhaps remembered by any one, in the same length of time. On the night of the first of November we had a light snow, which fell to the depth of two inches; but soon disappeared. On Sunday the 12th inst. a N. snow storm commenced in the afternoon; and in many parts of the country eight inches, in some places a foot of snow fell; and from present appearances is destined for aught we can see, to remain until next spring stretch its gentle wand over the land and commands it to retire. On Saturday evening the 24th inst. the wind blew strongly from the North West; and brought with it a terrific blast. In several places at the city the mercury in Fahrenheit stood at 3° on Sunday morning; and on the Monday it fell to zero. We should not be surprised, if the Green Mountains it took it into its head to sink lower than this. This is a hard pinch for so early in the season; and what is to become of us if the gripe is soon relaxed, it is not easy to predict, unless it be to still with the flies, until we are resuscitated when the dog-days come on. That would be, however, rather a long nap; and there is not the same certainty our waking up when they do. But then how much should save and avoid by such a suspension; cold finger-frosts, and feet of ice; the terrible operation getting out of bed when the mercury is at zero; all public and private quarrels and contentions; the fifteen gal jug war, the congressional squabbles and excitements, the partisan battles in and out of Government; all the logical disputes and fisticuffs; all the pain of think and all the plague of writing; the printer's devil, the imp of a thousand terrors, would not even appear to in our dreams; we should escape too the din and clamor of Mormon wars, and Canadian wars, and Texas revolutions, and Abolition riots, and fierce elections. To also think of the ecstasy of the return—to hear the noise of by-gone days and to find piles and piles of fresh intelligence, fresh at least to us, at which we might sit day after day, before and after breakfast, with no feet the stock falling until, in this; Esquimaux climate, must go into winter quarters again, and with only peril of a surflet. This too without any "detriment to the republic;" for humbling as the reflection may be our self-esteem, no man is of so much importance that the world will go on just as well without as him. The tides will still ebb and flow; the moons will wax and wane; the earth roll round in its diurnal and annual circles; and the glorious and mighty orb of day will daily his brightening and vivifying face, unruined by terrestrial changes or commotions, and looking down upon busy, bustling, anxious, converted men, proudly tread the earth and presumptuously and haughtily tread the earth and presumptuously and haughtily as they lord it over each other, as mere notes fluttering and tossing in his own glorious and quenchless beam.

H. C.

TRUE PLEASURE.—The pleasure resulting from having done something useful, is without alloy. Who has observed with satisfaction, the cheerful, pleasant countenances of children, beaming with delight after having executed some little duty, or work of utility.

RIGHTON MARKET—MONDAY, NOV. 26, 1838.

Reported for the New England Farmer.

At Market 750 Beef Cattle, 200 Stores, 2800 Sheep, and 1150 Swine.

Prices—Beef Cattle.—First quality, \$7 50 a \$7 75. Second quality, \$6 75 a \$7 25. Third quality, \$5 50 a \$6 00.

Barrelling Cattle.—Mess, \$6 50 a \$6 75. No. 1, \$5 75 a \$6 00.

Stores—Two Year Old, \$16 a \$27. Three Year Old, \$22 a \$35.

Sheep.—We quote lots at \$1 02, \$1 88, \$2 12, \$2 33, \$2 42, \$2 02, \$2 88, and \$3 25.

Swine.—“Dull” and prices have declined. Nearly all the lots to peddle were sold at 5 for cows and 6 for barrows. One lot small shorts at 5 1-2 and 6 1-2. At retail 6 1-2.

Error.—In our last week's report, first quality of Beef Cattle should have been reported as high as they are this week.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass., in a shaded Northernly exposure, week ending November 25.

TULIPS, RANUNCULUSES, PINKS AND VIOLAS.

S. WALKER, of Roxbury, offers for sale in beds, or in such quantities as may suit purchasers, from 1 to 2500 bulbs of choice Tulips. The bulbs were imported from Holland, France and England, to which yearly additions have and will continue to be made of the newest and choicest varieties. Persons wishing to purchase a bed of superb Tulips will do well to make a selection for themselves when the bulbs are in bloom, (about the 1st of June.) The prices will conform to the quality of the flowers selected, but in no case will the charge exceed the lowest market prices, in the country where the bulbs were raised, and cheaper than the like quality can be imported.

Tulips in beds of from 30 to 100 rows, containing from 100 to 200 bulbs, or by the dozen, 100 or 1000.

Viola grandiflora—Pansy, or Hovartisee. Upwards of 2000 superb varieties will be exhibited and offered for sale, when the Tulips are in bloom.

Ranunculuses—fine mixtures, from \$2 to \$5 per 100.

Pinks—fine named varieties, from 25 cents to \$1 each.

For particulars apply to S. WALKER, or to JOSEPH BRECK & CO.

FARM FOR SALE.

A Farm situated in the southwesterly part of Townsend, on the road leading from Townsend west village to Worcester. Said farm contains 110 acres of land divided into mowing and pasturing, and a large share of wood and timber; a one story house, with two front rooms, kitchen, luteary, and two bed rooms, well finished; parlor papered; wood house; well, under cover, forty feet barn, and shed, a large sheep house, fifteen by thirty feet, a large cooper shop, and another small house well finished, on the lower floor; a good aqueduct which comes into the barn yard, and a good orchard.

The subscriber will sell a part or all, and give possession this fall or winter, or next spring. Those who wish to buy, will do well to call on the subscriber, who lives on the premises, and look for themselves. ASA H. ADAMS.

Nov. 29, 1838.

NOTICE.

A person now in the Nursery business, on a limited scale, who has peculiar advantages for its extension, not possessed by any other individual in this country, wishes to connect himself with some person who can furnish a small capital sufficient to make the business both pleasant and profitable. Inquire at the office of the N. E. Farmer.

Nov. 21, 1838.

ROHAN POTATOES.

Orders will be received for Rohan Potatoes by JOSEPH BRECK & Co. or communication may be directed to JOHN A. THOMPSON, Catskill, N. Y. who has them for sale.

Boston, Nov. 7, 1838.

PREMIUMS FOR BUTTER AND CHEESE.

The Trustees of the Massachusetts Society for promoting Agriculture, give notice, that they will award their premiums, for Butter and Cheese, to be exhibited in December next, at the Central Hall, over the Quincy Market, in Boston, which has been kindly granted to them, for that purpose, by Mr H. R. KENDALL. The premiums are as follows, viz:

For the best lot, in tubs, pats, or firkins, not less than 300 pounds, \$100 00
 For the next best, not less than 300 pounds, 50 00
 For the best, less than 300 pounds, and not less than 100 pounds, 30 00
 For the best lot of Cheese, not less than one year old, and not less in quantity than 300 pounds, 50 00
 For the best lot of Cheese less than one year old and not less in quantity than 300 pounds, 30 00

The claimant on the several premiums on Butter, must state in writing, the following particulars, viz:—the number of cows kept on his farm; his mode of keeping; the treatment of the milk and cream before churning; the mode of churning, winter and summer; the measures adopted to express the butter milk; the quantity and sort of salt employed, whether saltpetre, or any other substances have been used in the process; the best time for churning and keeping Butter in hot weather, and the best mode of preserving it, in and through the summer and winter, and in what vessels.

The claimants for the several premiums on Cheese, must state the mode of making the same, and the following particulars, viz:—the number of cows kept; whether the cheese is made from the proceeds of one, two, or more milkings; whether any addition is made of cream; the quantity and sort of salt used; the quantity of rennet; the mode of pressing, and the treatment of the Cheese afterwards.

Farmers in the several States are invited to compete for these premiums, at the exhibition in December. Claims for the premiums must be made in writing, addressed to BENJAMIN GUILD, Esq. Boston, post paid, on or before the 1st of December next; and the parcels deposited not less than the 4th, at the place above designated, on which day, at 10 o'clock, before noon, the committee will proceed to examine the lots offered for premium, and none will be admitted after that hour.

The premiums will be awarded at the same place on Wednesday the 5th.

Each lot must be numbered but not marked, and any public or known mark, must be completely concealed, nor must the competitors be present; in default of either of these requisitions, the claimant will not be entitled to premium.

It is particularly recommended to the competitors, that the Butter be put up in the nicest manner.

There will be a public auction after the examination by the Committee, and those who desire to sell, will have an opportunity without any charge for auctioneer's fees, but the government duty must be paid by the owners of the butter and cheese. After the premium has been awarded, all the articles submitted must be taken care of by their respective owners, the Committee having no further control or responsibility in regard to them. The Committee will be at liberty to withhold from the auction sale, any parcels either of butter or cheese, which they may have reason to suppose, from the ordinary quality of the same, or other circumstances, may have been sent merely for sale.

DUP'CH BULBS.

Just received from Rotterdam, our annual supply of splendid Dutch Bulbs, consisting of Double Red, Yellow, Blue and White Hyacinths, Single " " " " " "

Single and Double Tulips, Crown Imperials, Double and Single, of sorts, English, Spanish and Persian Iris, Polyanthus Narcissus, of sorts, Ranunculuses, Anemones, Fritillarias, Crocus, of sorts.

JOSEPH BRECK & CO.

Boston, Oct. 16, 1838.

PEAR TREES FOR SALE.

At the Pomological Garden, Salem, Mass., a good collection of Standard Pear Trees, all of which have been proved. They comprise the choicest of the old and new varieties.

Also 5,000 superior Backhorn Plants for hedges. Salem Oct. 8, 1838. ROBERT MANNING.

MISCELLANEOUS.

MYSTERIOUS ROBBERY AND HAPPY DISCOVERY.

As the season of Thanksgiving and pumpkin-pies is approaching, as well as that season when the icy hand of winter with merciless grasp seizes upon the scanty pittance of the poor, a slight sketch illustrative of the best mode of making even an ordinary breakfast a luxurious repast, will not be out of time; and if any are disposed to be captious, let them by way of experiment make a trial, and if it does not result to their satisfaction we will bear the blame.

It was late on one of those bitter cold nights which are not unfrequently felt in our climate in the dead of winter, when the full moon looks down upon the crusted snow, sparkling and creaking as the sleighs glide along,—that one of our most benevolent and wealthy citizens was aroused from his slumbers by a rap at his door. Without disturbing the family, the door was opened, and he listened to the tale of a half starved foreigner, whose wants were not all his own, for the partner of his joys and sorrows as well as their offspring, for whom he had found some poor shelter, were waiting his return.

Morning came, and the industrious servant girl was up betimes to spread the ample breakfast board. Priding herself in the success of her baking the previous day, as well as congratulating herself on the ease with which she should live for the several succeeding ones her batch would last, she opened the closet,—but what was her surprise when not a drop cake could be found! In vain every place was searched,—nor could the surprise of her mistress and the searching of the family make any discovery. Robbers had been there,—but yet not a door was found unbolting, or a window raised!

Fortunately, however, a brown loaf was found in the oven—and the smoking cone rose like the peak of Teneriffe from the centre of the table when the family gathered around it. It was, however, by the robbing idea rendered quite as impalpable to most of those who surrounded it as the peak itself; while the good man who had been rather silent, never seemed to eat with a better relish.

Well, wife, I have not made a better meal these three months—I hardly knew before the goodness of a brown loaf—it seems to me the travellers on whom I bestowed your drop cakes at midnight, have heaved this loaf with a blessing.

The mystery of the lost bread was now explained, and the loaf was at once found by all around the board to possess a peculiar richness.

The discovery thus made has doubtless been practiced to a greater or less extent by the discoverer, ever since. As he has not sought a patent for his discovery, no one need fear encroaching upon his right, who is desirous of knowing the flavor of the leaven of benevolence; having the free privilege of making a trial forthwith. This leaven works admirably in the winter months.—*Portsmouth Journal.*

"THE BIGGER THE FOOT THE BETTER THE LUCK."—I have seen men, mercy, by noise and fluency lead the conversation in companies, where there was taste, talent, and learning, though they possessed neither of the three.

I have frequently seen men take their seats in the Legislature, because they begged suffrages and gave away whiskey, while those who disdained to stoop to such measures, were left at home.

I have seen a brainless fop marry a fine girl, and break her heart before the first year, though her hand had been solicited in vain by the wise and honorable.

I have seen stupid creatures, who scarcely knew the top of a tobacco hill from the bottom, plod on and get rich, while men of real intellect and industry, have lived in poverty.

"Gather up the Fragments that nothing be lost."

PREPARATION OF FOOD.—It is not what goes through an animal nourishes him, but what remains in him. Therefore prepare the food for animals, so that it will be thoroughly digested, that it may become a component part of their bodies, and "not be cast out into the draught."

Husband your manure.—It is the stuff out of which grass and grain is made.

Economy.—The crumbs of manure should all be carefully swept up for preservation and use. *Many littles make much, and much wants more.* Enough is more than we have.

Necessity of good example.—Children are prone to follow the example, and to fall into the habits of those they associate with; hence the importance of excluding them from the society of the immoral, the ignorant, the vulgar and the lazy; for it is as much a duty to protect them from moral as from physical disease, and of the two, the former is most to be dreaded.—*Farmer's Cabinet.*

Two country lawyers, overtaking a wagoner on the road, and thinking to be witty upon him, asked why his fore horse was so fat and the rest so lean? He knowing them, answered, "The fore horse is a lawyer, and the others are his clients."

Tulips, Ranunculuses, Anemones, Arriolas, Carnations, Picotees, Pinks, and Geraniums.

H. GROOM, of Walworth, near London, England, by appointment Florist to Her Majesty Queen Victoria, begs respectfully to call the attention of his friends and the admirers of flowers in America generally, to his extensive collection of the above flowers, which from his having been very successful in their cultivation this season he can offer at very moderate prices. He would particularly recommend to those persons about commencing the growth of the Tulip (which in England is becoming very fashionable) the under collections in beds, as it is by far the cheapest mode of purchasing them.

FRUIT AND ORNAMENTAL TREES, MULBERRIES, &c

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pears, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Feaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honeysuckles, Foxgloves, Dahlias and other Herbaceous Flowering Plants.

100,000 Morts *MULTICAULIS* are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Brousses and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. D. BRECK, Commission Store, No. 132 Water Street, New York, M. S. PEWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Noanquam Hill, Newton, near Boston.
August 1, 1838. WILLIAM KENRICK.

A good assortment, consisting of white and blue plain Hyacinth Glasses; white and blue painted do.; plain glass of sizes do.; ground glass, painted and plain, do. of various sizes and patterns.

Crocus Glasses, plain white, for sale at the N. E. Agricultural Warehouse and Seed Store.
Nov. 7. JOSEPH BRECK & CO.

WHEAT FARMS FOR SALE IN WESTERN NEW YORK.

In the counties of Monroe, Orleans, Genesee and Erie—varying in quantity from 50 to 300 acres, each—under a good state of cultivation and improvement, with suitable buildings, fences, &c., watered with durable streams, and most of them have wheat on the ground. Five or eight years credit can be given, if wanted, on the whole principal sum, with annual interest. These farms are situated in the midst of a rich agricultural district, unsurpassed in the richness and productivity of its soil, lying on the banks of the Erie canal, and in the vicinity of Rochester, Lockport and Buffalo, affording at all times a ready and sure market for all the articles of produce, which at present prices amply repay the husbandman, and enables him with a few crops to pay the first cost of his lands. A favorable opportunity is here presented to the enterprising farmer who would wish to obtain a good farm on liberal credit, with sufficient means to secure the payment of one third of the purchase money. Letters (post paid) promptly attended to.

JOHN C. NASH.

Rochester, N. Y. Oct. 18, 1838.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone manure more than ten years, and has spent much time and money to ascertain how bone may be converted to the best use, and is fully satisfied that they form the most powerful stimulus that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders for any amount, which will be promptly attended to.

Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston.
Sept. 20. NAHUM WARD.

FRUIT AND ORNAMENTAL TREES

The subscribers will be happy to receive orders for *Fruit and Ornamental Trees, Shrubs, &c.* We shall be enabled to furnish at Nursery Prices, and at short notice, Trees and Shrubs of every description, and hope to give satisfaction to all who may be disposed to favor us with their orders.
Oct. 22. JOSEPH BRECK & CO.

AGRICULTURAL.

THINGS TO BE REMEMBERED.

Winter is coming;—the long files of wild geese on their way to the "sunny south," long since foretold its approach; and the fleecy flakes have already heralded its advent. Ready, or unready, it will soon be upon us; and much of our prosperity as farmers, and our comfort as individuals, is depending on the preparation we are making, or have made, to meet it. The man has little pretension to the character of a good farmer, who has not already made ample provision for his flocks and his herds; and prepared indoor and out, for the wants and comforts of his family; such will not be offended if reminded of things by them already anticipated, while the heedless and the negligent need continual prompting to keep up with the month.

It should be remembered that an animal in high order the first of December is already half wintered. The quantity of food required to keep such an animal in good heart through the winter, and bring him out smart and active in the spring, is much less than when he is poor in the fall, and the danger of loss is reduced to the lowest possible rate. See then that your stock is in good condition.

It should be remembered that an animal provided with a good warm stable or bed, will, to winter equally well, require only three fourths of the food necessary for one that runs at large and is exposed to the severity of the weather. Never undertake to fatten an animal, without first making it comfortable. Much is annually lost by neglecting this precaution.

It should be remembered that where grain is fed to stock, cooking it will cause it to afford at least one fourth more nourishment than if given raw. Grinding aids its nutritive effect materially; but cooking, as by steaming, still more. Thus it has been found by actual experiment, that half a bushel of corn, ground into meal and made into pudding, is equal in effect to three pecks, fed to swine in the usual way, a saving of no small moment where numbers of hogs are fed. In feeding potatoes, the saving by steaming or boiling is equal to one half. Cobs and corn-stalks, made fine and steamed, will keep a horse or cow in better condition than the best hay; and these things are usually wasted.

It should be remembered that it is miserable policy to burn green wood; yet how many there are who rarely use any other. Did you ever calculate the quantity of dry wood it takes to drive off in steam the water from a green oak or beech stick?—if you have, you can estimate the direct loss there is in the use of unseasoned wood. Add to this the vexations consequent on loss of time, temper, and comfort, and you will hesitate before you conclude to pass the winter by drawing and burning one green stick at a time. Wood cut in October will not season as well as if cut in the early part of the year; but the winds will carry

off some of the moisture, and the wood will be much better than if direct from the forest or stump. No wood, however, should lie long after being cut into fire wood, without being placed under cover.

It should be remembered that the winter is the farmer's time to store his mind with useful knowledge; and his books and papers should be provided accordingly. In the winter, if he has calculated his affairs aright, the farmer is prepared to enjoy himself, and the society of his friends; to study books relating to his business, or those on subjects of general interest; and to attend to the education and welfare of his children. No farmer should be without a shelf of well selected books, among which should be found some of the best works on agriculture, such as the manuals of Chaptal or Davy; and no farmer who values his profession, or wishes to conduct his operations understandingly and profitably, will fail of having at command, one or more of the agricultural periodicals of the country.

It should be remembered that ergot will produce disease in animals, and he who, *knowing* this fact, undertakes to winter his cattle on this substance, or on hay that contains it in large quantities, must expect little sympathy, if he finds his stock of cattle sadly decreased in the spring by the hoof-ail.

It should be remembered that all animals require shelter, and none perhaps more so than sheep; yet the barbarous and irrational custom prevails of giving them the "cold side of the barn," and allowing them to endure the severest storms without protection of any kind. Is it wonderful then that multitudes of these valuable animals perish yearly; or that farmers pay dearly for their inattention in this respect?

It should be remembered, that care, prudence and economy, are necessary to success in life in any department, and in none more so than in that of the farmer. Riches are of no value, any farther than they furnish the means of benefiting ourselves and others. The greater part of the men who have attained competence and wealth in this country have done it by their own unaided exertions; and the men who have made themselves the most distinguished in the annals of our country, have come up from the ranks of the people, supported only by their industry, integrity and talents. A farmer has no right to be ignorant, he has no right to be idle;—industry and intelligence take a bond of fate, and ensure success. The favors of fortune are open to all; but no matter of what nature they may be, they can only be won by intelligent and well directed toil.—*Genesee Farmer.*

(From the Genesee Farmer.)

