1819.

CYCLOPÆDIA:

OR, A NEW

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

T

T, A consonant, and the nineteenth letter in the alphabet; the found of which is formed by a ftrong expulfion of the breath through the mouth, upon a fudden drawing back of the tongue from the fore part of the palate, with the lips at the fame time open.

The T, at the beginning and end of words, has always the fame found, nearly refembling that of D, for which reafon they are often put for each other; and Quinctilian even rallies thofe who made any fcruple of writing the one indifferently for the other: as *at* for *ad*, *fet* for *fed*, *haut* for *haud*, &c.

The cuftomary found of T is that which occurs in the words *take*, *temptation;* but before an *i*, when followed by a vowel, it has the found of an obfcure *s*, as *nation*, *falvation*, except when *s* precedes *t*, as *Chriftian;* and in derivatives from *y*, as *mighty*, *mightier*.

The T is one of the five confonants which the abbot de Dangeau calls *palatal:* thefe five are *D*, *T*, *G*, *K*, and *N;* the four firft of which have the fame relation to each other, as the labials *B-P* and *V-F* have; *D*, for inftance, having the fame relation to *T*, that *B* has to *P*, and *V* to *F*.

The T, the fame author obferves, is a letter of a ftrong found; fo that a feeble one cannot be heard before it. Hence, to form the fupine of *rego*, the *T* of *tum* changes the *g*, and ftrengthens it to the found of a *c*, fo that we fay *rectum;* as in the preterperfect tenfe *rexi*, which we pronounce *reckfi*.

Th has two founds: the one foft, as *thus;* the other hard, as *thing*. The found is foft in thefe words, *then*, *thence*, *there*, with their derivatives and compounds, *that*, *thefe*, &c.; and in all words between two vowels, as *father;* and between *r* and a vowel, as *burthen*. In other words it is hard, as *thick*, *thunder*. Where it is foftened at the end of a word, an *e* filent muft be added, as *breath*, *breathe*. Johnfon.

T is ufed as an abbreviature on ancient monuments, &c. for Titus, Titius, and Tullius.

T, among the *Ancients*, was ufed as a numeral letter, fignifying 160, according to the verfe,

"T quoque centenos & fexaginta tenebit."

When a dafh was at the top, thus, $\overline{T}$, it fignified 160 thoufand.

T', with a kind of acute accent over it, denoted among the Greeks 300; and if the accent was below it, thus T, it denoted 300,000. The ט of the Hebrews fignified 9; and with two points fixed horizontally over it, thus, ט̈, it fignified 9000.

Sometimes an acute accent over this, or any one of the firft nine letters, multiplies its value by a thoufand.

We fhall here obferve, that the number 15 fhould be reprefented by יה, *i. e.* 10 and 5; but, becaufe thefe letters conftitute part of the word יהוה, *Jehovah*, the letters טו, *i. e.* 9 and 6, reprefent 15, to prevent, as the Jews allege, the profanation of the peculiar name of God. For the fame reafon, טז, *i. e.* 9 and 7, are ufed inftead of יו, *i. e.* 10 and 6, to exprefs 16.

T, on the French coins, denotes thofe that were ftruck at Nantes.

When the Roman tribunes approved of the decrees of the fenate, they teftified their confent by fubfcribing a T.

T, in *Mufic*, is the initial of tenor, vocal and inftrumental; of *tacet*, for filence: as *adagio tacet*, when a performer is to reft during the whole movement. In concertos and fymphonies, *t* is the initial of *tutti*, the whole band, after a folo part. It alfo frequently ftands for *trillo*, or *tr*, a fhake.

T is alfo a mark or brand, with which by ftat. 4 Hen. VII. every perfon convicted of felony, fave murder, and admitted to to the benefit of the clergy, ſhall be marked on the brawn of the left thumb.

T, or Tau, in *Heraldry*, is a kind of croſs-potent, or truncated; found in all the armories of the commanders of the order of St. Anthony.

The azure T, or Tau, is ſeen in arms above 400 years old. Its origin, according to ſome authors, is taken from the Apocalypſe; where the ſame is a mark that the angel impreſſes on the foreheads of the elect: others take it to repreſent a crutch, a ſymbol proper enough for this order, which was ſworn to hoſpitality. But the truth, F. Meneſtrier obſerves, is, that it is the top of a Greek croſier.

The biſhops and abbots of the Greek church wear it ſtill; and if it be found on the habit of St. Anthony, it is only to ſhew that he was an abbot.

T *Bandage*, in *Surgery*, is ſo called from its reſembling that letter in ſhape. It conſiſts of two bands of linen, of greater or leſſer breadth, according to circumſtances. The tranſverſe piece of the bandage ſerves to go round the body above the hips. The perpendicular portion is ſewed at one of its ends to the middle and back point of the band, which ſurrounds the pelvis; and its other or anterior extremity is generally ſlit into two portions, or tails, about ſix or eight inches in length. The perpendicular piece of the T bandage applies itſelf between the glutæi muſcles and to the perinæum; while the two tails, which we have juſt now deſcribed, are carried between the thighs and the pudenda to the right and left, and are laſtly faſtened to the tranſverſe piece, which ſurrounds the body. The T bandage is chiefly employed for keeping on the dreſſings, after the operation for the fiſtula in ano, in diſeaſes of the perinæum, and in thoſe of the anus, groins, &c.

Beſides the common T bandage, ſurgeons make uſe of another, which they call *double*, and which is furniſhed with two perpendicular pieces, ſewed to the tranſverſe one, about four inches apart. The double T bandage is repreſented to be particularly calculated for caſes of lithotomy, and for diſeaſes in the perinæum; becauſe the two perpendicular bands may be made to croſs each other on the part affected, and leave the anus uncovered; an advantage which the ſingle T bandage certainly has not.

The T bandage admits of application alſo in other modes. When the croſs band is broad, it may be applied round the cheſt, while the perpendicular portion, being ſlit into two, may be made to paſs over the ſhoulders, ſo as to keep the bandage from ſlipping downward. There is no kind of bandage which can be more conveniently applied to the cheſt, than that which has juſt now been deſcribed. See Bandage.

TA, in *Geography*, a fortified city of China, of the ſecond rank, in the province of Se-tchuen; 650 miles S.W. of Pekin. N. lat. 31° 18′. E. long. 107° 15′.—Alſo, a river of China, which runs into the Eaſt ſea, N. lat. 36° 55′ E. long. 121° 34′.

Ta, *Lough*, a lake of the county of Wexford, Ireland, not far from Carnſore Point. It receives two or three ſmart rivulets, and having no outlet, the waters accumulate, and gradually overflow the adjacent grounds; till the peaſantry, once in three or four years, let them off, by making a cut through the high ſand-bank that parts the lake from the ſea; which cut very ſoon fills up again.

Ta, a name given in China to their pagodas. Theſe are moſt numerous in hilly parts of the country, upon the ſummits of which they are frequently erected. They are generally from 120 to 160 feet high, which height is equal to four or five of their diameters at the baſe; and they conſiſt moſtly of an unequal number, five, ſeven, or nine galleries or ſtories, diminiſhing as they riſe, with as many projecting roofs.

Ta, τα, one of the four ſyllables uſed by the ancient Greeks in ſolmiſation, or the firſt leſſons in ſinging.

TAAIF, in *Geography*, a town of Arabia, in the province of Hedſjas, ſituated upon a lofty mountain, in a country ſo agreeable, that the Arabs compare its environs to thoſe of Damaſcus and Sana. This city ſupplies Jidda and Mecca with excellent fruits, particularly raiſins; and carries on a conſiderable trade in almonds, which abound in its territories. Near Taaif is the lofty mountain of Gazvan, which, according to Arabian authors, is covered with froſt and ſnow in the midſt of ſummer.

TAAMBOOTERA, a large town of the Birman empire, on the Irawaddy.

TAAPAN, a town on the eaſt coaſt of Mindanao. N. lat. 7° 38′. E. long. 124° 5′.

TAAS, or Taæs, a city of Arabia, in the province of Yemen, ſituated at the foot of the fertile hill of Sabber, and encompaſſed with a wall, between 16 and 30 feet thick, and flanked with ſeveral towers. Within the circuit of the wall ſtands the fortreſs of Kahhre. The city has only two gates, each fortified with three towers; affording a very inſufficient defence againſt any aſſault but that of Arabs, unſkilled in the uſe of artillery. The ſaint who is the patron of Taæs is the famous Iſmael Mulk, reported by tradition to have been once king of this country. His remains are interred in a moſque bearing his name. Near this moſque is a garden, which was poſſeſſed by Iſchia, his ſon. The city has ſeveral other deſerted and ruinous moſques. The laſt lords of Taæs have choſen to diſtinguiſh themſelves, not by moſques, but by noble palaces, and have contented themſelves with a ſmall kubbet for their oratory and burial-place. Theſe palaces are now the ornaments of the city. Near the city are the ruins of two ancient cities: one called Thobad, ſituated near mount Sabber; and the other Oddena, upon the ſummit of mount Sabber, over-againſt Kahhre. This was formerly the reſidence of the kings of the country. Its only remains are the ruins of ſome moſques. Taæs has undergone ſeveral revolutions; but after various events, which we cannot recite, the Imam ſent a Dola to this city, and it is now under the ſame government as the other cities in his dominions; 48 miles E.N.E. of Mocha. N. lat. 13° 33′. E. long. 44° 10′.

TAASINGE, an iſland of Denmark, about 16 miles in circumference, ſituated between Funen and Langeland, with a town upon it of the ſame name. N. lat. 55°. E. long. 10° 37′.

TAAUT, Thoyt, or *Thot*, in *Ancient Mythology*, the name of a deity among the Phœnicians, and probably the ſame with the Egyptian *Thoyt*, *Thot*, or Hermes, the *Theutate* or Teutat of the Greeks, and the Mercury of the Latins. His coſmogony has been tranſmitted to us by the Phœnician writer Sanchoniathon, whoſe account is preſerved by Euſebius, De Præp. Ev. lib. i. cap. 10. To him the Phœnicians aſcribe the firſt invention of letters. See Mercury.

TAAWIRRY, in *Geography*, an iſland in the South Pacific ocean. There are two ſituated within the reef of the iſland of Otaheite, and on the eaſt ſide of the main iſland. Within theſe iſlands there is anchorage within the reef that ſurrounds them. The French veſſels under the command of M. Bougainville lay here. The name of the other iſland is Boourou.

TAB, the ancient *Aroſis*, a river of Perſia, in the province of Fars or Farſiſtan, formed by the junction of two ſtreams, within a few miles of the town of Zeitoon. Both theſe

these streams take their rise in the recesses of the mountains of Fars; the first at the foot of the high hill of Kamarah, and the other near that of Ardicoone, 12 fursungs (the fursung being estimated at three English miles and three quarters) N.W. of Shirauz. This branch of the river is mentioned by Arrian in the march of Alexander. It divides Fars from Chusistan, and passes through the centre of the town of Endian, being navigable for boats of 20 tons burthen. Nine miles above the town is a ford; and 16 miles below it, the Tab falls into the sea. When the river passes Zeitoon, the waters are perfectly sweet; but in its course over the hills, towards Endian, they become corrupted, and at that place are so brackish as to be hardly fit for use.

TABA, a town of Africa, on the Grain Coast.

TABA *Islands*, four small islands in the East Indian sea, lying north-west and south-east near the east coast of Borneo. N. lat. 2° 6′. E. long. 118° 12′.

TABA, or *Tabo-seil*, in *Modern History*, a name by which the Negroes, who inhabit the Gold Coast in Africa, describe their king, whose power is very arbitrary, insomuch that they regard him as a being superior in nature to themselves.

TABAB MANAM, in *Geography*, a town of Abyssinia; 100 miles S.S.E. of Gondar.

TABACUM, in *Botany*, whence comes its common English name Tabacco, or, at present, Tobacco. (See NICOTIANA.) Bauhin says, after Monardez, that this appellation is derived from an island so called; but it should seem to originate from the Indian name of the plant, *Tubac*, or *Tubacka*.

TABÆ, in *Ancient Geography*, a town of Asia, in Cilicia.—Also, a town of Asia, on the confines of Pisidia, on the coast of the sea of Pamphylia.—Also, the name of three towns in Asia Minor; one in Caria, another in Peræa, and a third in Lydia.

TABAFRA, in *Geography*, a town of Africa, on the Ivory Coast; 15 miles E. of Druin.

TABAGO, an island in the Pacific ocean, near the coast of Mexico; about three miles long, and two broad. It is mountainous, and on the north side the high land declines with a gentle descent to the sea. Near the strand the soil is a black mould, and deep, but towards the top of the mountain strong and dry. The north side of the island makes a very pleasant appearance, and seems to be a garden of fruit-trees, inclosed with others of the forest-kind. The principal products are plantains and bananas, which grow very well from the foot to the middle of the mountain; but those near the top are small, as wanting moisture. There was formerly a small town near the sea, on the north side of the island; but it was ruined by the privateers that then frequented those seas. Before it is a good road, about a mile from the shore, where ships may ride very safely in 16 or 18 fathom water; 18 miles S. of Panama. N. lat. 8° 40′. W. long. 80° 9′.

TABAGUILLA, or *Little Tabago*, a small island in the Pacific ocean, near Tabago.

TABAJANA, a town of Africa, in the country of Woolly; 12 miles W.S.W. of Medina.

TABALLAR POINT, a cape on the east coast of the island of Borneo. N. lat. 2° 12′. E. long. 117° 4′.

TABALTHA, in *Ancient Geography*, a town of Africa, on the route from Tuburbum to Tacapæ, between Cellæ Picentinæ and Septimunicia. Anton. Itin.

TABALUM, a town of Asia Minor, in the vicinity of Ionia. Herodotus.

TABANA, MANKOUP, a town in the interior of the Tauric Chersonesus. Ptol.

TABANIE′, in *Geography*, a town of Egypt, on the east branch of the Nile; 6 miles S.W. of Mansora.

TABANUS, the *Ox-fly*, in *Entomology*, a genus of the Diptera order of insects; the generic characters of which are, that the mouth has a fleshy proboscis, terminated by two lips, and that the rostrum is furnished with two awl-shaped palpi, placed on each side of, and parallel to, the proboscis. Gmelin, in his edition of the Linnæan system, enumerates 38 species.

The insects of this genus very much resemble those of the *Musca*; which see.

Species.

ROSTRATUS. With brownish eyes, and sucker of the length of the body.

BARBATUS. With black eyes, and sucker half the length of the body. Both these species are found at the Cape of Good Hope.

MAURITANUS. With blackish eyes, a black spot on the second segment of the abdomen, and sucker equal to the body. Found in Barbary and Spain.

BOVINUS. Greenish eyes; marked down the back by a series of large, whitish, triangular spots, and on each side is a similar appearance, but less distinct than that of the dorsal row. This is the largest of the British species, and, like others of its species, is seen generally in the hottest part of the day, during the middle and the decline of summer. It is very troublesome to cattle. Its larva is large and dusky yellowish, like that of a tipula, marked by transverse blackish streaks or rings; residing under ground in moist meadows, &c.; and changing into a cylindric brownish chrysalis, with a roundish or slightly pointed extremity, from which within a month proceeds the perfect insect.

AUTUMNALIS. With glassy wings, and brown abdomen, and a whitish three-fold spot. Found in Europe.

CALANS. With green eyes, a white line on the back, and red antennæ. Found in South America.

TARANDINUS. With green eyes and feet, and the segments of the abdomen yellowish at the margin. Found in the north of Europe.

EXÆSTUANS. With green eyes, the segments of the abdomen white at the margin, and whitish legs. Found in Surinam.

FERVENS. With green eyes, yellow abdomen and antennæ, and brown head and thorax. Found in South America.

MEXICANUS. With a livid body, green antennæ, and greenish wings. Found in Surinam.

RUSTICUS. Cinereous, with grey eyes, and two black points in the front. An European insect.

BROMIUS. With a purple fascia about the eyes, and cinereous body. Found in Germany, and the northern part of Europe.

OCCIDENTALIS. With eyes having double brown fasciæ, a brown body, and the abdomen marked with three yellow lines. Found in Surinam.

TROPICUS. With eyes having triple purplish fasciæ, and the sides of the abdomen ferruginous. An European insect of a brown colour, smaller than T. bovinus, and less common, troublesome to cattle, and especially to horses.

ANTARCTICUS. With eyes like the former, black abdomen, and segments with whitish margins. Found rarely in Norway.

PLUVIALIS. With eyes waved with four-fold fasciæ, and brown-speckled wings. This is an European species, very troublesome with us in the latter part of summer, fastening on on the legs, hands, &c., and peculiarly teasing on the approach of rain.

Cæcutiens. With eyes that are of a very lucid green, marbled with black spots and streaks, and wings marked by large black bands or patches. This is an European insect, not uncommon with us in autumn.

Lugubris. With black eyes and body, brown wings, and white spots. Found in Europe.

Morio. With eyes and body wholly black, and glassy wings. An inhabitant of Barbary.

Lineatus. With greenish eyes, lineated thorax, obscurely blueish abdomen, and red antennæ. Found in America.

Fasciatus. With green eyes, brown body, and wings having a brown fascia. Found in Sierra Leone.

Atratus. With blueish abdomen, and black wings. An American insect.

Pellucens. Black, with fasciated eyes; the first segment of the abdomen blueish, and whitish legs. A German species.

Ruficornis. With fasciated eyes, white wings, brown side, and red antennæ. Found in America.

Paganus. With green eyes, three yellow fasciæ, and both sides of the abdomen ferruginously spotted. Found in England.

Italicus. Cinereous, with brown eyes; obscure abdomen, with the base palely pellucid. Found in Italy.

Cayennensis. With eyes brown before, and behind green; black abdomen; the second and third segments yellow, the rest white at the margin. This and the next are found in Cayenne.

Punctatus. Cinereous, with testaceous eyes, and white wings speckled with black.

Inanis. Cinereous, like the former, with brown eyes, and pellucid abdomen, having a brown apex.

Borealis. With eyes having three purplish fasciæ, black abdomen, and the margins of the segments whitish. Found rarely in Norway.

Longicornis. With spotted eyes, wings half brown, a white spot, and longer antennæ. Found in Brasil.

Striatus. Cinereous, with brown abdomen, and three abbreviated white lines. A Chinese species.

Bidentatus. Ferruginous; the abdomen having on each side two yellow spots, and the scutellum bidentated. Found in Austria.

Bispinosus. Brown, ferruginous, abdomen black at the base, and scutellum bispinose. Found in Gottingen.

Mærens. Varied with whitish and black; black eyes; white wings; side and fascia black. Found in Cayenne.

Griseus. Black, with greyish thorax; the second segment of the abdomen having on the hind part a cinereous fascia, the fourth, fifth, and sixth being on both sides cinereous, and the wings ferruginous.

Albipes. With eyes having four fasciæ; the abdomen with a black ring, and the legs white. Found in Bulgaria.

Maritimus. Cinereous, with glassy wings; margin and broad fascia black. Found in Carniola, Austria, and France.

TABARA, in *Geography*, a town of Spain, in the province of Leon; 14 miles N.W. of Zamora.

TABARABA, a river of Mexico, in the province of Veragua, which runs into the Pacific ocean, N. lat. 8° 40'. W. long. 82° 48'.

TABARCA, a town of Africa, in the kingdom of Tunis, situated on the north coast, at the mouth of the Zaine, of which little but ruins are existing, and a small garrison; 60 miles N.W. of Tunis.

Tabarca, or *Tabaquer*, an island in the Mediterranean, near the coast of Africa, at the mouth of the river Zaine, which separates Algiers from Tunis. The Lomellines, a noble Genoese family, have been in possession of the little island that lies before Tabarca, at the mouth of the Zaine, ever since the time of the famous Andrea Doria, to whom the Tunisceans gave it, with the solemn consent of the grand seignior, in ransom for one of their princes, whom Andrea had taken captive. This place is defended by a small castle, well armed, and in good order, and protected the coral fishery which was carried on in these seas. But, in the year 1740, that monster of princes, Aly Bashaw, the reigning king of Tunis, took it by treachery from the Genoese; and, contrary to all justice and the right of nations, put some of them to the sword; and the rest, in number 300 or 400, he carried into captivity. N. lat. 36° 55'. E. long. 9° 8'.

Tabarca. See Plana.

TABARD, or Taberd, derived from the low Latin, *tabarda*, denotes a short jacket or coat, open on both sides, with a square collar and hanging sleeves. From the wearing of this garment, some of those on the foundation of Queen's college, Oxford, are called *Taberdarii*.

From an inn in Southwark, whose sign was the *Tabard*, afterwards changed to the *Talbot*, Chaucer and his companions set out on a pilgrimage to the shrine of Becket at Canterbury; on which was founded his Canterbury Tales.

TABAREK, a town of Persia, in the province of Irak; 8 miles S.E. of Casbin.

TABARIA, or Taberayan, or *Tabarieh*, anciently *Tiberias*, a town of Palestine, situated on the west bank of a lake, called in the scriptures the "Lake of Gennesareth," and the "Sea of Tiberias," and at the foot of a high and sharp mountain; surrounded with walls, except towards the water. This town was built by Herod Antipas, to the honour of Tiberius, and was long the capital of Galilee, and after the destruction of Jerusalem, for some time the residence of the high priest. This city Herod was obliged to people mostly with Galileans and strangers, because it being built on a ground which was full of sepulchres, the going over which pollutes the Jews seven whole days, he could scarcely get any of that nation to settle there, though he endowed it with considerable privileges, and gave its inhabitants the greatest encouragement, *viz.* lands to some, houses to others, to take off their qualms of conscience about treading on dead bodies. At the destruction of Jerusalem the town submitted to Vespasian, and received the Jews which escaped. In the year 1100, it was taken by the Christians under Godfrey; but in 1116, it was retaken by the Saracens, through the treachery of Raymond III. count of Thoulouse. During the time of Christianity it was the see of a bishop, suffragan of Nazareth. Near it are some warm baths. The Christians have a church here, and the Jews a seminary. In 1759, it suffered much by an earthquake; 16 miles S. of Safad.

TABAS, a town of Asiatic Turkey, in Natolia; 34 miles S. of Dignizlu.

Tabas, the ancient *Tabienne*, a town of Persia, in the province of Chorasan, situated in a range of hills, 337 miles from Herat and 150 from Yezd. It contains a population of about 20,000 persons, and carries on a trifling trade with Herat and Yezd.

TABASCO, a province of Mexico, bounded on the north by the gulf of Mexico, on the east by Yucatan, on the south by Chiapa, and on the west by Guaxaca, about 100 miles in length, but narrow. The climate is not reckoned healthy, nor is the soil remarkable for its fertility.

The inhabitants, however, have good farms well-ftocked with cattle, which fell to good advantage. They have alfo great plenty of Indian corn and cocoa-nuts, which they fend to Vera Cruz. Moft of the country is flat and moift, has many marfhes and lakes well-ftocked with fifh. It rains nine months out of the twelve, fo that the air is exceffively damp; and in February, March, and April, remarkably hot, when infinite fwarms of gnats and other infects are produced. The coaft, from the beginning of September to the end of March, is fubject to tempeftuous northerly winds, which render failing dangerous during that feafon. The Spaniards brought hither vines, lemon, orange, and fig trees, which all thrive here very well. Here are large thickets of mangroves and bamboos, and woods of cedar, Brafil wood, &c. frequented by lions, tigers, wild bears, and deer. They have a great number of rabbits, apes, and fquirrels, with the common fruits of America; and three or four harvefts of maize in a year; befides rice, barley, and all forts of garden-herbs, different fpecies of European fowls, and others to us unknown. This province was accuftomed to pay its tribute to the ancient kings of Mexico in chocolate.

Tabasco, a river of North America, which runs into the bay of Campeachy, N. lat. 18° 15′. W. long. 93° 40′. On the banks of this river are fome of the largeft cabbage and cotton trees fuppofed in the world.

Tabasco, a town of Mexico, and capital of a province, to which it gives name, called alfo by the Spaniards "Nueftra Sennora de la Vittoria," from a great victory obtained here by Cortez, on his firft arrival. It ftands on an ifland, at the mouth of the river Grijalva, which divides itfelf near the fea into two branches, of which the weftern falls into the river Tabafco, which rifes in the mountains of Chiapa; and the other continues its courfe till within four leagues of the fea, where it fubdivides, and feparates the ifland above mentioned from the continent. Near it are plains, which abound with cattle and other animals, particularly the mountain-cow, fo called from its refembling that creature, and feeding on a fort of mofs found on the trees near great rivers. The ifland of Tabafco, on which the town of that name is built, is about 12 leagues long and 2½ broad. The town is not very large, but well-built, and confiderably enriched by a conftant refort of merchants and tradefmen at Chriftmas. N. lat. 18° 20′. W. long. 93° 46′.

TABASHEER, in *Medicine*, a drug of high repute in many parts of the Eaft, the knowledge of which has been communicated to the weftern world by the works of the Indian phyficians, by all of whom it is mentioned as an important article in the Materia Medica; and it is ftill confidered to be adminiftered under this and other names in Turkey and in various parts of India. The Arabian medical writers generally agree, that the Tabafheer is a production of the Indian reed. The genuine Tabafheer, according to Dr. Patrick Ruffell (Phil. Tranf. vol. lxxx. p. 275.) is undoubtedly a production of the Arundo Bambos of Linnæus; and the bamboo in which it is found, is vulgarly called the female bamboo, and diftinguifhed by the largenefs of its cavity from the male, employed for fpears and lances. The bamboo, however, yields this drug only in a fmall quantity, varying according to the foil or fituation in which the bamboo grows. For a farther account of it, we refer to the Phil. Tranf. ubi fupra. See Arundo.

TABASO, in *Ancient Geography*, a town of India, on this fide of the Ganges, between Bynda and Pfeudofiomus. Ptol.

TABASSERAN, in *Geography*, a diftrict of the tract of land fituated along the Cafpian fea, between the rivers Terek and Kur, and one of the divifions of the province of Dagheftan, dependent on Perfia. It lies between the Durbach and Rubas, towards their fources; extending about fix German miles inland from above the territory of Derbent as far as the higheft ridge of the Lefgian mountains, which is here very rocky and woody. Reineggs calculates the ftrength of the different tribes inhabiting Tabafferan, who, befides the Tartarian, fpeak another language peculiar to themfelves, at about 10,000 families: and, according to him, the reigning family have held the fovereignty over the country for more than 600 years. See Reineggs' General Hiftorico-topographical Defcription of Caucafus, &c. The town of Tabafferan is the refidence of a prince, and the centre of the trade carried on between Perfia and Dagheftan.

TABAXIR, in *Botany*, pronounced *Tabafheer*, appears to be a Perfian name, appropriated to the Bamboo, *Arundo Bambos* of Linnæus, or rather originally to an internal fecretion of the ftem of that plant. This is at firft of a milky afpect, but fubfequently concretes into a folid form, and very hard fubftance, compared to fugar, but more like fand or pebbles, being indeed a real filiceous earth. The difcovery of its true nature was made by Mr. Macie, now Smithfon, and publifhed in the Philofophical Tranfactions for 1791, vol. viii. p. 368. See Arundo, and Tabasheer.

TABAZET, a word ufed by fome writers to exprefs highly-refined fugar.

TABBAJEE, in *Geography*, a town of Africa, in Neola. S. lat. 13° 32′. W. long. 11° 8′.

TABBAY, one of the Weftern iflands of Scotland, near the eaft coaft of Skye. N. lat. 57° 16′. W. long. 5° 51′.

TABBY, a mixture of ftone and mortar, which becomes as hard as a rock, ufed in Morocco. The walls of the city are formed of this fubftance.

Tabby, in *Commerce*, a kind of thick filk, ufually watered. It is manufactured like the common taffety, excepting that it is ftronger and thicker both in the woof and warp.

The watering is given it by means of a calender, the rolls of which are of iron, copper, or wood, which, bearing unequally on the ftuff, render the furface of it unequal, fo as to reflect the rays of light differently.

TABBYING, or Watering, the paffing a ftuff under a calender, to make the reprefentation of waves on it as on a tabby. It is ufual to tabby mohairs, ribbands, &c. Tabbying is performed without the addition of any water, or dye; and furnifhes the modern philofophers with a ftrong proof that colours are only appearances.

TABE, in *Geography*, a river of Pruffia, proceeding from the Niemen, and running into the Curifch-Haff.

TABEA, in *Ancient Geography*, a town of Afia Minor, in the Greater Phrygia. Strabo.

TABEIPILLY, in *Geography*, a town of Hindooftan, in Myfore; 25 miles W.N.W. of Bangalore.

TABELLA, or Tablet, *Tabularium*, in *Pharmacy*, a folid kind of electuary, or confection, made of dry ingredients, ufually with fugar, and formed into little flat morfules, or fquares, more ufually called *lozenges*, and fometimes *morfelli*, *troches*, &c.

Powders, fruits, falts, &c. are diffolved with fugar, and made into *tabulæ*, as thofe of the juice of liquorice for colds, &c.

We have *cordial*, *ftomachic*, *aperitive*, and *hepatic* tablets. Jellies and broths are fometimes reduced into a fort of tablets, to be carried in the pocket, and called *pocket-foup*. *Tabellæ manus Chrifti* are made of fugar of rofes pearled. *Tabellæ magnanimitatis* are a fort taken by feeble old men, when

when matched with young wives, to affift them in the affair of generation.

Tabellæ *Votivæ*, in *Antiquity*, a name given to certain tablets, which were hung up in the temples: for, according to an ancient cuftom, which prevailed all over Greece, fuch as recovered from any diftemper ufed to write in a tablet the nature and fymptoms of their refpective maladies, and the remedies which had been moft fuccefsful. Thefe tablets Hippocrates is faid to have copied and followed when he firft began to practife: and, if we believe Pliny (lib. vii. c. 37.), he learned from thefe the firft rudiments of phyfic.

A tablet of this nature was difcovered at Rome, not many years ago, among the ruins of the ancient temple of Æfculapius, with this infcription in Greek. Julianus being afflicted with vomiting of blood, and abandoned by men, the gods haftened to his relief, and having nourifhed him for the fpace of three days with honey, reftored him to his health: for which favour he came to return them thanks in the prefence of the people. Tables of a fimilar kind, under the fame denomination, were hung up in the temples by thofe who had efcaped fhipwreck, &c.

TABELLIO, Tabularius, in the Roman law, a *fcrivener;* a kind of officer often confounded with the notary, *notarius:* yet the two differed in this; that the notaries only drew up and kept the minutes of acts and inftruments on paper, and in notes, or fhort-hand; whereas the tabelliones delivered them engroffed fair, on parchment, in the full executory form. The fame alfo put the feals to contracts, and rendered them authentic.

The domeftic clerks of thefe tabelliones, who at firft wrote under them, in procefs of time came to be called *notaries*.

Pafquier obferves, that the tabelliones at Rome were public flaves, appointed for the keeping of contracts made between private perfons. According to Loyfeau, a contract written by a notary was not perfect, or obligatory, till the tabellio had written it fair: after which, the parties fubfcribed it, *i. e.* they wrote at bottom, that they approved the contents; for fignatures were not then in ufe. See Signature.