SOUR KROUT.

MR. TUCKER.—The manner of preparing this article of food, is not as generally known as its value entitles it to be; and with a desire to extend it to the benefit of your readers, I have written this for publication in your paper.

In the fall, after we have had two or three freezing nights, collect as many solid heads of cabbage as you wish to preserve, salt up, (say fifty for a family of 6 or 8 persons,) take off all the green and imperfect leaves, cut each head lengthwise through the heart, and cut that clean out. A cabbage knife should now be procured on which the cabbage should be cut fine, and a strong cedar or other barrel, previously well soaked and cleaned at hand, the bottom of which to be laid over with cabbage leaves; fine salt now to be well mixed with portions of the cabbage in the proportion of a pint of the former to a heaped bushel of the latter, and those gradually packed in the barrel by gently stamping with a suitable wooden rammer. When the barrel is nearly full, it should be placed in a cool dry cellar, on boards, the bottom secured from pressing out; a barrel head or pieces of boards laid on the top of the cabbage, and a heavy weight laid on them. In a week or ten days the pickle should cover the cabbage, or a weak brine must be prepared and poured over when fermentation will commence; and from this time to the end of the season, once a week, the froth should be skimmed off, and the boards, weight, and sides of the barrel, cleanly washed. At the end of two weeks it will be fit to cook; and as much of its savory and salutary quality depends on this, I will describe the manner I do it. I take up at a time as much as will make two messes, (as warming up what is left the first day is no injury to it) put it in a tin boiler with a piece of fat pork; and, if I have it, a spoonful or two of goose or other dripping, and just sufficient water to boil it nearly dry over a smart fire in three hours. Boiled potatoes should always be eaten along with sour kroust, as alone it is too fat, cooked in this manner, to make a meal. The potatoes are better boiled in a separate vessel, but they can be boiled with the kroust; though very apt to get heavy. Sour kroust should be all used before the approach of warm weather, as the quantity of salt here recommended is too small to preserve it. When it is intended to be used on ship board in a warmer climate, more salt is necessary, and in that case it should be rinsed or soaked in fresh water before cooking. WINTER DIET.

THE MOUNT VERNON FARMER.

The fame of Gen. Washington as a soldier and statesman is universally known and highly admired by all who appreciate talents, worth and love of country; but his character as a farmer was less known in his day, and his memory in this respect is not venerated according to its desert. Possessing ample means and the most ardent love of rural life, he was one of the first experimental and practical farmers in Virginia. His estate at Mount Vernon consisted of 10,000 acres of land in one body, equal to about fifteen miles square. It was divided into farms of convenient size, at the distance of two, three, four and five miles from his mansion house. These farms he visited every day in pleasant weather, and was constantly engaged

in making experiments for the improvement of agriculture.

Some idea of the extent of his farming operations may be formed from the following facts: in 1783 he had 500 acres in grass—sowed 600 bushels of oats—700 acres with wheat, and prepared as much more for corn, barley, potatoes, beans, peas, &c., and 150 with turnips. His stock consisted of 140 horses, 112 cows, 285 working oxen, heifers and steers, and 500 sheep. He constantly employed 250 hands, and kept 24 ploughs going during the whole year, when the earth and the state of the weather would permit. In 1786, he slaughtered 150 hogs, weighing 18,500 lbs., for the use of his family, besides provisions for his negroes.—*Silk Culturist*.

(From the Pawtucket Gazette)

FARMING.

It is a source of regret to see in this country so little attention paid to agriculture. With a climate of almost every variety, a soil of almost boundless extent, and in point of richness and fruitfulness surpassed by none under heaven, and able men enough to cultivate it, yet we annually import from the populous kingdoms of the old world ship load after ship load of grain and hay. This is a singular fact, but not less true than singular.

In these degenerate days it is considered more fashionable by our young men to measure tape by the yard and molasses by the gallon, to tinker in a jeweller's shop, or stick type in a printing office, to sit behind the counter of a bank, or learn to shave notes in a broker's office, to prescribe physic, or practice law, than it is to cultivate the soil.—Hence the sons of our farmers, as soon as they are capable of entertaining three ideas, become restless and wish to leave the farm and paternal roof, and rush into some city or town, there as they fondly imagine, to become rich and happy. They detect not their error until it is too late to retrace their steps; the Rubicon is passed, and they must go on. Hundreds of them might perhaps return were it not for "pride, erring pride;" but when they are about to embark on their fortune-seeking expedition, in their last interview with their half weeping sister or sympathizing cousin, with the pomposity and consequential air of a corporal in miniature, they make it known in words big with the fate of young fortune hunters, that their countenances will not be again seen by a country lass, till their pockets are filled with the world's wealth, and their heads with the world's wisdom.

The consequence of all this, is, that almost every branch of business in our cities and large towns is crowded with practitioners, and ceases, in a great degree, to be either honorable or profitable. Only a very few ever rise to eminence, but how many more drag out a wretched existence, and go down to the grave "unwept, unhonored, and unsung!" and not a few are followed to the tomb by the curses and maledictions of those whom they have injured.

Could those who are about to embark on the rough sea of life be taught wisdom without experience, how different would they shape their course. But they are like the child who wished to go to the show, and was refused permission by its parents.

"You used to go," was the plea of the child.

"Yes, my dear; but we have seen the folly of it."

"Well, I want to see the folly of it too." And a young man may be told by older people the folly of certain acts, but, like the child, "he wants to see the folly of them too."

The life of the farmer is better calculated than any other to secure happiness to him who performs its duties. He is not subject to those vicissitudes of fortune which drive slumber from the fevered pillow of the trader, speculator and gambler. The winter's storm disturbs not his peace, for he has no ship at sea to be wrecked by the winds and waves; a fall in the price of merchandise affects him not, nor is it of importance to him whether the banks discount or not. He is elevated above the wrangler of the city; independence is his shield and buckler; in the spring he sows his seed and if God prospers the labor of the husbandman, an ample harvest will be the reward of his toil.

Nor do we think it necessary for those who live by tilling the soil to leave their own New England. Our land needs nothing but proper cultivation to make it yield sufficiently to satisfy all our reasonable desires. At present it is neglected. We know that in the far west labor is less required to raise the same amount of produce, but there are disadvantages to be encountered there which more than offset this single circumstance. Besides, man is supposed to be bound by ties creditable to his nature to the scenes of his childhood and the tombs of his fathers. These ties should not be ruthlessly severed. The first and principal reason urged by the savage against removing to a new place of abode, is, that he will have to leave the ashes of his fore-fathers behind him. Should this noble principle be less active in the breast of the Christian than of the savage? There are a thousand objects around the place of our nativity ever dear to memory. The west may possess much to recommend it—its mountains, rivers, and prairies—

"No, never arched the blue sky o'er
A land more fair and free;
But the stream around my father's door
Is dearer far to me."

There are other considerations which should bind us to "this our native land." The pilgrims landed here, and consecrated the soil to civil and religious liberty. If, as many think, innovations are made on the rights of individuals, let us endeavor to correct the evil, but not desert the home of our ancestors. New England will ever be celebrated for the part she acted in our revolutionary struggle, and her sons may ever feel proud, under all circumstances, to point to her as their home.

"Land of the forest and the rock,
Of clear blue lake and mighty river,
Of mountain reared aloft to mock
The storm's career, the lightning's shock,
My own green land forever.

O, never may a son of thine,
Where'er his wandering steps incline,
Forget the sky that beamed above,
His childhood like a dream of love."

SWINE.

There is a great number of breeds of swine, highly recommended before the public; some preferring claims to favor of one kind, and some of another. Some fat easy, are quiet, and orderly, but are not heavy enough for the farmer, as it is said; as the Chinese in its pure or nearly pure state. Another sort are large and heavy, but require a

long time to perfect their growth and get fat, are restless and uneasy, and evidently have little or none of the quiet eastern blood in their carcasses. Of this kind are the large Hampshire and Woburn breeds, from which many of the varieties of the swine in this country are descended. There are other kinds, such as the Berkshire, and what is called the smaller Woburn and Bedford swine, who unite in a great measure the quick fattening properties of the Chinese, and the greater weight of the heavier varieties, and are evidently fortunate crosses of some of the English kinds with the Chinese pig.

Of the several varieties in this country the kind most esteemed are the Chinese, of which there are comparatively few pure blooded animals, and these are principally kept for the purpose of crossing; the Mac Kay breed from the vicinity of Boston, and quite as favorable in that section, but evidently a cross from the Berkshire, with some other breed of English derived hogs, most probably from color and form the Cheshire white pig, a very valuable and fortunate cross however, and the Berkshire variety, which has been widely disseminated through the northern states, and has proved of superior value and well worthy of the notice it has received.

That new varieties of the hog may be produced, ad infinitum, is evident from the nature of the case, and there can be no good reason given, why by fortunate and skilful selections from the different and most esteemed kinds, a breed or breeds superior to any yet known may not be produced; combining in the greatest possible degree the requisites of size, quiet easy feeling, and fine flavored meat, which it is clear all the present kinds do not possess. In the making of pork the color of the animal should weigh but little, still an inferior variety of white, would meet with more favor, than a superior one, if unluckily it was of a black or dark color; this has been seen in the case of the Berkshire, a prejudice as unworthy the farmer, as that which still leads many to prefer the old fashioned red cow or ox, be they ever so badly built, to clean handsome formed Durham, because the latter is spotted.

Numbers of the best Berkshire swine have within a few years been introduced into this country; some by Mr. Hawes of Albany county, from which Mr. Bement's valuable stock are derived; and still more lately by the Messrs Brintnall of Orange county, some of which have attained a very great weight, two at eighteen months each weighing 500 pounds each. Parkinson in his treatise on live stock, after describing the Berkshire pig, as being thin skinned, hair curled, and without bristles, says:—"The pigs of this kind I took to America, received the appellation of Parkinson's no-bristle pigs. The Americans were so partial to this breed, that I sold sucking pigs weighing 20 to 32 lbs. each, at 20 dollars a sow, and 35 dollars a boar. I knew a pig of this kind, killed at the age of 15 months which weighed 574 lbs."

A letter from the Hon. Oliver Fiske, in the 3d volume of the New England Farmer, gives a version of the introduction of these pigs by Parkinson, rather different from the above, and which shows the origin of the excellent breeds of swine around Boston, such as the Mac Kay, Worcester, Bedford, &c. By the way this same "English farmer" Parkinson, is the individual who on his return to England, published a book on agriculture, in which he asserts,—that the American cattle are kept so

poor that their manure is of no value; and that the American cart contains no more than the English wheelbarrow. Mr. Fisk says:—This breed of swine (the Berkshire) was introduced into this state by the Hon. T. Pickering, from the farm of Gen. Ridgely, at Hampton, 14 miles from Philadelphia. Gen. Ridgely informed him that they were brought into this country, as a present to General Washington from the Duke of Bedford, (hence the name Bedford, by which they are sometimes known) who committed them to the care of an English farmer by the name of Parkinson. This man took a farm in the neighborhood of Baltimore; but instead of sending the swine to Gen. Washington, Parkinson sold them. Gen. Ridgely esteemed them very highly, and sent Col. Pickering a pair of them in a vessel bound for Salem. From thence they were transferred to Roxbury, Worcester, &c.

When we consider the great value of swine to the community, the immense numbers that are annually fed for pork, and the prodigious saving that would result to farmers by substituting some of the improved and easily fed kinds for the former inferior sorts, we are pleased at the efforts made to bring such varieties to the notice of the farmer, and disposed to rank the introduction of such animals into any place, as a signal benefit. Slow as some farmers may be to break in on their long established usages, seeing with them is believing, and no one can see the fine swine of the Messrs Allen of Erie; Marks of Onondaga, or Bement of Albany, to mention no others, without being impressed with their superiority. Spite of old prejudices, we believe the Chinese crosses in some of their varieties; the Durlam Short Horns, the Leicester and South Downs, and the English roadster, will yet find their way securely into public favor.

DISEASES OF HORSES.

Fever is of two kinds—First, when it is an excited state of the system without any peculiar local affection, it is called *Idiopathic*. Second—when dependent (*i. e.* symptomatic) or inflammation of any part.

First—*Idiopathic Fever*. Without paying any regard to the question whether or not this disease can really exist of itself, without being dependent on some other lesion, I shall consider fever generally, under this head.

Symptoms.—It generally begins with a cold shivering fit, the horse is dull and listless, his legs and feet are cold, though sometimes not all of them, but one, two or three, as it may happen, breathing difficult, quick pulse, costiveness, no appetite, and the urine high colored. After the shivering (which first ushers it in) has lasted some little time, it is succeeded by the warm stage, which is an excited state, the skin is hot and dry, the eyes are suffused, pulse full and quick. This stage usually lasts for a few hours, when it may end in a slight sweating stage, or a cessation of the symptoms, until the time that the cold stage came on previously, when the same thing again occurs as just described. This state of fever may continue for several days, when it terminates either in inflammation of the brain or lungs, or gradually subsides. It is not of itself dangerous, but proves so by producing the above sequel.

Causes.—Changes of temperature from cold to hot, *vice versa*; any means by which the horse is much chilled or perspiration suddenly checked; fa-

tigue, over heated stables, and peculiar states of the atmosphere are the most frequent.

Treatment.—As fever depends on, or rather is an excited state of the system, our remedial means must be of an opposite character, *i. e.* depressing; the most powerful is bleeding and the quantity taken and the propriety of taking any, must be dependent on the degree of the disease. The medical means consist of purgatives and cooling salts, a drachm or a drachm and a half of aloes should be given night and morning until he is freely purged; with this fever medicine, digitalis (foxglove), one drachm, tartar emetic, a drachm and a half, and nitre three drachm mixed, to be given night and morning. Digitalis has the property of producing an intermittent pulse, *i. e.* after every six or seven beats, it (the pulse) ceases, while one, two or even more can be counted; where this is the case the medicine should be reduced to one half, and in a few days totally discontinued; but the nitre and the tartar emetic is still to be persevered in. If it does not produce this effect it shows the disease has proceeded too far to be arrested by it, or in all probability any thing else. If symptoms of inflammation of the lungs should appear, hellebore should be *cautiously and carefully* administered in half drachm doses, three times a day: if it produces unpleasant effects discontinue it. The horse should be placed in a cool and well ventilated stable, and be kept warmly clothed.

Second—*Symptomatic Fever* is merely the system sympathizing with some local affections; of course by subduing this affection the feverish disturbance will cease.—*London Farmers Magazine*.

Massachusetts Horticultural Society. EXHIBITION OF FRUITS.

Saturday, Nov. 24th, 1838.

Beautiful specimens of the Dix pear were exhibited, the produce of the original tree. From the condition of these pears, it was evident they had been kept till the latest period they were capable of being, in perfection.

Mr R. Ward of Roxbury exhibited pears produced from a tree imported from France, the name having been lost, they have received the local name of "Pond Lily Pears," from a very perceptible resemblance in the smell of the fruit to that of the common water lily.

Mr Magoon of Medford, exhibited a basket of beautiful pears, the produce of his garden, name unknown; in size, shape and color, they resemble the Bezi d' Montigny, more than any other pear, ripening as they do at a period when good pears are not common, they are highly deserving of cultivation. The committee observe of these pears and many others, exhibited at various times without names, that to avoid a hasty and perhaps erroneous conclusion respecting them, it is their intention to procure scions at the proper season, of all those which appear worth of a place in the fruit garden, to engraft them among many others, which have well authenticated names, and by a critical examination of the plants in the various stages of their growth, to arrive at just conclusions respecting their comparative merits, and also to establish the legitimate names by which they were known in the places where they originated.

Mr Manning exhibited Surpass St Germaine, Bishop's Thumb, and Pound pears, and Reinette du Canada apples.

For the Committee,

ROBERT MANNING.

(From the Farmer and Gardener.)

ICE AND ICE HOUSES.

In answer to your request for information as to the best plan of building ice houses, I will merely inform you that I have an ice house that has been used by my family for about fifty years, and has never failed to preserve an abundance of ice for our supplies. It is about 16 by 12 feet and judging from recollection, for it is now nearly half full, is about 16 feet deep. It was probably dug down to the sand or gravel, is walled like an ordinary cellar, the wall extending about three feet above the level of the adjacent ground, and earth thrown against it nearly to the roof. This serves to preserve a uniform temperature, and prevents leakage from rain, &c. The bottom of the cellar is supplied with pieces of timber, say eight by eight inches thick, which are placed about six inches apart, and this protects the ice from the influence of the earth below. When the ice is being put in, I take care to have the bottom and sides well provided with clean rye straw, and have the ice occasionally broken fine, and when the house is full I have it well covered up with the same material. This is all that is necessary to be particular about, as the straw is a non-conductor of caloric, and the ice being well embedded therein, does not melt in the warmest weather. Many years ago this house was lined with boards, which was only useful as a harbor for rats. The lining gradually decayed and has long since been removed and still the ice is kept as well as ever. Give your ice a dry cellar and plenty of rye straw, and rest assured you will require neither tan nor pulverised charcoal, nor boards to keep it cool. A PHILA. CO. FARMER.

THE FARMER A KING.—We city folks don't reflect that all our institutions and our liberties are in the hands of the farmers. Two thirds of all the votes given at the polls are given by them. We do not want the city folks to mix with farmers only to get up this or that candidate for office, but all parties must wish that when they hold so large a share of political power, they should be well informed of our situation. Again, if some of our merchants, lawyers, or doctors, should fall in love with agriculture, and leave the city and grow grain, we do not think it would injure city or country. Our children would at all events be better conditioned than by remaining here and becoming merchants, if such perilous times are to follow as we have seen.

Governor Hill states, in his address to the Merrimack county Society, in New Hampshire, that of the first farm settlers of that state, six out of ten began the world with nothing—yet scarcely one in ten of these has not succeeded in making a good living, and in the end a handsome estate. Now not one in ten even of our merchants, who start with more or less capital, dies rich; and because one in twenty, thirty, fifty, or a hundred, becomes immensely rich, thousands rush into trade.

Trade overdone is replete with trouble and misery. The farmer is a king, compared with a dependent merchant, whose reliance is on bank favors. —*Del. State Journal*.

Palmer Johnson of Claremont, says the Eagle, sold a cow and a calf for one hundred dollars. The sale took place some few weeks since.

GRUMBLING.

If there ever was a people, who, as a whole, had the most unqualified reasons for gratitude, it is the people of this country; and especially the farmers, who, abounding in basket and store, and commanding prices for their produce of which they could a few months since have scarcely dreamed, should be the very last to complain; but, to their shame be it spoken, there are still those that are dissatisfied among them, and such is human nature, probably would be were present crops and prices doubled. Of all men, these eternal grumblers are the ones we most cordially detest. Nothing is right with them. With barns and granaries filled to overflowing—with their fields sprinkled with flocks and herds—with orchards laden with fruit, and abundance of the best of all things to eat and drink, still they will grumble and complain.

In an excursion into the country, a few days since, we came across one of this class of grumblers, which may serve as a specimen of the whole genus, and in describing whom we may read a lesson to some, who, though not wholly given to complaining as yet, have a decided leaning that way. Our grumbler was a farmer evidently rich and "well to do," a good house, and what was a more decisive proof, several well-finished and well-filled barns. His fields were extensive and rich, and exhibited a goodly show of horses, cattle and sheep. Grumbler kept a tavern, where, of course, we made ourselves at home, and after taking care of the outward man we sallied out to look at the premises and the country. He was in his barn, busy in cleaning and depositing in his granary a large quantity of beautiful wheat which had just been threshed, in order to save stacking it, since his barns could hold no more.

An inveterate habit of complaining had wrought his face into deep furrows in which the sunshine of the countenance never rested; and the impression made on you in seeing him, was as if a man had been looking at you through the bars of a gridiron. Friend, said I, you seem to have a good crop of wheat, what was the amount of your harvest? Only 800 bushels, at the highest, was the reply, and ought to have had a thousand. Owing to the dry weather and the villanous worms, I shall get only 25 bushels to the acre, and I ought to have had thirty. People talk about a good wheat crop in the country, continued he, but I know it is a miserable failure. There was a beautiful field of corn of some 20 acres spread out before us, and I alluded to the certainty that there could be no failure in that crop, as the yellow ears showed it was then fit for gathering. Altogether mistaken in your opinion, said Grumbler, not over two thirds of a crop—60 bushels where I should have had 80, had it not been for the cut worm and the dry weather. There are few things I like better than a good potato, and at that moment one of grumbler's sons drove a wagon load of very fine ones past the door to deposit in his cellar, and I paid him a compliment on the quality of his roots. Ah, said he, in a tone like that of giving up the ghost, only half a crop, and poor little, heavy things, too, after all. I planted six acres and shall not get over twelve hundred bushels. Seeing how "the land lay," I touched him on most agricultural subjects connected with his farm and crops, and found that in going over the whole ground, from Dan to Beer-sheba, all was wrong, all was barren. Poor man, said I to myself, as I rode off, 800 bushels of wheat; more than a thousand bushels of corn; twelve

hundred of potatoes, and all other productions of the farm in abundance, with plenty of money in the chest, and from the mere habit of grumbling at everything, wretched and really poor. If riches thus MacAdamize the heart and render it callous to the blessings of Providence, happy is the man who has them not, but instead thereof, the sunshine of the mind, peace and contentment.—*Genesee Farmer.*

(From the Mechanic and Farmer.)

MUTUAL IMPROVEMENT.

One of the best improvements of the present age is that of establishing Lyceums and other associations for mutual improvement among their members, by bringing out, and encouraging the particular talent of each individual, and by affording the community, at a trifling cost, with popular instruction, by way of lectures. Every village can well afford to sustain an institution of this kind, and, in fact, if the inhabitants mean to keep up with the general intelligence of the community, or do what they ought to guard the rising generation from the temptations of evil company, dissolute habits, and blunted moral sensibility, there is a necessity resting upon them to be active in sustaining a pleasant and useful society, of the kind we have mentioned. In every village, a few men, at least, can be found, whose education will warrant their taking the lead in the exercises, and affording encouragement to others to do what they can, and by careful study, in a short time, be prepared to do better. There is talent lying idle, and perhaps may never see the light of day without some such means, and talent too, of no ordinary cast. We are certain of this, for we recollect, many years since, when we were an apprentice, in a shop where were about a dozen workmen, and while all were busily engaged in work hearing remarks and conversations, of the errors in practice, and the unjust inequalities, and the false prejudices in society, that since, when coming from older men who were scholars, have started us like electricity. And yet when calmly composed, have resulted in the same simple yet impressive truth, with less natural and consequently less forcible illustrations.

The season of the year, as the long evenings have come upon us, has naturally led us to write a word upon this subject, for the purpose of persuading our friends, and the friends of humanity, and good morals, and general intelligence in every town to take active measures for approaching winter, which, by a wise disposition of time, has in many parts of New-England, been appropriated as a season of intellectual harvest.

In small towns, all classes ought to join with one heart and one mind, in establishing a mutual improvement society, and give to all the benefit of the knowledge of each. The minister, in this way, would obtain much valuable information in the practical affairs of life, and the wants and trials of his flock; while the farmer and the mechanic, would be enabled to lay up a store of scientific principles, and practical results, which would afford amusement, and activity of mind, besides aiding them in their several pursuits. In short, there never was, and there never will be any one man who knows everything, and the nearest approach you can get to it, is, by some similar method to the one we recommend.

In some villages the mechanics should form an

association, and commence in employing lecturers occasionally, and in meeting to read and have debates or conversations on practical and scientific subjects. A very good exercise for some of them, would be, to collect the scattered scraps of the history of their town from its earliest settlement, and to collect as many specimens of its mineralogy, geology, and natural history as possible.

In other places, the young farmers would find a great deal of amusement and ultimate benefit, in preparing plans for laying out a farm, giving the arrangements, size, and location of the several buildings, with their different apartments; the form and style of the garden, shade trees, orchards, &c. These plans could be compared, amended and finally enlarged, to embrace, not only the form and location, but the manner of cultivating the several portions, and the different soils, together with the best materials for building, the time and manner of procuring them, &c. &c. An effort of this kind well begun and perseveringly pursued, would have no limit, short of the extent of human skill and knowledge. It would give an activity to the inventive faculties, and the mind, and lead those engaged in the business to examine books and other means of information, and thus make thinking, strong minded men, of those, who, without some such method might never rise above the dead level of ordinary capacities.

At the present time, it is a serious fact, and one frequently of great annoyance and cause of complaint, that a majority of the young men who offer themselves for work as farmers, have acquired very few correct principles of farming or much skill in practice, except in relation to a few of the more common duties. We have known cases of young men who thought they understood the business of farming, when set at work to hoe a garden would invariably cover up half the weeds and pass so slovenly over the beds as to do about as much injury as good, or if employed in transplanting were so thoughtless or ignorant of the principles of vegetable life as to destroy half the plants, and generally about their work executed it in so bungling a manner as to try the patience of a Job. We know a man, who is now getting to be a pretty good farmer, who declared a while since that he should have been the gainer, while young, had he given a year's work to some neat and well skilled farmer for the information he should have gained. The facts show the necessity for an increase of knowledge in the principles of the science of agriculture, and the importance of attending to it in the manner we have pointed out, or some other of equal extent.

We might pursue this subject through the whole of the community, and trace some of its effects in every family. But we are aware that we are limited to the length of a newspaper article, and must rest satisfied with merely throwing out a few hints, for those who are disposed to avail themselves of them, with the sincere hope that some measures, active and immediate, will be taken to carry some such plan into effect.

The responsibility rests upon the active intelligent men in every town to begin, and a duty is upon every one, however humble, to put his shoulder to the wheel, and lift with his whole strength. Heave! ho! then, altogether! and take a mutual interest in what will mutually benefit all.

At the late election in Texas, the number of votes cast amounted to 5000.

FLEMISH HUSBANDRY.

Of the cultivation of Leguminous Plants, Peas, Beans, Tares, and Green Crops, Clover, Spurry.

Peas are cultivated on the light soils, but as is the case with buckwheat, they are only sown when the land is not thought sufficiently rich for other crops, and when there is a deficiency of manure; as little or none is given to the land for this pulse. They are generally sown broad-cast in the month of April, and the seed ploughed in; two bushels of seed per acre is the usual quantity. The ground is prepared by being ploughed once or twice in autumn, and again in spring, but less care is bestowed on this crop than on any other. When the plants are about four inches high, they are well hand-weeded; the produce is from twentyeight to thirtytwo bushels per acre. Neither peas nor flax are sown again on the land which has borne a crop of peas, in less than eight or ten years. The white pea, which is split for ship store, is preferred as the most valuable; but the grey pea for hogs is also common.

The cultivation of beans on the heavy soils, which alone are fitted for this pulse, is by no means so perfect as in England, especially in Kent. The broad-cast method of sowing prevents the use of the horse-hoe; and as a principal object in sowing beans in Flanders is to smother the weeds, they are sown so thick, that the hand-hoe is of little use. The manner in which the land is prepared is as follows: having been ploughed in autumn, and well harrowed to destroy the weeds, it is ploughed again very deep in March, and the stiches are reversed, the crown being where the interval was before. It is again well harrowed, and about three bushels of beans per acre are sown regularly by hand and harrowed in; after this ten or twelve tons of manure are put on evenly, or, if the soil is very heavy and cold, eight tons of manure and fifty bushels of lime. This is ploughed in with a very shallow furrow, only two or three inches deep, and then the land is laid smooth by passing the harrows reversed over it. Some farmers sow the beans after the manure is spread, and plough in both together; others plough in the manure first, and then sow the beans, and cover them with the harrows. This last method does not sufficiently cover them, and if the weather should be dry soon after sowing, the beans will not come up so regularly.

A few intelligent proprietors have seen the deficiency of this method both in the crop and in the state of the land after it, and have adopted another practice taken from the gardeners. A man with a strong hoe like the Devonshire hack, makes holes in a line, at a foot or more from each other and women follow and drop two or three beans in each hole, which are covered with the earth scooped out of the next row of holes as the workman returns. The distance between the rows is the same as between the holes in the rows; and by making the holes in one row opposite the intervals of the other, the whole field is planted in a quincunx order, as is usually done with cabbage plants. There is a great saving of seed in this way of planting beans; and when the plants come up they are well hoed and weeded, and the earth is drawn up all around the stems. The produce is much greater, and the land is as clean as after a fallow. Another method where the land is sound and dry, is to spread the manure, and rake it into the furrows as fast as they are made by the plough; beans are then dropped on the manure and covered with the earth

of the next furrow when the plough returns, till the whole field is planted. If this is done in every second furrow only, the crop will be all the better, and the land more easily hoed. Horse-hoes have not yet been introduced into practice; some such instruments have been brought from England, but they are mere objects of curiosity, and are despised by the ignorant. In heavy soils some of the best farmers trench-plough the land, by means of two ploughs following each other in the same furrow. This is most advantageously done before winter, that the frost may mellow the poorer earth brought up. A good liming and manuring soon bring the whole mass into a fertile state; and in this deep soil beans grow luxuriantly. In some districts where the soil is lomy, they sow peas and beans together, and sometimes tares also; the object is to produce green food for the cows and pigs in summer. In this case the clover plants can be made to grow, the better for the land; as nothing cleans it more effectually. The crop is cut at the time when the pods are just formed, and while the top is still in bloom; it is used in a fresh green state, as tares are in England. If any extent of ground is devoted to this crop, portions are sown at different times to have a regular succession; it produces the heaviest crop of green food that can well be got from the land. This practice is worthy of imitation in our stiff soils. It seems not to exhaust the land, and leaves an admirable surface to sow wheat in with a single slight ploughing; or if it be thought advantageous, there is ample time thoroughly to pulverize the soil during summer and autumn.

Tares are occasionally sown for their seed, like peas, but they do not enter into the usual rotations, and as the generality of soils are light, clover is preferred. In the heavy soils they are mixed with peas and beans for green fodder as we noticed above. A more extensive cultivation and succession of winter tares and spring tares, might afford a useful addition to the food for horses in summer; especially as clover cannot be sown with advantage on the same land oftener than every seven or eight years.

Clover is the glory of Flemish farming, and in no country is it found in greater perfection. It was from Flanders that the cultivation of this productive and useful plant was introduced into Great Britain. Sir Richard Weston, in an account of a journey into the Netherlands in 1645, speaks with admiration of the fields of clover he had seen there, when clover was not known in England as a cultivated crop, and only found amongst natural grasses in rich meadows. The large broad clover, commonly called red clover, (*Trifolium Pratense*), is that which is chiefly cultivated in Flanders. This is sown in spring at the rate of 8 lbs. of seed per acre amongst the barley, oats or flax, or in the rye or wheat which were sown in autumn. When it is sown among flax, which is drawn without injuring the clover, it is cut the same year. With barley it is apt to become too rank and impede the drying of that crop at harvest. In the second year the clover comes to perfection; it is then mown at least twice, but often three times in the season, furnishing a heavy green crop each time. The great use of clover for cattle tempts farmers to repeat the crop too often on the same ground, and the consequence is a failure, not only on account of the soil being deteriorated for this plant by too frequent production of it, but also by encouraging a most destructive parasitical plant called the *Orobanche*, which

in some places in Flanders threatened to put an end to the cultivation of clover. The minute seeds of this plant fix themselves to the roots of the clover and vegetate at their expense. The plant affected becomes weak, and ultimately dies away, and the *Orobanche* spreads so rapidly, that whole fields of clover are soon destroyed, if the progress of it be not arrested in time; the only sure remedy is to keep the land in good tillage, and not to sow clover in it again for at least eight or ten years; if it be sown sooner the *Orobanche* will again make its appearance. This plant is known in England, but its devastations have never been so great as to lead to any public notice of it. It is easily discovered, rising several inches out of the ground, and the stem being of a peculiar scaly lorn.

In the spring of the next year after the clover is sown, it is almost universally dressed with Dutch peat-ashes, at least in the lighter soils. From thirty to fifty bushels are spread on an acre about the end of February: showery weather is favorable to their being washed to the roots of the clover. In strong soils the top-dressing often consists of the compost, which we have described as being collected in the crouppisior, which is rich and well mixed with lime. When weeds appear among the young clover, they are carefully pulled up at the time when the top-dressing is put on; and if the plants seem weak and thin, a sprinkling of diluted tank liquor invigorates the growth.

The greatest part of the clover is given to cattle in a green state, it being then most nutritive; hay is only made of any surplus quantity which could not be consumed in the season. This is usually made about the middle or end of June. In the making of clover hay, there is nothing superior to the methods used in England, excepting that small proprietors sometimes reap it and tie it in bundles, as is done with corn, especially if the seed be ripe; by this means the leaves are less scattered about, and in them is contained the principal nourishment of the plant. In order to have clover seed free from admixture with the seeds of weeds, women and children are sometimes employed to gather the heads of the clover, singly, when ripe; they collect them in baskets and carry them to the barn till they can be thrashed, which is usually done in dry frosty weather; because then the capsules are brittle, and the seed separates more easily from them.

The Waes county is that which chiefly supplies the market with clover seed; and Lokeren is the place where the greatest quantity is sold. Many farmers from other districts prefer buying this seed to saving their own.

The value of an acre of clover is very considerable. The first crop is often sold on the ground for 120 francs, nearly 5*l.* per acre, and the seed from the second crop, which in the Waes county frequently amounts to five or six cwt., may be worth there as much more, making the whole produce amount to 10*l.* with very little outlay. Taking the difference in the value of agricultural produce, this is fully equal to 15*l.* per acre in England, a sum which few crops of clover will realize here, when the expense of making the hay is deducted. When the clover-plant fails, the land is ploughed in autumn, and some other crop is sown; or fresh clover seed is sown in the vacant places, in the following spring, and the bush harrow or the trainee is drawn over to bury it; by this means a good crop is often secured by the end of July.

Spurry,—*Spergula Arvensis*—is a plant which

grows very rapidly in light sandy soils. It is often sown immediately after barley harvest to be cut in time for the sowing of rye. The produce is trifling, but it costs little, and cows are very fond of it. It is said to give their milk and butter a very agreeable flavor. Ten or twelve pounds of seed are sufficient for an acre. A variety much larger and more productive than that which is a mere weed in our light soils is sometimes sown in the end of March, and, with the help of liquid manure, produces a tolerable crop in less than two months; after which a crop of potatoes may still be had, or at least, a very good crop of turnips. This is sometimes a convenient way of bringing a field into a regular course again, when, from some circumstance or other, the usual rotation has been disturbed.

Lucerne, which is so highly prized in some countries, is not cultivated to any great extent in Flanders. The poor light sands are not very favorable to this plant, which likes a rich deep soil. In western Flanders there are some soils well adapted to its growth, but it is not so common as to form any marked feature in Flemish husbandry. Barley is sometimes sown to be mown green in spring; but rye, which is chiefly sown for that purpose in England, is seldom cut green. This arises probably from a reluctance to cut down a plant, which, when it comes to perfection, produces the principal food of the people. That this is no sufficient reason the slightest reflection will convince us; for rye cut in a green state does not exhaust or deteriorate the soil, as it would when left to ripen its seed, and it may therefore be sown again on the same land without waiting the usual time allowed for its recurrence. The question is simply as to the value of the seed sown when compared with that of the green crop.

Buckwheat is sometimes cut for fodder in the light sands, and helps to make up for a deficiency of clover.—*Library of Useful Knowledge.*

NEW ENGLAND FARMER, AND GARDENER'S JOURNAL.

BOSTON, WEDNESDAY, DECEMBER 5, 1838.

AGRICULTURAL SOCIETIES AND PREMIUMS. No. VI.

We have already extended this subject much farther than was our first intention; and we shall throw into as narrow a compass as we are able our few remaining remarks.

The premiums of the Massachusetts Society are proposed with great judgment, and embrace a large variety of subjects. The premiums of the county societies are more restricted in amount and in number of objects. We are not disposed in this place to view these subjects critically. There are few subjects named which we should wish to exclude; but there are some which might be advantageously combined with others; and the amount of the award might be made much more an object of ambition by abolishing many of the smaller premiums of one and two dollars, which are now given in some of the county societies, and bestowing the amount to be distributed in larger sums; or as we have before remarked, in an article of usefulness and permanent value.

We should be glad likewise to see agricultural experiments of any and every description much more a subject of premium than it now is. In the State society the number of these experiments on which a premium is offered is

quite limited. In some of the county societies no premium is offered for these experiments. There can be no objection to pointing out particular experiments to be tried and the modes of conducting them; but at the same time we would have premiums offered upon agricultural experiments generally leaving it open to any competitor, who might be disposed to offer the result of his inquiries and experience. All that should be required to ensure success should be that the subject of the experiment should be an important one, and of a practical and useful character; that it should be conducted in such a manner as to time, continuance, and mode of management that the results should be as far as possible conclusive; and that the whole process should be exactly and fully detailed. It may be said that all this would be necessarily included in the management of a farm. It might be given under this head we know; but it is not necessarily included; and there are many cases in which the history of some particular experiment might be given, when the individual would not think of entering his farm for a premium. No conditions beyond those above alluded to being prescribed, it should be left wholly within the discretion of the board to determine whether the premium should or should not be awarded. There is one little matter, not always attended to, but which we believe has in some cases operated to deter some farmers from entering a claim, which is certainly deserving of consideration. Unsuccessful competitors should, if so they chose, be at liberty to withdraw their statements. Many individuals, from a pride which we may consider foolish or not, who would be very willing to have their success published, are extremely averse to having their ill-success exposed; and the liberty to withdraw their communications might be properly accorded to them, especially since the right of the society to these papers, where nothing is paid for them on the part of the Trustees, must be considered at least as questionable. We mention this as a difficulty, which we have known to operate upon some minds.

We mention another regulation, which we deem reasonable, and the adoption of which would be advantageous. The premiums of the State society are of course open to any of the citizens of the Commonwealth, wherever they may be resident; and successful competitors at any of the county societies are not on that account excluded from the competition in the State society. What we wish is that competitors for the county premiums should be open to any citizens of the State. We would do this as a matter of convenience. Many individuals resident on the borders of the counties would in many cases enter the list in a county adjoining that which they belong, because the place of exhibition might be much more accessible than that of their own county society, which they do not go to because of its remoteness. This often occurs, but it is not necessary to particularize instances. The only point to be fixed is that no individual should become a competitor for the same article or animal at two different county societies; and this might be easily arranged. The objects of the State would be equally well served; and general convenience would be in some cases essentially served.

The subject of manures ought in a particular manner to be made a matter of premium. We are very much in this case in the dark. The application of lime, plaster, ashes, leached and unleached, wood, coal, peat ashes, the application of sea manures, of bog mud, the various forms of application, are all points in which we are very much in want of the clear light of experience. It is difficult to prescribe exactly the conditions under which such experiment shall be made; but the societies might propose a handsome premium to any well conducted and detailed experiment by which some important and practical truth might be elucidated or established.

The subject of feeding cattle is one of great importance to the farmers in this Commonwealth. Premiums for this object are now offered by several of the societies. They might be advantageously extended. It is of little importance to exhibit a noble yoke of cattle or a fat hog at the show, compared with knowing how cattle and swine may be made fat in the shortest time and at the least expense; compared with knowing whether it be more eligible to give them food raw or cooked, mixed or plain, coarse or ground; whether soiling or pasturing cattle on the same land be to be preferred; whether corn or barley or rye or oats or buckwheat be most useful; whether potatoes, carrots, turnips, parsnips, or beets be the best food. We want experiments to show the comparative value of hay or straw, or corn-fodder. We want to know the most economical mode, attested by satisfactory experiments, of keeping our live-stock, our horses, our working oxen. A well conducted experiment or experiments by which these matters should be determined, would be of great value to the agricultural community; and a premium sufficiently large should be offered to compensate for any extraordinary trouble or expense incurred in attempting them.