"Quoniam tabellionum ufus in regno Angliæ non habetur, propter quod magis ad figilla authentica credi eft neceffe, ut eorum copia facilius habeatur, ftatuimus, ut figillum habeant non folum archiepifcopi, et epifcopi, fed eorum officiales."

TABENNE, in *Geography*, an ifland in the river Nile, between Dendera and the ruins of the ancient Thebes; famous on account of the retreat of the monk Pacomius and feveral hundred of his brethren.

TABENUS Campus, in *Ancient Geography*, a country of Afia Minor, on the confines of Phrygia and Myfia. Strabo.

TABERG, in *Geography*, a town of Sweden, in the province of Smaland, fituated on a mountain of the fame name, which abounds in iron-ore; 8 miles S. of Jonkioping.

TABERISTAN. See Mazanderan.

TABERN, in *Rural Economy*, a term fometimes applied to a cellar, or other fimilar excavation, for the containing of liquor of the domeftic kind.

TABERNA Meritoria, among the Romans, Mars' hofpital, or a place where difabled foldiers were maintained at the charge of the government.

TABERNACLE, Tabernaculum, *q. d. a tent;* among the Jews, was a kind of moveable chapel, fo contrived as to be taken to pieces, and put together at pleafure, for the convenience of carrying it from place to place, during the migration of the Ifraelites in the wildernefs for forty years. It was erected by Mofes, in confequence of the exprefs command of God, partly to be a palace of his prefence as the king of Ifrael, and partly to be the medium of the moft folemn public worfhip, which the people were to pay to him. It was erected on the firft day of the firft month of the fecond year after the Ifraelites' exodus from Egypt. Exod. xl. 2. 17. 26. 29. 34, 35.

The tabernacle was of a rectangular figure, thirty cubits long, ten broad, and ten high; or, according to Dr. Cumberland's reduction to Englifh meafure, fifty-five feet long, eighteen broad, and eighteen high. The two fides and one end were compofed of broad boards, ftanding upright; each board being about two feet nine inches broad, faftened at the bottom by two tenons in each board, fitted into two mortifes on the foundation; at the top by links or hafps, and on the fides by five wooden bars, which run through rings or ftaples in each of the boards. Each fide confifted of twenty of thefe boards, and the end of eight. Both the boards and bars were overlaid with gold; and the rings and hafps were of the fame metal. The foundation, on which they ftood, confifted of folid blocks of filver, two under each board; each of which was about fixteen inches long, and weighing a talent, or about an hundred weight. The number of thefe blocks was about an hundred; ninety-fix of which were laid under the forty-eight boards, and the other four were the bafes of the columns that fupported the veil or curtain, which divided the infide of the tabernacle into two rooms. Hence fome have derived the ancient fafhion of fetting porphyry columns on bafes of white marble.

The tabernacle had four different coverings, or carpets, thrown over one another. The firft and loweft was made of fine linen, richly embroidered with figures of cherubims, in fhades of blue, purple, and fcarlet: and confifted of ten breadths, which were joined together with blue loops and clafps of gold. The next over this was made of a fort of mohair, the breadths of which were joined with clafps of brafs. The third carpet was made of ram's fkin dyed red; and the uppermoft of all was made of *tachafh*, *i. e.* as has been generally fuppofed, badger's fkins.

The eaft end of the tabernacle had no boards, but was fheltered with a fine embroidered curtain, hung upon five pillars of Shittim wood, overlaid with gold, and fuppofed by Philo to touch the ground.

The infide of the tabernacle was divided into two rooms, by means of a veil or curtain, hung upon four pillars; the veil was curioufly manufactured of the richeft ftuff, and adorned with cherubims and other ornaments, embroidered upon it. By this veil the tabernacle was divided, and learned writers have reafonably conjectured, in the fame proportion with the temple, afterwards built according to its model: that is, two-thirds of the whole length were allotted to the firft room, and one-third to the fecond; fo that the room beyond the veil, which was called the *holy of holies*, was exactly fquare, being ten cubits each way: and the firft room, called the *fanctuary*, was twice as long as broad.

Round the tabernacle there was a fpacious court, one hundred cubits long, and fifty broad, furrounded with pillars fet in bafes of brafs, and filleted with filver, at the diftance of five cubits from one another. The chief things in this court were the altar of burnt-offering, and the brazen laver. See Exod. ch. xxviii. and ch. xxx.

In the fanctuary, or firft room of the tabernacle, were the altar of incenfe (Exod. xxx. 1—10.), the golden candleftick (Exod. xxv. 31, &c.) valued by Cumberland at upwards of five thoufand and feventy-fix pounds fterling, and the table of fhew-bread, defcribed Exod. xxv. 23—30. Within the fecond veil, in the holy of holies, was the ark of teftimony, testimony, and its lid or cover, called the *mercy-seat*, described Exod. xxv. 10—21. See Ark *of the Covenant*.

The learned Spencer (De Leg. Hebr. diss. i.) suggests, that Moses projected the tabernacle, with its furniture and appurtenances, after the fashion of a similar structure, which he had observed in Egypt, and which was in use among other nations; or, at least, that God directed it to be made with a view of indulging the Israelites in a compliance with their customs and modes of worship, so far as there was nothing in them really sinful: and he alleges evidence of such portable temples among the heathens, in which they deposited the most valuable sacred or religious utensils. But it has been replied to this conjecture, that it is not probable. But, on the other hand, it should seem more likely, that the heathens took these things from the Jews, who derived the whole of their religion from God, than that the Jews, or rather that God should take them from the heathens: and, besides, the Jewish tabernacle was ordered to be directly the reverse of the heathen tabernacles, both in its form, which was capable of being taken to pieces, whereas theirs was carried about entire; and in its situation, which was accommodated to the people's worshipping towards the West; whereas it was the general practice of the heathens to worship with their faces towards the East. (See Ezek. viii. 16. and Virgil Æneid. xii. l. 172—174.) The value of the gold and silver only, used for the work of the tabernacle (Exod. xxxviii. 24, 25.), amounted, according to bishop Cumberland's reduction of Jewish talents and shekels to English coin, to upwards of one hundred and eighty-two thousand five hundred and sixty-eight pounds. Jennings's Jewish Ant. vol. ii. b. 2. c. 1. Anc. Univ. Hist. vol. i. part ii. p. 651, &c. folio.

We have also an account of two other tabernacles before the building of Solomon's temple, besides that above described. One of these was erected by Moses for himself; in which he gave audience, heard causes, and inquired of God; and, perhaps, also the public offices of religious worship were performed in it for some time; whence it was called the *tabernacle of the congregation* (Exod. xxxiii. 7.) The other was that which David erected in his own city, for the reception of the ark, when he received it from the house of Obededom. 2 Sam. vi. 17. 1 Chron. xvi. 1.

Tabernacles, *Feast of.* See Scenopegia.

Tabernacle is also used, of late, for a place of religious worship, appropriated to the use of those that are called Methodists.

Tabernacle, in *Architecture*, an ornamented chest, generally made of precious wood, metal, or marble, and placed upon Roman Catholic altars, as a receptacle for the ciborium and pyxis.

Tabernacle, in *Pointed Architecture*, a niche surmounted by a canopy of tracery work.

TABERNÆMONTANA, in *Botany*, was so called by Plumier, in memory of one of the fathers of modern botany, James Theodore, surnamed Tabernæmontanus, that being the latinized appellation of Berg Zabern, a town in the district of Deux-Ponts, where he was born. He died at Heidelberg in 1590, having published a ponderous and learned German *Kreuterbuch*, or Herbal, the wooden figures of which were subsequently printed by themselves, under the title of *Tabernæmontani Eicones*, in long quarto.—Linn. Gen. 118. Schreb. 165. Willd. Sp. Pl. v. 1. 1244. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 71. Swartz Ind. Occ. 535. Brown Prodr. Nov. Holl. v. 1. 467. Plum. Gen. 18. t. 30. Juss. 145. Lamarck Dict. v. 7. 527. Illustr. t. 170.—Class and order, *Pentandria Monogynia.* Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juss. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, small, in five acute converging segments, permanent. *Cor.* of one petal, salver-shaped; tube cylindrical, many times longer than the calyx, tumid at the base; limb horizontal, in five deep, oblong, obtuse, obliquely twisted segments, scarcely so long as the tube. Nectary of five cloven glands, surrounding the germen. *Stam.* Filaments five, small, inserted into the middle of the tube; anthers erect, arrow-shaped, converging, generally enclosed in the tube. *Pist.* Germens two, simple; style solitary, central, thread-shaped; stigma oblong, capitate, cloven, dilated at the base. *Peric.* Follicles two, horizontally spreading, tumid, pointed, each of one cell and one valve. *Seeds* numerous, ovate-oblong, obtuse, rugged, imbricated, imbedded in pulp.

Eff. Ch. Corolla salver-shaped; its limb obliquely twisted, in five deep segments. Anthers arrow-shaped, within the tube. Follicles two, tumid, divaricated. Seeds imbedded in pulp.

"A genus of shrubs, with opposite simple *leaves*. *Stipulas* between the footstalks, connected below, loose above. *Cymes* somewhat forked. *Calyx* permanent."—*Brown*, by whose remarks we have profited in some of the above characters. The species are all of tropical origin, and contain more or less of an acrid milky juice. The *flowers* are white or yellow, mostly fragrant and ornamental. Two North American herbaceous species, with alternate *leaves*, and blueish *flowers*, one of them, *T. Amsonia* of Linnæus, having a funnel-shaped *corolla*, and no pulp in the *fruit*, are well separated by Walter, Michaux, and other late writers, under the generic name of *Amsonia*.

1. T. *citrifolia*. Citron-leaved Tabernæmontana. Linn. Sp. Pl. 308. Willd. n. 1. Ait. n. 1. Jacq. Amer. 38. t. 175. f. 13. (T. lactescens, citri foliis undulatis; Plum. Ic. 246. t. 248. f. 2. T. n. 1; Browne Jam. 182.)—Leaves elliptical, pointed. Panicles axillary, stalked, cymose, of few flowers.—Native of the West Indies. Jacquin observed it in Martinico; Browne in Jamaica. The French in the former island call it *Bois laiteux*, from the milky juice with which every part abounds. The *stem* is shrubby, erect, branched, from five to eight feet high, smooth like every other part. *Leaves* opposite, stalked, from four to six inches long, and from two to three and a half broad, of a fine shining pellucid green; paler beneath; wavy at the edges; furnished with a central rib, and many strong, curved, nearly opposite, transverse ones. *Flowers* white, with a light agreeable scent, in opposite, axillary, somewhat umbellate, stalked *panicles*, about twice or thrice the length of the *footstalks*. Jacquin describes the *follicles* as always green, acute, filled with soft orange pulp, enveloping the brown rugged *seeds*.

2. T. *laurifolia*. Laurel-leaved Tabernæmontana. Linn. Sp. Pl. 308. Willd. n. 2. Ait. n. 2. Jacq. Amer. 39. (Nerium arboreum, folio latiore obtuso, flore luteo minore; Sloane Jam. v. 2. 62. t. 186. f. 2.)—Leaves elliptical, bluntish. Panicles axillary, nearly sessile, cymose, smooth, shorter than the footstalks.—Native of banks of rivers in Jamaica. We have seen no specimen. Sloane describes this as a *tree*, whose *trunk* is as thick as one's leg, fifteen feet high, with long crooked *branches*, leafy at the end. The *leaves* appear to be rather less pointed than in the former, and of a darker green. *Flowers* yellow, very sweet-scented; the tube of their *corolla* half an inch only in length; in the first species it measures full an inch. The *flower-stalks* are smooth, not scaly. Linnæus erroneously refers Browne's plant to this species, on the authority of Solander, who marked the original specimen *T. laurifolia*.

3. T. *squamosa*. Scaly-stalked Tabernæmontana.—Leaves ovate,

ovate, bluntifh. Panicles from the forks of the branches, cymofe, with fcaly flower-ftalks.—Gathered by Commerfon, in the ifland of Mauritius. The *branches* are round, forked, rough with minute white tubercles. *Leaves* three or four inches long, and two or three broad, very fmooth, opaque, flightly wavy, with one rib, and many tranfverfe veins, on fmooth *footftalks* three quarters of an inch in length. *Panicles* in pairs from the forks of the branches, each cloven and fomewhat fubdivided, divaricated, of about ten apparently white or yellowifh *flowers;* their partial ftalks clothed with numerous, roundifh, imbricated *bracteas*, gradually larger upward, which we have not feen in any other fpecies. Tube of the *corolla* above an inch long; limb fomewhat fhorter, rough with glandular hairs, on the upper fide, about the centre. We cannot refer this to any defcribed fpecies, even in Lamarck.

4. T. *odorata*. Fragrant Tabernæmontana. "Vahl Eclog. Amer. fafc. 2. 22." Poiret in Lamarck Dict. n. 17. (Cameraria Tamaquarina; Aubl. Guian. 260. t. 102. C. lutea; Willd. Sp. Pl. v. 1. 1244.)—Leaves elliptic-lanceolate, pointed, fmooth and fhining, on fhort ftalks. Umbels from the forks of the *branches*, of about four flowers. Corolla flightly downy externally.—Found by Aublet, on the banks of rivers in Guiana, flowering in May. Vahl was induced by the remarks of Von Rohr to remove this plant hither. (See CAMERARIA, n. 3.) The *leaves* in Aublet's fpecimen are highly polifhed, about four inches long, and above one wide. *Partial flower-ftalks* above an inch long, fmooth, naked, fimple. *Flowers* yellow, with a fweet pleafant fmell; their limb longer than the tube, which meafures about three quarters of an inch.

5. T. *echinata*. Prickly-fruited Tabernæmontana. Aubl. Guian. 263. t. 103. Willd. n. 3.—Leaves on fhort ftalks, elliptic-lanceolate, pointed; fomewhat downy beneath. Umbels denfe, many-flowered, from the forks of the branches. Follicles muricated.—Native of Guiana, flowering in Auguft. The *ftems* are numerous, knotty, four or five feet high. *Leaves* five or fix inches long, and two broad, fmooth and green above; clothed with a flight whitifh down beneath. *Flowers* fmall, yellowifh; their tube dotted with red. The *follicles* are ovate, deflexed, an inch long, covered with crowded foft tubercles. *Aublet*. We have feen no fpecimen. The author mentions no pulp in the feed-veffels.

6. T. *grandiflora*. Large-flowered Tabernæmontana. Linn. Mant. 53. Willd. n. 4. Jacq. Amer. 40. t. 31. Lamarck f. 2.—Leaves ovato-lanceolate, acute. Stem forked. Segments of the calyx unequal, very lax.—Found by Jacquin in woods at Carthagena, but rarely, flowering from July to September. A *fhrub* eight feet high, with forked divaricated, leafy *branches*. *Leaves* three or four inches long, tapering at each end, fmooth and fhining, on fhort ftalks. *Flowers* large, inodorous, two or three together on a ftalk, at the fide of each uppermoft fork of the branches. *Calyx* divided into five whitifh, flat, ovate fegments, very unequal in length, and loofely fpreading, ill agreeing with the ufual character of the genus; but the *fruit*, which is in this cafe much more important, is that of a *Tabernæmontana*. Its furface is fmooth and green. *Jacquin*.

7. T. *cymofa*. Cymofe Tabernæmontana. Linn. Mant. 53. Willd. n. 5. Jacq. Amer. 39. t. 181. f. 14.—Leaves ovato-lanceolate, acute. Cymes axillary, many-flowered. Stamens in the bafe of the tube. Follicles coloured, recurved, very obtufe.—Frequent in woods and bufhy places at Carthagena, flowering in July and Auguft.—An elegant *fhrub*, from fix to fifteen feet in height. *Leaves* flightly wavy, half a foot long. *Cymes* large and handfome, convex, denfe, each of about forty dirty-white or reddifh fcentlefs *flowers*, the fize of the firft or fecond fpecies. *Follicles* large, very blunt, red, fpotted with brown; one of them generally abortive.

8. T. *obtufa*. Blunt-leaved Tabernæmontana.—Leaves obovate, obtufe. Panicles terminal, aggregate, forked, level-topped, many-flowered.—Gathered by Commerfon, in the ifle of Bourbon. The *leaves* are three or four inches long, flat, fmooth and fhining, with fine clofe tranfverfe veins; very obtufe, and often emarginate at the extremity; tapering at the bafe into a *footftalk* about an inch in length. *Panicles* three, in our fpecimen, at the end of the branch, on ftalks, nearly equal to the adjoining leaves, repeatedly forked, confifting of numerous yellow *flowers*, fmaller than in moft of the foregoing. We know nothing of the *fruit*.

9. T. *amygdalifolia*. Almond-leaved Tabernæmontana. Jacq. Amer. 39. t. 181. f. 15.—Leaves oval-lanceolate, acute, fmooth and fhining. Anthers projecting out of the tube.—Frequent in woods and thickets at Carthagena. A branching milky *fhrub*, fix feet high. *Leaves* flat, highly polifhed. *Flowers* but few on a ftalk, white, powerfully fcented. *Filaments* in the upper part of the tube, fo that their *anthers* project above the orifice, in the form of a pointed cone. *Follicles* pointed, green and fhining, refembling thofe of *T. citrifolia*, but fcarcely half, or one-third, fo large; their pulp orange. When this fhrub begins to flower, it is moftly without leaves. *Jacquin*.

10. T. *difcolor*. Two-coloured Tabernæmontana. Swartz Ind. Occ. 535. Willd. n. 7. Poiret in Lamarck n. 3.—Leaves elliptic-lanceolate, fmooth, tapering at each end. Stalks two-flowered, terminal, thread-fhaped.—Native of bufhy places in Jamaica. *Swartz*. The *ftem* is fix feet high, with fmooth, oppofite *branches*, quadrangular when young, leafy at the ends. *Leaves* two or three inches long, ftalked; dark green above; pale beneath. *Footftalks* bordered, about half an inch in length. *Flower-ftalks* very flender, fmooth, one and a half or two inches long, divided rather below the middle, and bearing two whitifh or yellowifh *flowers*, with one or two ftraggling *bracteas*. Tube of the *corolla* half an inch long; limb fhorter. The *inflorefcence* is terminal in Dr. Swartz's own fpecimen, as he defcribes it; and yet it is called axillary in the fpecific character; perhaps becaufe it is, as in other fpecies, clofely attended by leaves.

11. T. *multiflora*. Many-flowered Tabernæmontana.—Leaves ellliptic-lanceolate, fmooth, pointed. Stalks lateral and terminal, many-flowered, thread-fhaped, corymbofe.—Gathered by the late Mr. Chriftopher Smith, in the ifle of Banda. This much refembles the laft in general habit, though the leaves are fomewhat larger, with an oblong obtufe point, and more reticulated beneath. The *flowers* too are rather larger, and differ effentially in compofing ample, repeatedly fubdivided, corymbofe *panicles*, about the ends of the branches, accompanied here and there by very minute, fcattered, fcale-like *bracteas*. The *corolla* feems flefh-coloured in the dried fpecimen, with long flender fegments; its tube an inch long.

12. T. *undulata*. Wave-leaved Tabernæmontana. "Vahl Eclog. Amer. fafc. 2. 20." Poiret in Lamarck n. 5.—Leaves lanceolate-elliptical, pointed, undulated, fmooth, nearly feffile. Branches forked. Flowers fomewhat cymofe. Follicles fmooth.—Native of South America, and the ifland of Trinidad. The *leaves* are five or fix inches in length, tipped with a long point; contracted at the bafe; bright green above; pale and yellowifh beneath. *Flowers* three or four together, in fmall, folitary, axillary

ac

or terminal, cymofe *clufters*. *Tube* an inch long. *Follicles* an inch and a half in length, reflexed, even, rather pointed. We have no knowledge of this fpecies, or of the two following, but from the authors quoted.

13. T. *heterophylla*. Various-leaved Tabernæmontana. "Vahl Eclog. Amer. fafc. 2. 22." Poiret in Lam. n. 7. —"Leaves elliptic-lanceolate; partly fomewhat heart-fhaped, pointed, rather wavy, fmooth. Branches forked. Flowers racemofe."—Native of Cayenne. The *leaves* immediately under the forks of the *branches* are lanceolate, three or four inches long, and moderately ftalked: the reft are feffile, much fhorter, and almoft heart-fhaped. The *flower-ftalks* are folitary, in the forks as well as at the fummits of the branches, fmooth and flender, each bearing from five to feven *flowers*, whofe *corolla* is half an inch long, with fome filky hairs about the mouth. *Vahl*.

14. T. *Pandacaqui*. Pandacaqui Tabernæmontana. Poiret in Lam. n. 8. (Pandacaqui; Sonnerat Nouv. Guin. 49. t. 19.)—Leaves elliptic-lanceolate, fmooth, with a blunt point. Panicles axillary, corymbofe, many-flowered, half as long as the leaves.—Native of the Philippine iflands, where it was found by Sonnerat. He fays the natives of the ifle of Luçon apply the milk of this fhrub to their wounds. The *ftem* is four or five feet high. *Leaves* two or three inches long, fmooth, even, and quite entire, on fhort ftalks. *Flowers* white; their tube an inch long; limb fcarcely half that length. He did not fee the fruit. The younger Linnæus moft unaccountably referred this plant, in the *Supplement*, to *Chiococca racemofa*, with which it accords as little as can well be. It is now, on Juffieu's authority, removed to the prefent genus; and as he fpeaks decifively on the fubject, *Gen. Pl.* 145, we prefume he was acquainted with the *follicles*.

15. T. *perficariæfolia*. Knot-grafs-leaved Tabernæmontana. Jacq. Coll. v. 4. 139. Ic. Rar. t. 320. Willd. n. 8. Poiret in Lam. n. 9.—Leaves lanceolate, fmooth, tapering at each end. Corymbs from the forks of the branches, in pairs, divided.—Native of the ifland of Mauritius. The *ftem* is fhrubby, erect, flender, repeatedly branched. *Leaves* four or five inches long, more or lefs tapering at the end, dark green, fhining, with a white rib and veins; their margin flightly undulated. *Footftalks* hardly an inch in length. *Flowers* yellowifh-white; their tube and limb each meafuring nearly an inch. We have from Commerfon a fpecimen collected in the ifland above-mentioned, which anfwers to Jacquin's defcription and figure, except the *leaves* being lefs elongated; but it can fcarcely be more than a variety. Another from the ifle of Bourbon would appear to be the fame plant, but its *inflorefcence* is lateral, from the bofoms of the leaves, not from the forks of the branches. Still we dare not defcribe this as a feparate fpecies.

16. T. *neriifolia*. Oleander-leaved Tabernæmontana. "Vahl Eclog. Amer. fafc. 2. 21." Poiret in Lam. n. 10. —Leaves lanceolate, fmooth, veinlefs, acute at each end. Clufters axillary, folitary, of few flowers. Limb of the corolla downy about the mouth. Stamens prominent.—Native of Porto-Rico. Allied to the laft. *Leaves* two or three inches long, fcarcely wavy at the margin; paler beneath; marked with a few fine lateral diftant ribs. *Footftalks* half an inch long. *Clufters* twice the length of the footftalks, each of three or four *flowers*, with a fmall, linear, deciduous *bractea* to each of their fhort partial ftalks. *Corolla* about half an inch long, with wedge-fhaped fegments, a little downy on their inner fide towards the bafe. The *ftamens*, (we prefume the *anthers* only,) project out of the tube. *Vahl*. The fpecific character given by this author being quite infufficient, we have ventured to enlarge it from his defcription, without feeing the plant.

17. T. *mauritiana*. Brittle Tabernæmontana. Poiret in Lam. n. 11.—Leaves ovate, obtufe, membranous; fcarcely downy beneath. Clufters axillary, of few flowers. Branches with brittle joints.—Gathered by Commerfon in the ifland of Mauritius, and by Sonnerat in the Eaft Indies. We find no fpecimen in our collection anfwerable to Poiret's defcription. He fays the plant is remarkable for its woody, cylindrical, ftriated, fmooth *branches* being jointed at the infertion of the leaves, and very brittle at thofe joints; bearing very fmall, oval, whitifh tubercles. *Leaves* thin, membranous, oval, obtufe, rounded at each end, entire, a little wavy at the edges, three or four inches long, and two and a half wide; green and rather fhining above; paler beneath, and very foft to the touch, but hardly pubefcent; having one ftout yellowifh mid-rib, with fine parallel tranfverfe veins. *Footftalks* thick, from fix to eight lines in length. *Clufters* fhort and nearly fimple, towards the ends of the branches, a little drooping. *Corolla* yellowifh-white; its tube three or four lines long; limb fhort and obtufe. *Fruit* not examined. *Poiret*.

18. T. *Sananho*. Sananho Tabernæmontana. "Ruiz and Pavon. Fl. Peruv. v. 2. 22. t. 144." Poiret in Lam. n. 12.—Leaves oblong, pointed, fmooth, fomewhat wavy. Corymbs with four or five branches. Bracteas inverfely heart-fhaped. Follicles roundifh-obovate, pointed.—Native of the extenfive forefts of Peru, flowering in Auguft and September. A *fhrub* twelve or fifteen feet high, or more, with fmooth cylindrical *branches*. *Leaves* fix or eight inches long, ftalked, fhining, fomewhat veiny. *Flowers* yellowifh-white, lateral and terminal, from fifteen to twenty in each corymb. *Corolla* large, with a very long angular tube. *Follicles* the fize of an apricot, of a dirty white, containing many brown ftriated *feeds* lodged in pulp. *Poiret*.

19. T. *arcuata*. Curve-fruited Tabernæmontana. "Ruiz and Pavon Fl. Peruv. v. 2. 22. t. 143." Poiret in Lam. n. 15.—Leaves obovate-oblong, pointed, entire, on fhort ftalks. Corymbs axillary, ternate, many-flowered. Follicles recurved.—Common in the great forefts of Peru, about Pozuzo, flowering in November and December. A *tree*, thirty or forty feet high, difcharging, when wounded, a very copious milky juice, which hardens in the air into a gum-refin of a brown hue. The *branches* form an ample leafy head, and are forked, pale, flightly compreffed. *Leaves* eight or nine inches long, on fhort, rather twifted, ftalks. *Flowers* yellowifh-white, with fmall, oval, pointed *bracteas*. *Follicles* oblong, thick, three inches in length, reddifh, full of red wrinkled *feeds*, in a crimfon pulp.

20. T. *fafciculata*. Clufter-flowered Tabernæmontana. Poiret in Lam. n. 14.—Leaves oval-lanceolate, pointed, fmooth, ribbed. Clufters axillary, fomewhat umbellate, many-flowered. Segments of the corolla linear. Branches jointed.—Native of Cayenne. Seen by Poiret in Lamarck's herbarium. He defcribes the *branches* as very brittle at the infertion of the *leaves*, which are ftalked, two or three inches long, an inch or more in width, rather obtufe, though pointed; fhining above, reddifh beneath. *Flowers* plentiful about the ends of the branches, in fhort, tufted, inclined *corymbs*, whofe ramifications are fomewhat forked and jointed, with little fhort deciduous *bracteas*. Tube of the *corolla* but two or three lines long; limb in five narrow, linear, obtufe fegments. *Fruit* unknown. If it fhould prove muricated, Poiret thinks this fpecies may not differ much from *T. echinata* of Aublet. See fpecies 5.

21. T. *coronaria*. Garland Tabernæmontana. Ait. n. 3. Roxburgh MSS. (Nerium coronarium; Willd. Sp. Pl. v. 1. 1236. Jacq. Ic. Rar. t. 52. N. divaricatum; Linn. Sp. Pl. 306. Willd. ibid. Jaſminum zeylanicum, folio oblongo, flore albo pleno odoratiſſimo; Burm. Zeyl. 129. t. 59. Nandi-ervatam; Rheede Hort. Malab. v. 2. 105. 107. t. 54, 55.)—Leaves elliptical, pointed, ſmooth. Stalks forked, corymboſe, from the forks of the branches, as long as the leaves.—Native of the Eaſt Indies, in a ſandy ſoil, flowering two or three times in a year. It is ſaid to have been introduced into the Engliſh ſtoves by the late Mr. Gordon, in 1770. This plant blooms at various ſeaſons, and is ornamental as well as fragrant, though inferior in both reſpects to the *Gardenia florida*, with which ſome of its ſynonyms have been confounded. Its genus is now more correctly determined in the ſecond edition of Hort. Kew. than in the firſt; but a faulty ſpecific character ſtill remains, taken (as it ſeems) from Jacquin's plate, which exhibits a weak imperfect ſpecimen. The *ſtem* is ſhrubby, buſhy, ſmooth, three or four feet high, with copious forked ſpreading *branches*. *Leaves* two or two and a half inches long, paler beneath, on channelled *footſtalks* half an inch in length. The *corymbs*, in various wild or cultivated, ſingle or double-flowered, ſpecimens before us, conſiſt of from three to ſix cream-coloured *flowers*, and are elevated on a ſtalk, an inch and a half long, always ſolitary, from the forks of the branches. The ſingle *corolla* has a rather ſlender tube, an inch long, with broad ſegments to the limb, about the ſame length; but in a double ſtate both parts are much enlarged and thickened.

Mr. Brown has determined the *Nerium divaricatum* of Linnæus, erroneouſly marked as biennial, to be the ſame plant with the above. We ſhall now proceed to enumerate three new ſpecies from his *Prodromus*.

22. T. *orientalis*. Smooth Indian Tabernæmontana. Brown n. 1.—"Leaves lanceolate-oblong, pointed, very ſmooth, as well as the branches. Cymes repeatedly compound, ſmooth. Bracteas awl-ſhaped, not ſoon deciduous."—Gathered in the tropical part of New Holland, by Mr. Brown, who ſuſpects the *Curutu-Pala*, Hort. Malab. 83. t. 46, cited by Linnæus for his *T. alternifolia*, ſee our 25th ſpecies, may belong to the preſent plant, the *leaves* being erroneouſly repreſented as alternate.

23. T. *pubeſcens*. Downy New Holland Tabernæmontana. Br. n. 2.—"Leaves elliptic-oblong, ſomewhat pointed, downy beneath like the young branches. Branches of the cymes erect, hairy as well as the calyx. Bracteas very minute, deciduous."—Native of the tropical part of New Holland. *Mr. R. Brown.*

24. T. *ebracteata*. Naked-flowered Tabernæmontana. Br. n. 3.—"Leaves ſomewhat elliptical, downy as well as the cymes. Branches and flower-ſtalks ſpreading. Bracteas none."—Found by Mr. Brown in the ſame country as the two laſt. We have ſeen no ſpecimens of any of theſe three ſpecies.

25. T. *alternifolia*. Alternate-leaved Tabernæmontana. Linn. Sp. Pl. 308. Willd. n. 10. Poiret in Lam. n. 20. (Curutu-Pala; Rheede Hort. Malab. v. 1. 83. t. 46.)—Leaves ſcattered, ovato-lanceolate.—Native of ſandy ground on the coaſt of Malabar, flowering all the year, but eſpecially in the rainy ſeaſon. A ſmall *tree*, from ſix to twelve feet high, a foot in diameter. The *leaves* are three or four inches long, pointed, on ſhort thick *footſtalks*, more or leſs alternate, or diſperſed, according to the figure, which is our only authority for that character. *Panicles* lateral or terminal, corymboſe, drooping, of about nine white fragrant *flowers*, whoſe tube is near two inches long, the limb dilated and notched, very much twiſted. *Follicles* tawny, ovate, an inch long, with a recurved point. Linnæus depended ſolely on the Hortus Malabaricus for this ſpecies, of which he had no ſpecimen. The circumſtance of the alternate *leaves*, unexampled in any known *Tabernæmontana*, has excited a reaſonable ſuſpicion of error. See our 22d ſpecies.

26. T. *bufalina*. Buffalo-horned Tabernæmontana. Loureir. Cochinch. 117. (Capſicum ſylveſtre; Rumph. Amboin. v. 4. 133. t. 67.)—Leaves lanceolate, ſmooth. Stalks lateral, in pairs, ſingle-flowered, pendulous.—Native of moiſt ſhady vallies in Amboina, and of buſhy places in Cochinchina, where it is called *Cây ſùng tlâu*. A *ſhrub* five feet high, branched, nearly erect. *Leaves* oppoſite, from five to eight inches in length, ovato-lanceolate, ſhining, entire. *Flowers* white, on long ſimple ſtalks. *Tube* long and ſlender, inflated at the baſe. *Follicles* rather long, pointed, ſwelling, ſmooth, with an unequal ſurface. *Seeds* oblong, angular, imbedded in red pulp. The fruit in Rumphius's plate is more like the following. *Loureiro.*

27. T. *bovina*. Bull-horned Tabernæmontana. Loureir. Cochinch. 118. (*Cây ſùng bò* of the Cochinchineſe.)—Leaves lanceolate, ſmooth. Stalks axillary, ſolitary, nearly erect, about five-flowered.—Native of the plains of Cochinchina. A *ſhrub* four feet high, with drooping branches. *Leaves* oppoſite, entire. *Flowers* white. *Follicles* ſhort, recurved, tumid, pointed, even in the ſurface. *Seeds* roundiſh, angular, lodged in red pulp.

Loureiro, from whoſe work and that of Rumphius all our knowledge of the two laſt ſpecies is derived, attributes to them an emollient and relaxing quality. Their viſcid milky juice is ſaid gently to draw out thorns from the fleſh.

The herbaceous plants, ſuppoſed by Linnæus to belong to this genus, conſtitute, as we have already ſaid, and as Linnæus himſelf originally thought, a very diſtinct one, of which we ſhall now treat by the name of *Amſonia*. We can give no poſitive account of the meaning or origin of this name, except that its author, according to Miller, was Clayton. Linnæus, in his own copy of Gronovius's Flora Virginica, ed. 1. p. 26, has written *Amſonia*, as a generic name, to what Clayton took for a ſpecies of *Nerium*, and has ſubjoined alſo in manuſcript the characters of the follicles and ſeeds. This plant, in the ſecond edition of Sp. Pl. is the *Tabernæmontana Amſonia*; and ſo it remained, till Mr. Walter reſtored it to rank as a genus; but without throwing any light upon the name. A ſimilar obſcurity envelopes the nearly ſimilar name of AMASONIA, (ſee that article,) which is reported in the Supplementum of Linnæus to be dedicated to the honour of Amaſon, a traveller in America, whom M. De Theis has baptized Thomas. But we have never been able to learn any tidings of ſuch a perſon. Whether *Amſonia*, being an error in orthography for *Anſonia*, may have been deſigned to commemorate the great lord Anſon, who brought home a new eſculent pea, and deſerved botanical commemoration as much as any other eminent navigator not a profeſſed botaniſt; and whether *Amaſonia* be a ſtill further corruption of the ſame name, we muſt leave in doubt. We have only to obſerve, that if both theſe names ſhould prove to have the ſame origin, or be thought, as they certainly are, too nearly alike, the former, *Amſonia*, ought to be retained in preference to the latter, which is of much later date.

AMSONIA. Walter Carolin. 98. Michaux Boreal-Amer. v. 1. 121. Purſh 184. Ait. Hort. Kew. v. 2. 72. —Claſs

—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juff. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, fmall, in five deep, acute, triangular, fpreading fegments, permanent. *Cor.* of one petal, funnel-fhaped; tube many times longer than the calyx, gradually fwelling upwards, hairy in the throat; limb about as long as the tube, in five deep, lanceolate, varioufly fpreading, oblique fegments. Nectary of five minute glands, furrounding the germen. *Stam.* Filaments five, fmall, inferted into the upper part of the tube; anthers erect, arrow-fhaped, converging, within the tube. *Pift.* Germens two, fimple, ovate; ftyle folitary, central, thread-fhaped, about as long as the tube; ftigma oblong, obtufe. *Peric.* Follicles two, erect, long, cylindrical, pointed, deftitute of internal pulp. *Seeds* numerous, pointed, rough, naked, abrupt and oblique at the point.

Eff. Ch. Corolla funnel-fhaped; its limb in five deep oblique fegments. Anthers arrow-fhaped, within the tube. Follicles two, cylindrical, erect. Seeds cylindrical, naked.

1. A. *latifolia*. Broad-leaved Amfonia. Michaux n. 1. Purfh n. 1. Ait. n. 1. (Tabernæmontana Amfonia; Linn. Sp. Pl. 308. Willd. Sp. Pl. v. 1. 1246. Apocynum virginianum erectum, alternis afclepiadis foliis, floribus pallidè cæruleis, radice craffâ; Pluk. Almag. 35. Phyt. t. 115. f. 3.)—Stem fmooth. Leaves ovato-lanceolate; flightly hairy beneath. Panicle taller than the lateral branches. Limb of the corolla afcending.—Native of fhady wet woods in Carolina, flowering in May. *Purfh.* Cultivated by Miller in 1759, and hardy in our climate. The *root* is flefhy, perennial. *Stem* herbaceous, erect, a foot high, round, leafy, nearly or quite fmooth, terminated by a compound fmooth panicle of greyifh-blue fcentlefs *flowers*, and bearing two or three alternate leafy *branches*, which do not rife above the panicle till the flowers are paft. *Corolla* very hairy about the mouth; its tube pale, nearly half an inch long. The *leaves* are all alternate, on fhort footftalks, entire, pointed, two or three inches in length, and one in breadth; paler beneath, and minutely hairy about the edges and veins.

2. A. *triftis*. Brownifh-flowered Amfonia.—Stem fmooth; its branches overtopping the panicle. Leaves ovate; flightly hairy beneath. Limb of the corolla reflexed.—Brought from North America, by Mr. Lyon. We received a fpecimen in flower, in June 1808, from Mr. Vere's garden, at Knightfbridge. This is rather taller than the foregoing, and diftinguifhed by its leafy lateral *branches* rifing high above the panicle. The *flowers* are fmaller, of a dingy brown hue; the fegments of their limb ftrongly reflexed, at leaft in fading. *Follicles* fmooth, cylindrical. Perhaps Mr. Walter might have this fpecies in view when he attributes tawny flowers (*flores fulvi*) to his *A. ciliata*, our 4th fpecies.

3. A. *falicifolia*. Willow-leaved Amfonia. Purfh n. 2. —"Stem fmooth. Leaves linear-lanceolate, acute at each end, very fmooth."—Gathered by Mr. Lyon in Carolina and Georgia, flowering in May. *Flowers* the fame as the firft fpecies, more abundant. *Purfh.*

4. A. *anguftifolia*. Narrow-leaved Amfonia. Michaux n. 2. Purfh n. 3. Ait. n. 2. Venten. Choix. t. 29. (A. ciliata; Walter n. 2. Tabernæmontana anguftifolia; Willd. Sp. Pl. v. 1. 1247.)—Stem downy. Leaves linear, erect, fringed.—In fandy barren ground of Carolina and Georgia, flowering in May and June. *Flowers* of the fame difpofition and colour as in *A. latifolia* and *falicifolia*. *Purfh.* This fpecies is faid to have been introduced into the Englifh gardens, in 1774, by the late Mr. James Gordon. Its copious narrow *leaves* are glaucous beneath, and fmooth, except at the edges, where they are fringed with long foft hairs, fuch as clothe the *ftem*. Ventenat fays the upper ones are quite fmooth, but this is not the cafe in our fpecimen. The teeth of the *calyx* are fometimes tipped with a tuft of hairs. Walter fays the *flowers* are tawny; others defcribe them, as we find them, like thofe of *A. latifolia*, blue, with a pale, or fomewhat tawny, tube. The *follicles* of all the fpecies, as far as we have feen, are flender, cylindrical, and fmooth, about two inches long.

Tabernæmontana, in *Gardening*, contains plants of the woody, exotic, and hardy perennial kinds, among which the fpecies chiefly cultivated for garden purpofes are, the citron-leaved tabernæmontana (T. citrifolia); the laurel-leaved tabernæmontana (T. laurifolia); the Virginian tabernæmontana (T. amfonia); and the narrow-leaved tabernæmontana (T. anguftifolia).

Thefe are all plants of the more tender and delicate kind, but more efpecially the two firft forts, which require the conftant aid of artificial heat in this climate.

Method of Culture.—All thefe plants may be increafed by feeds, which muft be procured from the countries where the plants grow naturally, and be fown early in the fpring on a hot-bed; and when the plants are come up, and fit to remove, be carefully planted out into fmall pots filled with light rich earth, and then plunged into a hot-bed of tanners' bark, being careful to fhade them in the heat of the day, until they have taken new root; after which they fhould have free air admitted to them every day when the weather is warm; but on cold nights have the glaffes of the hot-bed covered with mats every evening, foon after the fun goes off from the bed: they muft be often refrefhed with water, but not in large quantities, efpecially while they are young, as they are full of a milky juice, and are fubject to rot with much moifture: they may remain during the fummer feafon in the hot-bed, by ftirring up the tan to renew the heat when it wants it, and a little new tan being added; but when the nights begin to be cold, the plants fhould be removed, and plunged into the bark-bed in the ftove, where, during the winter feafon, they muft be kept in a moderate degree of warmth, and in cold weather have but little water given them: they fhould conftantly remain in the ftove, where, in warm weather, they may have free air admitted to them by opening the glaffes, but in cold weather be kept in a warm ftate. With this management they thrive and produce flowers; and, as their leaves are always green, make a pleafant diverfity among other tender exotic plants: they may be increafed likewife by cuttings in the fummer feafon, which fhould be cut off from the old plants, and laid to dry in the ftove five or fix days before they are planted, that the wounded parts may heal over: thefe fhould then be planted in pots filled with frefh light earth, and be plunged into the hot-bed of tanners' bark, and clofely covered with a hand-glafs, fhading them from the fun in the middle of the day in hot weather, refrefhing them now and then with a little water: when they have taken root, they may be planted out into feparate pots, and be treated in the fame manner as thofe raifed from feeds are recommended to be.

It may be noticed, that the third and fourth forts are capable of living in the open air here, provided they are planted in a warm fituation: they love a light foil, rather moift than otherwife; of courfe, when planted in dry ground, they fhould be frequently watered in dry weather. They are beft increafed by offsets from the roots, which fhould be planted out in the autumnal feafon.

Among thefe, the two firft forts afford variety in the ftove, and the latter forts in this as well as the borders in mild climates.

TABERNÆMONTANUS, James Theodore, in *Biography*, a phyfician and botanift, was born at Berg-Zabern, in Alface, and having practifed as an apothecary, and acquired fome knowledge of botany, went to France, where he took the degree of M.D. Advancing in his profeffion, he became firft phyfician to the Elector-Palatine, the bifhop of Spire, and other perfons of rank. He died at Heidelberg, whither he had removed from Worms, in the year 1590. Apprehending that Providence had furnifhed every country with remedies fuitable to its difeafes, he confided much in the efficacy of herbs; and particularly in the powder of mugwort. His German Herbal confifts of three volumes, publifhed feparately in the years 1558, 1590, and 1592, and containing figures, copied either by himfelf or others from nature. This work was well received, and has been often reprinted. He alfo publifhed in German a treatife on baths and mineral waters. Haller. Eloy. Gen. Biog.

TABERNAS, in *Geography*, a town of Spain, in the province of Grenada; 15 miles N.N.E. of Almeria.

TABERNE, a town of Curdiftan; 50 miles E.S.E. of Kerkuk.

TABES, in *Ancient Geography*, a town of Afia, in the mountains of Parétacéne, upon the frontiers of Perfia and Babylonia. Strabo and Quintus Curtius.

Tabes, in *Medicine*, a wafting or confumption of the body, accompanied with hectic fever. The diftinction which nofologifts have made between tabes and atrophia, is founded on the prefence of hectic fever in the former, and its abfence in the latter form of difeafe. Such a definition of tabes, however, would comprehend phthifis, a term which is generally reftricted to that fpecies of confumption which has its origin in difeafes of the lungs. (See Consumption.) The ground of the diftinction between tabes and atrophy, has already been fully difcuffed under the head of Atrophy: and the train of fymptoms conftituting the fever that accompanies tabes, is fufficiently detailed under the article *Hectic* Fever. Dr. Cullen has enumerated three fpecies of tabes; the firft, which he calls the *purulent*, arifing from fuppuration, either of an internal or external part, and the feat of which may be various, according to the organ originally difeafed; the fecond, the *fcrofulous*, being the confequence of fcrofula affecting different parts, but more efpecially the mefenteric glands; and the third, the *venenata*, proceeding from the operation of a poifonous fubftance received into the body. The other affections which had been claffed by Sauvages under tabes, fuch as the tabes dorfalis, nutricum, fudatoria, a fanguifluxu, fyphilitica, and a hydrope, are referred by Dr. Cullen to the genus Atrophy; which fee.

Tabes *Dorfalis*, a fpecies of confumption arifing from the exceffive evacuation of femen: its fymptoms and treatment are detailed under Atrophy.

Tabes *Mefenterica*, or mefenteric confumption, is a difeafe that more particularly affects children, and arifes from obftruction and enlargement of the mefenteric glands. Children are liable to its attacks from the age of three or four years, and become lefs fo when they have attained that of eight or ten, unlefs they are of fcrofulous habits, in which cafe the difeafe may fupervene at a much later period. Its relation to fcrofula is clearly marked, from its more frequent occurrence in families where this difeafe is hereditary: but it may, at the fame time, arife independently of that affection, from a great variety of caufes. It may be induced by any protracted difeafe of infancy producing much conftitutional difturbance, and more efpecially by fuch as are attended with diforder of the functions of the alimentary canal. It may often be traced to improper treatment, or unwholefome food; to long-continued irritation from teething; to the fuppreffion of eruptions, or the incautious ftopping of diarrhœa; and fometimes appears to be the confequence of exanthematous fevers, as the meafles, fmall-pox, or fcarlatina. The prefence of worms in the inteftines, has very frequently been accufed of laying the foundation of this difeafe: but it may be queftioned, whether they are not more generally the confequence than the caufe of derangement in the primæ viæ attendant on this diforder.

The fymptoms which attend the early ftages of this affection, and before the enlargement of the glands has become fenfible, are fimilar to thofe which accompany many of the difeafes of the alimentary canal, more efpecially thofe produced by worms, and can hardly be diftinguifhed from them. Indigeftion occurs in various degrees, denoted by the ufual figns, fuch as acid eructations, fetid breath, great irregularity in the action of the bowels, and in the appearance of the ftools; occafional fever, occurring, however, lefs in regular paroxyfms than happens in the remitting fever of infants, but giving a hectic flufh to the cheeks, which, when the fever has fubfided, are of a pallid hue. The appetite is extremely irregular; fometimes it is nearly gone, at other times it is voracious, and attended with a fenfe of craving, unlefs fpeedily fatisfied. The fymptom which particularly characterifes this difeafe, when occurring in conjunction with thofe above ftated, is fhooting pains in the abdomen, varying confiderably, both in their feat and their intenfity, at different times. Thefe pains, though felt more or lefs every day, occur only at intervals, and frequently, after a longer intermiffion than ufual, they return with more feverity than before.

The belly now begins to fwell and to grow hard, while, at the fame time, the limbs and countenance are emaciated: the ftrength and fpirits decline; the hectic fever is more and more diftinctly marked, and exerts its ufual undermining influence on the conftitution. Cough frequently attends this complaint in its latter ftages, and the fymptoms become blended with thofe of true pulmonary confumption. The difeafe of the mefenteric glands is often, indeed, found, on diffection, to have extended to other vifcera, and more efpecially to the lungs: and tubercles, and even purulent matter, are not unfrequently found in them, although the fymptoms during life did not particularly indicate any affection of thefe organs. The mefenteric glands themfelves exhibit different appearances, according to the progrefs which the difeafe has made: in the early ftages they are enlarged in their fize, and are fomewhat fofter to the touch than in a natural ftate: but upon being cut into, do not exhibit any fenfible deviation from their natural ftructure. If the patient, however, has not already funk from the exhauftion of the conftitutional affection, the difeafe proceeds to fuppuration, the pus being intermixed with the white, foft, and curdy matter which is fo peculiar to fcrofula.

Mefenteric confumption is a difeafe of frequent occurrence, and when it has proceeded a certain length, is almoft invariably fatal. Yet we find, in fome rare inftances, that the powers of the conftitution are fometimes called forth in an extraordinary manner under the moft unpromifing circumftances, and the difeafe recovered from. In the early periods of life, indeed, we fee nature abounding in refources, which a more mature age cannot fupply: and there is, to ufe the language of the late Dr. Gregory, "a greater luxuriancy of life and health in infancy than at any other period. Infants, it is acknowledged, are more delicately fenfible to injury than thofe advanced in life; but to compenfate this, their fibres and veffels are more capable of diftention, their whole fyftem is more flexible, their fluids are lefs acrid, and lefs difpofed to putrefcence; they bear all evacuations more eafily,

eafily, except that of blood; and, which is an important circumftance in their favour, they never fuffer from the terrors of a diftracted imagination. Their fpirits are lively and equal; they quickly forget their paft fufferings, and never anticipate the future. In confequence of thefe advantages, children recover from difeafes, under fuch unfavourable circumftances as are never furvived by adults. If they wafte more quickly under ficknefs, their recovery from it is quick in proportion, and generally more complete than in older people; as difeafes feldom leave thofe baneful effects on their conftitutions fo frequent in adults. In fhort, a phyfician ought fcarce ever to defpair of a child's life, while it continues to breathe."

The plan of treatment to be purfued in this difeafe, muft be founded very much on the fame principles as that of fcrofula in general, modified, however, in fome degree, by its peculiar feat, and by the functions of the parts affected. It is chiefly in the earlier ftages that we can expect much efficacy from an alterative courfe of remedies in the removal of the glandular obftructions. As there is often much ambiguity between the fymptoms of this difeafe and thofe occafioned by the prefence of the round worm in the inteftines, we fhould firft fatisfy ourfelves that this is not the fole caufe of the diforder. In both difeafes there is a tumid belly, and emaciated extremities: fo that the chief ground of diftinction is derived from the effect of ftrong purgatives, which bring away worms in the one cafe, and none in the other. It is obferved by Dr. Baillie, that ftartings and grinding of the teeth during fleep, occur very commonly in worms, but are rarely obferved as fymptoms of fcrofulous enlargement of the mefenteric glands. Some difcrimination, likewife, between the two difeafes, may fometimes be derived from examining ftrictly into the nature of the conftitution. If decided marks of fcrofula fhew themfelves in an external part of the body, they will lead a practitioner more fatisfactorily to the opinion, that the mefenteric glands are alfo affected with the fame difeafe.

The principal alterative remedy on which any dependence can be placed is mercury, particularly in the form of calomel; half a grain, or a grain of which, may be given two or three times a week, in conjunction with, or fucceeded by, fome mild purgative. On the intermediate days, fmall dofes of alkalies, with rhubarb, may be exhibited. Great attention fhould, at all times, be paid to the ftate of the bowels, which fhould be kept freely open: while the acrimony of their contents fhould be counteracted by abforbents, fuch as magnefia, when there is no diarrhœa, or by prepared chalk, or gentle aftringents, in fmall dofes, when this latter ftate prevails. For the removal of fever, the fame means are to be employed as have already been pointed out when treating of the infantile remitting fever, under the head of *Difeafes of* INFANTS. The calomel, combined with purgatives, may be continued, for feveral weeks, till a favourable change has been effected in the fize and hardnefs of the belly. The milder vegetable tonics, fuch as chamomile, or cafcarilla, may then be tried, and according as the conftitution will bear them, preparations of iron fhould be given, in order to ftrengthen the digeftive organs, and the fyftem in general. Together with thefe means, every circumftance which can contribute to general health fhould be attended to. Pure air, regular exercife, gentle frictions of the body and limbs, an eafy drefs, frequent wafhing of the whole body with foap and warm water in young children, or the cold bath in older children, and efpecially a light and nutritious diet, with fuch mild aromatics as may affift digeftion, are fome of the principal and moft effectual means of fecuring the ground that has been gained, and of preventing a return, as well as guarding againft an attack, of the difeafe. For greater details on thefe points, fee *Difeafes of* INFANTS, and SCROFULA.

TABEYRO, in *Geography*, a town of Spain, in Galicia; 5 miles S.E. of St. Jago.

TABIANA, in *Ancient Geography*, an ifland of the Perfian gulf, near and weft of the ifle of Sophthe, and overagainft the promontory of Taoce.

TABIANA, in *Geography*, a town of the duchy of Parma; 13 miles W. of Parma.

TABIDIUM, in *Ancient Geography*, a town in the interior of Africa, towards the fource of the river Bagrada.

TABILLOLA, in *Geography*, a town on the fouth coaft of the ifland of Machian. N. lat. 0° 13'. E. long. 127° 21'.

TABINSK, a town of Ruffia, in the government of Upha, on the Bielaia; 40 miles S. of Upha. N. lat. 54°. E. long. 56° 14'.

TABLADA, a town of South America, in the province of Carthagena; 80 miles S. of Mompox.

TABLANATZ, a town of Iftria; 24 miles N.E. of Pedena.

TABLAS, one of the Philippine iflands, about 25 miles long from north to fouth, but narrow and interfected by a deep bay on the eaft and weft coafts. N. lat. 12° 30'. E. long. 121° 40'.

TABLATURE, in *Anatomy*, a divifion or parting of the fkull into two tables.

TABLATURE, *Tablatura*, in *Mufic*, in general, is when to exprefs the founds or notes of a compofition, we ufe letters of the alphabet, or cyphers, or any other characters not ufed in the modern mufic.

TABLATURE, in its ftricter fenfe, is the manner of writing a piece for the lute, theorbo, guitarre, bafs viol, or the like; which is done by writing on feveral parallel lines (each of which reprefents a ftring of the inftrument) certain letters of the alphabet, referring to the frets on the neck of the inftrument: of which A marks, that the ftring is to be ftruck open, *i. e.* without putting the finger of the left hand on the head; B fhews, that one of the fingers is to be put on the firft ftop; C, on the fecond; D, on the third, &c.

The time of the notes is fignified by marks over the letters of a hooked form, that anfwer to the minim, crotchet, quaver, &c. in the French tablature; but the Italians and Spaniards, till of late years, made ufe of figures inftead of letters.

The tablature of the lute is ufually written in letters of the alphabet, and that of the harpfichord in the common notes.

TABLE, TABULA, a moveable, ufually made of wood, or ftone fupported on pillars, or the like; for the commodious reception of things placed upon it.

Mofes made a table, in the tabernacle, for laying the fhew-bread upon, defcribed by Philo Judæus as two cubits long, one broad, and one and a half high.

Among Chriftians, the *table*, or *Lord's table*, fignifies the facrament of the Lord's fupper. See COMMUNION.

TABLE, *Round*, *Knights of the Round Table*, a military order fuppofed to have been inftituted by Arthur, the firft king of the Britons, in the year 516.

They are faid to have been twenty-four in number; all felected from among the braveft of the nation.

The round table, which gave them their title, was an invention of that prince, to avoid difputes about the upper and lower end, and to take away all emulation as to places.

Lefley affures us, he faw the table at Winchefter: at leaft, he fays, if he might believe the keepers of it, who ftill fhew ſhew it with great ſolemnity. He adds, that the names of a great number of knights, written around it, ſeemed to confirm the truth of the tradition.

Larrey alſo, and ſeveral other authors, make no ſcruple to relate this fable of knighthood as matter of hiſtory: but that it is a fable, is certain; F. Papebroch having ſhewn, that there was no ſuch thing as an order of knights before the ſixth century.

Camden alſo obſerves, that the table at Wincheſter is of a ſtructure much more modern than the ſixth century. It is to be added, that Arthur himſelf is eſteemed by many no more than a fabulous prince.

An excellent hiſtorian obſerves, that Arthur was undoubtedly a great general, though his actions have given occaſion to innumerable fables; and though the inſtitution of the "Knights of the Round Table" has ſerved as a foundation for many fabulous relations, it is not to be deemed altogether chimerical. For where is the improbability that Arthur ſhould inſtitute an order of knighthood in Britain, when we learn from the letters of Caſſiodorus, that Theodoric, king of the Oſtrogoths, inſtituted one in Italy in the ſame century. Rapin's Hiſt. of Eng. vol. i. p. 39. fol.

However, others have ſuppoſed that the round table was not any military order, but rather a kind of juſt, or military exerciſe, between two perſons armed with lances. Several authors ſay that Arthur, duke of Bretagne, renewed it. See Matthew Paris, the abbot Juſtiniani, and F. Helyot.

Paulus Jovius ſays, it was under the empire of Frederic Barbaroſſa that the knights of the Round Table firſt began to be talked of; others attribute their origin to the factions of the Guelphs and Gibellins. King Edward I. built a houſe called the Round Table, the court of which was two hundred feet in diameter. Du-Cange Gloſſ. *Tabula*.

Table, in *Architecture*, a ſmooth, ſimple member, or ornament, of various forms, but moſt uſually in that of a long ſquare. See Platband.

Table, *Projecting*, is ſuch a one as ſtands out from the naked of the wall, pedeſtal, or other matter which it adorns.

Table, *Raked*. See Raking-*Table*.

Table, *Razed*, an emboſſment in a frontiſpiece, for the putting an inſcription, or other ornament, in ſculpture. This is what M. Perrault underſtands by *abacus* in Vitruvius.

Table, *Crowned*, that covered with a corniche, and in which is cut a baſſo-relievo, or a piece of black marble incruſtated, for an inſcription.

Table, *Ruſticated*, that which is picked, and whoſe ſurface ſeems rough, as in grottos, &c. See Rustics.

Table, *Water*. See Water-*Table*.

Table, *Plain*, a ſurveying inſtrument. See Plain *Table*.

Table, in *Perſpective*, denotes a plain ſurface, ſuppoſed to be tranſparent, and perpendicular to the horizon.

It is always imagined to be placed at a certain diſtance between the eye and objects, for the objects to be repreſented thereon by means of viſual rays paſſing from every point thereof, through the table to the eye.

Whence it is alſo called *perſpective plane*. See Perspective.

Table, in *Anatomy*. The cranium is ſaid to be compoſed of two tables, or laminæ; *i. e.* it is double, as if it conſiſted of two bones laid one over another. See Skull.

Table *of Pythagoras*, called alſo *multiplication-table*, is a ſquare formed of an hundred or more leſſer ſquares, or cells, containing the products of the ſeveral digits, or ſimple numbers, multiplied by each other. See this table under Multiplication.

Tables, *Laws of the Twelve*, were the firſt ſet of laws of the Romans; thus called, either becauſe the Romans then wrote with a ſtyle on thin wooden tables, covered with wax; or, rather, becauſe they were engraved on tables, or plates of copper, to be expoſed in the moſt noted part of the public forum. Wood, braſs, or ivory, might be ſucceſſively employed.

After the expulſion of the kings, as the Romans were then without any fixed or certain ſyſtem of law; at leaſt, had none ample enough to take in the various caſes that might fall between particular perſons; it was reſolved to adopt the beſt and wiſeſt laws of the Greeks.

One Hermodorus, to whom a ſtatue was erected in the forum, was firſt appointed to tranſlate them; and the decemviri afterwards compiled and reduced them into ten tables. After immenſe care and application, they were, at length, enacted and confirmed by the ſenate, and an aſſembly of the people, in the year of Rome 303.

The following year they found ſome things wanting therein, which they ſupplied from the laws of the former kings of Rome, and from certain cuſtoms, which long uſe had authorized: all theſe, being engraven on two other tables, made the *law of the twelve tables*, ſo famous in the Roman juriſprudence; the ſource and foundation of civil or Roman law. See Civil *Law*.

The laws of the twelve tables were alſo called *decemviral laws*, from the officers entruſted with the compoſing them. See Decemviri.

Theſe laws of the decemviri were dictated by the rigid and jealous ſpirit of an ariſtocracy, which had yielded with reluctance to the juſt demands of the people. But the ſubſtance of the twelve tables was adapted to the ſtate of the city; and the Romans muſt have emerged from barbariſm, ſince they were capable of ſtudying and embracing the inſtitutions of their more enlightened neighbours. Mr. Gibbon ſuggeſts, that a motive of national pride induced Livy and Dionyſius to believe, that deputies from Rome viſited Athens under the wiſe and ſplendid adminiſtration of Pericles, and that the laws of Solon were transfuſed into the twelve tables. If ſuch an embaſſy, ſays the hiſtorian of the Roman empire, had indeed been received from the barbarians of Heſperia, the Roman name would have been familiar to the Greeks before the reign of Alexander, and the fainteſt evidence would have been explored and celebrated by the curioſity of ſucceeding times. But the Athenian monuments are ſilent; nor will it ſeem credible that the patricians ſhould undertake a long and perilous navigation, to copy the pureſt model of a democracy. In the compariſon of the tables of Solon with thoſe of the decemvirs, ſome copied reſemblance may be found; ſome rules which nature and reaſon have revealed to every ſociety; ſome proofs of a common deſcent from Egypt or Phœnicia. But in all the great lines of public and private juriſprudence, the legiſlators of Rome and Athens appear to be ſtrangers or adverſe to each other.

Whatever, as the ſame hiſtorian proceeds, might be the origin or the merit of the twelve tables, they obtained among the Romans that blind and partial reverence which the lawyers of every country delight to beſtow on their municipal inſtitutions. The ſtudy is recommended by Cicero as equally pleaſant and inſtructive. "How admirable," ſays the Roman orator, with honeſt or affected prejudice, "is the wiſdom of our anceſtors! We alone are the maſters of civil prudence; and our ſuperiority is the more conſpicuous, if we deign to caſt our eyes on the rude and almoſt ridiculous juriſprudence of Dracon, of Solon, and of Lycurgus."

The

The twelve tables were committed to the memory of the young, and the meditation of the old; they were tranfcribed and illuftrated with learned diligence; they had efcaped the flames of the Gauls, they fubfifted in the age of Juftinian, and their fubfequent lofs has been imperfectly reftored by the labours of modern critics.