Among other useful objects of premium we should place well written essays on any subject of husbandry either of a scientific or a practical character. The essays published by the Highland Agricultural Society and induced by the handsome premiums offered by that society are among the most valuable papers anywhere to be found. We shall hereafter give some of these communications to the readers of the New England Farmer. The board of Trustees might either prescribe the subjects or leave the subject to the choice of the individual. Whether the essays be deserving of a premium either for its utility or ability should rest with them to determine. In this way science might be made a direct contributor to agricultural improvement; and increase that debt, already large, under which agriculture is now laid to her.

We have by no means exhausted this subject. We have indeed but partially examined it. We throw out these suggestions for the consideration of those intelligent gentlemen to whom the disposal of the bounty of the State and the donations of private liberality is entrusted. Great good has already been accomplished by these bounties; but we believe that much more might be effected. The trust is a responsible one. Premiums certainly should not be given merely because they are offered. They should not be bestowed through mere favoritism or caprice. The conditions on which they are offered should be absolute as far as they can be made so; and rigidly adhered to. Exceptions are often made in favor of individual cases, which strict right would scarcely justify. This we admit is often done through mere kindness and a willingness to give pleasure, or a reluctance to occasion disappointment. Such cases give occasion for complaints on the part of the captious or dissatisfied, which are not always without reason. The aggregate amount distributed is comparatively large; and we shall deem ourselves happy, if our suggestions will in any measure contribute to render its application more efficient to the excellent purposes for which it is designed. We forbear further remarks for the present; as we never desire to ride a tired horse; but we may resume the subject at some convenient season.

H. C.

MAMMOTH CALF.

We would call the attention of farmers to the great calf Cromwell, now exhibiting in Dock Square, which weighs 700 lbs., and only 7 months old the 29th of November.

He was raised by Mr Albert Reed 2d, of Abington,

and is probably the largest of his age ever seen in the country. As he will remain but a short time in Boston, those who are desirous to give him a look, should call soon.

SALE OF MULBERRY TREES.—A lot of the *Morus Multi-caulis* or many stalked Mulberry, was offered for sale on Tuesday 4th inst. in Boston, at the office of Messrs Cunningham & Co. They were warranted to be genuine and were neatly done up in bundles of fifty trees. The first lots of trees four to five feet in height, untrimmed, sold for one dollar a tree; and other lots some trimmed and others with the lateral branches on, sold from 37 and a half cents to one dollar per tree. The cuttings with two buds on each sold for 1 cent each. The buyers were not numerous nor the bidding very brisk; and it was understood that a considerable portion of the trees remained unsold; the owner not being satisfied to put them up for what they would bring. The trees were of one year's growth and were a fine lot.

BRIGHTON MARKET.—MONDAY, Dec 3, 1838.

Reported for the New England Farmer

At Market 375 Reef Cattle, 75 Stores, 200 Sheep, and 1175 Swine.

Prices.—Beef Cattle.—A small advance was effected and we quote to correspond. First quality, \$7 75 a \$8 00. Second quality, \$7 00 a \$7 50. Third quality, \$5 50 a \$6 50.

Stores.—We noticed only a very few sales except working oxen.

Sheep.—All at market were of a fair quality. A few lots were sold at \$2 25, \$2 50 and \$2 75.

Swine.—Sales were a little better than last week's to peddle were sold at 5 a 6 for sows, and 6 a 7 for barrows. At retail, 6 a 7 1-2.

THERMOMETRICAL.

Reported for the New England Farmer.

Range of the Thermometer at the Garden of the proprietors of the New England Farmer, Brighton, Mass. in a shaded northerly exposure, week ending December 2.

TULIPS, RANUNCULUSES, PINKS AND VIOLAS.

S. WALKER, of Roxbury, offers for sale in beds, or in such quantities as may suit purchasers, from 1 to 2500 bulbs of *Belgian Tulips*. The bulbs were imported from Holland, France, and England, and they vary, additions have and will continue to be made of the newest and choicest varieties. Persons wishing to purchase a bed of superb Tulips, will do well to make a selection for themselves when the bulbs are in bloom, (about the 1st of June.) The prices will conform to the quality of the flowers selected, but in no case will the charges exceed the low of market prices. In the country where the bulbs were raised, and cheaper than the like quality can be imported.

Tulips in beds of from 30 to 100 rows, containing from 10 to 700 bulbs, or by the dozen, 100 or 1000.

Viola grandiflora—Pansy, or Heartscase. Upwards of 2000 superb varieties will be exhibited and offered for sale, when the Tulips are in bloom.

Ranunculus—fine mixtures, at from \$2 to \$5 per 100.

Pinks—fine named varieties, from 25 cents to \$1 each.

For particulars apply to S. WALKER, or to JOSEPH BRECK & CO.

ROHAN POTATOES.

Orders will be received for Rohan Potatoes by JOSEPH BRECK & Co., or communication may be directed to JOHN A. THOMPSON, Catskill, N. Y. who has them for sale. Boston, Nov. 7, 1838.

WHEAT FARMS FOR SALE IN WESTERN NEW YORK.

In the counties of Monroe, Orleans, Genesee and Erie—varying in quantity from 50 to 300 acres each—under a good state of cultivation and improvement, with suitable buildings, fences, &c., watered with durable streams, and most of them have wheat on the ground. Five or eight years credit can be given, if wanted, on the whole principal sum, with annual interest. These farms are situated in the midst of a rich agricultural district, unsurpassed in the richness and productiveness of its soil, lying on the banks of the Erie canal, and in the vicinity of Rochester, Lockport and Buffalo, affording at all times a ready and sure market for all the articles of produce, which at present price apply toward the husbandman, and enables him with a few crops to pay the first cost of his lands. A favorable opportunity is here presented to the enterprising farmer who would wish to obtain a good farm on liberal credit, with sufficient means to secure the payment of one third of the purchase money. Letters (post paid) promptly attended to.

JOHN C. NASH.

Rochester, N. Y., Oct. 18, 1838.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders to any amount, which will be promptly attended to. Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston. Sept. 20. NAHUM WARD.

FRUIT AND ORNAMENTAL TREES

The subscribers will be happy to receive orders for *Fruit and Ornamental Trees, Shrubs, &c.* We shall be enabled to furnish at Nursery Prices, and at short notice, Trees and Shrubs of every description, and hope to give satisfaction to all who may be disposed to favor us with their orders. Oct. 22. JOSEPH BRECK & CO.

FARM FOR SALE.

A Farm situated in the southwesterly part of Townsend on the road leading from Townsend west village to Worcester. Said farm contains 110 acres of land divided into mowing and pasturing, and a large share of wood and timber; a one story house, with two front rooms, kitchen, livery, and two bed rooms well finished; parlor papered; wood house; well, under cover, forty feet barn, and shed, a large sheep house, fifteen by thirty feet, a large cooper shop, and another small house well finished, on the lower floor; a good aqueduct which comes into the barn yard, and a good orchard.

The subscriber will sell a part or all, and give possession this fall or winter, or next spring. Those who wish to buy, will do well to call on the subscriber, who lives on the premises, and look for themselves. ASA H. ADAMS. Nov. 29, 1838.

NOTICE.

A person now in the Nursery business, on a limited scale, who has peculiar advantages for its extension, not possessed by any other individual in this country, wishes to connect himself with some person who can furnish a small capital sufficient to make the business both pleasant and profitable. Inquire at the office of the N. E. Farmer. Nov. 21, 1838.

PEAR, PLUM, GRAPE VINES, &C.

1000 Reef Trees of the most approved kinds; 1000 Plum Trees, of the most approved kinds and extra size—many of them have borne the past season; 500 Quince Trees; 3000 Isabella and Catawba Grape Vines from 6 to 15 feet high, most of them have borne fruit—Black Hamburg, Sweet-water, Paul's seedling; 30,000 Giant Asparagus Roots; 5000 Wilmot's Early Rhubarb or Pie Plant, lately introduced.

Also—a good assortment of Gooseberries, Roses, &c. of different kinds.

All orders left at this office, or with the subscriber at Cambridge-port, will meet with immediate attention.

SAMUEL POND, Cambridge-port, Mass.

Nov. 1.

BULB GLASSES.

A good assortment, consisting of white and blue plain Hyacinth Glasses; white and blue painted do.; plain glass of sizes do.; ground glass, painted and plain, do. of various sizes and patterns.

Crocus Glasses, plain white, for sale at the N. E. Agricultural Warehouse and Seed Store.

Nov. 7.

AGRICULTURE.

BY C. W. EVERETT.

How blest the Farmer's simple life!

How pure the joy it yields!

Far from the world's tempestuous strife,
Free, 'mid the scented fields!When Morning dews, with roseate hue,
O'er the far hills away,
His footsteps brush the silvery dew,
To greet the welcoming day.When Sol's first beam in glory glows,
And blithe the sky lark's song,
Pleased, to his toil the Farmer goes,
With cheerful steps along.While noon broods o'er the sultry sky,
And sunbeams fierce are cast,
Where the cool streamlet wanders by,
He shares his sweet repast.When twilight's gentlest shadows fall
Along the darkening plain,
He lists his faithful watch dog's call,
To warn the listening train.Down the green lane young hurrying feet
Their eager pathway press;
His loved ones come in joy to greet,
And claim their sire's caress.Then, when the evening prayer is said,
And Heaven with praise is blest,
How sweet reclines his weary head
On Slumber's couch of rest!Nor deem that fears his dreams alarm,
Nor cares, with carking din;
Without, his dogs will guard from harm;
And all is peace within.Oh, ye who run in folly's race,
To win a worthless prize!
Learn, from the simple tale we trace,
Where true contentment lies!Ho! monarch! flushed with Glory's pride!
Thou painted, gilded thing!
Hie to the free-born Farmer's side,
And learn to be a king!

ALWAYS BEHIND HAND.

There is a portion of mankind who are always either naturally or habitually behind hand. This trait of their character is easily discovered in everything that relates to their conduct and pursuits in life. Such a man goes too late to bed, and as a necessary consequence gets up too late in the morning. Being out of bed too late he is too late to breakfast, and this deranges his household all the forenoon; having been behind hand at breakfast, he is of course behind hand at dinner, and lastly at supper. If he makes an appointment, he never gets to the place in season; and if he is to meet a board of directors, or a committee, or any other public body whatever, is always twenty min-

utes or half an hour too late, and upon being reminded that he has obliged his associates to wait, and thereby to waste their time, he charges the delay to his watch, which, like its owner, is always invariably at least a quarter of an hour too slow.

If he has made arrangements to leave town in a stage, he commonly forces the carriage to wait some time, or, what is not very uncommon, is left behind. If he intends to make his departure in the steamboat, you will meet him two streets off as the last bell tolls, and after running down to the wharf till he is out of breath, he finds the boat hauled off, and if he gets aboard at all, it is by the long boat, and often at the hazard of his life. If he is an attendant upon public worship, he never reaches the church until after the services commence, and greatly disturbs the congregation by entering in the midst of their devotional exercises.

In short, such men labor, and toil, and drudge on through life, just as uniform and regular in their concerns half an hour too late, as punctual people are in season. If such persons could, by some exertion, redeem that half hour, and set their watches right, they might go on with the same ease they do now, and always be in season.—*Indiana Farmer.*

There is one trait in the character of our American boys which, I think, deserves to be checked; and that is the incessant war they carry on against familiar birds, and the lesser quadrupeds. As soon as a boy can hurl a stone, he becomes a Nimrod, and goes forth as a mighty hunter against the blue-birds, the cat-birds, swallows and robins, that venture into our gardens, orchards, and fields. Not even the little wren that comes with his fair offer of a dozen beautiful songs a day for the rent of some nook or cranny about the house, is safe from the whizzing missile. Not even the little sparrow, that would build beneath the window, is tolerated. Not even the little ground squirrel, that enlivens the woods, is permitted to eat his nut in safety. And when the boy becomes a youth, the same exterminating war is carried on, though with a different weapon. With the fowling piece in his hand, he roams the orchard and the field, slaughtering, without discrimination, jays, wood-peckers, sparrows, blackbirds, bob-o-links, and the rest of the feathered family.—*Fireside Education.*

Appearance Indicative of Character.—The appearance of a farm, its buildings, and the live stock belonging to it, indicate with surprising accuracy the character and standing of its owner; if they look well, well; if bad, bad. A judicious traveller won't miss in summing up his opinion once in fifty times.

Boys, that have been properly reared are men in point of usefulness at sixteen, whilst those that have been brought up in idle habits are nuisances at twenty-one.

Remedy.—The best remedy to prevent a failure of crops, is plenty of manure and good tillage.

A good rich soil retains moisture much longer than that which is exhausted and poor.

The power of Science.—The transmutation of the baser metals into gold and silver, is a small affair compared with changing darkness into light, want into plenty, misery into happiness; yet science can do all this.—*Farmer's Cabinet.*

ANECDOTE.—A gentleman recently stopped at a tavern, and being in a hurry, ordered the ostler to give his horse some oats, "as soon as he had done breathing." He remained as long as he thought necessary, and, on going out, asked the ostler if he had given his horse oats, according to his directions? "Arrah, the devil an oat I've given him," answered Pat—"ye tould me to give them to him when he got done braythin' an' I've watched him every minute, an' faith he's braythin' yet.—*N. H. Spectator.*

THE BITER BIT.—On Sunday morning, a railroad man, called Jem, went into the inn at West Haddon, and, leaving his basket in the kitchen went into the tap to drink a pint of beer. The landlord, being tempted by curiosity opened the basket, in which he found a leveret, and doubting Jem's either being licensed or allowed to shoot, thought he run no risk of being publicly complained of if he rung the changes upon his guest, which he did by abstracting the hare and putting a dead cat in its place. On getting home, Jem found out the fraud, and returning with his basket to the inn he found mine host had gone to church, and being past 11 o'clock, the servant refused to draw him any ale. After much persuasion he induced the girl to leave the kitchen to get him some spring water and in her absence he opened a large pot of the fire, in which was a fine leg of mutton, and very ingeniously exchanged the tabby for it, carrying home the prize. Jem sent his brother there after church time, making him fully acquainted with the facts, and the landlord, wanting some brot ordered a basin out of the pot; not liking cith color or flavor, he caused an examination, and instantly detected the cause and its author on witnessing the cat's mortal remains. "Oh," said Jem's brother, "I dares for to say—that there cat first ate the mutton, and then committed suicide to avoid detection."

FRUIT AND ORNAMENTAL TREES, MULBERRYES &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Pear Apples, Plums, Peaches, Cherries, Quince Gooseberries, Raspberries, Currants, Strawberries, Grapes, &c. The stock of Cherries and Peaches now ready is particularly large. Also, Ornamental Trees, Shrub Roses, Houey-suckles; Pæonies, Dahlias and other Heraceous Flowering Plants.

100,000 MORUS MULBERRIS is now offered for sale; the trees genuine & fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, & varying with the size, and the quantity which may be desired. Also, Broussa and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and orders promptly executed, on application to B. D. BEE Commission Store, No. 132 Water Street, New York, M. PEWELL Seed Store, No. 7 Arch Street, Philadelphia, or the subscriber, Noanumt Hill, Newton, near Boston.

AGRICULTURAL.

FLEMISH HUSBANDRY.

Of the Cultivation of Roots, Potatoes, Turnips, Beets, Carrots, Parsnips, Chicory.

If we are indebted to the Flemish for the introduction of clover and turnips into our agriculture, they are equally so to us for the valuable potato. This root is now become a great substitute for corn throughout all Europe, and its influence on the population cannot be denied; when corn fails potatoes are generally most abundant, and thus prevent that distress, which is so great a check to population. In Flanders potatoes form a part of every rotation, the light soils being peculiarly adapted to the growth of this root; and as a great part of the produce is consumed by cattle, and thus gives an adequate return in manure, the objection often made to its extensive cultivation, that it exhausts the soil and returns little to it, is not well founded. Were it not for potatoes to keep the cattle, during the latter part of the winter and beginning of spring, when the supply of turnips fails, a much smaller number could be kept; for hay is a dear fodder in most parts of Flanders.

Potatoes were at first only known as an esculent root in gardens; and it was a long time before their real value was found out. In 1740 they were for the first time sold in the market of Bruges, in consequence of the zeal of an individual of that town, Mr Verhulst, who distributed some sets gratuitously to the farmers in the neighborhood. From that time the cultivation increased rapidly, and spread all over the country. The varieties which are mostly sold in the towns are the earliest and best flavored, which are chiefly raised in sheltered gardens. The plant being a native of a warmer climate cannot bear the least frost. It is therefore not safe to plant it in the fields before March or April. The sets which are planted to produce an increase, are not seeds but buds, and as such perpetuate the qualities, good or bad, of the parent stock. Each variety proceeds from some original plant raised from seed, and is subject to age and decay with its parent. Hence varieties continually degenerate or wear out, and fresh or new varieties must be produced by sowing the seeds; recent experiments and observations fully bear out the truth of this assertion. It is therefore not sufficient merely to find a superior variety, the age of the parent plant should also be noted. Some will last longer than others, but all old varieties sooner or later show marks of decay; and the sooner they are exchanged for younger and more vigorous the better. In Flanders the principal crop of potatoes is planted in April. Potatoes require much manure to give a great return, although those which grow in poor soils are much pleasanter to the taste. For cattle, however, quantity is of more consequence than flavor. The soil in which potatoes are to be planted should be well prepared by deep and repeated ploughing, or what is still better, by trenching with the spade. In Flanders the sets

are planted in rows two feet wide or more, and the same distance between the sets, so that each plant may have the earth drawn up to the stem, and a small hillock made round it. Sometimes the land is ploughed and manured as for other crops, excepting that the quantity of manure is at least double the quantity usually put on for corn. The sets are then dropped into holes regularly made with a blunt dibble, and filled up with earth. These sets are either small potatoes picked out for that purpose, or larger cut into pieces, taking care that there shall be at least two eyes or buds left in each piece. When potatoes are planted to any considerable extent, the method is similar to that which we described for beans, the furrows being proportionably deeper; the sets are dropped upon the dung in every second or third furrow about eighteen inches apart, and covered by the return of the plough. In this manner nine or ten bushels of potatoes will plant an acre. The crop averages about three hundred bushels, if the land is well prepared, and the potato-plants have been well hood and moulded up. This is not a very great return, considering the quantity of manure. The quality of the potatoes depends on the nature of the soil as well as on the variety planted; in light sands the potatoes are small, and mealy when boiled; in good loams they grow large and more juicy, but are not so well flavored; the latter producing a greater bulk, are preferred for cattle.

There is a potato called *Schelde Windeke* potato, from the name of a village near Alost; they grow in a strong soil and are remarkably mealy and good; but they rapidly degenerate when planted in a different soil. The potatoes which are preferred for cattle are called *Elsen Motten* and *Kaltenbollen*, both very large. A variety was introduced from England into the neighborhood of Ghent some years ago, by a gentleman of the name of Lankman, which are in great repute, and go by his name. It would be difficult to point out the variety from which these sprung, as the soil in which they are transplanted has, no doubt, had a great influence on their present quality. A few small Flemish potatoes, which we once sent to a friend at Kenilworth, produced in that rich soil some of the largest potatoes we ever met with. None of the original potatoes were so large as a hen's egg.

When we were on the subject of manures, we mentioned the pond weeds as highly useful in planting potatoes. Long litter and even old thatch is excellent to plant the sets in, if the soil is not very light. Potatoes are usually taken up in the end of September; this is done by means of a three-pronged fork, which is less apt to cut the roots than the spade. The ground is at the same time cleared of the roots of couch grass, and other perennial weeds; and when the harrows have gone over the field, and all the potatoes are picked up which had escaped the fork, no other preparation is required to sow wheat, or winter barley. When the seed is sown, the stitches are marked out by the plough, the intervals dug out, and the earth is spread over the seed, after the urine cart has deposited half the

usual quantity of liquid manure in these intervals. This is sufficient on land which has had a double manuring for the potatoes.