It is a great pity this fyftem of law fhould have perifhed through the injuries of time: we have now nothing of it, but a few fragments difperfed in divers authors. J. Gothrofed has collected them together, and we have them in Rofinus, and fome other authors. The Latin is very old and barbarous, and remarkably obfcure. See Civil *Law*.

Although thefe venerable monuments of antiquity were confidered as the rule of right and the fountain of juftice, they were overwhelmed by the weight and variety of new laws, which, at the end of five centuries, became a grievance more intolerable than the vices of the city.

The laws of the twelve tables have been juftly charged with inexcufable feverity. They are written, fays Mr. Gibbon, like the ftatutes of Draco, in characters of blood. They approve the inhuman and unequal principle of retaliation; and the forfeit of an eye for an eye, a tooth for a tooth, a limb for a limb, is rigoroufly exacted, unlefs the offender can redeem his freedom by a fine of 300 lbs. of copper. Befides the flighter chaftifements of flagellation and fervitude very liberally diftributed by the decemvirs, nine crimes of a very different complexion are adjudged worthy of death: *viz.* 1. Any act of treafon againft the ftate, or of correfpondence with the public enemy; 2. Nocturnal meetings in the city, under any pretence of pleafure, or religion, or the public good; 3. The murder of a citizen; 4. The malice of an incendiary; 5. Judicial perjury; 6. The corruption of a judge, who accepted bribes to pronounce an iniquitous fentence; 7. Libels or fatires; 8. The nocturnal mifchief of damaging or deftroying a neighbour's corn; 9. Magical incantations. The cruelty of the twelve tables againft infolvent debtors merits peculiar notice. After the judicial proof or confeffion of the debt, 30 days of grace were allowed before a Roman was delivered into the power of his fellow-citizen. In this private prifon, 12 ounces of rice were his daily food: he might be bound with a chain of 15 pounds' weight; and his mifery was thrice expofed in the market-place, to folicit the compaffion of his friends and countrymen. At the expiration of 60 days, the debt was difcharged by the lofs of liberty or life: the infolvent debtor was either put to death, or fold in foreign flavery beyond the Tyber; but if feveral creditors were alike obftinate and unrelenting, they might legally difmember his body, and fatiate their revenge by this horrid partition.

When the manners of Rome were infenfibly polifhed, the criminal code of the decemvirs was abolifhed by the humanity of accufers, witneffes, and judges; and impunity became the confequence of immoderate rigour. The Porcian and Valerian laws prohibited the magiftrates from inflicting on a free citizen any capital, or even corporal punifhment; and the obfolete ftatutes of blood were artfully, and perhaps truly, afcribed to the fpirit, not of patrician, but of civil, tyranny. Gibbon's Decl. and Fall, &c. vol. viii.

Tables *of the Law*, in *Scripture Hiftory*. See Decalogue.

Tables, *New*, *Tabulæ Novæ*, an edict occafionally publifhed in the Roman commonwealth, for the abolifhing all kinds of debts, and annulling all obligations.

It was thus called, in regard that all antecedent acts being deftroyed, there were nothing but new ones to take place.

Table, among *Jewellers*. A *table diamond*, or other precious ftone, is that whofe upper furface is quite flat, and only the fides cut in angles: in which fenfe, a diamond cut *table-wife*, is ufed in oppofition to a rofe-diamond. See Diamond.

Table, in the *Glafs-Manufacture*, denotes a circular fheet of finifhed window-glafs. Thefe tables are generally four feet in diameter, and each of them weighs 10, $10\frac{1}{2}$, or 11 pounds. Twelve of thefe is called a *fide* or a *crate* of glafs. Some tables of glafs have been four, and even five feet in diameter. Such have been made by Meffrs. Attwood and Smith, formerly Hammond and Smith, of Gatefhead, in the county of Durham; and thefe tables are the more valuable, as they yield larger fquares than ever were made, except in plate-glafs, and the quality alfo is of the beft kind. The centre of the table of glafs, where the punting iron was attached, is of courfe fomewhat thicker, and is denominated by the workmen "bull's eye:" neverthelefs, the reft of the plate is of an uniform thicknefs.

Table is alfo ufed for an index, or repertory, put at the beginning or end of a book, to direct the reader to any paffage he may have occafion for.

Thus we may fay, *table of matters; table of authors quoted; table of chapters*, &c. Tables, of themfelves, fometimes make large volumes, as that of Dravitz on the civil and canon laws.

Tables *of the Bible*, are called *Concordances*. See Concordance.

Table-*Rents*. See Bord-lands.

Tables *of Houfes*, among *Aftrologers*, are certain tables, readily drawn up, for the affiftance of practitioners in that art, for the erecting or drawing of figures or fchemes. See House.

Tables, in *Mathematics*, are fyftems of numbers, calculated to be ready at hand for expediting aftronomical, geometrical, and other operations. See Canon.

Tables, *Aftronomical*, are computations of the motions, places, and other phenomena of the planets, both primary and fecondary. See each planet.

The oldeft aftronomical tables are the Ptolemaic, found in Ptolemy's Almageft; but thefe now no longer agree with the heavens.

In 1252, Alphonfo XI. king of Caftile, undertook the correction of them, chiefly by the affiftance of Ifaac Hazen, a Jew; and fpent four hundred thoufand crowns therein. Thus arofe the *Alphonfine* tables, to which that prince himfelf prefixed a preface. But the deficiency of thefe, alfo, was foon perceived by Purbachius and Regiomontanus; upon which Regiomontanus, and after him Waltherus and Warnerus, applied themfelves to celeftial obfervations, for the farther amending of them; but death prevented any progrefs therein.

Copernicus, in his books of the celeftial revolutions, inftead of the Alphonfine tables, gives others of his own calculation, from the latter, and partly from his own obfervations.

From Copernicus's obfervations and theories, Eraf. Reinholdus afterwards compiled the *Prutenic* tables, which have been printed feveral times, and in feveral places.

Tycho de Brahe, even in his youth, became fenfible of the deficiency of the *Prutenic* tables; which was what determined him to apply himfelf, with fo much vigour, to celeftial obfervations: yet all he did, by them, was to adjuft the motions of the fun and moon; though Longomontanus, from the fame, to the theories of the feveral planets publifhed in his "Aftronomia Danica," added tables of their motions, now called the *Danifh* tables; and Kepler likewife, from

from the fame, in 1627, publifhed the *Rudolphine* tables, which are much efteemed.

Thefe were afterwards, anno 1650, turned into another form, by Maria Cunitia, whofe aftronomical tables, comprehending the effect of Kepler's phyfical hypothefis, are exceedingly eafy, and fatisfy all the phenomena, without any trouble of calculation, or any mention of logarithms; fo that the Rudolphine calculus is here greatly improved.

Mercator made a like attempt in his Aftronomical Inftitution, publifhed in 1676, and the like did J. Bap. Morini, whofe abridgement of the Rudolphine tables was prefixed to a Latin verfion of Street's "Aftronomia Carolina," publifhed in 1705.

Lanfbergius, indeed, endeavoured to difcredit the Rudolphine tables, and framed *Perpetual* tables, as he calls them, of the heavenly motions; but his attempt was never much regarded by the aftronomers; and our countryman Horrox warmly attacked him, in his defence of the Keplerian aftronomy.

Since the Rudolphine tables, many others have been publifhed; as the *Philolaic* tables of Bullialdus; the *Britannic* tables of Vincent Wing, calculated on Bullialdus's hypothefis; the *Britannic* tables of Newton; the French ones of the count de Pagan; the *Caroline* tables of Street, all calculated on Dr. Ward's hypothefis, and the *Novalmajeftic* tables of Ricciolus. Among thefe, however, the Philolaic and Caroline tables are efteemed the beft; infomuch that Mr. Whifton, by the advice of Mr. Flamfteed (a perfon of undoubted authority in fuch cafes) thought fit to fubjoin the Caroline tables to his aftronomical lectures.

The *Ludovician* tables, publifhed in 1702, by M. de la Hire, are conftructed wholly from his own obfervations, and without the affiftance of any hypothefis; which, before the invention of the micrometer, telefcope, and the pendulum clock, was held impoffible.

Another fet of tables, Dr. Halley, the aftronomer royal, long laboured to perfect.

M. le Monnier, in 1746, publifhed in his "Inftitutions Aftronomiques" tables of the motions of the fun, moon, and fatellites, of refractions, and of the places of the fixed ftars. M. de la Hire has alfo publifhed tables of the planets, and M. de la Caille tables of the fun. Mayer conftructed tables of the moon; and we have many aftronomical tables of various kinds, and computed with different views, in our modern books of aftronomy, navigation, &c. For an account of feveral, and efpecially of thofe publifhed annually under the direction of the commiffioners of longitude, fee ALMANAC, EPHEMERIDES, and LONGITUDE.

For TABLES *relating to annuities*, &c. fee ANNUITIES, EXPECTATION *of Life*, LIFE-*Annuities*, MORTALITY, and SURVIVORSHIP.

TABLES, *Sexagenary*. See SEXAGENARY.

For TABLES *of the Stars*, fee CATALOGUE and STAR.

TABLES *of Sines*, *Tangents*, and *Secants*, of every degree and minute of a quadrant, ufed in trigonometrical operations, are ufually called *Canons;* which fee. See alfo SINE.

TABLES *of Logarithms*, *Rhumbs*, ufed in geometry, navigation, &c. See LOGARITHM and RHUMB.

TABLES, *Loxodromic*, are tables in which the difference of longitude, and quantity of the way in any rhumb, are exhibited to every ten minutes of every degree of the quadrant variation of the latitude. See RHUMB.

TABLE *of Heights*, in Englifh feet, from the level of the fea.

The Cafpian fea, lower by - - - - -	306
The Thames at Hampton, Roy - - - -	$14\frac{1}{2}$
The Tiber at Rome - - - - - -	33
The Seine at Paris, mean height - - -	$36\frac{1}{2}$
The Thames, at Buckingham-ftairs, $15\frac{1}{2}$ feet below the pavement in the left-hand arcade - -	43

By barometrical comparifon with the Seine and the Mediterranean; but this height is probably too great. Roy fuppofes the low water of the fpring tides at Ifleworth to be only one foot above the mean furface of the ocean. He allows feven feet for the difference of the low water at the Nore and at Ifleworth, and taking 18 feet for the height of the fpring tide, adds one-third of this for the mean height of the fea. At Hampton, the Thames is $13\frac{1}{2}$, feet above low water-mark at Ifleworth.

The pagoda in Kew gardens, from the ground		$116\frac{1}{2}$
The weft end of the Tarpeian rock - -		151
The Palatine hill - - - - - -		166
The Claudian aqueduct, bottom of the canal -		208
The Janiculum - - - - - -		293
The crofs at St. Paul's, from the ground - -		340
St. Peter's, fummit of the crofs - - -		535
From the ground	471	
Arthur's feat, from Leith pier-head - -		803
Lake of Geneva - - - - - -		1230
Its greateft depth	393	
Mount Vefuvius, bafe of the cone - - -		2021
Skiddaw - - - - - - -		3270
Chamouny, ground floor of the inn - - -		3367
Mount Vefuvius, mouth of the crater - -		3938

For the heights of other mountains, &c.; fee MOUNTAIN.

It may be obferved, with refpect to general Roy's calculation of the mean height of the fea, that it does not appear that in rivers, or even in narrow feas, we ought to add one-third of the height of the tides only to that of low water, in order to find the level; for it is probable that even the original tides may often refemble thofe of lakes, where, for want of breadths, the effects of a fpheroidical tide cannot take place, and the elevation and depreffion are very nearly equal.

TABLE, in *Heraldry*. Coats, or efcutcheons, containing nothing but the mere colour of the field, and not charged with any bearing, figure, or moveable, are called *tables d'attente*, *tables of expectation*, or *tabulæ rafæ*.

TABLE *Bay*, in *Geography*, a bay fituated on the weft coaft of the fouthern extremity of Africa, near which are the fort and town of the Cape of Good Hope. This bay is formed by three lofty mountains. Cape Town, the capital of the colony, lies on the S.E. angle of the bay. The primary object to which Table bay is fubfervient, is the convenience of a plentiful ftream of pure limpid water, rufhing out of the mountain, and this circumftance determined the firft fettlers in their choice of the fcite for the town. If this had not been the cafe, the firft fettlers would unqueftionably have given the preference to Saldanha bay, the only defect of which is the want of frefh water near it; whereas Table bay is faulty in every point that conftitutes a proper place for the refort of fhipping, and fo boifterous for four months in the year, as totally to exclude all fhips from entering into it. The anchoring ground in this bay is tolerably good; but the fhifting of the fand leaves bare fometimes whole ridges of the fame kind of hard blue fchiftus that appears every where on the weft fhore of the bay. Thefe ridges are fo fharp, that a cable that comes acrofs them will be cut in pieces. Hence it has happened, that the bay is full of anchors, which have never been fifhed up, and thefe contribute, as well as the rocks, to cut and chafe the

the cables of ſhips. If ſome pains be not taken to remove the anchors, the number of which is annually increaſing, a clear anchorage for a ſingle large ſhip will not be found. It has been propoſed to ſink mooring-chains for large ſhips, inſtead of their lying at anchor. During the S.E. winds, which blow from September to the end of April, and which is the ſeaſon when all ſhips bound for the Cape reſort to Table bay, the only danger is that of their being driven out to ſea from the wear and tear of the cables. However, as the ſea is not high, it is hardly poſſible for a ſhip to go on ſhore, unleſs it be on the S. point of Robben iſland, which being diſtant ſeven or eight miles, may be always avoided. Within this iſland and the continent there is excellent anchorage, where ſhips ſo driven out uſually bring up. Here alſo ſhips intending to come into Table bay generally wait the abatement of a S.E. wind, if it ſhall happen to blow too ſtrong for their working up againſt it. This iſland is too ſmall and too far to afford the leaſt ſhelter to Table bay from the N.W. winds that blow in the winter months. Naval officers ſeem to be divided in opinion as to the preference of Table bay or Simon's bay, (ſee SIMON's *Bay*,) which lies on the eaſtern ſide of the peninſula, in the great bay of Falſe, and which is the uſual reſort of ſhipping for five months in the year. Both are defective, but the latter appears to be more ſecure, from the circumſtance of few, if any, ſhips having been ever known to drive on ſhore from their anchors, whilſt ſcarcely a ſeaſon paſſes without the loſs of ſome in Table bay. In the winter months, when the wind blows from N. to N.W., 40 or 50 ſhips may lie at anchor perfectly ſecure in Simon's bay, and eight or ten may be ſufficiently ſheltered in the ſtrongeſt ſouth-eaſtern. From a ſurvey of the Great Falſe bay in 1797, the exact ſituation was aſcertained of a very dangerous rock, placed directly in the paſſage of ſhips into Simon's bay. The months in which ſhips uſually reſort to this bay, are from May to September incluſive. The diſtance from Cape Town, being 24 miles, and the badneſs of the road, moſtly deep ſand and ſplaſhes of water, render the communication at all times difficult, but more eſpecially in winter; and few ſupplies are to be had at Simon's town, a name given to a collection of about a dozen houſes. We have a chart of this bay in the ſecond volume of Barrow's Africa. S. lat. 53° 50′. E. long. 18° 15′.—Alſo, a bay on the E. coaſt of Labrador. N. lat. 53° 44′. W. long. 20° 57′.

TABLE *Iſland*, a ſmall iſland near the coaſt of Spitzbergen. N. lat. 80° 57′. E. long. 20° 30′.—Alſo, one of the New Hebrides, in the South Pacific ocean. S. lat. 15° 38′. E. long. 167° 7′.—Alſo, a ſmall iſland in the Eaſt Indian ſea, near the iſland of Paraguay. N. lat. 9° 15′. E. long. 118° 2′.—Alſo, a ſmall iſland in the Eaſt Indian ſea. N. lat. 14° 8′. E. long. 93° 32′.

TABLE *Mountain*, a mountain of Ireland, in the county of Wicklow; 15 miles W. of Wicklow.—Alſo, a mountain of Africa, near the Cape of Good Hope, ſo called from its flat ſummit. In fine weather this mountain is viſible at ſea at the diſtance of 28 or 30 miles. Table mountain ſupplies Table bay and Hout bay with ſtreams of water.

TABLE *Mountains*, mountains of North Carolina. N. lat. 36°. W. long. 81° 40′.

TABLE *Point*, a cape on the S. coaſt of the iſland of Bali. S. lat. 8° 45′. E. long. 115° 11′.

TABLE *River*, a river of Louiſiana, which runs into the Miſſiſippi, N. lat. 37° 12′. W. long. 90° 11′.

TABLE-*Wheel*, in *Rope-Making*. To lay ropes, &c. from a ſix-thread line to a two-inch and half rope, a table-wheel is fixed in the wheel-houſe, at the upper end of the rope-walk, in a frame fixed in the ground, with two ſliding cheeks. The bands which work the whirls, go ſeparately over each whirl, and round the turning-wheel. Some have ſix ſets of whirls of different ſizes, with iron ſpindles, and nibbed or forelock hooks at the outer end. A tackle-board, twelve inches broad, and three inches thick, with ſix holes for the hooks to go through, is fixed above the cheeks upon cleats.

TABLEAU, Fr. This word is uſed frequently in muſic, ſays Rouſſeau, to expreſs the whole deſign of a compoſition in the ſcore: as "this ſcore is quite a picture;" "this opera is full of admirable paintings and imitations of nature."

TABLET, in *Pharmacy*. See TABELLA.

TABLIER, LE, in *Geography*, a town of France, in the department of the Vendée; 6 miles S.S.E. of La Roche ſur Yon.

TABLING *of Fines*, is the making a table for every county, where his majeſty's writs run; containing the contents of every fine paſſed each term.

It is to be done by the chirographer of fines of the common pleas; who, every day of the next term, after engroſſing any ſuch fine, fixes one of the ſaid tables in ſome open place of the ſaid court, during its ſitting; and likewiſe delivers to the ſheriff of each county a content of the ſaid tables made for that reſpective county, the term before the aſſizes, to be affixed in ſome place in the open court, while the juſtices ſit.

TABLING, in *Ship-Building*, letting one piece of timber into another by alternate ſcores or projections from the middle, ſo that it cannot be drawn aſunder either lengthwiſe or ſidewiſe; ſuch are beams, &c.

TABLING, in *Sail-Making*, a broad hem made on the ſkirts of ſails, by turning the edge of the canvas over and ſewing it down. It is to ſtrengthen the ſail for ſewing on the bolt-rope.

TABO DAGROU, or *Little Dieppe*, in *Geography*, a town of Africa, on the Grain Coaſt.

TABO *Dune*, a ſea-port of Africa, on the Ivory Coaſt; 90 miles from Cape Palmas.

TABOA, a town of Portugal, in the province of Beira, on the Mondego; 9 miles S. of Viſeu.

TABOCANA, a town of Africa, in the kingdom of Quoja. N. lat. 5° 55′.

TABOCURU, a river of Braſil, which runs into the Atlantic, near the iſland of Maranhao. S. lat. 2° 40′. W. long. 45° 30′.

TABOGA. See TABAGO.

TABOLATO, a town of Mexico, in the province of Culiacan; 30 miles W. of Culiacan.

TABON, in *Natural Hiſtory*, a name given by the people of the Philippine iſlands to a bird called in other places *daie*, and remarkable for the largeneſs of its eggs; though ſome accounts of theſe are certainly fabulous.

TABONES, in *Geography*, one of the ſmall Philippine iſlands, near Maſbate. N. lat. 12° 12′. E. long. 123° 5′.

TABOO, a town of Africa, and capital of a country, ſituated to the E. of Sahara. N. lat. 24°. E. long. 12° 10′.

TABOO, a term uſed in the Sandwich iſlands to denote a kind of religious interdiction, of very powerful and extenſive operation. With places and perſons that were tabooed, all intercourſe was prohibited. The word was alſo uſed to expreſs any thing ſacred, or eminent, or devoted. Cook's Third Voyage, vol. iii. p. 164.

TABOR, or *Hradiſlie Hory Tabor*, *i. e.* the camp of Mount Tabor, in *Geography*, a town of Bohemia, in the circle of Bechin, founded by the Huſſites, ſituated on a mountain, near the river Luznice, is naturally ſtrong, and it it is fortified in the ancient manner, with a ditch, walls, and bulwarks. It had been the camp of John Zifka in the year 1420, and was raifed to a royal borough by the emperor Sigifmund. It was taken by ftratagem by Rodolph II. in 1611, and alfo in 1621, 1648, and 1744; 10 miles N.E. of Bechin. N. lat. 49° 27′. E. long. 14° 28′.

TABOR, *Mount*, a mountain of Paleftine, frequently mentioned in the Old Teftament. (See Jofh. xiv. 22. Judg. iv. 6. 12. Pf. lxxxix. 12. Jer. xlvi. 18. Hof. v. 1.) It ftands about the middle of Lower Galilee, between Nazareth and the country of Gennefareth. According to Jofephus, it is 30 furlongs in height, and 26 in compafs. It is an infulated mountain, fituated on a plain (that of Efdraelon), and having a level area at the fummit, very fertile and pleafant. According to Maundrell, this area is of an oval figure, extending in breadth about a furlong, and two furlongs in length. Jofephus fays, that he caufed it to be furrounded by walls, within the fpace of 40 days, that he might thus, without doubt, render it more inacceffible to the Romans.

An ancient tradition informs us, that Jefus was transfigured upon mount Tabor (fee Matt. xvii. 2. Mark, ix. 2. Luke, ix. 28.), and that this is the place which is called by St. Peter the "holy mount." (2 Pet. i. 18.) Some learned authors, however, are of opinion, that the transfiguration happened upon a mountain near Cæfarea Philippi, *i. e.* upon mount Panium, which is very high, according to Jofephus. We find the city called Tabor, mentioned 1 Chron. vi. 77; but it is not well known, how it was fituated with relation to the mount.

TABOR, *Tabour*, *Tabret*, or *Tabourin*, a fmall *drum;* (which fee.) It is an accompaniment to a fmall pipe or fife; inftruments very animating in a country dance.

TABORITES, or THABORITES, in *Ecclefiaftical Hiftory*, a branch or fect of the ancient Huffites.

The Huffites, towards the beginning of the 15th century, dividing into feveral parties, and about the year 1420, into two great factions; one of them retired to a little mountain or rock, fituate in Bohemia, 15 leagues from Prague, and there put themfelves under the conduct of Zifka; building themfelves a fort or caftle, and a regular city, which they called *Tabor* or *Thabor*, either from the general word *thabor*, which in the Sclavonic language fignifies *caftle;* or from the mountain *Tabor*, mentioned in Scripture; and hence they became denominated *Thaborites*. Thofe of the other party were denominated *Calixtins*.

The Taborites not only infifted upon reducing the religion of Jefus to its primitive fimplicity, but required alfo that the fyftem of ecclefiaftical government fhould be reformed in the fame manner, the authority of the pope deftroyed, and the form of divine worfhip changed: they demanded the erection of a new church and hierarchy, in which Chrift alone fhould reign, and all things fhould be carried on by a divine direction and impulfe. In maintaining thefe demands, fome of their leaders went fo far as to flatter themfelves with the chimerical notion, that Chrift would defcend in perfon upon earth, armed with fire and fword, to extirpate herefy, and purify the church from its numerous corruptions. This enthufiaftic clafs of Huffites alone, Mofheim fays, we are to look upon as accountable for all thofe acts of violence, which are too indifcriminately laid to the charge of the Huffites in general, and to their two leaders, Zifka and Procopius, in particular. After the time of the council of Bafil, in 1433, which endeavoured, though without fuccefs, to reconcile the Taborites with the Roman pontiff, they began to review their religious tenets, and their ecclefiaftical difcipline, with a defign to render them more perfect. This review, conducted with great prudence and impartiality, gave a rational afpect to the religion of this fect, who withdrew themfelves from the war with Sigifmund, in which they were engaged, abandoned the doctrines, which, upon ferious examination, they found to be inconfiftent with the genius and fpirit of the Gofpel, and banifhed from their communion all thofe whofe difordered brains or licentious manners might expofe them to reproach. The Taborites, thus new-modelled, were the fame with thofe Bohemian brethren (or Picards, *i. e.* Beghards, as their adverfaries called them) who joined Luther and his fucceffors at the Reformation, and of whom there are at this day many of the defcendants and followers in Poland and other countries. Mofh. Eccl. Hift. vol. iii.

TABORNOST, in *Geography*, a town of Africa, in the country of Darah; 120 miles S.E. of Morocco.

TABORO, a mountain of Naples, in Principato Citra, on the confines of Lavora.

TABOROWKA, a town of Poland, in the palatinate of Kiev; 16 miles W.N.W. of Bialacerkiev.

TABOTUVO, a town of Africa, on the Ivory Coaft; 45 miles S.W. of Druin.

TABOU, a town of Africa, on the Ivory Coaft; 36 miles S.W. of Druin.

TABOURET, *Privilege of the*, in France, is a privilege fome great ladies enjoy, to fit, or have a ftool, in the queen's prefence.

TABRE, in *Geography*, a town of Hindooftan, in the Carnatic; 15 miles E. of Volconda.

TABREEZ, or TAURIS, a city of Perfia, the capital of the province of Adirbeitzan, or Azerbijan. Sir William Jones, and other learned perfons, are of opinion, that this city was the ancient Ecbatana. M. D'Anville, adjudging that honour to Hamadan, conceives Tauris to be Gaza, or Gunzaca, where Cyrus depofited the treafures of Crœfus, and which was afterwards taken by Heraclius. According to the Perfians, Zobeida, the celebrated wife of Haroun-ul-Rafhid, was its founder; but on their authority we can place little reliance. It is certain, however, that Tauris was a favourite refidence of Haroun-ul-Rafhid; and though he had not the honour of founding this city, it is probable that he improved and embellifhed it in a confiderable degree. In the days of Chardin, it was one of the largeft and moft populous cities in the Eaft, and, according to that traveller, contained half a million of inhabitants. But no town has fuffered more from the ravages of war. Situated towards the frontiers of contending empires, it has alternately been occupied by Turks, Tartars, and Perfians, and has been captured and facked eight different times; but its ruin has been chiefly owing to the number of earthquakes which have, at different times, levelled its proudeft edifices with the duft.

Tabreez does not now contain more than 30,000 inhabitants, and is one of the moft wretched cities in Perfia. It is feated on an immenfe plain at the foot of a mountain, on the banks of a fmall river, the waters of which are confumed in the cultivation. This river, called Agi, proceeds from the mountains at Buftum, and enters the plain of Tabreez three miles N. of that city. This city is furrounded with a decayed wall, and the only decent houfe in the place is a new barrack, erected by the prince for the accommodation of his troops. The ruins of the ancient city are very extenfive and very mean, being nothing but a confufed mafs of old mud walls. Tabreez is fituated in N. lat. 38° 10′. E. long. 46° 37′. Kinneir's Mem. of the Perfian Empire.

TABUDA, in *Ancient Geography*, a river of Belgic Gaul, in the country of the Morini, near Gefforiacum Navale. Ptol.

TABUE',

TABUE', in *Geography*, a town of Egypt, on the Nile; 9 miles S.W. of Menuf.

TABUIL, a town of South America, in the province of Tucuman; 20 miles E. of St. Fernando.

TABULAR Spar, in *Mineralogy*, *Spathon tables*, Haüy; a fpecies of lime-ftone, generally of a greyifh-white colour, but fometimes inclining to greenifh-yellow or reddifh-white. It occurs maffive and cryftallized in rectangular four-fided tables. The luftre of the principal fracture is fhining and pearly; the ftructure is imperfectly lamellar. Tabular fpar occurs in large diftinct prifmatic concretions, which are promifcuoufly aggregated: it is tranflucent, and phofphorefces when fcratched with a knife: its fpecific gravity is 2.86. It is fometimes friable. When put into nitrous acid it effervefces, and then falls into grains. It is infufible by the blowpipe. The analyfis, as given by Klaproth, is

Silex - - -	50
Lime - - -	45
Water - - -	5

This mineral is of rare occurrence; its locality, as given by Stütz, is at Dognafka, in the bannat of Temefvar, in Hungary, where it occurs in blue-coloured primitive lime-ftone, with garnets, actinolite, tremolite, and variegated copper. It is faid by Eftner to occur at Ozavitza. In the new fyftem of mineralogy propofed by Berzelius, this mineral is denominated a *bifiliciate of lime;* the oxygen contained by the different conftituent parts being in the proportion of 6.3 and 1; the filex containing twice the oxygen of the lime, and the water the fixth part.

TABULARIUM, among the Romans, the name of that part of the treafury where the Elephantine books were kept.

TABULARIUS. See Tabellio.

TABULARUM Apertura. See Apertura.

TABULATUM. See Tabella.

TABUM, a word ufed by medical writers, to exprefs a thin, fanious, and putrid humour, flowing from old ulcers, or from mortified parts, in cafes where the vital powers are not fufficient for the generation of a perfect or concocted matter.

TABY, in *Geography*, a town of Sweden, in Eaft Gothland; 14 miles S.E. of Nordkioping.

TACA, a town of Japan, in the ifland of Xicoco; 20 miles S.W. of Tofa.

TACALALPO, a town of Mexico, in the province of Tabafco; 23 miles S.W. of Tabafco.

TACALAYO, a town of South America, in the province of Chaco; 35 miles N. of St. Salvador de Jugui.

TACALEA, a town of South America, in the province of Carthagena, at the conflux of the Cauca and Madalena; 85 miles S.E. of Carthagena.

TACAMAHACA, in *Gardening*, a tree of the ornamental and fweet-fmelling kind, which is often planted out in fhrubberies, borders, and other parts of pleafure-grounds with much propriety and advantage in its appearance, and the grateful odour which it diffufes all around it. See Populus.

Tacamahaca, or *Tacamacha*, a kind of refinous gum, diftilling from the trunk of a very large tree, a fpecies of poplar, growing in New Spain, Canada, and other parts of America; but in the greateft abundance, as it is faid, in the ifland of Madagafcar.

The tree is not unlike our poplar-tree, only bigger and taller; its leaves long and green, its fruit red, of the fize of our walnuts, exceedingly refinous, and containing a ftone like our peaches. See Populus *Balfamifera*.

The wood of the tree makes good timber for fhips, and the gum it yields ferves there for their caulking, though its chief ufe with us is in medicine.

Two forts of this refin are fometimes to be met with. The beft, called tacamahaca in fhells, from its being collected in a kind of gourd fhells, is fomewhat unctuous and foft, of a pale yellowifh or greenifh colour, a bitterifh aromatic tafte, and a fragrant delightful fmell, approaching to that of lavender and ambergris. This fort is very rare. That commonly found in the fhops is in tranfparent grains or globes, of a whitifh, yellowifh, brownifh, or greenifh colour, and of a lefs grateful fmell than the foregoing.

The firft is faid to exude from the fruit of the tree; the other from incifions made in the trunk. The tree, as raifed among us, affords in its young buds, or the rudiments of the leaves, a refinous juice of the fame kind of fragrance.

Tacamahaca is chiefly ufed as an ingredient in warm nervine plafters; though the fragrance and tafte of the finer fort indicate its being applicable to other purpofes, as an internal balfamic corroborant. Both kinds diffolve in rectified fpirit into a gold-coloured liquor, with a fmall quantity of remaining impurity: they alfo impregnate water confiderably with their fmell and tafte, but give out very little of their fubftance to this menftruum. Lewis. The Indians are faid to ufe it for all kinds of pains. Schroder affirms, that he has feen intolerable pains in the leg removed by it.

TACAMES, or Atacames, in *Geography*, a government of South America, in the province of Quito, fituated W. of the weftern Cordilleras of the Andes, bordering northward on the department of Barbacoas, in the government of Popayan, weftward on the South fea, and fouthward on the territory of Guayaquil, and reaching along the coaft from the ifland of Tumaco and the houfe of Hufmal, which lie in N. lat. 1° 30', to the bay of Caracas, and the mountains of Balfamo, in S. lat. 0° 34'. This jurifdiction was long neglected after the conqueft of it by Sebaftian de Belalcazar, the introduction of the Chriftian religion, and its homage to the king of Spain. At length, however, it was difcovered that by making fettlements here, the intercourfe and commerce betweeen Quito and Terra Firma would be facilitated; and with this view, Paul Durango Delgadillo was, in the year 1621, appointed governor of Atacames and Rio de las Efmaraldas. He was fucceeded by Francifco Perez Menacho in 1626, and other governors, who failed in the accomplifhment of the object for which they were appointed: at length Don Pedro Vicente Maldonado, in 1741, laid open a direct communication betwixt Quito and the Rio de las Efmaraldas, and in recompence of his fuccefs he was confirmed as governor in 1746, and in the following year the country was formally conftituted a government. This government contains twenty towns, which are but fmall and poor, five of them fituated on the fea-coaft, and the others being inland places. The inhabitants of the five towns are Spaniards, Meftizos, Negroes, and Cafts, which fprung from thefe three claffes. Thofe of the other fifteen are in general Indians, among whom are few Spaniards, Mulattos, or Negroes. The fpiritual concerns of the diftrict are entrufted to eleven priefts, who refide in the great towns, and occafionally vifit the others, in which are chapels of eafe.

The temperature of Atacames is like that of Guayaquil, and accordingly it produces the fame kinds of vegetables, grains, and fruits; fome of them to greater perfection, on account of its more elevated fituation. It likewife produces in great abundance vanillas, achote, farfaparilla, and indigo. Confiderable quantities of wax are made here, and the forefts of the country afford a great variety of trees of large fize and lofty height, fit for domeſtic and naval purpoſes. (Juan and Ulloa's Voyage, vol. i.) M. d'Anville, in his map of Quito, has marked the ſuppoſed loſt mine of Emeralds, about 20 miles to the ſouth of the town of Tacames, which is ſituated in a bay of the Pacific ocean, to which it gives name; 110 miles N.W. of Quito. N. lat. 0° 52'. W. long. 62°.

TACAPHORIS, in *Ancient Geography*, a town of Africa, in the interior of Marmarica. Ptol.

TACARIGUA, *Bay* or *Lake*, in *Geography*, is ſituated in the government of Caraccas, in America, about one and a half league from the mouth of the river Tuy. Its form is circular, and its meaſure is about ſeven leagues from the ſea, on the N.E. to its deepeſt receſs on the S.E. It abounds in all kinds of ſea-fiſh, and is remarkable for the great number of alligators which are ſeen in it.

TACASARTA, in *Ancient Geography*, a town of Egypt, upon the route from Memphis to Peluſium. Anton. Itin.

TACASUKI, in *Geography*, a town of Japan, in the iſland of Niphon; 12 miles N.W. of Meaco.

TACATO, a town of Japan, in the iſland of Niphon; 48 miles S.S.W. of Jedo.

TACATUA, Tackus, in *Ancient Geography*, a town ſituated on the coaſt of Africa, between Ruſicades and Hippone; E. of the promontory of Tapſos, and W. of that of Hippi.

TACAU, in *Geography*, a town of Japan, in the iſland of Niphon; 90 miles N.W. of Jedo.

TACAXI, a ſmall iſland of Japan, on the S. coaſt of the iſland of Ximo, at the entrance into the gulf of Ximabara.

TACAZZE', a river of Africa, next to the Nile the largeſt in Upper Abyſſinia. Its principal branch riſes in Angot, in a plain champaign country, about 200 miles S.E. of Gondar, near a ſpot called Souami Midre. It has three ſpring-heads, or ſources, like the Nile: near it is the ſmall village Gourri, ſignifying cold. The other branch of the Tacazzé riſes in the frontiers of Begemder, near Dabuco, whence, running between Goulion, Laſta, and Beleſſen, it joins with the Angot branch, and becomes the boundary between Tigré and Amhara. This river was called the Siris, or the river of the dog-ſtar, whilſt the uncivilized people, the Cuſhites of the iſland of Meroë, reſided upon its banks. It was then called the Tannuſh Abay, or the leſſer of two rivers that ſwelled with the tropical rains, which was the name given to it by the peaſants from a compariſon of it with the Nile. It was the Tacazzé in Derkin, or the dwelling of the Taka, before it joined the Nile in Baja, and it was the Aſtaboras of thoſe of the ancients that took the Nile for the Siris. It is now the Atbara, giving its name to that peninſula, which it incloſes on the E. as the Nile does on the W. and which was formerly the iſland of Meroë. Tacazzé is a pleaſant river, ſhaded with fine lofty trees, and having its banks covered with tamariſks and buſhes ſingularly fragrant. Its ſtream is very limpid, its water excellent, and it abounds with a great variety of fiſh: its coverts are alſo full of all ſorts of game. During the inundation, it carries in its bed nearly one-third of all the water that falls in Abyſſinia, riſing to about three fathoms, tearing up rocks and large trees in its courſe, and forcing down their broken fragments ſcattered in its ſtream, with a noiſe like thunder echoed from a hundred hills. This river, though in many reſpects beautiful, has its diſadvantages. From the falling of the firſt rains in March till November, it is death to ſleep in the country adjoining to it, both within and without its banks. The inhabitants retire and live in villages on the top of the neighbouring mountains; and theſe are all robbers and aſſaſſins, who deſcend from their habitations in the heights to lie in wait for, and plunder the travellers who paſs that way. Its abundance of fiſh draws together a number of crocodiles: in its adjacent thickets are vaſt multitudes of lions and hyænas. The ford of this river is ſituated in N. lat. 13° 42' 45". Bruce's Travels, vol. iii.

TACCA, in *Botany*, a Malay name, uſed by Rumphius, and adopted by the claſſical Forſter, as well as by the younger Linnæus. The word being, though barbarous and unmeaning, eaſy of pronunciation, we are induced to acquieſce in theſe authorities, and to retain it, along with *Aucuba*, *Pandanus*, and a few other names ſo circumſtanced. Sir Joſeph Banks and Dr. Solander had called the ſame genus, very elegantly and judiciouſly, *Chaitæa*, from χαίτη, *a flowing mane*, or *head of hair*, in alluſion to the ſpreading tuft of long capillary filaments, apparently a ſort of bracteas, or abortive ſtalks, accompanying the flowers.—Forſt. Gen. t. 35. Linn. Suppl. 37. Schreb. 229. Willd. Sp. Pl. v. 2. 200. Mart. Mill. Dict. v. 4. Brown Prodr. Nov. Holl. v. 1. 340. Ait. Hort. Kew. v. 2. 306. Juſſ. 56. Lamarck Illuſtr. t. 232. Gærtn. t. 14.—Claſs and order, *Hexandria Monogynia*. Nat. Ord. *Narciſſi*, Juſſ. Akin to *Aroideæ* and *Ariſtolochiæ*, Brown.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, in ſix very deep, elliptic-oblong, equal, converging, permanent ſegments. *Cor.* none. *Stam.* Filaments ſix, oppoſite to the ſegments of the calyx, into whoſe baſe they are inſerted, and half as long, equal, dilated, flat, oblong, incurved and vaulted at the ſummit; anthers ſeſſile in the hollow of each filament, of two diſtinct lobes. *Piſt.* Germen inferior, roundiſh; ſtyle ſhort, cylindrical, with three furrows; ſtigmas three, ſpreading, dilated, cloven. *Peric.* Berry ovate, angular, of one cell. *Seeds* numerous, ovate, ſtriated, "inſerted into three receptacles annexed to the coat of the berry." *Brown*.

Eſſ. Ch. Calyx in ſix deep equal ſegments. Petals none. Filaments vaulted. Stigmas ſtellated. Berry inferior, angular, with many ſeeds.

1. T. *pinnatifida*. Pinnatifid Tacca, or Otaheite Salep. Linn. Suppl. 251. Forſt. Prodr. 36. Pl. Eſcul. 59. Willd. n. 1. Ait. n. 1. Loureir. Cochinch. 300. (Tacca; Rumph. Amboin. v. 5. 324—328. t. 112—114. Chaitæa Tacca; Banks Ic. Ined. apud Bibl. Linn. Leontice Leontopetaloides; Linn. Sp. Pl. 448. "Leontopetaloides; Amman. in Comm. Petrop. v. 8. 211. t. 13.")—Leaves pinnatifid.—Native of the Eaſt Indies, Cochinchina, the tropical part of New Holland, and the Society Iſlands; brought to England by Capt. Bligh, in 1793, but has not yet flowered. *Aiton*. The *root* is tuberous and perennial. *Leaves* one or two, radical, on long ſtalks, erect, deeply three-cleft, with deeply and variouſly pinnatifid, acute, entire lobes, a foot long, ſmooth, reticulated with veins. *Footſtalk* hollow, ſmooth. *Flower-ſtalk* radical, about a yard high, hollow, erect, unbranched, terminating in a ſimple umbel of ſeveral drooping, green, ſomewhat glaucous, *flowers*, accompanied by an *involucrum* of about as many upright, partly pinnatifid, green leaves, near two inches long; with a greater number of much longer thread-ſhaped bodies, ſuſpected by Mr. Brown to be abortive flower-ſtalks. The *berries* are black, larger than a gooſeberry, but little juicy when ripe.

Forſter ſays the freſh root is intenſely bitter and acrid, though ſomewhat milder when cultivated. By being grated, and repeatedly waſhed in freſh water, it yields a very white mild powder, like ſtarch, which is dried in the ſun, and then ſerves for food, either in the manner of Salep, or baked in the form of cakes, which are even better than thoſe made of Sago. The former mode of uſing this powder is is cuſtomary in the South-ſea, the latter in the Molucca, iſlands. This root is alſo applied as a plaſter, we preſume freſh, for deep wounds made with darts or other weapons. It is well known that a ſimilar powder, or mild wholeſome flour, is obtained, by waſhing, from the roots of *Jatropha Manihot*, and various ſpecies of *Arum*, even our common *Arum maculatum*, as well as from raw potatoes.

2. T. *integrifolia*. Entire-leaved Tacca. Gawler in Curt. Mag. t. 1488. Ait. Epit. 375.—Leaves ovate, undivided.—Native of the Eaſt Indies, from whence it was ſent by Dr. Roxburgh to ſir Abraham Hume, and flowered in the ſtove at Wormleybury, in June 1812. The *leaves* are four or five inches long, probably often more, ſmooth, quite ſimple and entire, with one rib and many oblique veins; each on a ſtout, channelled, brown *footſtalk*. *Flowers* umbellate, erect or decumbent, of a dingy green, with purple ſtalks. Leaves of the *involucrum* large, ovate, pale green with many purple ribs, and accompanied by a few white thread-ſhaped ſtalks, reſembling the former. We have ſeen no ſpecimen in flower.

TACE, Ital., in *Muſic*, be ſilent.

TACET, Lat., is uſed when a vocal or inſtrumental part is to be ſilent during a whole movement: as in a maſs, *Chriſte tacet*; in a concerto or ſonata, *Largo tacet*, &c.

TACET, JOSEPH, in *Biography*, an eminent performer and maſter on the German flute, born, we believe, in France; but who came to England ſo early, and continued here ſo long, that by forgetting his own language, he ſpoke Engliſh like a native of the iſland. He was the firſt to adopt the additional keys of Quantz to the German flute, in order to correct the bad notes, and increaſed their number from three to five; though, we believe, he ſeldom uſed them all.

TAC-FREE, in *Old Charters*, an exemption from payments.

TACHAN, in *Geography*, a ſmall iſland in the Chineſe ſea, near the coaſt of Cochinchina. N. lat. 12° 35′. E. long. 109° 14′.

TACHAR, a town of Thibet; 23 miles S. of Tourfan.

TACHARD, GUY, in *Biography*, a French Jeſuit, who, after accompanying chevalier de Caumont, and the abbé de Choiſi, on an embaſſy to Siam, returned to Europe in 1688, and having made another voyage to the Indies, died at Bengal about 1694. His "Two Voyages to Siam," in 2 vols. Paris, 1686 and 1689, re-printed at Amſterdam in 1700, well received at the time of their publication, have ſunk in reputation on account of the credulity and exaggeration of the author, of which ſatisfactory evidence has been given by chevalier de Forbin, in his Memoirs. Nouv. Dict. Hiſtor.

TACHAR-SEGHIN, in *Geography*, a town of Thibet; 50 miles S. of Tourfan.

TACHAS, in *Ichthyology*, a name given by ſome authors to the manati, or ſea-cow.

TACHASARA, in *Ancient Geography*, a town of Aſia, in the interior of Media, between Zalaca and Pharambara. Ptol.

TACHAU, or TACHOW, in *Geography*, a town of Bohemia, in the circle of Pilſen, taken by Ziſka by aſſault, and ſacked in the year 1427; 34 miles W. of Pilſen. N. lat. 49° 47′. E. long. 12° 40′.

TACHBACH, a town of Germany, in the county of Henneberg; 8 miles E.S.E. of Meinungen.

TACHEMAL-ONDOUC, a town of Chineſe Tartary. N. lat. 45° 59′. E. long. 122° 31′.

TACHEMPSO, or TACHOMPSO, in *Ancient Geography*, an iſland of Ethiopia, in the vicinity of Libya, partly occupied by the Egyptians, and partly by the Ethiopians.

TACHENS, in *Geography*, a lake of the archbiſhopric of Salzburg, five miles long, and about one wide; 14 miles N.W. of Salzburg.

TACHIA, in *Botany*, called *Tachi* by the Galibis in Guiana, becauſe the hollow ſtem and branches of this ſhrub ſerve as a retreat for ants, the above word ſignifying, in the language of thoſe people, an ant's neſt. Aublet Guian. 75. t. 29. See MYRMECIA.

TACHIBOTA. See SALMASIA.

TACHIGALIA, *Tachigali* of the Galibis in Guiana. See CUNÆA.

TA-CHOUI-CAO-HOTUN, in *Geography*, a town of Corea; 425 miles E. of Peking. N. lat. 40° 11′. E. long. 124° 53′.

TACHYGRAPHY, called alſo BRACHYGRAPHY, formed from ταχυς, *ſwift*, and γραφη, *writing*; the art of quick or ſhort writing.

There have been various kinds of tachygraphy invented: among the Romans, there were certain notes uſed, each of which ſignified a word.

The rabbins have a kind of tachygraphy formed by abbreviations, which made a kind of technical words; wherein each conſonant ſtands for a whole word: as רמבם, רשי, *raſchi*; which ſtands for *rabbi Schelomoh Jarri*. See NOTARICON.

In France, &c. the only tachygraphy uſed is, the retrenching of letters, or even whole ſyllables of words, as in *ſdm* for *ſecundum*, *aut* for *autem*, *d* for *ſed*, *o* for *non*, *participaon* for *participation*, &c.

The firſt printers imitated theſe abbreviations; but at preſent they are almoſt laid aſide, except among ſcriveners, &c.

In England we have great variety of methods of tachygraphy, or ſhort-hand; more by far, and thoſe much better, eaſier, ſpeedier, and more commodious, than what are known in any other part of the world: witneſs Shelton's, Wallis's, Rich's, Maſon's, Webſter's, Weſton's, Macaulay's, Annet's, Gurney's, Lyle's, Byrom's, Rees's, and ſeveral other ſhort-hands. See STENOGRAPHY.

TACISSO, JEUNG, in *Geography*. See TASSASUDON.

TACIT ACCEPTANCE. See ACCEPTANCE.

TACIT *Community*. See COMMUNITY.

TACIT *Decree*, in *Roman Antiquity*, ſecret deliberations, to which none but old ſenators were ſummoned.

J. Capitolinus mentions a decree of this ſecret kind, which he calls *S. C. tacitum*, and ſays, that the uſe of them among the ancients was derived from the neceſſities of the public, when upon ſome imminent danger from enemies, the ſenate was either driven to ſome low and mean expedients, or to ſuch meaſures as were proper to be executed before they were publiſhed, or ſuch as they had a mind to keep ſecret even from friends; on which occaſions they commonly recurred to a tacit decree, from which they excluded their clerks and ſervants. performing that part themſelves, leſt any thing ſhould get abroad. Capitol. de Gordian. c. 12.

In the early times of the republic, there are ſeveral inſtances mentioned by hiſtorians of ſuch private meetings of the ſenate, ſummoned by the conſuls to their own houſes; to which none but the old or proper ſenators were admitted, and of which the tribunes uſually complained. Vide Dion. Halic. l. x. 40. l. xi. 55. 57. Middlet. of Rom. Sen. p. 90.

TACITUS, CAIUS CORNELIUS, in *Biography*, a well-known hiſtorian, was born about the year of the Chriſtian era 57, at Interamna, or the modern Terni. His father was a Roman knight, and procurator of Belgic Gaul. Devoted from his youth to the cultivation of literature and rhetoric,

rhetoric, his reputation at maturity was fo well eftablifhed, that he was permitted by Julius Agricola, at the expiration of his confulate, which occurred in the year 77, to form a matrimonial connection with his daughter. Thus introduced into public life, he was honoured by the patronage of Vefpafian, Titus, and Domitian. Having difcharged the office of prætor, he withdrew from the capital for four years; and on his return he found the latter emperor exercifing a tyranny which he bitterly lamented. His profpects, however, were brightened by the acceffion of Nerva to the confulfhip, in the year 97; and as his affociate Verginius Rufus died before the termination of his office, Tacitus was appointed to be his fucceffor, and commenced his literary career, if the "Dialogue concerning Orators" be not his compofition, with an eloquent oration at the funeral of Verginius, of whom Pliny fays that he "crowned the felicity of his life by poffeffing the moft eloquent of eulogifts at his death." In the early part of Trajan's reign, he concurred with his friend Pliny the Younger, in the accufation of Marcus Prifcus for the crimes with which he was chargeable during his proconfulate of Africa. The conduct of Tacitus and Pliny on this occafion was honoured by the encomium of the fenate in their fentence and condemnation of the culprit. The future circumftances of his life, and the precife time of his death, are unknown; but as he makes no allufion to the reign of Adrian, it is moft probable that he did not furvive that of Trajan.

The principal works of Tacitus were his "Annals," and his "Hiftory." The former comprehended the Roman affairs from the death of Auguftus to that of Nero; but it has been tranfmitted to us in a very mutilated ftate. The latter comprifed the period from the end of Nero to the death of Domitian; and now exifts in an imperfect ftate, as the narrative does not extend far beyond the acceffion of Vefpafian. His other works are, a "Life of Agricola," and a treatife "On the Manners of the Germans." The ftyle of his writings is fingularly concife, abrupt, and elliptical, fo that the reader is often at a lofs to comprehend his meaning. His aim feems to have been to comprize much in a fmall compafs, and he has thus furnifhed a great variety of political maxims, which, by the brevity with which they are expreffed, are peculiarly adapted to imprefs the memory. It is obferved, however, by one of his biographers, that he occafionally difcovers "an affectation of converting common remarks into aphorifms, and of philofophizing when he was only required to narrate." Neverthelefs, as the fame author remarks, "no profe writer in any language furpaffes or perhaps equals him in force of defcription, and the choice of circumftances by which he dramatizes a fcene, and brings it before the eyes of his reader; and no want of perfpicuity appears in his ftyle when employed in the relation of ftriking events." The writer whom we are now citing extols the moral merits of Tacitus as an hiftorian, and gives him his full fhare of praife for inculcating the nobleft principles of action, both public and private, and difplaying the evils arifing from uncontrolled power, united, as it generally muft be, with vice and tyranny. "He was guarded," fays the biographer, "by philofophy againft credulity, and by the love of truth againft calumny." He adds, "upon the whole, whatever defects may be juftly imputed to him, his works can never fail to keep a diftinguifhed place among the moft valuable treafures which antiquity has bequeathed to us." The following editions of the works of Tacitus are thofe which are held in the higheft eftimation: *viz.* Ryckii, Lugd. Bat. 1687, 2 vols. 12mo.; Gronovii, Traj. 1721, 2 vols. 4to.; Ernefti, Lipf. 1752 and 1772, 2 vols. 8vo.; Brotier, Paris, 1771, 4 vols. 4to. and 1776, 7 vols. 12mo. Many tranflations in different languages are extant. Brotier Præf. Gen. Biog.

Tacitus, M. Claudius, an emperor of Rome, who was advanced to this eminence from the rank of fenator, to which he belonged at the time of Aurelian's death, A.D. 275. He was then about 75 years of age, having been conful twice, bearing the character of diftinguifhed wifdom and moderation, and enjoying a patrimony valued at between two and three millions fterling. An interregnum took place in confequence of the refufal of the army and fenate to nominate an emperor, and had lafted nearly eight months. Tacitus wifhed to refer the choice to the army; but finding that he was the perfon to whom the attention of the public was directed, he withdrew to his country feat in Campania, and continued there two months. At length, the conful convoked the fenate, and Tacitus appeared in the affembly. Being afked his opinion on the fubject that had occafioned delay, he arofe to reply; but he was immediately faluted, amid general acclamations, with the titles of Auguftus and emperor. The plea of his age and infirmities was of no avail; conftrained to accept the high honour on Sept. 25, A.D. 275, he entered on his office; the Roman people and the prætorian guards approving and confirming his election. His firft object was to reftore to the fenate rights and privileges, which ferved to render the conftitution a limited monarchy. After thus gratifying the fenators, he proceeded to regulate and reform the public morals; exhibiting in his own conduct an example of fimplicity and frugality, whilft he was unufually munificent in his attention to public objects. To literature he was a diftinguifhed patron; and he paid particular refpect to his anceftor, the hiftorian Tacitus, directing ten copies of his works to be annually depofited in the public libraries. In order to fecure the attachment of the army, he vifited the camp at Thrace at the commencement of the year 276, promifed the ufual donative, and inflicted punifhment on the principal perfons who had been concerned in the murder of Aurelian. In procefs of time, diffentions broke out amongft the troops, and the malcontents being joined by the murderers of Aurelian, who had made their efcape, either by direct violence, or by the vexation which they occafioned to the aged emperor, terminated his life at Tyana, in Cappadocia, after a reign of 200 days. Crevier. Gibbon.

TACK, in *Sail-Making*, the foremoft lower corner of all fore and aft fails.

Tack, a rope ufed to confine the clues of the main and fore courfes forward occafionally in a fixed pofition, and alfo to confine the tacks of ftay-fails, boom-fails, and fore-fails of floops; and the outer lower corners of ftudding-fails. The tacks of the main and fore courfes are ropes cable-laid, and made tapering, having a large wall-knot at one end, which prevents its drawing through the clue of the fail.

Tack is alfo applied by analogy to that part of any fail to which the tack is ufually faftened. A fhip is faid to be on the ftarboard or larboard tack when fhe is clofe-hauled, with the wind upon the ftarboard and larboard fide: and in this fenfe, the diftance which fhe fails in that pofition is confidered as the length of the tack; although this is more frequently called a *board*. Falconer.

Tack, *To*, in *Sea Language*, is to change the courfe from one board to another, or to turn about the fhip from the ftarboard to the larboard tack, in a contrary wind.

Tacking is alfo ufed, in a more enlarged fenfe, to fignify that manœuvre in navigation, by which a fhip makes an oblique progreffion to the windward, in a zigzag direction. This, however, is more ufually called *beating*, or *turning* to windward.

windward. In order to explain the theory of tacking a ſhip, recourſe muſt be had to the two firſt laws of motion, recited under *Laws of* NATURE: according to which, it is eaſy to conceive how a ſhip is compelled to turn into any direction, by the force of the wind acting upon her ſails in horizontal lines. For the ſails may be ſo arranged as to receive the current of air, either directly, or more or leſs obliquely: hence the motion communicated to the ſails muſt neceſſarily conſpire with that of the wind upon their ſurfaces. To make the ſhip tack, or turn round with her head to the windward, it is therefore neceſſary, after ſhe has received the firſt impreſſion from the helm, that the head-ſails ſhould be ſo diſpoſed as to diminiſh the effort of the wind, in the firſt inſtant of her motion, and that the whole force of the wind ſhould be exerted on the after-ſails, which operating on the ſhip's ſtern, carries it round like a weather-cock. But ſince the action of the after-ſails to turn the ſhip will unavoidably ceaſe, when her head points to the windward, it then becomes neceſſary to uſe the head-ſails to prevent her from falling off, and returning to her former ſituation. Theſe are, accordingly, laid aback on the lee-ſide, to puſh the veſſel's fore-part towards the oppoſite ſide, till ſhe has fallen into the line of her courſe thereon, and fixed her ſails to conform with that ſituation.

The firſt effort to turn the ſhip in tacking, communicated by the helm, which is then put to the lee-ſide, being announced by the pilot, or commanding officer, who then calls out, *Helm's a-lee!* the head-ſails are immediately made to ſhiver in the wind, by caſting looſe their ſheets or bowlines. The pilot then calls, *Up tacks and ſheets!* which is executed by looſening all the ropes which confine the corners of the lower ſails, in order that they may be more readily ſhifted to the other ſide. When the ſhip has turned her head directly to windward, the pilot gives the order to turn about the ſails on the main and mizen-maſts, by the exclamation, *Haul main-ſail, haul!* the bowlines and traces are then inſtantly caſt off on one ſide, and as expeditiouſly drawn in on the other ſide, ſo as to wheel the yards about their maſts: the lower corner of the main-ſail is, by means of its tack, pulled down to its ſtation at the cheſs-tree; and all the after-ſails are, at the ſame time, adjuſted to ſtand upon the other board. Finally, when the ſhip has fallen off five or ſix points, the pilot cries, *Haul off all!* or, *let go*, and *haul!* the ſails on the fore-maſt are wheeled about by their braces; and as the ſhip has then a tendency to fall off, ſhe is checked by the effort of the helm, which for that purpoſe is put *hard-a-lee*. The fore-tack, or the lower corner of the fore-ſail, being fixed in its place, the bowlines are hauled; and the other ſails, which have been neglected in the hurry of tacking, are properly arranged to the wind; which exerciſe is called *trimming the ſails*. Falconer.

TACK *of a Flag*, a line ſpliced into the eye at the bottom of the tabling, for ſecuring the flag to the haliards.

TACK-*Stopper*. See STOPPER.

TACK, in *Rural Economy*, a term provincially made uſe of in ſome diſtricts, as Glouceſterſhire, to ſignify a ſort of ſhelf, within the dairy, for laying cheeſe upon while they are drying, and afterwards.

TACK, or *Tack of Land*, in *Agriculture*, is a word uſed in ſome parts of the nation, as thoſe of the north, for the term of a leaſe. It, in ſhort, denotes the means by which land is holden by the farmer, from the proprietor or real owner, in the intention of cultivation and improvement, for the advantages of the produce. It was in its origin a ſort of feudal or military tenure of land: accordingly it is found, the writer of the corrected Agricultural Report of the County of Peebles ſays, that, as military tenants, at firſt, became tenants for life, from being tenants at will; ſo the firſt notion of giving the ſecurity of independence to the cultivator of the ſoil, in Scotland, as elſewhere, was to give him ſecurity of poſſeſſion for life. The life-rent tack ſeems, it is ſaid, the firſt adopted ſpecies or kind of tack-holding, rendering the poſſeſſor independent, his ſituation reſpectable, and his rights and intereſts regarded. Superior privileges were accordingly beſtowed upon the life-rent tack; the property in this tack was, and is, conſidered to be ſo complete, as to imply the full power of its alienation, in defiance of the proprietor's ſuppoſed eſſential and inherent right of the *delectus perſonæ;* and, when granted to a woman, was not conſidered as forfeited upon her marriage, as implying aſſignment contrary to the proprietor's right of *delectus*, in conſequence of its falling under the huſband's *jus mariti;* although ſuch, it is ſaid, is the abſurd conſtruction of Scots law, in regard to the effect of a woman's marriage, upon a tack for definite time, to which ſhe ſhould fall heir by inheritance, or even, perhaps, acquire by perſonal contract. The period of nineteen years ſeems, it is ſaid, in Scotland, to have been conſidered as equivalent to the life of a perſon of age to enter upon a life-rent tack; and that, from this analogy, various privileges, originally communicated to the life-rent, would ſeem to have been extended to this ſpecies or kind of tack. As nineteen years may, however, be conſidered as a favourable exchange for a life-rent, this is, it is thought, probably the reaſon why the Scots tenant ſeems to have generally preferred this ſecurity; inſomuch that the mention of a tack, without ſpecification of the term, in common habit ſuggeſted the idea of a nineteen years' leaſe. The privileges granted to cultivators, by legiſlating proprietors, ſeem, it is ſaid, to have been granted ſlowly, with reluctance, and to no greater extent than what indiſpenſable utility obviouſly and abſolutely required. A ſhort-ſighted avarice, it is obſerved, wiſhed to graſp at the fruits of the cultivation effected by the tenant's ſtock, as ſpeedily as poſſible; even ſo prematurely, as to allow no ſufficient ſecurity of time for their being effected at all: and the genius of law ſeems, it is thought, to have been univerſally inimical, both in modern and in ancient nations, to the long duration of leaſes, which ſeemed to keep back the proprietor from reaping the benefit of the increaſed value of his property. And that, when ſubſequent views of utility ſuggeſted the propriety of tacks of ſtill longer duration, they were ventured upon with timidity, as an extenſion of a ſpecies of tenure, to which the genius of law was unfriendly; which, as yet, ſhe had not recognized to that extent, and which ſhe might be ſcrupulous in ſanctioning. Such tacks, therefore, it is ſaid, ſought ſhelter under the form of the privileged tack of nineteen years, which had acquired an analogical ſtability, and whoſe taliſmanic influence was thought able to protect them: the whole term meant durſt not, it is ſaid, be avowedly expreſſed; but the tack was granted for two nineteens, or three nineteens of years, until the number of years propoſed ſhould be completed in nineteens.

The tack, though ſtill ſomewhat loaded and encumbered by a remnant of the ſhackles and tyranny of the feudal ſtate, ſo as to conſiderably obſtruct and impede the credit and enterprize of agricultural purſuits, yet probably, in conſequence of the different enactments and deciſions ſince made, empower the holders by it, in the above part of the kingdom, perhaps to enjoy more ſecurity, it is thought, than what was ever beſtowed upon the actual cultivators of the ſoil or land, either in ancient or in modern times. See TENANT and TENURE.