Turnips are not often cultivated as a main crop, or a substitute for the old fallows, as it is in England and Scotland; but mostly as a second crop after barley or rye, which we call *edlich* turnips in England. But as the barley and rye harvest are early in Flanders, and not an hour is lost in getting the turnip-seed sown, they are often of a very good size before winter.* The crop however can bear no comparison, in point of weight, with a turnip crop in Norfolk, still less in Berwickshire and Northumberland; but it is obtained at a small expense, and does not interfere with any other crop. In a farm of twenty acres, if five acres were set apart every year for turnips, the remainder would scarcely give sufficient occupation to the farmer and his family, and produce sufficient corn to feed them and to pay the rent. It is by the quick succession of crops that a small farm is made to produce much more in proportion than a large one, and that every member of a family is constantly and busily employed. As soon as the corn is cut, the portion of the field which is cleared is ploughed and harrowed, liquid manure is poured over it, and the seed is sown; so that in twentyfour hours an acre, which was but just cleared, is again producing a fresh crop. The ploughing and sowing goes on every day, and follows on the heels of the reapers; of such consequence may be the delay of two or three days, that the seed sown first will be out and in the rough leaf, when that which was two or three days later is only just coming up, and is subject to all the depredations of insects. When the turnips are furly up, they are watered with diluted urine; and their growth is rapid beyond belief. We have seen turnips sown in the middle of July, after barley harvest, which in the end of August already showed very promising bulbs. If it were not for this acceleration of the growth, no crop of any weight could be raised by the end of September, when they are usually pulled up.

The cultivation of the beet-root had been introduced into Flanders under the dominion of Bonaparte, for the manufacture of sugar; it was then a forced cultivation, and was abandoned as soon as peace had restored the usual supply of sugar from the colonies; and although the revival of this manufacture in France, where considerable fortunes have been lately realized by it, has induced several speculative individuals, and also a company with a large subscribed capital to re-establish manufac-

* Mr Van Aelbroeck sowed some turnips in May, 1837, and they were of sufficient size in August to be given to the cows. Large turnips are not thought so sweet as the smaller, which do not give that disagreeable taste to the milk, which prevents many farmers in England from giving them to milk cows. The introduction of early turnips in Flanders might be of great advantage. If winter tares were sown to be cut in May, and turnips to follow immediately, these two crops, with the intermediate ploughing, would prepare the land admirably for wheat or colza, and not only give two useful crops, but have all the meliorating and cleansing effect of a fallow.

ories of beet-root sugar in different parts of Belgium, the Flemish farmers in general are not much disposed to raise the beet-root for sale. They imagine, whether correctly or not, that the land suffers from this crop, when there is no return of manure, as much as it would from potatoes sold off the farm, while the latter are much more profitable; and the carriage of this heavy produce to any distance through roads almost impassable in autumn greatly diminishes the return. The manufacturers of sugar have found, in consequence, that they cannot rely on a regular supply from the farmer, and that they must enter into the cultivation of the beet-root to a large extent on their own account, to keep up a proper supply. The company established near Waterloo have purchased a large tract of land, a great part of which is in woods, which they are cutting down and converting into arable land for this purpose; on this fresh soil, which is by no means rich, the beet-root appears to thrive well. A large sugar manufactory is erected at Bruges, another near Ghent, and a smaller near Dixmude, and various other places, which will require many hundreds of acres for beet-root annually, and thus make this root an important article of cultivation. The mode in which this root is cultivated has nothing peculiar in it. The land is ploughed and well manured; the seed is dibbled, as in the garden, in rows a foot or eighteen inches wide and a foot asunder in the rows; when the plants are up they are weeded and hoed by hand; the seed is put into the ground in the beginning of May, and the roots taken up in September and October. A common crop is from fifteen to twenty tons of roots from an acre of land.

This cultivation has not been adopted for a sufficient number of years to ascertain what rotation is most profitable, where beet-root is the principal object. Those who are sanguine think that alternate crops of beet-root and corn may be kept up by good tillage and manuring. The old farmers are of opinion that there will soon be a great falling-off in the crops. Time will show who are right. In the mean time the cultivation of the white and yellow beet, which contain most saccharine matter, is extending rapidly. A small portion only of these useful roots is raised for the cows. They are not supposed to be so good for the milk as turnips, and they take up the whole season. Should the cultivation be greatly extended, it may have a great effect in causing a variation in the usual rotations of crops, now generally adopted. The advantage to agriculture of the beet-root sugar manufactory, where good land is not over-abundant, is still problematical.

The *Ruta Baga*, or Swedish turnip, which is so highly valued by the British farmer, is not generally cultivated in Flanders. If a few small patches of it are seen, it is only as an experiment made by some rich proprietor. It does not enter into the regular system of cultivation, and is not so well suited to sandy soils as the turnip.

Carrots grow well in light soils, which have been trenched to a good depth, and they consequently form a part of the regular rotations in all light soils; when they are sown as a principal crop, it is generally next after potatoes, buckwheat, or turnips. The land, having been well stirred for these crops, is ploughed before winter, and manured with half the usual quantity of cow dung, or of the sweepings of streets, with which is mixed a third part of pigs' dung, from the notion that the smell of this dung keeps off the moles and field mice,

who otherwise would injure the crop. This is ploughed in six or seven inches deep, and the land is left so all winter. In the beginning of April a very deep ploughing is given, two or three inches deeper than the last; twenty hogsheads of liquid manure are then poured over this, and 2-12 lbs. of carrot seed are sown. The harrows reversed are drawn over the land; the intervals between the stiches, are dug out with the spade, and the earth thrown evenly over the seed. It is then slightly rolled. Some put on no dung, but only liquid manure, on the land intended for carrots. If the preceding crop was potatoes, the ground is already sufficiently manured, and any additional quantity would have a tendency to produce forked carrots, which is the consequence of over manuring; but if they follow buckwheat, which has had no manure, a fresh supply is necessary to ensure a good crop of carrots. The more the manure is decomposed and intimately mixed with the soil, the better for this crop. When the carrots come up, they require to be most carefully weeded; this is the principal expense. It is done by women and children, who go on their hands and knees and pull up every weed. If carrots were sown in drills much of this labor might be spared, by using horse-hoes between the rows, and small hand-hoes between the plants in the rows. Should the carrots fail, turnips or spurry are immediately sown, that no time may be lost. In May the carrots are thinned out where they grow too close, and those which are pulled out are given to the cows; they are left about six inches apart.

There are two sorts of carrots sown in the fields; the one is the large Dutch orange carrot common in England, the other is a white carrot which is very hardy, grows to a great size, and is more productive in light sands than the orange. It has lately been introduced into England; some fine specimens of the root were exhibited at the Smithfield show in December 1836. From a trial on a small scale, we are inclined to think that it will be a valuable addition to our roots for cattle in winter. The white carrot is that which is generally preferred for sowing in another crop, as flax or barley, which is a common practice. In this case the carrot seed is sown a week or two after the principal crop. The flax or corn grows faster than the carrot, which is thus kept down, and only pushes its slender root deep into the ground without making much top, or swelling to any size. In weeding care is taken not to pull out the carrots, which are easily distinguished from weeds. After the flax is pulled, the ground is gone over and weeded again; liquid manure is then spread over, and the carrots soon begin to grow, and the roots to swell. If the main crop was barley, the stubble is carefully pulled up, and the carrots are then treated as before. Thus by the middle of October a good weight of carrots is produced on land, which had already given a profitable crop that season; and a great supply of winter food is obtained for the cattle. Carrots are occasionally sown amongst peas. The peas ripen in July, and are pulled up; and then the carrots are treated as we have been describing. If the row culture were introduced, and the carrots and peas drilled in alternate rows, the success would probably be more complete. This is done in the intervals of the colza or rape with good success. About fifteen small cart-loads of carrots, or about ten or twelve tons per acre, is considered a fair crop. Judging from the produce of about one-eighth of an acre of good sand, in which the white

carrot was sown in England, in March 1836, without manure, the rows a foot apart and well weeded and hoed, the crop would have reached twenty-two tons per acre; the common orange carrot in the same ground did not produce half that weight.

Parsnips are sown in land too heavy for carrots and in a deep rich loam, the produce is very great. They have the advantage of bearing the severest frost, and therefore do not require to be hoisted but may be left in the ground until they are required for use. They are not thought so good for milk cows as carrots, but superior for fattening cattle. The quality of the soil must decide which of the two may be sown to most advantage.

There is another root, the cultivation of which is often very profitable, although of comparative small use on the farm. This is chicory, of which the dried roots are roasted and used instead of coffee. A considerable commerce in this root has sprung up lately, which has caused a duty of 20 per ton to be laid on its importation into Britain. It is the same plant which Arthur Young so strongly recommended for its leaves for cattle and sheep but it has not been found to answer the expectation in this point of view. The roots contain strong bitter, which may be extracted by infusion it is also used in the brewing of beer to save hops. It is wholesome, and if it does not impart an unpleasant taste to the beer, there can be no objection to its use. At all events the cultivation of it whether for beer or coffee, is a part of Flemish agriculture, and deserves to be noticed. The seed is sown in the end of March or beginning of April. It is treated exactly as the carrot, when sown alone. The ground should be mellow and deep, rather heavy than light, and ploughed or trenched to a good depth. It is sown broad-cast in Flanders, and everything else is; but it would be much better if it were sown in rows eighteen inches apart. The leaves may be given to sheep or pigs; but they give a bad taste to the milk of the cows who eat them. The roots are taken up in September, and are then of the size of a small carrot; they are cut into pieces, and dried in a kiln. In that state they are exported. The price varies much, according to produce and demand. It is not an object of general cultivation, but only by particular persons and in particular soils; the market is overstocked at one time, and a great demand exists at another. Such a produce can never enter into a regular course, but may be raised as circumstances may afford a prospect of sale and profit.—*Library of Useful Knowledge.*

MORUS MULTICAULIS SPECULATION.

If our produce in silk is likely to increase in any thing like the increased demand for this species of the mulberry, and its rapid multiplication, we shall be able, in a few years, to clothe our entire female population in silken fabrics, and to export largely in the bargain. But the demand seems to originate from a hope of making money by speculating in the buds, or trees, rather than in the silk which they are to produce. Individuals have for some time been traversing the several states, from Canada to Florida, buying up these trees, and the prices have kept advancing till they have reached an extravagance beyond reason, and almost beyond credibility. The Farmers' Register informs us, that Thomas Hicks, of Virginia, laid out \$345, in 1836 and 1837, for trees of the multicaulis, and that he has recently sold from their product, 20,000 trees,

25 cents each, retaining 10,000 for his own use thus realizing a profit of nearly \$7,500 upon the day. In ten days, the seller might have received \$1000 more for those disposed of. This was in September. In October, the fever of speculation had reached, if not its climax, at least a dangerous height to buyers; for the U. S. Gazette informs us, that at a great auction sale of these trees, at Baltimore, on the 4th inst. 120,000 of them were sold, "at prices varying from 20 to 22 cents per foot, measuring to the utmost extremity, and counting the roots also. This amounts to \$1,210 per acre each tree of five feet high." At a sale at Gerantown the prices exceeded 20 cents per foot. At Burlington, N. J. a sale of 2430 was made by R. Greenmere, for \$2500, and another of 1000 selected trees for \$2000, being two dollars each. This is not a "Robin's alive" business, in which one will get sorely "saddle-lacked," we are greatly mistaken.

There is no tree more rapidly multiplied, probably than the *morus multicaulis*. Every uninjured seed will produce a plant in a summer. The practice is, among proficients in the art of propagating, to take off every branch and the top, or to take up the entire young plants, in the autumn—to bury them in the ground, or put them in a cellar during winter, and to plant them in the spring, either in cuttings of one or two eyes, or by covering the branch or young plant, laid horizontally in a furrow, with an inch or two of earth. Almost every bud will grow from two to four feet the first season, and ultimately become a tree. This will explain to the reader, why select trees, abounding in branches and buds, sold for two dollars at Burlington. They were cheap, if the prices can be kept up another year.

In regard to the culture of this mulberry in our latitude, we have only to repeat the opinion we have often expressed, that the tree will not stand our winters, except, perhaps, upon a poor dry soil, when the growth ceases, and the wood hardens, before the occurrence of severe frosts. Indeed this is now virtually conceded by the growers; for we believe it is the general practice to secure seedlings in the cellar, or to bury them in the ground, and to cut down the trees, cover the stumps, and secure the tops and branches for propagation. Cutting down at autumn is recommended as the best mode of increasing the foliage, and as facilitating the gathering of the leaves—as many sprouts spring from the stump in the spring, and the leaves of which may be gathered without climbing.

That the silk business will ultimately prosper among us, we have no doubt; but that the *multicaulis* is to supersede all other species of the mulberry, or that it possesses very remarkable properties not common to the family, we must be permitted to entertain doubts. Gen. Tallmadge, who visited the silk establishments of Italy, and was minute in his inquiries, tells us that the European black mulberry had a preference there. In France the white mulberry, it is alleged, produces the best silk. We have seen beautiful fabrics from our native red species. While those who have seen, at Constantinople, the silks produced from the *Brussa*, affirm that they exceed all others for lustre and value. Men are prone to recommend that which they wish to sell. In our mind, it matters little what species of mulberry we cultivate, provided it is hardy enough for the climate. If any kind is

well managed by household industry, they will in our opinion, become a certain source of profit to the owner.—*Cultivator*.

EXPERIMENT IN HARVESTING CORN.

In our last November No. we gave the result of an experiment in harvesting corn, going to show, that it is better to cut it up than to top it. We now give the result of another experiment of the same kind.

In the first week of September, we went with two neighbors into our corn-field where our men were cutting up corn, and caused 36 hills to be cut up, where we found them at work, which was of the fair average quality of the field, and stooked separately; adjoining which 36 hills were topped, in the usual way; and a third parcel of 36 hills, immediately adjoining the last, was left to ripen upon the entire stock. On the 23d September we proceeded to pick, husk and weigh the corn on the several parcels. The result was as follows:

No. 1, cut up, had 126 ears, which weighed 56 1-2 lbs.
No. 2, topped, " 127 " " 52 lbs. 2 oz.
No. 3, standing, 125 " " 52 lbs. 10 oz.

We found on trial, the same evening; that it required 78 lbs. of ears to give a bushel of shelled corn. The field was planted at exactly three feet between the rows, and at about two feet four inches in the rows; but assuming that the distance was three by two and a half feet, it would give to the acre 5,808 hills—and there probably was not 20 hills deficient in five acres. Upon these data the product on an acre, under the different modes of harvesting, would be as follows, omitting fractions:

No. 1 would give 9,274 lbs. or 119 bushels.
No. 2 " 8,409 1-2 " 108 "
No. 3 " 8,490 " 109 "

Although the parcels selected were supposed to be similar, it was perceived, after the corn was gathered, that an apple tree, giving a shade 6 or 7 feet broad, stood in No. 3—the whole field being a young orchard—which undoubtedly had an influence in lessening the product of that parcel—as it might reasonably have been expected to have exceeded that of No. 1.

In regard to the condition of the grain, of the different parcels, that of No. 1, which had been cut up and stooked, was unquestionably best; it was dry, sound and bright; while much of Nos. 2 and 3, which had been topped, or left standing entire, had fallen upon the ground, was wet or mouldy, and some of it had actually grown. The difference in the fodder was still more palpably in favor of No. 1—it evidently exceeding in value either of the other parcels more than one half.

Our neighbors, C. N. Bement and Sidney Chapin, were present, and assisted, in the cutting up, topping, picking, husking, weighing, and examining, the several parcels, and have authorized us to say that they fully concur in the preceding statement.

In our experiment of last year, the loss in topping, over cutting up, was found to be about six bushels; in the above detailed experiment, it appears to be eleven bushels on the acre. It will also be observed, on referring to our former experiment, that the number of ears, and the product, is less this than it was last year. This has been caused by the drought. None of the succors pro-

duced ears this year, though many produced them last year.

This experiment confirms us in the opinion we have long entertained, that there is a prodigious waste, both in corn and forage, and we insist in labor also, in the still common practice of topping corn. And we again beg, that those who remain incredulous in the matter, will make the experiment, as we have repeatedly done, and satisfy themselves. Say there are 300,000 acres of corn cultivated in this state, and that the loss by topping is only five bushels to the acre, the aggregate loss would amount to 1,500,000 bushels, equal at least in value to one million of dollars annually, to say nothing of the loss in labor and forage.

The cause of the topped corn having produced less than that which was cut up, although often stated, is here repeated: the topped corn was deprived of its elaborating organs—its lungs—the leaves above the grain, and of course received no further accession of growth, or but very little; while the corn cut up retained these organs, which continued to send down nourishment to the grain for some days through its green succulent stocks. Any farmer may satisfy himself readily that leaves are indispensable to growth, by a simple and easy experiment:—let him pluck all the leaves from a fruit-bearing branch of the apple, plum, or other fruit tree, at any stage of growth of the fruit—and he will find that the fruit on such limb will neither grow nor mature its flavor where there are no leaves—though it may change its color.—*Cultivator*.

Massachusetts Horticultural Society.

EXHIBITION OF FRUITS.

Saturday, Dec. 1, 1838.

From S. Walker, Roxbury, Nonpareil Apples and Chaumontelle pears.

From B. V. French, Braintree, Wilkinson pears. From James Eustis, South Reading, Trunnell, Spice and Ben apples; the latter a handsome and fine flavored fruit of medium size, and the annexed letter accompanied the specimens.

For the Committee, E. M. RICHARDS.

TO THE COMMITTEE ON FRUITS,—

Gentlemen—By request I send you further specimens of the Ben apple. The original tree was standing till within a few years past on land belonging to the late Doct. Hart of this place. Said land formerly belonging to a Benjamin Smith, therefore called the Ben apple, it is supposed to be a native. It can be traced back for a great number of years, and probably was never grafted, as a person has now a tree growing which bears the same fruit, which he pulled from the roots of the old tree when a sucker. Yours, &c.

JAMES EUSTIS.

S. Reading, Dec. 1, 1838.

Saturday, Dec. 8, 1838.

Yellow Winter Pears, from W. S. Packard, Dorchester. Dix Pears, from Mr Wm. O. Gordon, Dorchester. Baldwin Apples, from Chever Newhall, do. Danvers Winter Sweet, Hooper Apple, a fine Red and Pomme Sons Pippin, of Beuman's catalogue, from Robert Manning, Salem. Mr Manning also exhibited fine specimens of the Winter Orange, Glout Moreau Burgomaster, (of Boston) and Princes St Permain Pears. For the committee,

BENJ. V. FRENCH,

BEES.

Among all the different classes of winged insects, the most beneficial to man, and one of the most wonderful, are bees. Bees are common in most countries; but although naturalists have for ages considered them an important subject of inquiry, their history as yet is but imperfectly known. In some countries, bees are an object of great attention, and their honey and wax are considerable articles of commerce.

In every hive, bees are of three kinds; viz:—1st, the working bees, or males; 2d, males, or drones, which are less numerous, and 3d, the female bee, which is called the mother, or queen. The workers are the smallest, the males the largest, and the females are of the middle size.

The males are nearly double the size of the workers, but want stings. The females, or the queens have a sting, and are longer than the males, or the workers; in other respects they are exactly like them.

Bees usually collect together in hives. A hive generally contains from 15 to 20 thousand; in others from 30 to 60 thousand. In all these there is but one queen mother, or female; and the number of males does not exceed two or three hundred; the remainder is composed of working bees, which labor for the others, to support them. Neither the males nor females go abroad in quest of wax or honey. All the working bees are furnished with a trunk for their labors, and a sting for their defence.