TACKLE, in a *Ship*, a machine formed by the communication

munication of a rope with an affemblage of blocks, and known in mechanics by the name of *pulley*.

Tackles are ufed in a fhip to raife, remove, or fecure weighty bodies, to fupport the mafts, or to extend the fails and rigging. They are either moveable, as communicating with a runner; or fixed, as being hooked in an immoveable fituation; and they are more or lefs complicated, with blocks and fheaves, in proportion to the efforts which they are intended to produce. That part of the tackle which is fixed to one of the blocks, &c. is called the *ftanding part;* all the reft are called *running parts;* and that on which the men pull, when employing the tackle, is called the *fall.* The application of the tackle to mechanical purpofes is termed *hoifting* or *bowfing*. Falconer.

The power of a tackle will be, the friction not confidered, as the number of parts of the fall that are applied to fuftain the weight. If a tackle confifts of a double and a fingle block, and the weight to be hoifted is hung to the double block, there will be four parts of the fall; and the weight refting upon four ropes, equally ftretched, each muft bear the fame part of the weight. Thus, fuppofe the weight hung to the double block be four hundred, then one hundred applied to the fall or hauling part will fufpend it; and if as much more power be applied as will overcome the friction, it will purchafe the weight: but had the weight been hooked to the fingle block, it would have refted on three ropes only, each of which would bear a third part of the weight; therefore, a third part of the weight being applied to the hoifting part of the fall, would fufpend the weight, when hooked to the fingle block; as much more being applied as will overcome the friction, would purchafe the weight.

The blocks that are fixed are only for the convenience of turning the direction of the fall; they add nothing to the power of the purchafe, but, on the contrary, deftroy fo much as is neceffary to overcome their friction, and are, therefore, to be avoided as much as poffible.

Ropes, if tight laid, will not eafily bend round fmall fheaves, but will take up a confiderable part of the power to force them into their proper direction: hence it follows, that blocks with fmall pins, large fheaves, and flack-laid ropes, are the beft materials to obviate friction, and make tackles with more eafe.

The *anchor-ftock* tackle is compofed of a double block and a fingle block, ftrapped, with a hook and thimble. *Boom* tackles are compofed of double and fingle blocks, ftrapped, with tails, and are ufed in getting the ftudding-fail-booms in or out. *Bowline* tackle is compofed of a long tackle, and a fingle block, ftrapped, with a hook and thimble: it is ufed to bowfe up the main-bowline, when the fhip is upon a wind. *Burton* tackles are compofed of double and fingle blocks, and are ufed with pendants, to fet up the fhrowds, fupport the topfail-yards, &c. (See BURTON.) A *fifh* tackle is compofed of a long tackle, and a fingle block, ftrapped, with eyes, and is ufed with a pendant, to fifh the anchor, and get it into its place. *Garnet* tackle is compofed of a double block and a fingle block, ftrapped, with a hook and thimble: it is hooked to the fciatic-ftay in merchant-fhips, and is ufed to hoift goods, &c. in or out. (See GARNET.) *Jigger* tackles are compofed of double and fingle blocks, ftrapped, with tails, and are ufed for topping the main and fore-yards by the lifts, &c. (See JIGGER.) *Luff* tackles are compofed of double and fingle blocks, ftrapped, with a hook and thimble, and are ufed occafionally at any part of the fhip. *Outhauler* tackle is compofed of two fingle blocks, ftrapped, with tails, and is ufed to bowfe out the jib-boom. *Port* tackles are compofed of a fingle block, attached to a fpan made faft to the outfide of the port-lid, and a runner with two fingle blocks, all of which are made faft to the fide of the beam neareft the port, and are ufed to hoift and lower the port-lids. *Quarter* tackles are compofed of double and fingle blocks, ftrapped, with eyes, and lafhed to the outer quarter of the yard and the lower block, with a hook and thimble: they are ufed to hoift up water and provifions. *Reef* tackles are compofed of two double or two fingle blocks: one block is fpliced into a pendant, and the other is ftrapped, with an eye; they are ufed to draw the extremities of the reefs clofe up to the yard-arms for reefing the fail. (See REEF.) *Relieving* tackles are luff tackles, ufed at the fore end of the tillar, when the tillar-ropes are damaged. (See RELIEVING *Tackle.*) *Ridge* tackle is compofed of a double block, and a fingle block, ftrapped, with an eye, and is ufed to fufpend the awning in the middle. *Rolling* tackles are luff tackles, ufed to the topfail-yards, to fupport them under a prefs of fail, and preferve the parrals. *Rudder* tackles are compofed of a long tackle block and a fingle block, ftrapped, with hooks and thimbles: they are ufed to fave the rudder, if unfhipped by accident, or to fteer by, if the tillar is broken. *Runner* tackles are compofed of double and fingle blocks, and a pendant; the lower block is ftrapped, with a hook and thimble: they are ufed to fet up the fhrouds, and to get the maft-heads forward, for ftaying the mafts. *Stay* tackles, main and fore, are compofed of double and fingle blocks, ftrapped, with hooks and thimbles, except the block fpliced into the pendant: they are ufed for getting the provifions, &c. out of the fore and main hold, and for getting the boats in or out. The pendant formerly travelled on the ftay, by iron thimbles; but this has been difcontinued in the navy, as they much injured the ftay by the friction. *Stayfail-ftay* tackles are compofed of double and fingle blocks; the lower blocks are ftrapped, with a hook and thimble: they are ufed to fet up the jib, and other ftayfail-ftays. *Shifting back-ftay* tackles are compofed of double and fingle blocks, ftrapped, with a hook and thimble, and are ufed to fet up the fhifting back-ftays, where wanted. *Topmaft-ftay* and *preventer-ftay* tackles are compofed of long tackle blocks and fingle blocks; the lower blocks are ftrapped, with a hook and thimble: they are ufed to fet the topmaft and preventer ftays. *Fore-top-gallant-ftay* tackle is compofed of a double and fingle block, and is ufed to fet up the fore-topgallant-ftay. *Tack* tackle is compofed of a double and fingle block, ftrapped, with hooks and thimbles, and is ufed for bowfing down the tack of fore and aft main-fails. The *top* tackle is compofed of double or treble blocks: it is attached to the top-rope-pendant, and is ufed to erect the topmafts, at the heads of the lower mafts. *Trufs* tackles are compofed of two double blocks, ftrapped, with hooks and thimbles, and are ufed to fecure the lower yards to their mafts, being hooked to the trufs-pendant. *Winding* tackle is compofed of a fourfold and a treble block, or a treble and a double block, ftrapped, with eyes: it is attached to the winding-tackle-pendant, and is chiefly ufed to get in and out the guns. (See *Plate* II. *Rigging*, *fig.* 17.) *Yard* tackles are compofed of double and fingle blocks; the double blocks are fpliced into the lower ends of the pendants *f*, and the fingle blocks are ftrapped, with hooks and thimbles: they are ufed to hoift the boats in or out.

TACKLE-*Fall*, that end of the rope of a tackle which is bowfed on, or the rope which compofes the tackle.

TACKLE, *Gunner's*, that which ferves to hale the ordnance in or out.

TACKLE *Pendants*. See PENDANT.

Tackle, *Tack*, is a ſmall tackle uſed occaſionally to pull down the tack of the principal ſails of a ſhip to their reſpective ſtations. There is alſo a tackle of this kind conſtantly fixed to the tacks of the main-ſail in brigs, ſloops, and ſchooners, for the ſame purpoſe. Falconer.

TACKRAMAH, in *Geography*, a town of Africa, on the Gold Coaſt. N. lat. 4° 52′. W. long. 3° 10′.

TACKSMAN, in *Agriculture*, the tenant or perſon who holds or takes a tack of land of another. In ſubſetting, the original perſon of this kind is, it is ſaid, by the writer of the Peebles Corrected Agricultural Report, conſidered as bound to the proprietor, as well as the ſub-tenant; whilſt, in aſſignment, the original tenant is free, ſubſtituting the other in his place. In conformity to the analogy of the feudal law, therefore, it is ſaid, as well as to the greater ſecurity of the proprietor, the Scottiſh law is conſidered as more favourable to ſubſet, than to aſſignation; becauſe, in ſubſet, the firſt tenant does not relinquiſh his poſition as a *quaſi* vaſſal, and the purpoſes of the metaphorical *delectus* may be, thus, conſidered as metaphorically, or analogically fulfilled by this *fictio juris*, or *quaſi:* moreover, too, the ſecurity of the proprietor, ſo far from being weakened, is greatly ſtrengthened, in having his right of hypothec unimpaired, and the ſecurity of two inſtead of one. Upon this principle, it was conſidered, it is ſaid, by the Scottiſh law oracle, Erſkine, that a power of ſubſet was implied, in all caſes where the contrary was not directly expreſſed; until the deciſion, in 1791, came to rectify the miſconceptions of the people, when it was decided, that, in a tack of nineteen years, it was implied, in law conſtruction, without any formal ſtipulation in the leaſe to that effect, that the power of *delectus* was retained; and that the tack was neither aſſignable nor ſubſetable.

But even Erſkine allows, it is ſaid, that, upon legal principles, an expreſs ſtipulation in the tack againſt aſſignees, both *legal* and *voluntary*, would prevent the tack from being evicted by the tenant's creditors: otherwiſe a tack, unaſſignable by the tenant's voluntary deed, would, according to him, be evictable by adjudication, at the inſtance of the tenant's creditors: but even in that caſe, the creditors would be guilty of *leſe-majeſte* towards the ſacred right of the *delectus*, were they to bring the reverſion of the leaſe to a fair ſale to the beſt bidder: they are debarred, therefore, it is ſaid, from ſuch unhallowed and irreverend meaſures; they can only enter upon adminiſtration, as reſponſible factors of the tenant's concerns.

TACKUMBREET, in *Geography*, a town of Africa, or, as it may be rather denominated, the ruins of an ancient town called "Siga," or "Sigeum," once the metropolis of Mauritania, ſituated on the coaſt of the Mediterranean, at the mouth of the river Tafna; 44 miles S.W. of Oran. N. lat. 35° 30′. W. long. 0° 55′.

TACKYSERAI, a town of Hindooſtan, in Oude; 35 miles W. of Lucknow.

TACLAOUR, a town of Thibet. N. lat. 38° 5′. E. long. 80° 51′.

TACOLA Imperium, in *Ancient Geography*, a port on the weſtern coaſt of India, on this ſide of the Ganges: and now *Junkſeylon*.

TACOMA, in *Geography*, a town of Mexico; 16 miles N. of Mexico.

TACOMAR-Tree, a name by which ſome authors call the ſugar-cane.

TACON Mountain, in *Geography*, a mountain of America, in Maſſachuſetts, S. of Great Barrington.

TA-CONG-TO-CHE, a town of the iſland of Formoſa. N. lat. 22° 22′. E. long. 120° 4′.

TA-COO, a town of China, in the province of Pe-tche-li, within the mouth of the Pei-ho, or White river, and the firſt place of any note in the N.E. frontier of the country. The grand embaſſy to China arrived at this town in Auguſt 1795, and found here a conſiderable number of yachts, or large covered barges and boats of burden, fit for paſſing over the ſhallows of the *Pei-ho*, (which ſee,) and deſtined to convey the whole of the embaſſy as far as the river led towards the capital of the empire. Many of theſe veſſels were eighty feet long, and very capacious; and yet they were ſo conſtructed of light wood, as not to ſink more than eighteen inches into the water, though they were lofty above it. The cabins were high and airy above: there were births for the crew, and beneath the floors were lockers for ſecuring the neceſſaries. The yacht appropriated to the ambaſſador had an apartment, conſiſting of an anti-chamber, a ſaloon, a bed-chamber and a cloſet; and its windows were adorned with a great number of glaſs-panes; whereas the frames of the windows of the other yachts were generally filled with a kind of paper, manufactured chiefly in Corea, having in its compoſition an unctuous ſubſtance, which rendered the paper more durable when expoſed to the weather, as it was much leſs affected by the rain or any kind of moiſture, than that which is made in Europe. During the ambaſſador's ſtay before Ta-coo, he was viſited by the viceroy of the province, who, by order of the emperor, came from Pao-ting-foo, his uſual place of reſidence, at the diſtance of a hundred miles; and who took up his abode at the principal temple of Ta-coo, conſecrated to the god of the ſea, to whom invocations were frequently addreſſed under the appellation of "Toong-hai-vaung," or king of the Eaſtern ſea. Of this idol there were ſeveral figures in different brilliant edifices of porcelain, within one incloſure. Sir George Staunton, in his account of this embaſſy, has given an engraved repreſentation of this Chineſe Neptune, bearing in one hand a magnet, whilſt he is ſitting on the waves, with firmneſs, eaſe, and dignity, and thus conſcious of his own ſecurity; and in the other, a dolphin, denoting his power over the inhabitants of the ocean. His beard flowed in all directions, and his agitated locks ſeemed to be intended for a perſonification of the troubled element. At a ſmall diſtance from the "Hai-chin-miao," or temple of the ſea-god, is the hall of audience of Ta-coo, ſituated in the midſt of a ſpacious court.

TACOTALPA, a town of Mexico, in the province of Guaxaca, on the river Alvarado; 6 miles S.E. of Alvarado.—Alſo, a town of Mexico, in the province of Tabaſco; 30 miles S.W. of Villa Hermoſa.

TA-COU, a river of China, which runs into the ſea, 7 miles E.N.E. of Kiao.

TACOUR, a town of Hindooſtan, in Myſore; 10 miles S. of Bangalore.

TAC-POU-CHAI, a town of Thibet; 250 miles S.E. of Laſſa.

TAC-POU-NAI, a town of Thibet; 240 miles S.E. of Laſſa.

TAC-POUY Courou-namkin, a town of Thibet; 145 miles S.E. of Laſſa.

Tac-pouy *Laſoi*, a town of Thibet; 120 miles S.S.E. of Laſſa.

TACPOY, a town of Thibet, and capital of a diſtrict; 126 miles S.E. of Laſſa. N. lat. 27° 53′. E. long. 92° 52′.

TACQUET, Andrew, in *Biography*, a mathematician, was born at Antwerp in 1611, and having entered into the order of Jeſuits in 1629, was a teacher of the languages and mathematics for ſeveral years. He died in 1660. Tacquet was the author of ſeveral mathematical works, among which

which we may enumerate the following: *viz.* "Cylindricorum et Annularium, Libri V. Elementa brevi historica Narratione de Ortu et Progressu Matheseos," &c. printed at Venice in 1737, with Whiston's additions; "Arithmeticæ Theoria et Praxis;" "Theoremata selecta ex Archimede." After his death, several of his treatises were published under the title of "Andreæ Tacqueti Antverpiensis Opera Mathematica," containing "Astronomiæ Lib. VIII.," "Geometriæ Practicæ, Lib. III.," "Architecturæ Militaris, Lib. I.:" distinguished by their perspicuity. Montucla. Gen. Biog.

TACSAI Raki, in *Geography*, a lake of Thibet, about 36 miles in circumference. N. lat. 32°. E. long. 88° 34'.

TACSANLU, a town of Asiatic Turkey, in Natolia; 23 miles N.N.W. of Kiutajah.

TACSONIA, in *Botany*, Juss. 398, a name of Peruvian origin, given by that author to such species of Passion-flower, as have a tubular elongation of the base of their calyx. See Passiflora.

TACTICS, τακτικα, formed from ταξις, *order;* the art of disposing forces in form of battle, and of performing the military or naval motions and evolutions. The science of tactics is either *military* or *naval.*

Tactics, *Military*, comprehend great or general tactics, *la grande tactique* of the French writers, which includes every thing that relates to the order, disposition, and formation of armies, their encampment, and every other circumstance pertaining to stores, baggage, &c.; and also particular or subordinate tactics, more immediately comprising their movements and evolutions. With the former every general officer ought to be thoroughly acquainted; whilst the latter should be well understood by inferior officers and soldiers, and cannot be totally disregarded by those of the former description.

The Greeks were very skilful in this part of the military art; having public professors of it, called *tactici*, who taught and instructed their youth therein. We have an account of the progress of this art among them in Thucydides, Xenophon, and Polybius. Ælian also hath a particular book on this subject; and there is a great deal of it in Arrian, in his History of Alex. M. and in Mauritius, and Leo Imperator.

From the Greeks this art was transmitted to the Romans, among whom it arrived at its highest perfection. Vegetius has given us a compilation and abridgment of authors who have written on this subject; and his work contributed in a considerable degree to the establishment of military discipline in Europe; for which we are greatly indebted to Maurice, prince of Orange, Alexander Farnese, duke of Parma, Coligny, Henry IV. Gustavus Adolphus, &c.

Vossius, De Scient. Mathemat. mentions twenty-four ancient authors on the subject of tactics.

It does not appear what was the field-exercise of the infantry in our ancient armies. After the Revolution, our system of discipline was chiefly taken from the Dutch, who, under prince Maurice, were the best regulated troops in Europe. Previously to this, the Spaniards were reckoned to have the best disciplined infantry. The exercise was, at the commencement of the last century, and for many years afterwards, encumbered with a number of useless motions. The manner in which the soldiers were armed, with their heavy muskets, bandoliers, &c. obliged them to make wide motions, and to draw up with very extended ranks and files. For an account of the exercise and evolutions of the infantry and cavalry at this period, we refer to Grose's Military Antiquities, vol. i. Of late, great alterations have taken place in the field-exercise and manœuvres both of the cavalry and the infantry. Most of the dragoon regiments have been made light; and a new sword-exercise has been adopted for the cavalry. The whole system of the army has been rendered uniform, by regulations issued from the adjutant-general's office. Within the last 60 or 70 years, the British infantry has been gradually falling into the Prussian system; and the new regulations are almost wholly founded on the Prussian institution. For the particulars, the reader is referred to the "Rules and Regulations for the Formation, Field-exercise, and Movements of his Majesty's Forces," and the articles Manual *Exercise* and Battalion.

The subject of this article has been already discussed under the following heads; *viz.* Army, Battalion, Battle, *Order of* Battle, Camp, Campaign, Castrametation, Column, Engagement, Evolution, Exercise, Line, Phalanx, in which order the Gauls and other nations fought in the time of the Romans, and which order still prevails, under some disadvantages, throughout Europe; War, &c. &c.; so that we have here little to add.

We shall here observe, that the principal object of the Prussian tactics under Frederick the Great was that of concentrating forces, and attacking the chief points of the enemy, not at one time, but one after another; whereas the tactics which have been uniformly pursued by the French, since the commencement of their revolution, have been founded on the principle of attacking all points with divided forces at the same time; thus extending their force, whilst that of the Prussian was compressed.

Tactics, *Naval* or *Maritime*, comprehend the orders and signals which are directed to be observed by fleets preparing for action or actually engaged, together with the manœuvres and modes of attack that are then to be practised, and also a knowledge of the rates of ships, their various appendages, and the mode of constructing them. Of this branch of tactics, a copious account will be found under several articles, particularly Battle, Engagement, Exercise, and Line *of Battle*, under which last article we have referred to Clerk's (not Clarke's) Essay on Naval Tactics, of which a second edition was published in 1804, which those who are desirous of information on the various modes of attack to windward and leeward, and by cutting the line, will consult; but which does not admit of abridgment within the limits that we are under the necessity of prescribing to ourselves.

Tactics is also used for the art of inventing and making machines for throwing of darts, arrows, stones, fire-balls, &c. by means of slings, bows, and counterpoises. Vegetius, Hiero, &c. have written on these machines; and we have them described and figured by Lipsius.

TACTILE, or Tangible, in the *Schools*, something that may fall under the sense of feeling.

Though atoms be corporeal, yet are they not either tactile or visible, by reason of their smallness.

The principal tangible qualities are, heat, cold, dryness, hardness, and humidity. See Heat, &c.

TACTION. See Feeling.

Taction, in *Geometry*. See Tangent.

TACTUS, the *Touch*, in *Midwifery*, is the exploration of the state of the vagina and uterus, and of the situation of the fœtus, and whatever else is contained in it. Hippocrates, in his Treatise on the Diseases of Women, has been very full and exact in his directions upon this subject.

Tactus, *Tact*, in *Music*, before the use of bars, implied nearly the same thing as a bar: that is, the time when the hand or foot is beaten down in marking the measure. *Tatto*, Ital., the same.

TACUA, in *Ancient Geography*, a river of Italy, in Liguria, E. of Rutuba.

Tacua, in *Geography*, a town of Peru, in the dioceſe of Arequipa; 20 miles E. of Arica.

TACUBA, a town of Mexico, N.W. of the city of Mexico.

TACUMADARS, or Tigumedes, a town of Africa, in the country of Darah, the original country of the reigning ſherifs of Morocco.

TACZLI, a river of European Turkey, which runs into the Danube, near Kilia, in Beſſarabia.

TADAPOOLY, a town of Hindooſtan, in Myſore; 5 miles S.E. of Sattimungulum.

TADCASTER, a market-town in the Weſt Riding of the county of York, England, is nine miles S.W. from the city of York, and 190 miles N. of London. In the year 1811, it contained 382 houſes, and 1483 inhabitants. The name of this place implies a Roman ſtation, and accordingly we find, that the Calcaria of Antoninus was ſituated on the courſe of a Roman road, between Eboracum or York, and Mancunium or Mancheſter, at nine miles diſtance from the former; and this agrees with the ſcite of the preſent town. Dodſworth and ſome other antiquaries, however, place the Calcaria at Newton-Kyme, about a mile and a half W. of Tadcaſter. Horſley in "Britannia Romana," and Drake in "Eboracum," are deciſive in fixing the Roman ſtation at Tadcaſter. It appears that many Roman coins have been found here: ſome banks and ditches ſurround the town, and on the ſouth ſide of the river are remains of intrenchments, called the Caſtle. A conſiderable quantity of ſtone was taken from this fortreſs to build a bridge over the river Wharf at the beginning of the 18th century. This bridge is generally deſcribed as a very fine ſtructure; and its centre marks the union of the Weſt Riding of the county, with the Ainſty of York and liberty of St. Peter. Tadcaſter has a weekly market on Wedneſdays, and four annual fairs.

Tadcaſter and its vicinity have been twice diſtinguiſhed and annoyed by the deſtructive effects of civil warfare: firſt in the conflicts between the houſes of York and Lancaſter: and ſecondly, between the royaliſts and the republicans, about the middle of the 17th century. On the former occaſion, it is related, that between 30,000 and 40,000 Engliſhmen "fell in deciding the queſtion, whether a tyrant or an ideot ſhould be their maſter." After Edward IV. had been proclaimed in London, Margaret of Anjou, wife of Henry VI., raiſed an army, in the north, of about 60,000 men, all attached to the Lancaſterian intereſts. Theſe were aſſembled at York. When Edward with his army arrived at Pontefract, ſeveral ſkirmiſhes ſoon took place on the banks of the Aire, and on Palm-Sunday, 29th March, 1461, the memorable and fatal battle of Towton enſued. On this day it is ſaid, that Henry's army conſiſted of 60,000 men, and Edward's of about 48,600. Theſe commenced an engagement early in the morning, and fought with great fury during the whole day, with various degrees of ſucceſs. At length, however, Henry's ſoldiers fell back, whilſt Edward impelled his forward with increaſed impetuoſity. Many of the former were drowned, and ſeveral noblemen were ſlain, whilſt Henry and Margaret fled into Scotland. Edward and his ſoldiers retired to York, and afterwards went to London, where the new monarch was crowned. In the year 1642 another battle occurred at or near Tadcaſter. Sir Thomas Fairfax, with about 700 men, occupied this town in behalf of the Parliament, and were attacked by the royal army under the earl of Newcaſtle. After fighting a whole day, the former retreated during the night, and left the royaliſts in poſſeſſion of the place.

About five miles S.E. of Tadcaſter is Scarthingwell-Hall, the ſeat of lord Hawke, who has paid particular attention to agricultural improvements; and has fitted up a farm with every convenient and uſeful accommodation. (See Agricultural Survey of the Weſt Riding of the County of York.) Three miles ſouth of the town is Haſlewood-Hall, the ſeat of the Vavaſours, diſtinguiſhed for the fineneſs of its ſcenery, and the variety and beauty of the proſpects from its grounds. Bramham Park, the ſeat of James Lane Fox, eſq., is about four miles S.W. from Tadcaſter. —Drake's Eboracum, fol. 1736. Beauties of England, Yorkſhire, by J. Bigland, 8vo., 1815. Hargrove's Hiſtory, &c. of Knareſborough, 6th edit. 1809.

TADCUL, a town of Hindooſtan, in Myſore; 6 miles S.E. of Caveripatam.

TADEMERI, a town of Hindooſtan, in Myſore; 100 miles N.E. of Chittledroog. N. lat. 14° 35'. E. long. 78°.

TADEN, a town of the duchy of Holſtein; 14 miles E. of Meldorp.

TADEPATRY, a town of Hindooſtan, in the circar of Cuddapa; 24 miles N. of Gandicotta.

TADIPOODY, a town of Hindooſtan, in Golconda; 20 miles S.E. of Combamet.

TADIVAN, or Taduan, a town of Perſia, in the province of Farſiſtan, ſituated on a pleaſant plain, in the midſt of ſtreams, which deſcend from the neighbouring mountains, and planted with a variety of excellent fruit-trees; 60 miles S. of Schiras.

TADMOR. See Palmyra.

TADORNA, the *Anas tadorna* of Linnæus, in *Ornithology*, a name given by many authors to a ſpecies of duck, called by others *vulpanſer*, and in Engliſh the *ſhiel-drake*, or *borough-duck*; and by ſome the *bergander*. See Duck.

It is of a middle ſize between the duck and gooſe; its beak is broad, ſhort, and red; and at the origin of the upper chop there is a large red tubercle of fleſh; the head and upper part of the neck are of a fine blackiſh-green, the lower part of the neck white; the breaſt and upper part of the back ſurrounded with a broad band of bright orange-bay; the coverts of the wings and middle of the back are white; the neareſt ſcapulars black, the others white; the greateſt quill-feathers black; the exterior webs of the next are of a fine green, and thoſe of the three ſucceeding orange; the coverts of the tail white, and the tail of the ſame colour, except the two outmoſt feathers, which are tipt with black; the belly white, divided lengthways by a black line; the legs are of a pale fleſh-colour.

They inhabit the ſea-coaſts, and build in deſerted rabbit-holes; but their fleſh is not well taſted.

When a perſon attempts to take their young, they divert his attention by flying along the ground as if wounded, till the brood are ſecure, and then return and collect them together. Turner, therefore, concludes, that this bird is the chenalopex, or fox-gooſe of the ancients; and the natives of the Orkneys at this day call it the *fly-gooſe*.

Theſe birds lay 15 or 16 white roundiſh eggs. In winter they collect in large flocks. Ray and Pennant.

TADOUN, or Tadivan, in *Geography*, a town of Aſiatic Turkey, in Armenia, ſituated on the weſt coaſt of the lake of Van, having a harbour for boats; 120 miles S.S.E. of Erzerum.

TADOUSAC, a town of Lower Canada, at the mouth of the Saguenay, on the left ſide of the river St. Lawrence.

 The

The native Indians resort hither to exchange furs for cloth, and other European goods. It was first settled by the French, taken by the English in 1629, retaken by the French in 1633, and it was ceded with the rest of Canada; 100 miles N.E. of Quebec. N. lat. 48° 5′. W. long. 69° 40′.

TADPOLE. The animal called by this name is no other than the frog in its first state from the spawn; and this creature furnishes the curious in microscopic observations with a beautiful view of the circulation of the blood, especially when young.

The method of procuring them for this purpose in the greatest perfection, is this: let a small quantity of frog's spawn be kept for some days in water, and from this will be produced a vast number of young tadpoles; these, while very young, are perfectly transparent, and when placed before the double microscope, the heart may be easily seen, and its pulsation regularly observed; and the blood protruded thence may be beautifully seen circulating through the whole body; but particularly in the tail, where, though so very minute, more than fifty vessels may be seen at one view. The young brood grow more and more opaque every hour, and in a day or two the circulation of the blood can only be seen in their tail, or in the fins near the head. Baker's Microscope, p. 126.

TÆDA, in *Pharmacy*, a term used by some authors to express certain compositions made up in form of troches. These are sometimes meant as pessaries to be introduced into the vagina, and therefore made into this form; sometimes they are compositions of fragrant or other ingredients for fumigations.

Tæda, in *Botany*, a name given by some authors to the pinaster, or common wild pine, or mountain-pine.

TAEL. See Tale.

TÆNARIA, ταιναρειν, in *Antiquity*, a festival in honour of Neptune, surnamed *Tænarius*, from *Tænarus*, a promontory in Laconia, where he had a temple.

Tænaria, or *Tenarium*, now *Cape Matapan*, in *Ancient Geography*, a promontory of the Peloponnesus, S. of Laconia, between the gulf of Messenia and that of Laconia. Here were formerly a grotto, and a temple of Neptune, which rendered the place very famous, so that it was reckoned to be one of the mouths of hell, through which Hercules and Psyche descended thither. The temple was accounted an inviolable asylum. On this promontory there were also a statue of Arion, seated on a dolphin, and playing on the lyre, and a fountain of wonderful efficacy.

TÆNARIUM, a town of the Peloponnesus, upon the promontory above described.

Tænarium *Marmor*, the name of a marble used by the ancient architects and statuaries. There were two kinds of it, very different in colour, but perfectly agreeing in hardness, and in the high polish they are capable of. The first, or most frequent kind, was black, and was dug from the promontory called *Tænarus*, in the Lacedæmonian state; the other, which was more scarce, and much more beautiful, was of a green colour, with a cast of yellow; this was dug in the Tagetan quarries, and was called by some *marmor herbosum*, and *xanthon*.

TÆNIA, or Tenia, in *Architecture*, a member of the Doric architrave, resembling a square fillet, or reglet; and serving in lieu of a cymatium.

The word is Greek, ταινια, which literally denotes a *swathe*, *bandage*, *fillet*, or the like. Barbo renders it by *listel*, but Palladio uses the old name *tænia*.

Leon Baptista Alberti calls the tænia, *regulæ*, and *fasciola*; and Daviler, *bandelettes*. Philander says, there are two kinds, *viz.* that above-mentioned, which he calls the *lower*; and an *upper*, which serves for a capital to the triglyphs.

Tænia, in *Ichthyology*, the name of a fish of the anguilliform, or eel-shaped kind, common in the Mediterranean sea, and brought to market in Italy and elsewhere. This is a species of cepola in the Linnæan system. See Cepola.

Tænia *Cornuta*, the *horned tænia*, a name given by many authors to the species of cobitis, named by Artedi, the cobitis with a forked prickle placed under each eye. This fish is the *cobitis tænia* of Linnæus. See Cobitis.

Tænia, in *Zoology*, a genus of the Intestina order of worms; the characters of which are, that the body is flat and articulated, and that the head is furnished with four sucking bladders. Gmelin, in his edition of the Linnæan system, enumerates eighty-six species, besides several varieties. Their habitations are the viscera of men and of different animals. Our limits will not allow us to specify and describe them. For an account of the tænia intestinorum of the human body, or lumbricus latus, we refer to Tape-*Worm*.