These little animals, whom we behold so sociable in their community, are ever industrious to assist each other, and prevent their mutual necessities with surprising generosity; and shall we leave our fellow-creatures in distress? On the contrary, we are convinced that the finest of all pleasures consist in preserving persons from calamity, and it is a pleasure capable of increasing in proportion to our abilities to give.

The bees when they begin to form the different cells in the hive, commence at the top, where they lay a bed of glue, to which they fix the first cells of the comb, which they continue downwards, till they have no room left. The comb they divide into three cantons; one where they rear their young, another where they store their wax for future occasions, and the third where they preserve their honey for the winter. The wax is a provision altogether as necessary for the bees, in one sense, as the honey, for it is with the wax they build their apartments, and also where they treasure up their honey.

A bee is first an egg; this egg, which in time becomes a bee, is exceedingly white. The eggs of bees are cast into the empty cells, not carelessly into any cells, but only the middle cells, which always are appointed for the breeding cells, whilst those all around are reserved for the honey.—*Bellevue Falls Gazette.*

WAR AMONG THE SNAKES.

[Transcribed from a *New York paper*, of October 12th, 1835.]

Travelling through one of the southern States, my attention was attracted by a singular rustling in the thickets which bordered on the road. I stopped my horse to learn the cause; and soon discovered, at a few paces from the track, a rattle-snake of rather more than ordinary size, in a coil such as these reptiles always throw themselves into

on the approach or attack of an enemy, exhibiting every symptom of extreme rage, and displaying all those beauties for which its species are so remarkable when under the influence of passion. No cause for its disorder was at first visible; but in a short time a black snake darted from the surrounding bushes across the folds of his antagonist, and disappeared on the other side. The rattle-snake did not fail to strike at its darting assailant; but with what success the rapidity of their motion prevented me from determining. The rattle-snake remained in his coil, prepared for another assault, which was accordingly offered by his black foe returning, and again gliding over him with almost inconceivable rapidity, while the same attempt as formerly was made to punish the aggression. These movements were several times repeated with no apparent advantage to either party. The black snake seemed once or twice struck with the fangs of his enemy and yet returned with undiminished celerity to his subtle assault.

The density of the wood did not permit me to follow with my eyes his retreat; and however great my curiosity to ascertain how he employed the time of his absence, I could not prevail upon myself to indulge it by entering on so fatal a battle ground. At length the rattle-snake in one of his attempts to revenge the insolence of his assailant, struck his fangs deep into his own body; he extricated them, stretched himself with every appearance of agony on the ground; and turning on his back, in a short time expired. The crafty victor once more appeared, and seizing the lifeless body in his mouth, dragged it from the scene of action.

BOHAN UPAS OF THE WEST.

The Milk Sickness.—The mysterious disease which bears this name, is peculiar to the region west of the mountains, and prevails only in certain districts of that region. Many parts of Kentucky, Indiana, Illinois and Missouri have been greatly afflicted by it, hundreds have died its victims, and some districts of country are almost uninhabitable on its account. The Kentucky Legislature has long since offered a reward to any one who could ascertain the cause of this terrible disease, but all inquiries upon the subject have been hitherto unsuccessful. The *St Louis Bulletin*, however, contains a letter on the subject, said to be from the pen of an intelligent gentleman, in which the cause of the disease is referred to a tree, the properties of which are described to be very similar to those attributed to the Bohan Upas of the East Indies. The letter, which will be found interesting, is subjoined:

FEMME OSAGE TOWNSHIP,
St Charles Co. Mo. Nov. 9, 1838.

MR KOCH,—

Dear Sir—I herewith transmit to you one of the genuine apples of Sodom. It grew on a large Sodomite tree in Femme Osage bottom, in St Charles county. The tree is nine feet thick, one hundred and forty feet high, and straight in the body, there being no limbs for forty-six feet above the ground. In a fruitful year it is estimated that it bears one thousand bushels of fruit. The leaves resemble those of a pear tree, but are much larger and evergreen; the blossoms are similar to the tulip, and when in full bloom, it is considered the most grand, beautiful and imposing object in the vegetable kingdom. But it is of the most poisonous nature; its roots, bark, sap, leaves and fruit,

are all destructive poisons. Its twigs and branches operate as a slow, malignant and incurable poison of a peculiar quality, destructive of animals and man. It has been recently discovered, and satisfactorily tested, that the browsing upon the sprout about its root, is the cause of that mysterious disease, called the milk sickness.

The fruit, when fully ripe, has an inviting appearance, but it soon takes a dry rot, and the inside becomes a poisonous and disagreeable dust, in appearance resembling Scotch Snuff. Notwithstanding its noxious qualities, cattle and various other animals are fond of frequenting it and feeding on its leaves, and they frequently die in its vicinity. Numerous skeletons of animals may be found in the bottom, within a mile round, but when taken in small quantities, it terminates in lingering and uncontrollable milk sickness. Since the tree has been fenced in, no milk sickness has existed. The wood of the tree is as solid and heavy as lignum-vitæ or ebony, and from its similarity, some intelligent persons have conjectured that it is the celebrated tree called the Bohan Upas in the East Indies. When any part of the green tree is lacerated, a peculiar gum exudes from the wound like white native turpentine, which is esteemed one of the strongest poisons, and will blister and seriously injure and ulcerate the human body if applied externally.

It is thought by some persons that this tree might be advantageously used in the practice of medicine if its powerful medical qualities were properly understood, but its poison is so destructive that every person here is afraid to make any experiment with it. If the citizens of those parts of Illinois, Ohio and Kentucky, that are afflicted with the milk sickness, will make proper examination, I have no doubt that they will find somewhere in the sick district a solitary tree similar to the one I have described above, and if they will destroy or enclose the tree they will effectually prevent the disease. Many marvellous stories are told in the neighborhood, but respecting many of them I am very incredulous, but the foregoing statement I have prepared from personal observation, and from information in which I could place implicit confidence.

(From the *Bellevue Falls Gazette.*)

THE INCLINATION OF THE WHEAT-EAR.

How admirable are the expedients of Providence, exclaimed I, as I observed in the bending down of the full-grown wheat ear the accomplishment of an important purpose; namely, that of shedding off the rain, which otherwise must settle into the cells of the ear and do material injury to the ripening grain. While the ear is green and growing, moisture does it no harm; but when it comes to consolidate and ripen, moisture would be extremely injurious, if not ruinous.

The inclining wheat ear is often alluded to as denoting the modesty and humility of real worth. If we consider the reason why providence in its wise arrangements provided for its inclination, I fancy we shall find in it an illustration of prudence in taking measures to preserve our resources, mental, moral, or material, from being frittered and wasted away by adverse causes or by influences that do not belong to our present means of improvement and maturity; and whose impact on us we should therefore be seasonably prepared for easing off.

B. F.

MULBERRY TREES AND THE SILK BUSINESS.

Extract from a Letter from Mr. Chauncey Stone of Burlington, N. J.

In replying to your questions it will be necessary for me briefly to recapitulate them. Question

1. Have you been long engaged in cultivating the mulberry?
2. What species of morus do you deem preferable, and what kind of soil suits it best?
3. What is the best mode of propagating, planting, and managing it?
4. What is the value, expense and profit on an acre of mulberry trees for the first five years inclusive?
5. What kind of worm do you consider the most valuable?
6. What help does it require to raise 100 pounds of silk?

First.—I am one of the number who first commenced the silk business in this vicinity, and have devoted the two last years with close application practically to the culture of the *morus multicaulis* and rearing the silk worm.

Second.—I have taken much interest during the last few years in comparing the relative qualities of the different mulberries; and at present I know of none better than the *morus multicaulis* for this and the more southern latitudes for the silk business. The Alpine, the Canton, and the Brusa, are excellent species, and may be well adapted to the more northern latitudes. Most of the different species I have seen, which are fourteen or fifteen varieties, require four or five years' growth before having much foliage to part with; but the *multicaulis* will yield a large quantity the first year's growth without injury to the tree, and is eaten with great avidity by the silk worm. The mulberry that is most productive of fruit is less productive of foliage. The *multicaulis* produces very little fruit, and is not often grown from the seed. It will flourish on all soils where the peach does.

To select a location on which to plant a field for the silk business, I would prefer undulating grounds, having a deep mellow loam, and mixed with sand and gravel sufficient to prevent the soil from baking or crusting.

Third.—After having the ground made mellow, lay out the field in rows about four feet apart, and the surest mode, by taking one season with another, is to lay the tree down full length and cover deep enough to keep moist. The time for planting in this latitude, I think, will be during the first and second weeks in April, in common seasons. By planting a field of mulberries in this mode they must be taken up in the autumn, as they will stand too near each other to remain in the ground. But to plant a field of mulberries not to be taken up in the fall, my own views are to lay out the rows about five feet apart, and in the autumn take up every other tree in the rows, leaving them standing four feet apart; the remainder to have the tops cut off near the ground in the fall. In the following spring, many shoots from each stump will start up with vigor, and produce an abundance of foliage, and easy to be gathered. And where the field is large, I think every fifth row may be omitted and not planted, but used as a passage for a cart or wagon in which to transport the foliage to cocoonery. Our experiments made this season have proved the feasibility, that mulberry treated in the above manner will fulfil the most sanguine anticipations.

Fourth.—To answer this question it will require some philosophical speculations, as the feeding of silk worms from an acre of *multicaulis* of four or five years' growth, has not been done by me, or under my observation. At the rate of fifty pounds of reeled silk to the acre has been produced from the first year's growth of trees. But from an acre to be planted in the manner I have described, 30 pounds the first year will be a fair production, and by leaving the roots in the ground and pruning the tops in the autumn, I deem it not extravagant to estimate one hundred pounds reeled silk yearly on an average, the four succeeding years after the first year's growth of trees.

After the cocooneries and fixtures for feeding are prepared, we can feed the silk worms and reel the silk at an expense not over two dollars and fifty cents per pound, and it is then worth from four dollar and fifty cents to six dollars a pound to the manufacturer.

Fifth.—At present I know of none I prefer to the white mammoth worm, so called, but we have a kind that spins a large yellow cocoon, and is a very good kind. The silk of the white is worth most. We have a kind called the two crop kind, that can be reproduced the same year, but they spin a small cocoon.

Sixth.—It requires a person having experience to take charge of the feeding, who can manage during the first week alone after the worms hatch, and the second week a boy or girl will be wanted to pick leaves, and after that another person, equal to a full hand, will be all that will be required to finish the crop, which will be about three hundred thousand in number.

By this calculation I expect the cocoonery to be convenient to the mulberry field. It requires two hands to change the worms dexterously, but they can attend to that in the morning when the dew will be upon the leaves, and to gathering the foliage after the dew shall disappear. A stock of leaves will always be wanted before hand, lest there should be rainy weather, when they cannot gather them.

Those who raise silk and wishing to sell it in its raw state, had better reel it into skeins, and is then in a merchantable condition.

I have answered your interrogatories in a manner that appears most feasible to my views, but I do not pretend to lay down any particular modes or systems as applicable to all future generations.

SILK, MULBERRY TREES AND SO FORTH.

The Worcester *Ægis* and some other papers, have attempted to draw deductions from the present high price of mulberry trees, which will operate to the injury of the silk business. They argue that these exorbitant prices cannot be sustained another season, but when they fall, then will come the exploded *humbug*. These individuals are wholly mistaken. No man, in his sober senses believes, that when the tree have multiplied, the value they now command will be sustained; but we contend that the scarcity of trees keeps up present prices. Doubtless the trees another season will be multiplied greatly, and of course sell lower. Yet, if a man buys one stalk this year for 50 or 75 cents, which has twenty or thirty buds, and which another season will yield as many trees, if the price is at sixpence a tree next fall, will he not have a productive crop? The purpose is to grow silk,

first by filling the country with trees. It is only until that is accomplished that raw silk can be cultivated to advantage. The present prices of trees are so extravagant that nobody can be induced to use them to raise silk,—they are worth so much more to sell or to cut up into slips for the purpose of multiplying plants another season. A little forecast would teach these persons that silk is to be grown, and that it cannot be so long as the trees are so expensive. The purpose, therefore, is to reduce their price another season, by filling the country with this species of merchandize.

Another thing must be corrected and set right. It is stated in some papers, on the authority of Mr Pleasants of Virginia, that the silk companies at the north have ceased to exist, *except in name*. The *Ægis* alludes, with some emphasis, to the importance of disseminating correct knowledge on this subject, and then remarks, the incorporated company in Northampton, without producing a pound of silk, is abandoned and its "lands are offered for sale"! The admonition administered to other people applies with peculiar force to such statements as these, which are not merely disheartening, but *false*. Experience has taught, that the true way to grow silk to advantage, is on farms connected with other agricultural operations. The incorporated Company in this town purchased two or three hundred acres of land, much of which was set over with young mulberry trees. The trees had not reached a size sufficient to feed worms, before the price became enhanced and the sale of them yielded more profit than the growth of the raw silk. The Silk Company here not only exists in name, but in substance, having three hundred acres of land, 100,000 mulberry trees, and a superb brick factory four stories high and nearly one hundred feet long, which is already partially filled with machinery in operation. It will be completed in the spring, and the business of manufacturing sewing silk carried on with vigor. One of the hindrances at the present time arises from being compelled to import the raw material; for, with all the extravagant bounties offered by different legislatures, very little of the domestic article is yet sent to market. When the country is filled with trees and the price of them falls, then raw silk will be produced at a great profit. The incorporated company in this town, we are happy to inform our Worcester friends, still exists, and will show itself another season.—*Northampton Courier*.

Seven bushels of good sized potatoes were dug in Claremont, N. H. on the 1st ult., the product of a *single potato*, of the "lady finger kind," which was planted on the 15th of May last. This potato had 72 eyes and was cut into as many pieces. One of these was planted in a hill, and on the eighth day after planting, the sprouts (when there were more than two shoots springing from one eye) were separated and transplanted. In this way 110 hills were made. The vines measured one mile in length, and the weight of the crop was 515 lbs.

Said a purchaser to a horse dealer, "is that animal sure footed?" "Perfectly," said the Jockey, "when he puts his foot down, you'd think he never was going to take it up."

The number of police constables on duty on the day of the Coronation in London was 2,900.

**NEW ENGLAND FARMER,
AND GARDENER'S JOURNAL.**

BOSTON, WEDNESDAY, DECEMBER 12, 1838.

**MASSACHUSETTS AGRICULTURAL SOCIETY.
EXHIBITION OF BUTTER AND CHEESE.**

We are happy to lay before our readers the Report of the Committee of the Massachusetts Agricultural Society on Butter and Cheese offered for premium on the 11th inst, at Quincy Hall, Boston. The premiums were most liberal—on Butter one of a \$100—one of 50; one of 30. On Cheese one of \$50—one of 30.

The prices at which the several jars of butter which obtained the first premium were sold were as follows,—47 cts., 41, 43, 42, 41.

The prices of the butter of the 2d premium were as follows,—41 cts., 38, 36, 35.

The prices of the third premium butter were 37 cts., 33 1-2.

Other lots of butter of a fine quality were sold at very good prices. Several firkins of butter containing more than 100 lbs. each, from Horace Clapp of Honeville, New York, were of a fine quality. Some tubs, however, belonging to the same lot were injured, owing to some imperfection in the manner of putting up. We have no authority for the assertion but our own judgment, but had it not been for this circumstance we can hardly doubt that this lot of butter would have obtained the first premium.

REPORT.

The Committee of the Trustees of the Massachusetts Society for Promoting Agriculture appointed to award the premiums of the society for butter and cheese, exhibited at Quincy Hall, December 4, 1838, Report—that

The whole amount of entries for butter was	13
for cheese, old 2	11
“ new 9	11
	24

This number is smaller than usual at these exhibitions, although perhaps in point of quality the best butter and cheese on this occasion were fully equal to that of former exhibitions.

Of the butter, one lot (entry No. 7) was disposed of by the owner before the hour fixed for examination, and did not therefore become a subject of trial.

Of the remaining lots the committee found

- 8 of good quality.
- 2 partly good and part of fair or middling quality.
- 1 part good and part ordinary or inferior.
- 1 ordinary.

12

To lot No. 2, offered by Luther Chamberlain of Westborough, Massachusetts, consisting of 12 stone pots, the committee had no hesitation in awarding the first premium of One Hundred Dollars.

To lot No. 9, offered by L. B. Hapgood of Shrewsbury, Mass. consisting of 10 stone pots. The committee were unanimous in awarding the second premium of Fifty Dollars.

To lot No. 1, offered by William Bachop, of Barnet, in Vermont, consisting of 7 tubs. The committee, after some deliberation, awarded the third premium of Thirty Dollars.

To lot No. 3, consisting of 8 tubs offered by Nathan Cushing of Woodstock, Vermont; a part was so nearly equal to the last, that the committee hesitated in awarding the 3d premium until they ascertained that the quality of Mr Bachop's was more uniform.

As to the origin of the various lots entered, there were

7	lots from Vermont,
4	“ “ Massachusetts,
1	“ “ N. Hampshire,
1	“ “ N. York.
13	

Of the cheese, consisting of eleven lots the committee pronounced 8 lots to be of good quality, 3 lots of fair quality.

11

To lot No. 1 of the old cheese, consisting of 11 cheeses, from the dairy of David Lee of Barre, Massachusetts, the committee, (after careful comparison with a very good lot offered by Daniel Hunter of N. Braintree, Mass.) awarded the premium of Fifty Dollars.

To lot No. 4. of the new cheese, consisting of 10 cheeses, offered by Timothy Fisher of Burke, Vermont, they awarded the premium of Thirty Dollars.

The origin of the various lots of cheese was as follows, viz:

8	from Massachusetts,
1	from New Hampshire,
1	from Connecticut,
1	from Vermont.

11

The committee acknowledge with thanks the assistance in performing their duty of Messrs Edmund T. Hastings of Boston, and I. Hurd of Charlestown, also of Messrs. I. P. Davis, G. T. Winthrop, and N. A. Thompson of Boston,—and they would not omit to mention the very prompt liberality with which the use of the central hall over the Quincy market was placed at their disposal by Mr H. R. Kendall.

It is matter of much regret and surprise that the competition for the premiums offered by our Society is so very limited in the number of claimants. Unusual pains have been taken to apprise the public. Many more than the usual number of the Society's premium lists have been printed and distributed, advertisements have been repeatedly inserted in the N. E. Farmer and in several newspapers; and the premiums are confessedly of the most liberal amount.

The public sale of the butter and cheese exhibited, which took place on the 5th, by the high prices given, also amply testifies the disposition of the public to aid the society in encouraging and rewarding excellence in the dairies of N. England.

The documents herewith are the statements accompanying the several claims and a list of the entries with the remarks of the committee upon them.

For the Committee,

JOSIAH QUINCY, Jr.

Boston, Dec. 8, 1838.

MULBERRY FEVER.