TÆNIÓLONGA, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana, upon the Iberian sea. Ptol.

TÆNITIS, in *Botany*, from ταινια, *a riband*, or *fillet*, because of the long narrow shape of the frond.—Swartz Fil. 24. Willd. Sp. Pl. v. 5. 135.—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices*.

Ess. Ch. Sorus linear, nearly uninterrupted, longitudinal, between the rib and outer margin of the frond. Involucrum none.

1. T. *blechnoides*. Pinnate Tape-fern. Swartz Fil. 220. Willd. n. 1. ("T. pteroides; Schkuhr Crypt. 21. t. 6." Sprengel Crypt. 411. t. 10. f. 106. Pteris blechnoides; Willd. Phytogr. 13. t. 9. f. 2.)—Frond pinnate; leaflets linear-lanceolate, tapering at each end, entire, smooth.—Native of the East Indies. The whole *frond* is from eighteen to twenty-four inches, or more in height, smooth, with a smooth, furrowed, bluntly angular *stalk*. *Leaflets* opposite, the lower ones occasionally alternate, five or six pair, equal, about five inches long, and half an inch wide in the middle. Line of *fructification* on each side of the mid-rib, about half way between it and the margin. We must rely on the authors cited as to the absence of an *involucrum*. See Sorus.

2. T. *furcata*. Forked Tape-fern. Willd. n. 2. (Pteris furcata; Linn. Sp. Pl. 1531. Swartz Fil. 95. Lingua cervina furcata; Plum. Fil. 122. t. 141. Phyllitis aspera, furcis lineatis; Petiv. Fil. n. 125. t. 6. f. 6.)—Frond simple, repeatedly forked, linear-lanceolate, acute, wavy; scaly beneath.—Gathered by Plumier in the woods of Hispaniola. No other botanist appears to have even seen a specimen. The *root* is tufted, scaly, bearing several *fronds* about a foot high, leafy to the very base, once or twice forked, and rather spreading, of a very thin membranous texture; of a fine green, and very smooth, in front; paler at the back, clothed with reddish pointed scales, and furnished with a black shining rib. The *fructification* is stationed in a *sorus*, or line, two or three inches long, on each side of the rib, but nearer the margin, in the upper part of each very acute lobe of the *frond*, the margin in that part being even, not wavy. The want of an *involucrum* is only presumed from Plumier's figure, nor do we esteem the generic character, of this species at least, to be very certain.

Dr. Swartz hints at another possible species, the *Blechnum seminudum*, Willd. Phytogr. 13. t. 8. f. 2. But if it be so, the

the genus can have little pretenfions to be efteemed natural; and as Willdenow himfelf has not fubfequently followed this hint, we prefume he thought it unauthorized by his own fpecimen, which has the afpect of a confluent *Grammitis*.

TAENSAPAVA, in *Geography*, a river of Weft Florida, which runs into the Ibberville, N. lat. 30° 19′. W. long. 10° 12′.

TAFALE, a river of Africa, which runs into the fea, between the rivers Senegal and Nunez.

TAFALISGA, a town of Africa, in the kingdom of Jaaga, at the union of the Falema with the Senegal. N. lat. 14° 42′. W. long. 10° 12′.

TAFALLA, a town of Spain, in Navarre, honoured with the name of city by Philip IV. It has an univerfity; 15 miles S. of Pamplona. N. lat. 42° 35′. W. long. 1° 43′.

TAFARA, a town of Africa, in the kingdom of Bambarra, on the Niger; 115 miles S.W. of Sego.

TAFEELALAT, a town of Africa, in Sahara; 200 miles N. of Tombuctoo. N. lat. 19° 40′. E. long. 2° 15′.

TAFELBERG, a town on the E. coaft of the ifland of Ceram. S. lat. 3 20′. E. long. 131° 10′.

TAFELICHTE, a mountain on the borders of Lufatia, 3540 feet above the level of the fea.

TAFFAREL, or TAFF-RAIL, in *Ship-Building*, the upper part of a fhip's ftern, ufually ornamented with carved work, or mouldings, the ends of which unite with the quarter-pieces.

TAFFAROWY, in *Geography*, a mountain of Algiers; 13 miles S.E. of Oram.

TAFFETY, or TAFFATY, in *Commerce*, a kind of fine, fmooth, filken ftuff; having, ufually, a remarkable luftre, or glofs.

Alamode, } the *taffetas noirs* of Lyons.
Luftring, }

Taffetas noir luftre of the French, is our *alamode*.

Non luftre is our *luftring*.

There are taffeties of all colours; fome plain, others ftriped with gold, filver, filk, &c. others cheequered, others flowered, others in the Chinefe point, others the Hungarian; with various others to which the mode, or the caprice of the workmen, gives fuch whimfical names, that it would be as difficult, as it is ufelefs, to rehearfe them: befides, that they feldom hold beyond the year in which they firft rofe. The old names of taffeties, and which ftill fubfift, are, taffeties of Lyons, of Spain, of England, of Florence, of Avignon, &c.

The chief confumption of taffeties is in the fummer-dreffes for women, in gowns, linings, window-curtains, &c.

There are three things which contribute chiefly to the perfection of taffeties, *viz.* the filk, the water, and the fire. The filk is not only to be of the fineft kind, but it muft be worked a long time, and very much before it be ufed: the watering is only to be given very lightly, and feems only intended to give that fine luftre, by a peculiar property not found in all water: laftly, the fire, which is paffed under it to dry the water, has its particular manner of application, on which the perfection of the ftuff depends very much.

Octavio May, of Lyons, is held the firft founder of the manufacture of gloffy taffeties; and tradition tells us the occafion of it. Octavio, it feems, going backwards in the world, and not able to retrieve himfelf by the manufacture of taffeties, fuch as were then made, was one day mufing on his misfortunes, and, in mufing, chanced to chew a few hairs of filk which he had in his mouth: his reverie being over, the filk he fpit out feemed to fhine, and, on that account, engaged his attention. He was foon led to reflect on the reafon; and, after a good deal of thought, concluded, that the luftre of that filk muft come, 1. From his having preffed it between his teeth. 2. From his having wetted it with his faliva, which had fomething glutinous in it. And, 3. From its having been heated by the natural warmth of his mouth. All this he executed upon the next taffeties he made, and immediately acquired immenfe riches to himfelf, and to the city of Lyons the reputation it ftill maintains, of giving the glofs to taffeties better than any other city in the world.

It will not, we conceive, be lefs ufeful than curious, to infert here the defcription of the engine contrived by Octavio to give the glofs to taffety; and to add the manner of applying it, and the compofition of the water ufed in it.

The machine is much like a filk-loom, except that, inftead of iron points, here is ufed a kind of crooked needles, to prevent the taffety from flipping: at the two extremities are two beams, on one of which is rolled the taffety to take the glofs; and on the other, the fame taffety, as faft as it has received it. The firft beam is kept firm by a weight of about two hundred pounds, and the other turned by means of a little lever paffing through mortifes at each end. The more the taffety is ftretched, the greater luftre it takes: care, however, is to be ufed that it be not weakened by over-ftretching.

Befides this inftrument for keeping the ftuff ftretched, there is another to give it the fire: this is a kind of carriage, in form of a long fquare, and of the breadth of the taffeties: it moves on trundles, and carries a charcoal fire under the taffety, at the diftance of about half a foot.

Thefe two machines prepared, and the taffety mounted, the luftre is given it by rubbing it gently with a ball, or a handful of lifts of fine cloth, as it rolls from one beam to the other; the fire, at the fame time, being carried underneath it to dry it. As foon as the piece has its luftre, it is put on new beams to be ftretched a day or two; and the oftener this laft preparation is repeated, the more it increafes the glofs.

For black taffeties, the glofs is given with double beer and orange or lemon-juice; but this laft is the leaft proper, as being apt to whiten them. The proportion of the two liquors is, a gallon of orange-juice to a pint of beer, to be boiled together to the confiftence of a rich broth. For coloured taffeties, they ufe gourd-water diftilled in an alembic.

There are alfo feveral different forts of taffeties manufactured in China; as corded taffeties, which wear well; and alfo fome with flowers, and others beautifully ftriped; and a particular taffety, of which they make drawers, and other kinds of wearing apparel. This laft is thick, and yet fo pliant, that it may be folded and preffed with the hand, without leaving any mark in it. They alfo wafh it, like other ftuffs, without its lofing much of its luftre. The Chinefe workmen give the luftre to this taffety with the fat of the river-porpoife, which they purify by wafhing and boiling; and then with a fine brufh, they give the taffety two beds in the fame direction, on the fide which they intend to render gloffy.

TAFFI, ANDREA, in *Biography*, was one of thofe early mafters to whom the revival of the arts in Italy is attributed. His fhare lay in the practice of mofaic painting, which he learned of a Greek monk, named Apollonius, who had been called to Venice to work in the great church of St. Marco; and who afterwards accompanied Taffi to Florence. Andrea was born at Florence in the year 1213, and died there at the age of 81.

TAFILET, or TAFILELT, in *Geography*, a diftrict, formerly a kingdom of Africa, in the empire of Morocco, and country of Biledulgerid, extending along the eaft fide of mount Atlas; the habitations of which are about 1500 fcattered houfes, and of thefe feveral are defended by a tower, and each of them ftands amidft an inclofure of gardens, cultivated grounds, and plantations of palm-trees, forming a variegated and pleafant country, interfected by many rivers and rivulets, defcending from the eaft of mount Atlas, and ferving to water their lands. Tafilelt, as well as Draha, produces a fuperior breed of goats, and a great abundance of dates, which are fmall, but good, conftituting the wealth of the country, and fupplying food for the people, and even for the cattle. Although the Koran prohibits the ufe of fpirituous liquors, yet by ancient cuftom, brandy is made at Tafilelt of dates, which is very ftrong, and drank fo immoderately by the fherifs, that wine produces no effect upon them. Moft of thefe fherifs are poor, and employ themfelves in their grounds and gardens, and very frequently pillage one another. The countries fituated near the banks of the rivers of Draha and Tafilelt have feveral plantations of Indian corn, rice, and indigo. The town of Tafilelt, after which the kingdom was named under the fherifs of the reigning houfe, is not an ancient city. It derives its name from the word "Fileli," which denominates the inhabitants of the country, and alfo the ftuffs and carpets which are here manufactured. The foil of the extenfive plain on which it is fituated is a whitifh clay, which when moiftened refembles foap; and though it paffes a river that rifes in the Atlas, and purfues a courfe from the S.W. to the N.E., being at Tafilelt about as wide as the Thames at Putney, its water, traverfing the faline plains, is brackifh: after a courfe of about 450 miles, it is abforbed in the defert of Angad. It has feveral caftles of tarrace on its banks, inhabited by the fherifs or princes of the reigning family of Morocco. Wheat and barley have been lately cultivated near the river and the caftles. Another river of inferior note rifes in the plains N. of Tafilelt, and flowing in a foutherly direction, is abforbed in the Great Defert or Sahara. The water of this river is alfo brackifh, and unfit for culinary purpofes. The inhabitants of this country, it is faid, poffefs fuch a fenfe of honour, that a robbery is fcarcely known among them, though they ufe no locks. Commercial tranfactions are carried on amongft them by barter or exchange, fo that they have little fpecie; but in all tranfactions of magnitude, gold-duft is the circulating medium. They live in the fimple patriarchal manner of the Arabs, differing from them only in having walled habitations, which are invariably near the river. The climate during a great part of the year is intenfely hot, and the fhume, or hot wind from Sahara, blowing tempeftuoufly in July, Auguft, and September, and carrying with it particles of earth and fand, is very pernicious to the eyes of the inhabitants. A confiderable trade is carried on from Tafilelt to Tombuctoo, Houffa, and Jinnie, S. of Sahara, and alfo to Morocco, Fez, Sufe, Algiers, Tunis, and Tripoli. Indigo abounds, but by reafon of the indolence of the cultivators, it is of inferior quality. Here are alfo mines of antimony and lead-ore. The common drefs confifts of a loofe fhirt of blue cotton, with a fhawl or belt round the waift. A caravan paffes annually from hence to Tombuctoo. Woollen haiks, of a curious texture, being light and fine, are manufactured here. The Tafilelt goats are very prolific, and afford a rich milk in great abundance: and therefore they conftitute an article of confiderable export. The Tafilelt leather is very foft and fine, and much fuperior to that of Morocco: it is as foft and pliable as filk, and impervious to water. The tanners ufe the leaves of a fhrub called tèzra, which grows in the Atlas mountains, to which fome have afcribed the peculiar quality of the leather; though others afcribe it to fome quality in the air and water. The population of the diftrict of Tafilelt is ftated by Mr. Jackfon at 650,000. The town is 140 miles E.S.E. of Morocco. N. lat. 31° 20′. W. long. 6°.

TAFNA, a river of Algiers, which runs into the Mediterranean, near Tackumbreet.

TAFO, or TAFA, a town of Africa, on the Gold Coaft.

TAG, or TAGGE, in *Rural Economy*. See TEG.

TAG, or *Tag-Sore*, a difeafe in fheep, which confifts, as ftated in a paper in the third volume of the "Tranfactions of the Highland Society of Scotland," of fcabs and fores fituated on the under fide of the tail; arifing, in warm weather, from its being fouled with purging and other difcharges. The matter hardens there, irritates the tender veffels, and produces fores, which, if not attended to, run into mortification, and prove fatal, as in the legs. See SWELLING or *Leg-Evil*.

It is fhewn by the fheep turning frequently round to bite the tail.

As this complaint arifes principally from purging, and the naftinefs caufed by it, &c. the firft thing to be done is the reftraining and cure of this evacuation: after which the tail of the animal is to be clipped, and the fore part laid bare, wafhed carefully with milk and water, blood-warm, and then with lime-water. The fheep is then to be turned out into a dry pafture, and looked at again in two or three days, and if not then well, the wafhing muft be repeated, and the parts anointed with greafe and tar mixed together in equal proportions.

TAGABONA, in *Geography*, a river of Weft Florida, which runs into the St. Mark, N. lat. 30° 22′. W. long. 84° 34′.

TAGADEMPT, TAGADEONT, or *Tigedent*, a town of Algiers, anciently called *Vaga*; 60 miles E.S.E. of Oran.

TAGÆ, in *Ancient Geography*, a town of Afia, in Parthia, near the river Oxus, and on the confines of Hyrcania.

TAGAI, in *Geography*, a town of Ruffia, in the government of Simbirfk; 48 miles W. of Simbirfk. N. lat. 54° 20′. E. long. 47°.

TAGAL, a town of the ifland of Java, on the N. coaft, the refidence of a Dutch agent for the purchafe of rice; 35 miles E. of Cheribon.

TAGALA, *Tā-Gāla*, or *Gala* language, is among the Philippines what the Malayu is in the Malay iflands, or the Hindoftani in Hindooftan Proper. It poffeffes the combined advantages of the four principal languages in the world: it is myfterious as the Hebrew; it has articles for nouns, both appellative and proper, like the Greek; it is elegant and copious as the Latin; and equal to the Italian, as the language of compliment or bufinefs. This language has been cultivated only by the Spanifh miffionaries. The Tāgāla grammar of Fra. Gafpar de San Auguftin, was printed in 1703, and again in 1787. The alphabet confifts of feventeen letters, three of which are vowels, and fourteen confonants. The Tagala characters are faid to have been derived from the Malays, and they are read with as much difficulty as the eafe with which they are written. This Tagala is written with an iron ftyle on bamboos and palm-leaves, and the Spanifh miffionaries affert, that the ancient mode of writing was from top to bottom, like the Chinefe. This language, with a confiderable number of peculiar vocables, and great fingularity of idiom, is neverthelefs to be confidered as a cognate language with Malayu, Bujis, and Javanefe. Few languages, on a curfory examination, prefent a greater appearance of originality than the Tagala.

For

For a farther account of it, we refer to Dr. Leyden's Effay on the "Languages and Literature of the Indo-Chinefe Nations," in the Afiatic Refearches, vol. x.

TAGALAZ, in *Geography*, one of the Fox iflands, in the North Pacific ocean. N. lat. 53° 30'. E. long. 185° 26'.

TAGAMA, in *Ancient Geography*, a town of Africa, in the interior of Libya, upon the bank of the Niger. Ptol.

TAGAMA, in *Geography*, a country of Africa, in Nigritia, W. of Cafhna.

TAGANROG, a fort of Ruffia, on the fea of Azoph, firft built by Peter the Great in 1696; 32 miles W.N.W. of Azof.

Taganrog is fituated upon the cliff of a very lofty promontory, commanding an extenfive profpect of the fea of Azof, and the whole European coaft to the mouths of the Don. The number of inhabitants does not at prefent exceed 5000. The mole in the haven is fo fhallow, that fhips performing quarantine lie off at the diftance of 10 miles, and all veffels drawing from 9 to 10 feet of water cannot approach nearer to the town than this diftance. This town has funk into decay; and all the beft houfes are in its fuburbs. If it had water, its fituation is very favourable for commerce; but it can be carried on here only for three months in the year. In the winter the fea is frozen. Here are three fairs in the year. The fifh caught in great abundance in the fea of Azof is dried and fent over all the fouth of Ruffia. Fruit is brought from Turkey, fuch as figs, raifins, and oranges; Greek wine from the Archipelago, with incenfe, coffee, filk, fhawls, tobacco, and precious ftones. Copper of a very inferior quality comes from Trebifond, and is forwarded to Mofcow. Among the principal exports are caviare, butter, leather, tallow, corn, fur, canvas, rigging, lines, wool, hemp, and iron. The greateft advantage this town enjoys is its being the depofitory of Siberian productions. The Calmucks form large fettlements in the vicinity of Taganrog. It is the refort of people from a great variety of countries; infomuch that the inhabitants of fifteen different countries have been obferved in this place at the fame time.

TAGAPOLA, a fmall ifland among the Philippines; 25 miles W. of the ifland of Samar.

TAGARA, an ancient city of India, known to the Greeks about 2050 years ago. Arrian, in his Periplus Maris Erythræi, fays that it was a large city, and all kinds of mercantile goods throughout the Deccan were brought hither, and hence conveyed in carts to Baroach, or Barygaza. Arrian alfo informs us that Tagara was fituated at about 10 days' journey E. of another famous mart, called Plithana, or Pluthana; that Pluthana was 20 days' journey S. of Baroach; and that the road to it was through the Bala-gaut mountains. Pluthana, now called Pultanah, is fituated on the fouthern bank of the Godavery, about 217 Britifh miles to the fouthward of Baroach. If we divide thefe 217 miles by 20, the number of days travellers fpent in paffing from between Pultanah and Baroach, according to Arrian, we fhall have nearly 11 miles *per* day, or 5 cofs, which is the ufual rate of travelling with heavy loaded carts. Arrian informs us, that Tagara was about 10 days' journey W. of Pultanah. Allowing thefe 10 days to be equal to about 100 Britifh miles, Tagara, by its bearing and diftance from Pultanah, falls at Deoghire, or Deogire (which fee), a place of great antiquity, and famous through all India, on account of the pagodas of Eloura. It is now called Dowlatabad, and about four cofs N.W. of Aurungabad. It appears in Arrian's Periplus, that on the arrival of the Greeks into the Deccan, above 2000 years ago, Tagara was the metropolis of a large diftrict called Ariaca, which comprehended the greateft part of fubah Aurungabad, and the fouthern part of Concan. About the middle of the firft century, Tagara was no longer the capital of Ariaca, rajah Salbahan having removed the feat of the empire to Pattan. However, the rajahs, headed by Salbahan, having revolted, they gave him battle, and he was flain. Tagara became again the metropolis of Ariaca; at leaft this was the cafe towards the latter end of the eleventh century. When the Muffulmans carried their arms into the Deccan, about the year 1293, Tagara or Deoghir was ftill the refidence of a powerful rajah, and remained fo till the time of Shah-Jehan, when the diftrict belonging to it became a fubah of the Mogul empire. Thus Tagara was deferted, and Kerkhi, four cofs S.E. of it, became the capital, now called Aurungabad. Thus the ancient kingdom or rajahfhip of Tagara was deftroyed, after it had exifted, with little interruption, above 2000 years. Afiatic Refearches, vol. i.

TAGASA, a town of Fez, feated on a river about three leagues from the Mediterranean; 20 miles W. of Melilla.

TAGASTA, in *Ancient Geography*, a town of Africa, in Numidia, on the route from Hippone to Cæfarea. Anton. Itin.

TAGAVAST, in *Geography*. See TAGOAST.

TAGAZEE, a town of Africa, on the road from Mourzouk to Agades; 260 miles S. of Mourzouk. N. lat. 23° 32'. E. long. 12° 55'.

TAGAZOUTE, a town of Algiers; 45 miles S.E. of Oran.

TAGEBACHI, an ifland in the Red fea. N. lat. 25° 2'.

TAGETES, in *Botany*, a name which Fuchfius tells us is applied by Apuleius to the Tanfy, but which he himfelf adopts for a plant, not very diffimilar in foliage, now vulgarly called the French, or African, Marygold. He is followed by Dillenius, Linnæus, and every fubfequent writer. De Theis derives the word from Tages, an Etrufcan deity, grandfon of Jupiter, and teacher of divination; and fuppofes the beauty of its flowers may have procured the plant this mythological appellation. Of this intention we can find no traces in the above writers.—Linn. Gen. 430. Schreb. 561. Willd. Sp. Pl. v. 3. 2126. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 88. Tourn. t. 278. Juff. 182. Lamarck Illuftr. t. 684. Gærtn. t. 172.—Clafs and order, *Syngenefia Polygamia-fuperflua*. Nat. Ord. *Compofitæ oppofitifoliæ*, Linn. *Corymbiferæ*, Juff.

Gen. Ch. *Common calyx* perfectly fimple, of one leaf, tubular, oblong, with about five teeth, and as many longitudinal angles. *Cor.* compound, radiant. Florets of the elevated difk numerous, all perfect, tubular, longer than the calyx, erect, cut half way down into five linear fegments, villous at the infide: thofe of the radius five, ligulate, female, longer than thofe of the difk, their limb almoft as broad as long, very obtufe, contracted and downy towards the tube, permanent. *Stam.* in the perfect florets, Filaments five, capillary, very fhort; anthers united into a cylindrical tube. *Pift.* in the perfect florets, Germen oblong; ftyle thread-fhaped, the length of the ftamens; ftigma divided, flender, reflexed. *Peric.* none, the calyx remaining unchanged. *Seeds*, to both kinds of florets, folitary, linear, compreffed, rather fhorter than the calyx; crowned with five, more or lefs, erect, pointed, unequal fcales. *Recept.* naked, fmall, flat.

Obf. In a cultivated ftate, the two common garden fpecies have ufually, from luxuriance, more fegments in the calyx,

calyx, and more florets in the radius, than is natural; one of these luxuriant flowers is what Gærtner has delineated. Some more recently discovered species, on the other hand, have naturally but three or four radiant florets.

Eff. Ch. Receptacle naked. Seed-down of several erect pointed scales. Calyx simple, of one leaf, tubular, with five teeth. Florets of the radius five, permanent.

1. T. *patula*. French Marygold. Linn. Sp. Pl. 1249. Willd. n. 2. Ait. n. 2. Loureir Cochinch. 504. Curt. Mag. t. 150. (Flos aphricanus minor, simplici flore; Ger. Em. 750. Caryophyllus indicus minor; Camer. Epit 407.)

β. T. minor, flore fulvo maculato; Dill. Elth. 373. t. 279.—Stem spreading. Leaves pinnate; leaflets lanceolate, with hair-pointed serratures. Stalks single-flowered, somewhat swelling upwards.—Native of Mexico, from whence it was brought to the gardens of Europe, about the middle of the sixteenth century, and hence dispersed over other countries, being now, according to Loureiro, commonly cultivated in Cochinchina, China, and various parts of India. With us it is a tender annual, raised on a hot-bed in spring; and being planted out after midsummer, decorates almost every garden throughout the autumn. Its appellations of French Marygold, and African Flower, are altogether founded in error. The *stem* is about a foot or 18 inches high, branched and widely spreading. *Leaves* opposite, of five or six pair of dark green shining leaflets, with an odd one; all gradually smaller downwards. *Flowers* about two inches in diameter, yellow, with broad lateral stripes, or spots, to each radiant *floret*, of a peculiarly rich brown. They vary in size and tints, as well as scent, and are generally more or less double. The plant of Dillenius hardly deserves to be marked as a variety. The herb when bruised is very fetid, acrid, and supposed to be poisonous, though too nauseous to be very dangerous. Few flowers are more striking in appearance.

2. T. *erecta*. African Marygold. Linn. Sp. Pl. 1249. Willd. n. 3. Ait. n. 3. (Flos aphricanus major; Ger. Em. 749. Caryophyllus major indicus; Besl. Eystet. æst. ord. 14. t. 2. C. indicus; Camer. Epit. 406.)—Stem erect. Leaves pinnate; leaflets lanceolate, with hair-pointed serratures. Stalks single-flowered, swelling upwards.—Native of Mexico; introduced into the gardens of Europe about the same time as the foregoing, nor is the epithet of African more correctly applied to one than to the other. The same mode of culture suits both, and both are equally common. This species is much the tallest, and grows erect. The *leaves* are rather paler. *Flowers* twice as large, of a golden uniform yellow; sometimes orange-coloured. Columna, in his *Ecphrasis*, part 2. 47. t. 46, represents a quilled variety, as it is termed, whose radiant *florets* are funnel-shaped, and another whose *florets* are all of that sort.

3. T. *elongata*. Long-stalked American Marygold. Willd. n. 4.—Stem erect, nearly simple. Leaves pinnate; leaflets linear, serrated at the end; those of the lower leaves wedge-shaped. Stalks single-flowered, elongated, slightly swelling.—Native of South America. *Root* annual. *Stem* from three inches to a span high, either simple, or furnished with a branch or two from the bottom. *Leaflets* of the lower leaves obovato-lanceolate, serrated at the extremity; those of the upper linear, with a few slightly hair-pointed serratures at the end. *Stalk* solitary at the top of the stem or branch, and almost as long as the stem itself. *Flower* deep yellow, agreeing in form and structure with *T. patula*.

4. T. *minuta*. Small-flowered Chili Marygold. Linn. Sp. Pl. 1250. Willd. n. 5. Ait. n. 4. (T. multiflora, minuto flore albicante; Dill. Elth. 374. t. 280.)—Stem erect, densely panicled. Leaves pinnate; leaflets lanceolate, serrated. Stalks many-flowered, scaly.—Native of Chili. Cultivated in Dr. Sherard's garden, before the year 1728. A hardy annual, flowering in autumn, but seldom preserved in collections. The *stem* is ten or twelve feet high, covered with *leaves*, which are smaller than those of the first species. The *flowers* are very small and pale, forming dense, compound, tufted, erect *panicles*, at the ends of the branches; their *stalks* clothed with bristly scales. *Calyx* cylindrical. *Radius* of two, three, or four variously lobed florets. This is surely the Chili plant of which Feuillé (quoted by Dillenius) describes two varieties, differing in the number of their radiant *florets*; and which he says is extremely hot in quality. The Indians eat it to warm themselves after their return from fishing.

5. T. *caracasana*. Long-stalked South American Marygold. Willd. n. 6. (T. peduncularis; Cavan. Leccion. 201. n. 494?)—"Stem corymbose, furrowed, erect. Leaves pinnate; leaflets lanceolate, serrated at the end. Stalks elongated, single-flowered, erect. Calyx cylindrical."—Gathered by Baron Humboldt at the Caraccas.—*Root* annual. *Stem* corymbose at the top. *Leaflets* linear-lanceolate, serrated at the end, not fringed. *Flowers* like those of the next species, on long alternate stalks. *Leaflets* of the uppermost leaves entire. *Willdenow*. The plant of Cavanilles was raised in the garden at Madrid, from seeds collected at Cumaná by Bonpland, the companion of the celebrated Humboldt. The *stem* is described a foot and a half high, furrowed, much branched. *Flower-stalks* six inches long, tumid near the calyx, leafy in their lower part. *Corolla* entirely yellow, with six or eight rays shorter than in the following. We find nothing in his account which is not conformable to the plant before us, and should have been glad if we could have adopted his greatly preferable specific name.

6. T. *tenuifolia*. Fine-leaved Peruvian Marygold. Cavan. Ic. v. 2. 54. t. 169. Willd. n. 7. Ait. n. 5.—Stem panicled. Leaves pinnate; leaflets linear, serrated; their lower serratures elongated. Stalks alternate, single-flowered. Calyx club-shaped.—Native of Peru. *Cavanilles*. We have specimens from Mutis. Mr. W. Malcolm is said in Hort. Kew. to have cultivated this species in 1797, but being a late-flowering annual, greatly inferior in size and beauty to the popular species of the same genus, it has probably not been preserved. The appearance of the dried specimens is like a starved *T. patula*, with more numerous, much smaller, *flowers* than usual. The *calyx* abounds with oblong glandular dots, of which traces are likewise found in that species. The *corolla* is described of a full unspotted yellow.

7. T. *elliptica*. Oval-leaved Peruvian Marygold.—Stem erect, branched. Leaves pinnate; leaflets elliptical, with shallow serratures. Stalks corymbose, with lanceolate bracteas.—Native of Peru. We received a dried specimen from the late abbé Cavanilles, in 1804. The *stem* has a shrubby appearance, and is much branched, leafy and furrowed. *Leaflets* scarcely visibly serrated, pointed, smooth and even; the lower ones of each leaf gradually smaller, and mostly alternate. *Flowers* rather numerous, not very much smaller than in *T. patula* when not luxuriant; their partial stalks accompanied by alternate lanceolate *bracteas*. *Calyx* marked with scattered, apparently glandular, lines. This is certainly very distinct from all the species we can find described.

8. T. *micrantha*. Small-flowered Mexican Marygold. Cavan. Ic. v. 4. 31. t. 352. Willd. n. 8.—Stem much branched, spreading. Leaves pinnate; leaflets linear-awl-shaped, entire. Stalks axillary, single-flowered.—Gathered by Louis

Louis Née, near the town of Querétaro, in New Spain. It flowered in the Madrid garden, in October 1796. *Root* annual. *Stems* hardly a foot high, round, rather woody, fmooth like every other part of the plant. The flendernefs of the *leaves*, and fmallnefs of the *flowers*, give this fpecies the appearance of a PECTIS or HETEROSPERMUM (fee thofe articles); but the *calyx* is perfectly fimple, tubular, with five furrows and five teeth. *Florets* of the radius two only, whitifh and undivided: thofe of the difk generally five, yellow, fcarcely more than four-cleft. *Seeds* long, compreffed, each crowned with two briftles, and two intermediate, notched, unequal fcales.