This new disease has become quite epidemic and continues to rage violently. We cannot for our lives divine any especial reason, why it should have burst out all at once among us and so widely extend itself, excepting that all the diseases of this character, (we mean those brought on by speculation and avarice,) are highly contagious. We trust it would not be deemed disrespectful to the faculty, if we suggested that possibly the mulberry doctors have themselves had some hand in creating and aggravating the disorder with a view to their "****". It is not for us to give any words of caution. We have not the care of the public health; but we think it advisable for those, who desire to keep well to keep out of the way of contagion. The disorder has in some parts of the country risen to a state of raving madness, and men like

insects round a fire in the woods of a dark night, are seen dashing into the flames. We have no doubt that the silk business is to be one of the great interests of the country, and one of the most productive and profitable of agricultural employments, but the mulberry tree business and the raising of silk are not precisely the same. One would think, however, from present movements, that everything is to be accomplished the next year;—that the end of the world is to come then; and that the "wedding garment" is to be made of silk of man's own raising. When from a single multicaulis tree perhaps a thousand or more buds or cuttings can be taken in a single season, each of which will in one season, with good luck and good care, form a handsome tree, certainly there need be no difficulty apprehended in the propagation of the plant. When a hundred and sixty or two hundred or four hundred dollars are demanded for a pound of mulberry seed not at all sure to come up, which can be imported for a twentieth part of that sum with equal confidence of success, we cannot help asking ourselves, where does the money come from or where has the shrewdness of our merchants and sea-captains gone to? When half a dollar a piece is asked and paid for trees which were grown this season from seed sown last spring and represented to be of equal or super-ior value for feeding worms with any trees grown, and especially because it is stated that they will "stand our climate," we are really very curious to know what is to be the price next year of cabbage plants; and whether we cannot afford to raise them upon a considerable scale at somewhere about forty-nine cents a plant. When silk-worm eggs, which were formerly thought high at eight cents per thousand are now sold for twenty-five cents per hundred, and fifty cents per hundred are even contemplated, we are strongly inclined to believe, and we encourage those who are too anxious to begin at once to wait patiently, that our Connecticut wooden-nutmeg gentlemen before spring will have an ample supply to meet any demand, dropped on the best hot-pressed letter paper and made out of the purest yellow bees-wax. But the flame is kindled and the furnace glows with a white heat. Let those, whose wings are not made of asbestos, try the intensity of the flames if so they choose. H. C.

In Pennsylvania the Legislature has been interrupted in its organization and driven from its Hall by a mob, threatening violence and death to its members. The origin of the difficulty is wholly of a party character and arises out of a contest for seats by individuals whose election is disputed. The Governor has ordered out the militia to restore order and maintain the supremacy of the law. It is a most serious emergency; and the clouds hang heavily over that magnificent republic. It is hoped that the glitter of the lance will be sufficient to subdue the inflammation without the necessity of depletion; but we wait with extreme anxiety the course of events. Civil war, especially where parties are nearly equally divided, is the most dreadful of all public calamities. It is a game at which two parties play, and success itself is always fearfully expensive. H. C.

At the annual meeting of the Rhode Island Society for the Encouragement of Domestic Industry held at the society's hall in Pawtucket on the 17th day of October, A. D. 1838, the following officers were chosen for the year ensuing, viz:

President—James Rhodes.

Vice President—John Jencks 1st, Stephen T. Northam 2d, Nathan F. Dixon 2d.

Treasurer—William Rhodes

Secretary—William W. Hoppin.

Standing Committee—Dutec Arnold, Christoph

Rhodes, Albert C. Greene, Nathan Bowen, George Irish, Wilbur Kelly, S. H. Smith, Wm E. Richmond, Moses B. Ives, Bates Harris, John Foster, Stephen Waterman, (of Coventry,) Thomas Holden, Sim A Rhodes, Joel Aldrich, John Pitman, Jeremiah Whipple, Wm Anthony, Stephen B. Cornell, Lewis Dexter, John Brown Francis, Charles Collins, Nicholas S. Fry, Elisha Olney, Jr., Geo. Burton, Tully Dorrance, R. W. Greene, Nathaniel Mowry, 2d, Joseph Mauran, Christopher Smith.

NOTICE.

A meeting of the Standing Committee of the above named society will be held at the office of the Secretary, in Mallet's Building, on Wednesday the 26th inst. at 2 o'clock, P. M. W. W. HOPPIN, Secretary.

We hereby acknowledge the receipt of One Hundred and Fifty Dollars, from the Rhode Island Society for the Encouragement of Domestic Industry, to pay in advance for the New England Farmer, to be distributed among the members of this society.

AGRICULTURAL EXHIBITION.—At the exhibition of dairy produce on Wednesday last there was likewise an exhibition of improved agricultural machinery; of which we shall give a notice in the next Farmer.

BRIGHTON MARKET.—Monday, Dec. 10, 1853. Reported for the New England Farmer.

At Market 425 Beef Cattle, 1400 Sheep, and 340 Swine.

Prices.—First Cattle.—We quote to correspond with last week. First quality, \$7 75 a \$8 00. Second quality, \$7 00 a \$7 75. Third quality, \$5 50 a \$6 50.

Sheep.—Lots were taken at \$2 25, \$2 50, \$2 75, 3 00 and 3 50.

Swine.—An advance was effected. Lots to peddle were sold at 6 for sows, and 7 for barrows. At retail, 7 for sows and 8 for barrows.

TULIPS, RANUNCULUSES, PINKS AND VIOLAS.

S. WALKER, of Roxbury, offers for sale in beds, or in such quantities as may suit purchasers, from 1 to 2500 bulbs of choice Tulips. The bulbs were imported from Holland, France and England, to which yearly additions have and will continue to be made of the newest and choicest varieties. Persons wishing to purchase a bed of superb Tulips, will do well to make a selection for themselves when the bulbs are in bloom, (about the 1st of June.) The prices will conform to the quality of the flowers selected, but in no case will the charge exceed the lowest market prices, in the country where the bulbs were raised, and cheaper than the like quality can be imported.

Tulips in beds of from 30 to 100 rows, containing from 210 to 700 bulbs, or by the dozen, 100 or 1000.

Viola grandiflora—Paris, or Heartsease. Upwards of 2000 superb varieties will be exhibited and offered for sale, when the Tulips are in bloom.

Ranunculus—Best mixtures, at from \$2 to \$5 per 100.

Pinks—fine named varieties, from 23 cents to \$1 each.

For particulars apply to S. WALKER, or to JOSEPH BRECK & CO.

FOR SALE.

A pair of large size dark red oxen, very handsome and well made, and quick, valuable to any person who has considerable work. Also, a large size cow, white spotted, with short horns. Apply to A. J. ALLEN, Newton West Parish, or at 45 State St. Boston.

Dec. 12, 1853. 2wis

NOTICE.

A person now in the Nursery business, on a limited scale, who has peculiar advantages for its extension, not possessed by any other individual in this country, wishes to connect himself with some person who can furnish a small capital sufficient to make the business both pleasant and profitable. Inquire at the office of the N. E. Farmer.

Nov. 21, 1853.

GREEN'S PATENT STRAW CUTTER.

Joseph Breck & Co. at the New England Agricultural Warehouse and Seed Store, Nos 51 and 52 North Market Street have for sale, Green's Patent Straw, Hay and Stalk Cutter, operating on a mechanical principle, not before applied to any implement for this purpose. The most prominent effects of this application, and some of the consequent peculiarities of the machine are:

1. So great a reduction of the quantum of power requisite to use it, that the strength of a half grown boy is sufficient to work it very efficiently.
2. With even this moderate power, it easily cuts two bushels a minute, which is full twice as fast as has been claimed by any other machine even when worked by horse or steam power.
3. The knives, owing to the peculiar manner in which they cut, require sharpening less often than those of any other straw cutter.
4. The machine is simple in its construction, made and put together very strongly. It is therefore not so liable as the complicated machines in general use, to get out of order.

Tulips, Ranunculuses, Anemones, Auriculars, Carnations, Picotees, Pinks, and Geraniums.

H. GROOM, of Walworth, near London, England, by appointment Florist to Her Majesty Queen Victoria, begs respectfully to call the attention of his friends and the admirers of flowers in America generally, to his extensive collection of the above flowers, which from his having been very successful in their cultivation this season he can offer at very moderate prices. He would particularly recommend to those persons about commencing the growth of the Tulip (which in England is becoming very fashionable) the under collections in beds, as it is by far the cheapest mode of purchasing them.

Tulips arranged in beds with their names.

- First Class.
 - A bed of 30 rows containing 210 bulbs including several of the newest varieties, - - - - - £15
 - A bed of 45 rows, - - - - - £21
 - A bed of 60 rows, - - - - - 25 guineas

- Second Class.
 - A bed of 30 rows including many fine sorts, - - - £10
 - A bed of 45 rows do - - - - - £14
 - A bed of 60 rows do - - - - - £17 10s

Tulips not arranged. £7 7s to £13

100 Superfine sorts with their names from £7 7s to £13

Superfine mixtures, from - - - - - 7s 6d to 21s

Ranunculuses.

100 Superfine sorts, with their names from £3 3s to £5 5s

Superfine mixtures, from - - - - - 5s to 21s per 100

Anemones.

100 Superfine sorts with their names, - - - - - £2 10s

Superfine double mixtures from 10s 6d to 21s per 100

Auriculars.

25 Superfine sorts with their names, - - - - - £3 13s 6d

Catalogues with the prices of the other articles may be had on application.

Orders, received by JOSEPH BRECK & CO.

Nov. 1. eow.

BONE MANURE.

The subscriber desires to inform his friends and the public that he has been in the Bone business more than ten years, and has spent much time and money to ascertain how bones may be converted to the best use, and is fully satisfied that they form the most powerful stimulant that can be applied to the earth as a manure. He offers for sale ground bone at a low price, and is ready to receive orders to any amount, which will be promptly attended to.

Orders may be left at my manufactory, near Tremont road, in Roxbury, or at the New England Agricultural Warehouse and Seed Store, No. 52 North Market Street, Boston.

Sept. 20. NAHUM WARD.

FARM FOR SALE.

A Farm situated in the southwesterly part of Townsend on the road leading from Townsend west village to Worcester. Said farm contains 110 acres of land divided into mowing- and pasturing, and a large share of wood and timber; a two story house, with two front rooms, kitchen, buttry, and two bed rooms well finished; parlor papered; wood house; well, under cover, forty feet barn, and shed, a large sheep house, fifteen by thirty feet, a large cooper shop, and another small house well finished, on the lower floor; a good aqueduct which comes into the barn yard, and a good orchard.

The subscriber will sell a part or all, and give possession on this fall or winter, or next spring. Those who wish to buy, will do well to call on the subscriber, who lives on the premises, and look for themselves. ASA H. ADAMS.

OUR YANKEE GIRLS.

BY G. W. HOLMES.

Let greener lands, and bluer skies,
If such the wide earth shows,
With fairer cheeks and brighter eyes,
Match as the star and rose;
The winds that lift the Georgian's veil,
Or wave Circassia's curls,
Waft to their shores the Sultan's sail;—
Who buys our Yankee Girls?

The gay Grissette, whose fingers touch
Love's thousand chords so well;
The dark Italian, loving much,
And more than *one* can tell,
And England's fair-haired, blue-eyed dame,
Who binds her brow with pearls—
Ye who have seen them—can they shame
Our own sweet Yankee Girls!

And what if court or eagle vault
Its children loftier born,—
Who heeds the silken tassel's flaunt,
Beside the golden coron?
They ask not for the courtly toil
Of jewelled knights and earls—
The daughters of the virgin soil—
Our free-born Yankee Girls.

By every hill, whose stately pines
Wave their dark arms above
The home where some fair being shines,
To warn the wilds with love;
From barest rock to bleakest shore,
Where farthest sail unfurls,
That stars and stripes are floating o'er—
God bless our Yankee Girls!

(From the Bangor Whig.)

LINNEUS, ME. NOV. 19, 1838.

A Boy Taken by a Bear!—Mr Editor—About 7 o'clock last evening, Mr Isaac Saunders's son James, who is about eight years of age, was sent to the barn to feed the cattle, and while returning therefrom to the house, (the distance of about 40 rods,) had his attention arrested by the appearance of a huge black object directly ahead of him. He stood still for a moment, not knowing whether to advance or retreat. At length he concluded to go ahead, when the bear rose up on his hind legs, and put himself in an attitude to receive the youngster with his fore paws. The boy perceiving the attitude of the bear, and his apparent determination to maintain his ground, gave a loud screech, and turned and ran towards the barn. At this the bear started in pursuit, and came up with the boy, who was still screeching. Just as the men in the house, who had heard the alarm, were approaching the theatre of action, the bear seized the boy, with his fore paws, raised himself again upon his hind legs, and started with his prey with all possible dispatch for the woods. The men hotly pursued him for some three quarters of a mile, when the bear finding himself but a few feet ahead of his pursuers, turned around and stood face to face with them, when the men, each of whom was armed with an axe, made a motion to give him a gentle tap upon the head, but his left paw was ready for a fend off, while he held the boy tightly with his right one.

The men finding it was useless to fight with axes, on which they started for the house after a gun, which he loaded with buck shot, and returned to the woods. On his arrival at the scene of battle, the bear in attempting to turn and try leg-bail again, was shot through the left side of his body, which brought him to the ground, and caused him to relinquish his hold of the boy, who scampered home more frightened than hurt, having received no other harm than a most unbecoming hugging. Mr Saunders took the bear to his house. He weighed, when dressed, 302 pounds, and is said to be the largest ever caught in this town.

For some time past, a number of persons have had deprivations committed on their stock by some wild animal or animals. Sheep have been slaughtered repeatedly, and in one or two instances, swine, and even cows, have been attacked and killed. One man, Mr David Rollins, for instance, has lost two fine cows, and I have been compelled to drive my cattle into the barn for security.

Yours, &c. J. T.

THE SNOW OWL.—Taking a stroll among the market wagons that crowded our streets, on Wednesday, laden with poultry and other agricultural products, we noticed in one of them, a living specimen of the Snow Owl, which was captured in Topsfield. Every season, between the months of November and February, several of these beautiful birds are seen hovering around—always exciting a considerable degree of interest; their movements are generally so closely watched, that not a few of them are taken by the lovers of the chase and others.

They are inhabitants of the coldest and most dreary regions in the Northern hemisphere, being constantly found in Iceland, Norway, Lapland, and the country adjoining Hudson's Bay. In the Atlantic States they are merely a winter visitor, and in their migrations wander along the sea coast as far as Florida, sometimes stretching interiorly, as they are met with in Ohio and Tennessee, and have been seen in the vicinity of the Red and Arkansas rivers. In Massachusetts and Maine they are more abundant than in any other part of the United States.

To protect this bird from the external cold to which it is exposed, especially in its native haunts, nature has bountifully provided it with a complete encasement of the most soft, warm, and elastic plumage beneath the outer covering of feathers, and so closely matted together that it is difficult to penetrate to the skin.

Its short and curved bill is nearly hid by the mass of feathers that cover the face; the feet are covered with a long, thick hair-like plumage, resembling very much those of a dog, the claws, which are curved, black and sharp, only being visible; the eyes are deep sunk under projecting eyebrows; and are of a bright yellow color; the general color of the body is white, and usually more or less marked with spots of pale brown, according to the age or sex of the individual.—*Salem Observer.*

A STRANGER.—The New York Sun says that a stone cutter employed in a shantee near the corner of Seventh street and avenue C, was on Thursday breaking the ice in a pond in a vacant lot in that neighborhood, when he was suddenly and not very agreeably surprised. No sooner had he made a

hole than out jumped a large alligator! He raised an alarm and the animal was forthwith attacked and despatched without mercy. He measured from head to tail seven feet ten inches. The Sun says that one of these animals was picked up in the East river last July. But how they came there, or for what purpose, no one can tell.

"I've raised a new pair of boots," said A to B, putting one forward as a sample—"a handsome fit, eh?—I bought them to wear in genteel society!" "They will be likely to last you your life time," rejoined B, "and be worth something to your heirs."

A beggar who for thirty years had posted himself at the entrance of a celebrated Restaurant at Paris, said he never received aid from any going in, but always from those going out. Few people can afford to give alms on an empty stomach.

A man named Dickson recently escaped from the State Prison at Thomaston, Me. carrying off a suit of clothes from the tailor's room. The next night, however, he returned and gave himself up saying that he had got better quarters at the prison than he could find anywhere else.

EFFECTIVE PREACHING.—In 1104, when Henry I. was in Normandy, a prelate named Serlo preached so eloquently against the fashion of wearing long hair, that the monarch was moved to tears and taking advantage of the impression he had produced, the enthusiastic prelate whipped a pair of scissors out of his sleeves and cropped the whole congregation.

FRUIT AND ORNAMENTAL TREES, MULBERRIES &c.

Nursery of William Kenrick.

The Catalogue of Fruit and Ornamental Trees for 1838 is now ready, and will be sent to all who apply. It comprises a most extensive selection of the superior varieties of Peaches, Apples, Plums, Peaches, Cherries, Quinces, Gooseberries, Raspberries, Currants, Strawberries, Grape Vines, &c. The stock of Cherries and Teaches now ready is particularly large. Also, Ornamental Trees, Shrubs, Roses, Honey suckles; Pæonies, Dahlias and other Herbaceous Flowering Plants.

100,000

more MULBERRIES are now offered for sale; the trees genuine and fine, will be ready for delivery at the cities of Boston, New York and Philadelphia, in October next, at prices fair, and varying with the size, and the quantity which may be desired. Also, Broussa and other varieties.

Mulberry and other trees, when so ordered, will be securely packed for safe transportation to distant places, and all orders promptly executed, on application to B. D. BAZZELL, Commission Store, No. 132 Water Street, New York, M. S. PEWELL, Seed Store, No. 7 Arch Street, Philadelphia, or to the subscriber, Nonantum Hill, Newton, near Boston.

August 1, 1833.

AGRICULTURAL.

ON THE PRACTICABILITY AND MEANS OF IMPROVING OUR AGRICULTURE.

Address delivered before the Fulton County Agricultural Society, on the occasion of its organization, at Johnstown, Oct. 18, 1838, by J. BURL; published at the request of the Society.

GENTLEMEN OF THE SOCIETY,—To those who carry back their recollections thirty or forty years, the improvements which in that time have been made in the mechanic and manufacturing arts all appear surprising. Forty years ago we wanted all our cotton, and most of our woollen goods, except of household manufacture—all our hardware and cutlery, a great portion of our silks, saddlery, hats, &c. and I well remember, that in Albany, to give currency to his hats, a man was obliged to deceive his customers, by putting on them bills, representing them to be of British origin. Now most of these, and many other articles indispensable to our comfort, are not only produced within ourselves, in quantities sufficient for domestic use, but millions in value of them are annually exported to foreign countries. Not only are they produced in abundance, but they are produced at a far less price than formerly. East India handkerchiefs, a coarse slazy kind of cotton goods, were once reputed cheap at twenty-five cents a yard, and we have now better goods, made at our mills, at seven and eight cents a yard; and it is but little more than twenty years, since the invention of power-looms reduced the price of weaving from seven and twelve to one and two cents a yard. Iron is scarcely a manufactured article in use, which has not, in consequence of the improvements in mechanics and manufactures, been improved in quality, and diminished in price.

Whence these great and recent improvements in agriculture? They are not owing to the diminished price of labor; for that has increased, rather than diminished; nor to a reduction in the price of machinery—for these, too, are higher than formerly. They have been brought about by the diffusion of useful knowledge, and the consequent development of the powers of the mind. The manipulations in agriculture have been greatly abridged by labor-saving machinery, and many of the processes have been simplified and cheapened, and the results rendered certain, by the aid of science—by a knowledge of the laws which Providence has ordered for the government of matter, inorganic, as well as organic. Much has been put in requisition, as well as physical power. And these changes have in some measure been effected by a more systematic arrangement of business—by a division of labor—and by general and rapid dissemination, by means of the diffusion of a knowledge of the improvements which every day being made in these useful arts of agriculture.

Let us now turn to agriculture, the parent of all the arts, and the source of our purest and most substantial

enjoyments—the basis of our national prosperity and independence. This is as susceptible of improvement as the other arts of labor. What progress in its improvement have we made, during the last forty years? Have our labors been abridged by the general introduction of improved labor-saving implements of husbandry? Have our lands increased in fertility, and in the amount of their products? Has the diffusion of useful knowledge, on the business of husbandry, been as extensive as it has in manufacturing and mechanic arts? The valley of the Mohawk was long ago celebrated for its fertility and its wealth. Have enterprise, intelligence and improvement in rural affairs, kept pace with the spirit of the age? I fear these questions cannot be answered affirmatively. I fear that it will be found, on an impartial investigation, that while all the other arts of labor have, with rapid strides, been progressing in improvement, our farmers have too generally been taking a Rip Van Winkle nap;—that with all the natural means of improvement, and all the common incentives to employ them, they have been listlessly treading in the footsteps of their fathers, unmindful of the salutary changes which are enlightening and enriching those engaged in other branches of labor.

I have said that agriculture is susceptible of improvement, and that our farmers have the power and incentives to bring it about, if they would do as others do, make a joint stock of their knowledge, and thus individually profit by the experience of all. Scotland, in a little more than forty years, has increased her agricultural products four fold, and yet but few of her farmers are owners of the land they till. They are tenants at a heavy rent, which Prof. Low, one of her late agricultural writers, averages at more than eight dollars an acre per annum, while the burdens, in the form of taxes, are assumed by him to be about \$140 upon a farm of 500 acres. Thus the occupant of such a farm pays annually, in rent and taxes, about 4,500 dollars, which of course is a draw-back upon his net profits, and most of which the American farmer, with Scottish intelligence and industry might annually add to his income. Yet the Scotch farmer prospers under all these disadvantages.

What I have remarked of the increased profits of Scotch agriculture, will apply with very little abatement, to many districts of our own country, and particularly to the county of Dutchess, in our state. Entire farms in that county have netted the cultivators an annual profit of fifteen and seventeen dollars an acre. Forty years ago these farms did not probably net a quarter of this sum; and if I am able correctly to identify one to which I make reference, it was, forty years ago, mostly *old field*, a term denoting worn out land, and was lying in commons!

One of the best farmers of the age, a man of science and extensive practical knowledge in farming, has affirmed, that by doubling the expense, in labor and manure, he has, upon the same land, been enabled to treble his profits, and to quadruple his products. I allude to Von Thaer, who has for

twentyfour years been at the head of the great agricultural school in Prussia.

If I might be permitted, without being charged with egotism, to cite my own experience in the business of improvement, I would point to my farm, on the Albany barrens, which many of my hearers have seen. I presume, in its present and former state—as a further evidence that we can improve our lands. Twenty years ago, my soil was poor,—very poor—and my farm a part of the commons—a waste. It is now as productive, and its culture affords as liberal a profit, as any of the lands in yonder fertile valley. It is worth, for farm culture, the interest of two hundred dollars per acre; and this year the product has been greater than I have named, although but ordinary labor was bestowed in the culture. It may be said that I have expended capital in my improvements. This is true. I laid out extra money and labor to put it into good condition, and I am now realizing compound interest upon the amount of the outlay. For having put it into good condition, I am enabled to keep it so, and to cultivate it, with as little expense as I could cultivate poor lands that would not yield me a third of the profit that I now realize. Capital is useful to its owner in proportion to the income which it brings him; and if by vesting it in farm improvements, it is made to yield as much as it would yield in bank stock, or loaned on bond and mortgage, it would seem to be prudent, if not wise, so to vest it.

I believe it will not be denied, by any one conversant with the history of the times, that improvements in our agriculture have been trivial, compared with those which have been made in the other arts of labor, or those which have been made in husbandry in other districts and in some other countries. On the contrary, it is but too apparent, that, with individual and local exceptions, our old lands have been deteriorating in fertility without any material improvement in the mode of their culture. A bare reference to the wheat crop in the valley of the Mohawk, comparing it now with what it was forty years ago, will serve to substantiate this truth.

From the examples I have cited, and from the personal observation which most of you have been enabled to make, I think it will readily be admitted, that we are capable of greatly improving our farming operations, and of thereby adding to our wealth, our comforts, and to the substantial prosperity of our country. If by means of new farming implements—the improvement of our domestic animals—and a better system of culture—the labor which now nets us fifty dollars, can be made to net us one hundred dollars—which I consider within the range of probabilities—we may then double both our products and our profits; and, under the guidance of correct principles, double, too, our usefulness to society.

The progress of improvement in husbandry, will be graduated, in a measure, by the degree of intelligence which directs its labors. "It appears to be strange—and yet we see it to be true"—says the Rev. C. Young, "that the more ignorant a man

is, the more obstinately is he wedded to his own notions and ways—the more ready to scoff at and oppose everything that is new. Self-conceit and prejudice, the greatest foes to improvement, are the legitimate offspring of ignorance. And in proportion to the degree of ignorance, in a community, will be the hostility to improvement, and the derision, and even persecution, at which all attempts at innovation and reform will be met. The spirit of improvement is thus cowed, and even smothered. And if occasionally, a bold genius struggles into life, and exhibits his inventive powers, he hazards his peace—sometimes even his life. When Hargrave, less than a century ago, attempted to introduce the spinning-jenny, which he had invented, into the cotton manufacture, he was obliged to fly from Lancashire in England, where he lived, at the risk of his life. The first saw-mill ever erected in England was destroyed by a mob, because they thought it would take bread from the families of the sawyers." Fortunately in our day and country, acts of violence towards innovators upon old modes of farming are not to be apprehended. We can only complain of a listless indifference to improvement, and of a conceited ignorance, which rejects the useful, because it is new.

If our neighbor discovers on his farm a valuable mineral, and works it to great profit—we commend him for his good fortune. If the like mineral abounds on our own farms, and we can work it to equal advantage, what course, as prudent men, ought we to pursue? Should we not deem the man highly reprehensible, who neglected such an opportunity of adding to his wealth, by adopting the example of his fortunate neighbor? Now what are our farms but mines of wealth, if rightly improved? They are certainly so to many cultivators; and if we will follow their example in working the mine, and in husbanding the wealth which it yields, our farms will be such to us. If we lack the knowledge which precedes improvement, let us seek for it, by observation, by study, and a mutual interchange of opinions and information, with our brother farmers in associations like the one I am addressing. We shall see and hear, at these meetings, much that is new,—much that is instructing and useful, and much to stimulate us to new exertions in our business.

Again—if a man embarks in a speculating business, and prospers in it, how ready are his neighbors to become his rivals and competitors? Good farming is a speculation—with almost a certainty of gain—without the probability of loss. In agriculture, besides, competition excites no unkind feelings, as it is apt to do in other employments, or should not, for the improvements of every competitor may prove beneficial to all. What one makes does not lessen his neighbors' profits; but on the contrary, has a tendency to better the condition of all around him. There is no monopoly in good farming.

The propensity which has too much prevailed of late years, to quit farming for a more lucrative, a more genteel, or a less laborious employment, has been a great obstacle to agricultural improvement, and has tended much to lower the respectability of our yeomanry in the public estimation. How many farmers have we seen, who were doing well upon their farms, allured by a weak ambition, into some untried business, in which they had everything to learn—how many such, I say, have we seen bankrupted in fortune, and not infrequently in reputation. There is a vast difference in the chance of

a man's improving in the business to which he has been brought up, and his succeeding in a new one, of which he knows little or nothing. In the one case he has a capital in his experience; in the other, he enters into competition, without this capital, with those who are far his seniors in skill and in practice. A farmer may improve in his old business, at much less risk, and with less trouble, than he can learn a new one. He mistakes equally his interests and his happiness, therefore, who quits his farm, or neglects to improve it, upon the untried experiment of doing better elsewhere. There is no employment which promises a greater portion of health and independence, the main sources of our enjoyment, than that of agriculture; while the return it makes, to skill and industry, is as bountiful, probably, as is useful to ourselves, our families, or our country.

The first step to improvement, is to acquire better knowledge in our business;—the second, to apply this knowledge to the management of our farms. He that is conscious he can improve, and resolves that he will improve, will most surely succeed—and the means of improving will readily present themselves to his mind. Agricultural journals will afford him a ready and cheap means of instruction. They chronicle and bring to him, periodically, at trifling expense, the improvements that are continually being made in the business by which he lives, and expects to acquire wealth for himself and his children. They convey to him all the discoveries in the science, and improvements in the art of agriculture, which are made in Europe or America, and that are calculated to improve him in his business, and advance his condition in life. They explain to him the principles upon which the new system of husbandry is more productive, more certain, and more profitable than the old system; and they demonstrate the correctness of these principles by the successful results they give in practice. They explain to him the operation of manures—as essential to the growth and perfection of his crops, as hay, grain and pasture are to the growth and productiveness of his cattle—and enlighten him in the means of augmenting, and of applying them in the most economical manner. They bring to his knowledge every improvement and invention in the labor saving implements of the farm. They instruct him in the principles and most approved modes of draining—and of rendering salubrious and productive, those portions of his farm which have hitherto, perhaps been a prolific source of disease and death to his family, and neighborhood—a highly useful branch of modern improvement in husbandry, which we have yet to learn. They demonstrate to him, in principle, and by numerous illustrations in practice, the utility of alternating crops, and instruct him in the economy and management of root culture. They treat of the comparative value of different breeds of farm stock, and furnish the best examples of profitable management. They teach useful lessons in gardening and orcharding, and designate the fruits, roots and garden productions most useful to the family, and most profitable for market. They abound in instructions in household economy, and show, that under judicious management, the garden and the farm may be made to produce most of the necessities, and many of the elegancies and luxuries of life. They are in fact a sort of agricultural museum, in which all that is new—all that is useful in farming—may be found, and applied to the individual benefit of the reader. They are, in effect, a

sort of universal agricultural society, which collects into a focus, and from thence diffuses of the land, a knowledge of all that is useful in the improvement of the soil. But independent of these and other advantages I might particularize, agricultural journals are worth three their cost to the children of the family, in inducing in them a taste for useful knowledge, and a desire to improve their minds, their manners and their morals. The good seed, sown in the spring time of life, will produce its fifty and its hundred fold, in the summer manhood.

Another and very important means of improvement is agricultural societies or associations. Although these have been of long standing in Europe, and have contributed largely to agricultural improvement there, more new ones have been formed in the United States, in the last five or six years, than ever existed with us before. They afford a strong indication that the important business of husbandry is commanding, as it ought, particular attention of the American people; and that the benefits resulting from these associations have become palpable and important. Agricultural societies tend to bring under the eye, or to the understanding, of each member, and in a great degree to the public at large, the best household and farm products, and the best agricultural practices, the country or district in which they are established and thus enable each individual to appropriate his own use, the experience and the improvement of his neighbors. The example of every good farmer produces a beneficial influence upon those around him; who seeing his approved modes of management, and the advantages resulting from them, will not fail ultimately to adopt them. He the more good farmers there are, the greater will be the ratio of general improvement, and consequently of public benefit—for it is the earnings and products of agricultural labor, that mainly contribute to the prosperity of the other classes of society, and to augment the aggregation of national wealth. When the harvest is short, or the department of business feels the electric shock. When it is abundant, a new and happy impulse is given to every sort of business. These considerations show, that it is the interest alike of all to patronize and encourage every effort that is made to increase the products of the soil. One of the oldest societies in our country is that in Berkshire, in Massachusetts. I have occasionally attended their exhibitions, traversed the county, and marked its improvements in husbandry, during the twenty years; and I feel a perfect conviction in my mind, that the county has been benefited twenty dollars for every dollar expended in improvements, in a pecuniary point of view. But it is the rapid improvement of the soil alone which resulted from the establishment of her agricultural society—the improvements of the mind have gone on pace with, or rather preceded, the improvements in her husbandry. That county has probably the best schools in the country; and the general intelligence of her population ranks high.

Among other benefits likely to result from the establishment of agricultural societies, Mr. Atkinson, in a late address, before the society, at Danville, Ky, enumerates the following.

"They will elevate the character of the farmer, and agricultural class of society. They will increase their general intelligence, their agricultural wealth, and give them, as they deserve to have, control over the morals and politics of society.

"They will increase the national wealth.
 "They will be not only calculated to elevate the character of agriculture, but the standard and spirit of education; for as men increase in knowledge and in a useful character, aspirations to a higher standard in everything else, are enkindled.
 "They will furnish essential aid to the legislature of a state.
 "They will greatly increase live stock, in purity of blood and quality.

"They will increase labor saving modes of cultivation, as well as labor saving machines."

As intimately connected with the improvement of husbandry, which this society is specially formed to promote, permit me earnestly to recommend an early attention to the establishment of Common School Libraries. The improvement of the mind must precede the improvement of the soil. Physical power belongs to the brute, as well as to man; but at the application of intellect to aid and control its power, is the peculiar prerogative of man; and requires no argument of mine to show, that intellect is efficient and potent, in husbandry, as it is in the other business concerns of life, in proportion as it is brought under good culture;—that a well cultivated mind, like a well cultivated soil, can be rendered far more productive in usefulness, than one that has not received the advantages of culture. Common School Libraries will not only be useful in the particular business of farming, but in all the relations in life in which we or our children may be called upon to perform a part. All the gradations in society, from savage life, to the highest state of civilization and refinement, have principally been owing to the greater or less cultivation of the human intellect. Useful reading not only confers positive benefit, by the instruction and admonition which it imparts, but it often averts positive evil, by keeping us from loose or bad company, and thereby preventing the formation of idle or bad habits. The youth who finds pleasure in reading, and has the opportunity of storing his mind with useful knowledge, will seldom be driven to the haunts of vice and dissipation, to indulge his grosser appetites. And the mind too, like the soil, will grow weeds and briars, thistles and thorns— if not made, by good culture, to produce that which is so comely and useful. The liberal appropriation by the legislature, for the establishment of Common School Libraries, if seconded, as I trust it will be, by the public at large, will form a new and auspicious era in our history, and contribute essentially to render us, what we ought to be—a more intelligent and virtuous—that we may longer remain a free and independent—people.

The judicious cultivation of the soil is now deemed so essential to national prosperity, that it has become the settled policy of the most enlightened governments, to take a direct and efficient interest in the improvement of its agriculture. Schools of scientific and practical agriculture, in which youth are taught the best modes of practice, and instructed in the principles upon which that practice is based, are continually multiplying under governmental patronage on the old continent. National societies have been established for rewarding those who benefit the state by their improvements and discoveries in husbandry, and for diffusing the useful information which is thus brought to a common centre—and the rewards as well as the service of those who thus engaged in promoting the common weal, are in most cases paid from the public treasury. Prussia has wisely

engrafted instruction in agriculture upon her system of common school education; and even in what we have hitherto considered the benighted regions of Prussia, and among the oppressed of Ireland, we see evidences of wisdom, and the dawn of a brighter day, in the establishment of agricultural schools. Our sister state, Massachusetts, has been foremost among us to adopt a liberal and enlightened policy toward this her primary branch of industry. She has disbursed large sums from her state treasury, annually, to sustain and encourage county agricultural societies; and when the law making these appropriations, was about to expire, by its own limitation, so well satisfied was her legislature, of its utility, that the law was renewed with great unanimity. That state has also provided for an agricultural survey of her territory, which has been two years in progress, with a view of bringing before her whole agricultural population all that is found excellent in the business of her farming population. How far New York will profit by these examples of usefulness—or when she will begin to imitate them, will depend very much upon her farming population. What they demand will be granted. But little need be expected for the promotion of agricultural improvement from our public councils, while the farmers themselves generally manifest a reprehensible indifference in the matter.

In the brief remarks I have made, I have endeavored to show the practicability of improving our agriculture, and of thereby raising the character of our agricultural population; and have suggested some of the means by which the desired improvement may be brought about. I have already trespassed too far upon your patience, I fear, to go into any of the details of improved husbandry. Let it suffice to say, that they embrace a better economy, and more general application of manures—a system of thorough draining—the introduction of improved labor saving machines and implements—the improvement of farm stock—the exclusion of impure seeds—the extension of root culture—the alternation of crops where practicable—the improvement of our common roads—the introduction of system into all the departments of farm and household labor—the cultivation of *as much land as can be cultivated well*—and the keeping of *as much farm stock as can be profitably fed and fattened*—AND NO MORE. All those improvements have been made, and are making, elsewhere. They can be made here; they will be made here, by the intelligence, the enterprise, and the laudable competition, which this society will diffuse and call into action, if its labors are judiciously persevered in.

I am happy to recognize, gentlemen, in the formation of this association, a disposition in its members to aid in the work of agricultural improvement. The object is a worthy one, because it aims to enlarge the means of human sustenance and the measure of human enjoyment; and by encouraging and honoring industry, tends to advance the moral character and substantial prosperity of the country. I hope you may prosper in these public spirited efforts, and that FULTON county, may become as distinguished in the annals of agricultural improvement, as the individual whose name it bears, is already renowned in the history of steam navigation.

POTATOES.—The following experiment copied from the New York Farmer, contains very useful instructions to us in regard to the quantity of seed

potatoes necessary in order to insure the most profitable crop, and of the desirable size. This experiment seems to have been conducted with undoubted precision, and carried to an extent that speaks well of the zeal and patience of the cultivator, Mr Moore, Jr. of Trenton, near Utica, New York.

He planted potatoes of the same kind in each case, and the same soil, all manured exactly alike, in eleven different methods, as exhibited in the following table:

	No. potatoes,	lbs. oz.
1st. Planted one eye in a hill,	9	3 14
2d. " two eyes "	14	5 2
3d. " three eyes "	14	3 15
4th. " two sets of 2 eyes each	12	5
5th. " " 3 "	25	6
6th. " " 4 "	34	5 10
7th. " 3 sets of 2 "	24	3 8
8th. " " 3 "	27	4
9th. " " 4 "	24	4 10
10th. " " 5 "	32	5 3
11th. " whole potato, 11 eyes,	21	4 2

The size of the potatoes in No. 1 was nearly of the same size as could well be—in No. 2 were good size, even—in No. 3 were some very large, and others smaller—No. 4 were mostly of the same size; but all below were a great number of very small size.

THE TURNIP FLY,

Has been uncommonly destructive this year to the ruta baga crop. It seems now to be confidently affirmed, in some of the European agricultural journals, that sulphur, or brimstone, may be effectually employed as a preventive. One mode of using it is, slightly to moisten the seed and roll it in sulphur, previous to sowing. The other, to keep the seed for some time in sulphur, and to sow the sulphur with the seed. It is affirmed, that the young plants in this way become so strongly impregnated with the sulphur, that the fly will not touch them. Sulphur is so extremely subtle, that it is known to diffuse itself, in a very short time, through the vegetable, as well as the animal system; and it is known to be obnoxious or destructive to the whole race of insects. The turnip seed imbibes it, and imparts it, with the sap, to the young plumule, or stem. Although the prescription is now out of season, it should be laid by for trial at the sowing season.—Cultivator.

LARGE VEGETABLES.—A correspondent at North Bridton, Maine, writes that some vegetables raised there, beat "by a long chalk," some mammoth productions named in the papers, and inquires how much better they can do in Illinois. Mr Ithamar Brigham raised a beet weighing thirteen pounds, others were raised from six to nine pounds each. R. S. Bailey Esq., raised a Ruta Baga Turnip weighing twentyfive pounds. Mr David P. Kneeland of Harrison, raised the following produce on an acre: eightythree and one half bushels of corn, ten bushels white beans, four loads pumpkins.

Two children were burned to death, a short time since, in Bedford, Cuyahoga county, Ohio by the house taking fire. The parents of these children barely escaped; they could render no assistance to the little sufferers.

EARLY LAMBS.

Farmers in this country have, hitherto, in order to avoid the care necessary to rear lambs weaned as early as January or February, and the loss consequent on want of attention, endeavored to have their lambs dropped at as late a period as could be, and they attain sufficient strength and hardihood to endure the following winter. In this way, with the ordinary mode of treatment, more lambs are saved than would be were they to come at the early period named; but they are not the second year worth as much to the butcher, and their fleece will be lighter than if dropped early. Still, unless more food calculated to cause ewes to give a supply of milk, such as turnips, rowen hay, or other nourishing food, be provided; and the difference in price between early and late lambs is no more considerable than it now is, perhaps the present course is the best. But from the increasing inquiries made in our markets for early lambs; the more general consumption of mutton of all kinds among the people generally; and the better prices that heavy, early lambs, now command, we are induced to believe that with a little precaution, farmers who have flocks of the hardier kinds of sheep may find it for their interest, to make the breeding of early lambs a part of their business. The time required, falls at a period when it is little available as a source of profit in any other way, and might perhaps be made of account in this. To show how the business is managed abroad, we make the following extract from the Quarterly Journal of Agriculture, detailing the process as it is practised extensively in the county of Wicklow, for the Dublin market