9. T. *lucida.* Sweet Chili Marygold. Cavan. Ic. v. 3. 33. t. 264. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 740. Andr. Repof. t. 359. — Leaves fimple, finely ferrated. Panicle corymbofe.—Native of New Spain. Its feeds were brought to England in 1798, by the late marchionefs of Bute, along with many other novelties from the gardens of Madrid. The *root* is perennial, and will endure our ordinary winters, with a flight degree of protection. *Stem* erect, about two feet high, round, ftriated, leafy, fmooth; branched in the upper part. *Leaves* one and a half or two inches long, oppofite, on fhort, broad, combined *footftalks*, elliptic-oblong, fmooth, veiny, full of pellucid dots; their lower ferratures tipped with briftly points, or hairs. *Panicle* level-topped, many-flowered; its ftalks angular, fmooth, with linear-lanceolate *bracteas*. *Calyx* half an inch long, befprinkled with glandular dots. *Flowers* of a golden yellow, agreeably fcented; their radiant *florets* generally three, very broad. *Seed* crowned with from two to five linear-lanceolate unequal fcales. The ferratures of the *leaves* are very incorrectly reprefented in Cavanilles's plate, where they are made to refemble a fringe of fine hairs, which only belongs to the lower ones, and is not expreffed in any of the figures hitherto publifhed.

TAGETES, in *Gardening*, furnifhes plants of the herbaceous annual kind, among which the fpecies moftly cultivated are, the French marygold (T. patula), and the African marygold (T. erecta).

The firft fort has feveral varieties, as the pale yellow-flowered, deep yellow-flowered, golden yellow-flowered, crimfon-coloured, velvety, variegated crimfon and yellow, ftriped crimfon and yellow; each of which has both fingle and double flowers: and there are the large-flowered, fmall-flowered, fweet-fcented, and the dwarf French marygolds.

In the fecond fort, alfo, there are varieties; as thofe with pale yellow or brimftone-coloured flowers, with deep yellow flowers, with orange-coloured flowers; the fweet-fcented and the dwarf, &c.; each with fingle, double, and fiftulous flowers; the middling African, with orange-coloured flowers, and the fweet-fcented African, and perhaps fome others.

Method of Culture.—All thefe plants are increafed by feeds, which fhould be fown in the beginning of April upon a hot-bed; and when the plants appear, they fhould have plenty of frefh air, and, after they have attained fome growth, be tranfplanted on to another hot-bed, which is arched over by hoops, at the diftance of fix inches; watering and fhading them well till frefh-rooted, being afterwards gradually inured to the open air; and about the beginning of May they may be taken up with balls of earth about their roots, and be planted in pots, to be fet out in the courts, yards, &c. about the houfe, fhading them till frefh rooted, and giving them water occafionally. But the firft fort divides and fpreads out widely near the ground, in a rambling manner, and requires to be trimmed up at bottom to a fingle ftem, and its branches occafionally, to preferve the head fomewhat regular, and within due bounds.

In raifing them in the open ground, in cafe of the default of hot-beds and other conveniencies, the feed fhould not be fown before the beginning of April, when the plants are to be covered and protected in the nights, and in fevere weather; and when otherwife, not until the middle or latter end of it, and then in a warm rich fituation, either in drills of half an inch in depth, or on the furface, and raked in lightly. After the plants are a few inches high, they fhould be planted out either finally into the borders and other parts, or, when too fmall, into nurfery-rows for a little time, and then fet out where they are to remain.

Two or three plants may be placed nearly together, in patches at five or ten feet diftance; and when they fhew their flowers, fo as to judge of their properties, the worft may be cleared away, and one only of the beft left to each patch, &c. The fame way may be had recourfe to in planting in pots, &c.

In the future culture of all thefe kinds of plants, occafional waterings are neceffary, frequently the firft and fecond weeks after planting out, but more feldom afterwards. Thofe in pots fhould have it three times in the week conftantly, and morning and night in very hot weather.

Stakes are requifite to the ftrong large-headed plants, one to each. They fhould alfo be properly trimmed in their fide-branches near the bottom, and the too great ramblers, to produce regularity.

However, the fecond fpecies in particular, and the varieties of it, as they always grow firmly erect, both in ftem and branches, require but very little trouble after their final planting out: they afford ornament and variety, among other plants, in the borders, clumps, and other parts of pleafure-grounds, as well as in pots for particular places about the houfe, among other potted annual plants. The feeds of each fpecies, and their varieties, fhould be annually faved from the beft plants.

All the forts grow very well and freely in any common garden foil, which is in an open expofure, exhibiting a particularly confpicuous autumnal bloom, in long fucceffion; and when properly arranged, and difpofed in affemblage with other forts of plants, afford a highly ornamental variety and effect, in the great diverfity of the various forms and colourings of the flowers, in the different forts and varieties.

In faving the feed, it fhould be collected only from the fineft and fulleft double flowers, when perfectly ripe, keeping that of the different varieties quite diftinct. The prime large heads of feed of each fort, after being well dried, may either have the feed beat and rubbed out, or kept in them, putting the whole up into bags, boxes, or drawers, until the period of putting them into the ground. Frefh feed fhould conftantly be faved every year, as that of more than one year old will feldom grow well.

TAGGAH, in *Geography*, a town of Africa, in the country of Algiers; 24 miles S.E. of Seteef.

TAGGIA, a town of the Ligurian republic; 4 miles N.E. of St. Remo.

TAGGING. See SHEARING.

TAGHAYOOG BAY, in *Geography*, a bay on the weft coaft of the ifland of Paraguay. N. lat. 25° 2'.

TAGHMON, a poft-town of the county of Wexford, Ireland, on the road from New Rofs to Wexford, which was a borough before the union, and fent two members to the houfe of commons. It is 73 miles S, by W, from Dublin, and about 9 W. from Wexford.

TAGIA, a fmall ifland in the bay of Gunong-Tellu, on the eaft coaft of Celebes. S. lat. 0° 30'. E. long. 122° 6'.

TAGIABAD, a town of Perfia, in the province of Irak; 15 miles E. of Natens

TAGIAH, a river of Algiers, which runs into the Mediterranean, 24 miles E. of Oran.

TAGIDOG, a river of North Wales, which runs into the Alen, 4 miles N. of Wrexham.

TAGIL, a river of Ruſſia, which runs into the Tura, 48 miles W. of Turinſk.

TAGILSKOI, Verchnei, a town of Ruſſia, in the province of Ekaterinburg; 52 miles N. of Ekaterinburg.

Tagilskoi, *Niznei*, a town of Ruſſia, in the province of Ekaterinburg; 60 miles N. of Ekaterinburg.

TAGIOURA, a town of Africa, in the country of Tripoli; 10 miles E. of Tripoli.

TAGLARET, a town in the department of the Po; 7 miles W. of Pinerolo.

TAGLIACOZZI, or Taliacotius, Gasparo, in *Biography*, was born at Bologna in 1546, and practiſed with celebrity as a phyſician and ſurgeon in his native city from the year 1570 to 1599, where he died. The peculiar practice, implied in his name, was that of reſtoring loſt parts by inſition; and this practice he derived from ſome Neapolitan and Sicilian ſurgeons. It was founded on the principle, that two raw ſurfaces of living bodies or parts, attached to each other in cloſe contact, will adhere and mutually tranſmit circulating fluids. On this ſubject he publiſhed two treatiſes: *viz.* "Epiſtola ad Hieronymum Mercurialem de Naribus, multo ante abſciſſis, reficiendis," Francof. 1587; and "De Curtorum Chirurgia per Inſitionem, Lib. duo, additis Cutis traducis, Inſtrumentorum omnium, atque Deligationum, iconibus et tabulis," Venet. 1597, fol. A ſimilar practice has anciently prevailed in India, and is now occaſionally adopted after the common puniſhment of amputating the noſe; for reſtoring which, a piece from the ſkin of the forehead is ingeniouſly engrafted. Modern ſurgeons have availed themſelves of the principle, by bringing over flaps of the adjacent ſkin, in order to accelerate the healing after amputation, and other operations. Haller. Eloy. Gen. Biog.

TAGLIACOZZO, in *Geography*, a town of Naples, in Abruzzo Ultra; 18 miles S.W. of Aquila. N. lat. 42° 4′. E. long. 13° 19′.

TAGLIATO, Ital., in *Muſic*, is uſed for meaſure, which the French call *barré;* that is, when the character for common time is thus marked, , or , with a perpendicular line drawn through the middle of the C; it implies quick time, in which the notes are played or ſung twice as rapidly as in the uſual common time; a ſemibreve being performed like a minim, a minim like a crotchet, a crotchet like a quaver, &c. A *breve,* double the length of a ſemibreve, uſed to fill a bar; whence the terms *alla breve.* This time is ſtill uſed in muſic *à capella*, and *alla Paleſtrina;* in which the notes being chiefly open, and in fugue, muſicians uſually call a fugue conſiſting chiefly of ſemibreves and minims a *white fugue.* The time, too, when a line is drawn through the C, is called *cut time.*

TAGLIER, in *Geography*, a ſmall iſland in the gulf of Venice. N. lat. 44° 10′. E. long. 15° 17′.

TAGLIO, a river of the Ligurian republic, which runs into the Mediterranean, 4 miles E. of St. Remo.

TAGLO Bay, a bay on the ſouth coaſt of the iſland of Mindanao. N. lat. 6° 8′. E. long. 125° 40′.

Taglo *Point*, a cape on the north-weſt coaſt of Mindanao.

TAGNON, a town of France, in the department of the Ardennes; 8 miles S.W. of Rethel.

TAGOAST, Tagaost, or *Tagavaſt*, a large town of Africa, in the kingdom of Sus; ſaid by ſome to have been the birth-place of St. Auguſtine; ſituated in a fertile country, and defended by a garriſon of 400 men; 140 miles S.W. of Morocco.

TAGODAST, a town of Morocco, near the foot of mount Atlas; 60 miles N.E. of Morocco.

TAGOLANDE, an iſland in the Eaſt Indian ſea, about 10 miles in circumference. N. lat. 2° 18′. E. long. 125° 6′.

TAGOMAGO, a ſmall iſland in the Mediterranean, near the eaſt coaſt of the iſland of Iviça.

TAGORA, in *Ancient Geography*, a town of Africa, in Numidia. Anton. Itin.

TAGOURIE, in *Geography*, a town of Chineſe Tartary, in the province of Hami; 40 miles N.N.E. of Hatamtam.

TAGOU-ZAINAH, the towns of Taggah and Zaina in Algiers, being contiguous, and ſeparated only by a ſmall brook; 50 miles S.W. of Conſtantina.

TAGTE-RUSTAN, a mountain of Perſia, very much reſorted to by the Gentoos; 4 miles from Iſpahan.

TAGTESSA, a town of Morocco; 120 miles W.N.W. of Morocco.

TAGUA, a town and alſo diſtrict of Africa; 250 miles N.E. of Bornou. N. lat. 19° 10′. E. long. 27° 20′.

TAGUAN, in *Zoology*. See Sciurus *Petauriſta*.

TAGULMEMMET, in *Geography*, a town of Algiers; 5 miles S.E. of Muſtygannim.

TAGULO, a town on the ſouth coaſt of the iſland of Mindanao. N. lat. 7° 30′. E. long. 124°.

TAGUMADERT, a town of Africa, in the country of Darah; 20 miles S. of Tattah.

TAGURIN, a town on the weſt coaſt of the iſland of Luçon. N. lat. 16° 20′. E. long. 120° 48′.

TAGUS, or Tajo, a river, which riſing in the mountains of Molina, that ſeparate the kingdom of Aragon from Old Caſtile, paſſes by Aranjuez, Toledo, Talavera de la Reyna, croſſes Caſtile and Eſtremadura, and enters Portugal at Montalvao; traverſing Eſtremadura, it paſſes by Abrantes, Santarem, &c. and runs into the Atlantic about 10 miles below Liſbon. Its current is broken by many cataracts, ſo that on this account, and alſo on account of its rocks, it is not navigable far above Liſbon.

TAGYPEEL, a ſmall iſland in the Eaſt Indian ſea, near the N.E. coaſt of Borneo. N. lat. 6° 29′. E. long. 117° 54′.

TAGZA, a town of Algiers; 12 miles S.S.E. of Conſtantina.

TAHA *el Modain*, a town of Egypt; 5 miles S.W. of Samalut.

TAHABUCKOO, a town of Thibet; 5 miles N.W. of Jhanſu-Jeung.

TAHAIS, a town of Sweden, in the province of Savolax; 50 miles N.N.W. of Nyſlot.

TAHAL, a town of Spain, in the province of Grenada; 8 miles N.N.E. of Purchena.

TAHATE, a town of Arabia, in Yemen; 12 miles W. of Zebid.

TA-HEAN, a city of China, of the ſecond rank, in Yun-nan; 1130 miles S.W. of Peking. N. lat. 25° 52′. E. long. 101° 50′.

TAHEJ, a town of Hindooſtan, in Cutch; 150 miles W. of Amedabad. N. lat. 23° 16′. E. long. 69° 58′.

TA-HE-KAN, a ſmall iſland near the coaſt of China. N. lat. 37° 57′. E. long. 120° 30′.

TAHGUM, a town of Bengal; 14 miles W. of Koonda.

TAHIAO, a town of Corea; 35 miles S.S.E. of Long Konang.

TAHIRAN, a town of Perfia, in the province of Irak; 45 miles E.S.E. of Cafbin. N. lat. 35° 50′. E. long. 51°.

TAHNUM, a town of Gorkah; 20 miles N.W. of Gorkah.

TA-HOOROWA, one of the fmaller Sandwich iflands, fituated about nine miles from the S.W. part of Mowee; deftitute of wood, with a fandy, barren foil. N. lat. 21° 40′. E. long. 199° 30′.

TAHOU, a town of Africa, on the Grain Coaft. N. lat. 4° 50′. W. long. 6° 50′.

TAHRIE′, a town of Perfia, in Farfiftan, on the coaft of the Perfian gulf; 12 miles E.S.E. of Konkum. N. lat. 27° 45′. E. long. 52° 20′.

TAHTA, a town of Egypt, on the Nile; 32 miles S. of Siut. N. lat. 26° 57′. E. long. 31° 22′.

TAHUK, or TABUK, a town of Arabia, in the province of Nedsjas; 176 miles S.S.E. of Jerufalem.

TAI, a city of China, of the fecond rank, in Chan-fi; 175 miles W.S.W. of Peking. N. lat. 39° 6′. E. long. 112° 30′.—Alfo, a city of China, of the fecond rank, in Kiang-nan; 22 miles E. of Yang-tcheou. N. lat. 32° 30′. E. long. 119° 36′.—Alfo, a large lake. See TAI-HOO.

TAI-*Arabs*, an ancient and noble tribe, the mention of which often occurs in the Roman hiftory. They ftill continue in poffeffion of the fame tract of country which they had in the time of Julian, *viz.* between Moful, Nifibin, and the Khadour.

TAJACU, or the *Sus tajacu* of Linnæus, in *Zoology*, the name of an animal common in fome parts of America, called by many authors *aper mofchiferus*, or the mufk-boar. (See SUS.) It is of the fhape of our hog, but much fmaller, and has no tail, and its head is broader, and the fnout much lefs pointed than in our hog; it has two tufks in each jaw, thofe in the upper jaw pointing down, and hardly apparent when the mouth is fhut, the others hid; the neck is fhort and thick, and the whole body of a grifly colour, or mixture of black and grey; its body is covered with hairs, much thicker and ftronger than our hog's-briftles, fomething like the briftles of the hedge-hog, and like them alfo variegated with circles of black and white; thefe are four or five inches long on the back, and gradually diminifh to the fides; on the middle of its head, between the ears, it has a fort of creft, made up of black briftles; the belly almoft naked; from the fhoulders to the breaft is a band of white; its ears are fmall and erect, and its eyes fmall; its fnout, feet, and hoofs, are juft like thofe of the European hog; but the two pofterior or exterior hoofs are longer than in any other of the cloven-footed beafts.

What is moft fingular, however, in this creature, is a certain gland which he has upon the back, and which has given occafion to fome to fay its navel was placed there. This gland is fituated on the very ridge of the back near the rump, and is fo clofely covered with long briftles, that till they are removed by blowing, and keeping them back with the hand, the gland is not to be feen: when thefe are removed, there is feen a fpot almoft naked, in the middle of which the top of the gland is feen; the lips of this gland ufually ftand a little way above the flefh, and its aperture eafily admits a large ftylus; and this gland, when lightly preffed, fpews out a liquid fubftance of a brownifh-yellow colour, and fcent fomething like that of mufk or civet. The gland itfelf is placed between the fkin and flefh, and is not wholly covered by its conftringing mufcle, but only furrounded by it at its bottom.

This animal inhabits the hotteft parts of South America, and fome of the Antilles; lives in forefts, on the mountains, is very fierce, and if wounded, will turn on the hunter. It feeds on fruits and roots, toads and ferpents, which it fkins with great dexterity. It is reckoned very good food; but unlefs the dorfal gland be cut out as foon as it is killed, the flefh will be infected by it. The Indians call this animal *pequaris*, whence its name *pecary*. Ray and Pennant.

TAJAMENTO, or TAGLIAMENTO, in *Geography*, a river which rifes in Friuli, and runs into the gulf of Venice; 10 miles S.S.E. of Concordia.

TAJANJE, a river of Brafil, which runs into the Atlantic, S. lat. 27° 35′.

TAJARA, in *Ichthyology*. See RAIA.

TAIBEH, in *Geography*, a fortified town in the defert of Syria, having near its gate a fountain of frefh water; 85 miles E.S.E. of Aleppo. N. lat. 35° 10′. E. long. 38° 45′.

TAI-CHAN, a town of Corea; 20 miles W. of Haimen.

TAIDENT, a town of Africa, in Fezzan; 130 miles S.S.W. of Mourzouk.

TAJE-ELT, a town of Algiers; 35 miles S.S.E. of Bona.

TAIEZA, a town of Croatia; 45 miles E. of Bihacs.

TAIGAREE. See TEGERLY.

TAI-HOO, or TAI, a beautiful lake of China, faid to be near fifty leagues in circumference, dividing the provinces of Kiang-nan and Tche-kiang, and furrounded by a chain of picturefque hills. It fupplies Sou-choo-foo, at a fmall diftance from it, with fifh, and ferves the inhabitants alfo as a place of public refort and recreation. Many of the pleafure-boats on this lake are rowed by a fingle female; and the rowers are faid to follow more than one profeffion.

TAIIBI, in *Zoology*, the name of an American animal, defcribed by Marcgrave and other authors, and fuppofed by fome to be only the male of the opoffum. The Portuguefe in America call it the *cachorro de mato*, and by the Dutch it is called *bofchratte*. See DIDELPHIS.

TAIJEOURA, in *Geography*, a town of Africa, in the kingdom of Adel; 15 miles N.W. of Zeilah.

TAIL, CAUDA, that part of an animal which terminates its body behind.

The tail is different, both in figure and ufe, in the various fpecies. In land-animals it ferves to rid them of flies, and is ufually covered with hair, and ftrengthened with bones: in fifhes it is cartilaginous, and ferves them as a helm to fteer their courfe withal in fwimming.

In birds it is covered with feathers, and greatly affifts in all afcents and defcents in the air; as alfo to render their flight fteady, by keeping the body upright in that fubtile and yielding medium, by its ready turning and anfwering to every vacillation of the body.

TAIL *of Fifh*. This part in the fifh-kind is the fubject of very great diftinctions, among the characters of the feveral genera. It differs in the feveral kinds of fifh in a very obvious manner, in number, fituation, and figure. In regard to the firft difference, the *acus lumbriciformis*, and one of the kinds of the *ferpens marinus*, have no tail at all; in all other fifh there is a tail, and it is never more than one on each fifh.

In regard to fituation, there is this great difference, that in fome it is placed perpendicularly, in others horizontally. In almoft all the known fifhes it is placed perpendicularly, except in the dolphin, the phocæna, the orca, the manati, and all the whale-kinds; for in all thefe it is placed horizontally, when the body is laid in its natural pofture.

Koei-tcheou; 967 miles S.S.W. of Peking. N. lat. 27° 5'. E. long. 105° 14'.

TAI-TONG, a city of China, of the firſt rank, in Chan-ſi. It is ſituated in a mountainous country, and is the only place expoſed to the incurſions of the Tartars: it is very well fortified, according to the manner of the Chineſe, and has a very ſtrong garriſon; its territory is ſurrounded by the great wall, which has forts from place to place; its juriſdiction is very large, and extended over four great cities of the ſecond order, and ſeven of the third: its mountains abound with all kinds of ſimple and medicinal herbs, which the botaniſts gather with great care. Lapis lazuli is in great plenty here; and there is a kind of jaſper, which is tranſparent, and as white as agate: porphyry, marble, and jaſper of all colours are very plentiful; and here is alſo a great trade for ſkins; 155 miles W. of Peking. N. lat. 40° 5'. E. long. 112° 44'.

TAITOU SAHA, a ſmall iſland in the ſea of Japan. N. lat. 42° 32'. E. long. 130° 42'.

TAI-TSANG, a city of China, of the ſecond rank, in Kiang-nan; 567 miles S.S.E. of Peking. N. lat. 31° 30'. E. long. 120° 24'.

TAIVERAM, a town of Hindooſtan, in the province of Dindigul; 8 miles N.W. of Outampaleam.

TAJUNA, a river of Spain, which riſes in the north part of New Caſtile, and runs into the Xarama, a little before its union with the Tagus.

TAIWAN. See FORMOSA.

TAI-Y, a city of China, of the ſecond rank, in Quang-ſi, on the ſouth ſide of the Poſoi; 1125 miles S.S.W. of Peking. N. lat. 23° 24'. E. long. 106° 18'.

TAI-YUEN, a city of China, of the firſt rank, in Chan-ſi; 230 miles W.S.W. of Peking. N. lat. 37° 54'. E. long. 111° 56'.

TAIZALUM, in *Ancient Geography*, a promontory of the iſle of Albion, between the mouth of the Celnius and that of the Diva. (Ptol.) This is ſuppoſed to be Kynaird-Head, near Fraſerburgh, in Buchan; the Celnius being the river Spay, in the ſhire of Elgin, and the Diva the river Dee at Aberdeen.

TAK, EL, in *Geography*, a town of Perſia, in the pro vince of Segeſtan; 15 miles N. of Zareng.

TAKA, a town of Nubia, capital of a diſtrict, called Takaki, on the Beleſe; 50 miles S.E. of Ilak.

TAKAGUS, a town of Japan, in the iſland of Niphon; 60 miles N.W. of Meaco.

TAKAKAKKAN, a ſmall iſland in the Eaſtern Indian ſea, near the eaſt coaſt of Borneo. N. lat. 3° 8'. E. long. 116° 51'.

TAKALUOTO, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 61° 39'. E. long. 21° 10'.

TAKAMIDJA, a town of Japan, in the iſland of Niphon; 150 miles S.W. of Meaco.

TAKAUL, a town of Aſiatic Turkey, in Caramania; 40 miles N. of Cogni.

TAKE *and Leave*, in *Sea Language*. The ſailors ſay, a ſhip can *take and leave upon her when ſhe will*; when ſhe ſails ſo well, that ſhe can come up with another, or outſail her at pleaſure.

TAKE, *Thiſtle*. See THISTLE.

TAKE-*In*, *To*, in *Ship-Building*, is to come-up a ſett and make it faſt again cloſer to the plank, as it works nearer to the timbers.

TAKE-*In Sail*, *To*, is to diminiſh its ſurface by reefing, &c. particularly when the wind increaſes too much. See TAKING-IN.

TAKENO, in *Geography*, a town of Japan, in the iſland of Ximo; 40 miles E.S.E. of Ikva.

TAKERS—*Carr-Takers*. See CARR-TAKERS.

TA-KIA-TCHE, in *Geography*, a town of China, on the W. coaſt of the iſland of Formoſa. N. lat. 24° 22'. E. long. 119°.

TAKING-IN, in *Sea Language*, denotes the act of brailing-up and furling the ſails at ſea, particularly when the wind increaſes. It is generally uſed in oppoſition to *ſetting*.

TA-KIRON-HOTUN, in *Geography*, a town of the kingdom of Corea; 425 miles E. of Peking.

TAKLACOT, a town of Thibet; 60 miles N.E. of Kerion.

TAKMITZSKAIA, a town of Ruſſia, in the government of Tobolſk, on the Irtiſch; 36 miles S. of Tara.

TAKPO, a large province of Thibet, which is ſubdivided into ſeven takpos. On the N. it has the province of U, on the S. Combo, on the E. Cobang, and on the W. Tzhang.

TAKTANG, a river of Ruſſia, which runs into the Lis, N. lat. 62° 24'. E. long. 89° 44'.

TAKY, a town of Bengal; 30 miles E. of Calcutta.

TAL, a name uſed by ſome writers on the materia medica to expreſs the dung of peacocks; and by ſome of the chemical writers for any alkali ſalt.

TALA, in *Botany*, a name by which ſome authors call the plant, whoſe ſeed is the ſeſamum, or oily purging grain of the ſhops.

TALABON, in *Geography*, a town on the W. coaſt of the iſland of Gilolo. N. lat. 1° 40'. E. long. 127° 20'.

TALABONG, in *Ornithology*, a name given by the inhabitants of the Philippine iſlands to a ſpecies of heron, common among them; which is much ſmaller than our heron, and perfectly white all over.

TALABRIGA, in *Ancient Geography*, a town of Spain, in Luſitania, towards the ſouth, upon the Vatna, not far from the ſea, S.W. of Langobriga.

TALABROCA, the name of one of the moſt celebrated towns of Hyrcania. Strabo.

TALACACHA, in *Geography*, a town of South America, in the province of Tucuman; 15 miles S. of St. Miguel de Tucuman.

TALACOUAN, a town of Lower Siam, on an iſland in the Mecon; 30 miles S. of Juthia.

TALÆDITES, ταλαιδιτης, in *Antiquity*, gymnical exerciſes in honour of Jupiter Ταλαιος.

TALAFA, in *Geography*, a ſmall iſland in the South Pacific ocean, among thoſe called Hapaae, S.W. of Holaiva.

TALAGIR, a ſmall iſland among the Philippines; 25 miles W. of Samar.

TALAGOS, a town of Africa, in the country of Sierra Leone. N. lat. 10° 20'. W. long. 13° 40'.

TALAGUADA, a town of South America, in the province of Carthagena; 10 miles N.N.W. of Mompox.

TALAHSECHTE, an Indian town of Eaſt Florida, on the river St. Juan, near the bay of Apalache, in the gulf of Mexico; 52 miles N. of St. Mark. This town contains about 30 habitations, conſtructed of frame-work; and covered with the bark of the cypreſs-tree. The inhabitants form large handſome canoes of the trunks of cypreſs-trees, capable of holding 20 or 30 warriors. In theſe they deſcend the river on trading or hunting expeditions on the ſea-coaſt, iſlands, and keys as far as the point of Florida; and ſometimes they croſs the gulf and ſail to the Bahama iſlands, and even to Cuba, returning with cargoes of ſpirituous liquors, coffee, ſugar, and tobacco.

TALAI-

TALAI-HAI, a town of Chinefe Tartary. N. lat. 44° 17′. E. long. 120° 45′.

TALAI-HOTOC, a town of Thibet; 105 miles S.W. of Haratoubé.

TALALALUM, or Thalatatum, in *Ancient Geography*, a town of Africa Propria, on the route from Tacapæ to the Greater Leptis.

TALAMANCA, in *Geography*, a town of Spain, in New Caftile; 14 miles N.W. of Guadalaxara.

TALAMATA, a town of Hindooftan, in Coimbetore; 15 miles N. of Damicotta.

TALAN, a fmall ifland in the fea of Ochotfk. N. lat. 59° 30′. E. long. 149° 14′.

TALANGBOANG, a town on the W. coaft of Sumatra. S. lat. 4° 21′. E. long. 105° 44′.

TALANT, a town of France, in the department of the Côte d'Or; 2 miles N.W. of Dijon.

TALANTA, a town of European Turkey, in the ifland of Negroponte; 34 miles N.W. of Negroponte.—Alfo, a town of European Turkey, in Livadia; 18 miles N.E. of Livadia.

TALA-OSO, a town of Chinefe Tartary, in the country of Hami; 28 miles E.S.E. of Hatamtam.

TALAPOINS, a name given in Siam to thofe who dedicate themfelves to religion. See Siam.

TALAPOOSEE, in *Geography*, the great N.E. branch of the Alabama or Mobile river, in Florida. It rifes in the high lands near the Cherokees, and runs through the high country of the Oakfufkee tribes, in a wefterly direction, being full of rocks, falls, and fhoals, till it reaches the Tackabatches, where it becomes deep and quiet; from thence the courfe is W. about 30 miles to Little Talaffee, where it is united with the Coofa or Coofa Hatcha. The lower part of this river is, in moft maps, called Oakfufkee.

TALAPORUM, a town of Hindooftan, in Calicut; 20 miles N.N.W. of Tellicherry.

TALARHO-KARA-PALHASSUM, a town of Chinefe Tartary, in the country of the Eluths; 715 miles N.W. of Peking. N. lat. 47° 34′. E. long. 102° 34′.

TALARIUS Ludus, among the Romans, a game fomewhat refembling our dice-playing, and performed with a kind of gold or ivory dice, which they fhook as we do in a box, before they threw them. There was this difference, however, between their game and ours, that our dice have fix fides, becaufe they are cubical; but theirs had but four, and were conically fhaped. They made ufe of them for divination, as well as playing; and they concluded upon a good or evil augury, according to what came up. As they ufually threw four of them at a time, the beft chance was when four different fides came up. The fides were called by the name of fome animal, as the dog, vulture, bafilifk, &c.: or of fome deity, as Venus, Hercules, &c. Some authors have been of opinion, that they were marked with the forms of animals, or images of gods, and not with numbers or dots, as our dice are.

TALARN, in *Geography*, a town of Spain, in Catalonia; 22 miles N. of Balaguer.

TALASSEE, or Tallassee, a county confifting of a tract of land bounded by Eaft Florida on the S., N. by Alatamaha river, E. by Glynn and Camden counties, and W. by a line extending from the W. part of Ekanfanoka fwamp, in a N.E. direction till it ftrikes the Alatamaha river, at the mouth of the Oakmulgee.—Alfo, a town of the Upper Creeks, in the Miffifippi territory, on the S. fide of Talapoofee river; called alfo Big Talaffee.

TALASSIO, among the Romans, an acclamation ufed at marriages.

TALATUM, in *Ancient Geography*, the name of a temple of the fun, erected in Laconia, on the fummit of mount Taygetus.

TALAVAN, in *Geography*, a town of Spain, in Eftremadura; 25 miles S. of Plafencia.

TALAVERA *la Real*, a town of Spain, in Eftremadura; 13 miles S.E. of Badajos.

Talavera *la Reyna*, a town of Spain, in New Caftile, on the Tagus, fituated in a valley, and fortified; famous for its earthen-ware; 35 miles W. of Toledo.

Talavera *la Vieja*, a town of Spain, in New Caftile; 6 miles W.S.W. of Toledo.

TALAVERUELA, or *Talavera de Badajos*, a town of Spain, in Eftremadura, on the Guadiana; 9 miles E. of Badajos.

TALAUMA, in *Botany*, a word probably of South American origin, applied in the herbarium of Surian, now poffeffed by Juffieu, to the plant on which Plumier originally founded his genus Magnolia. See under that article, fp. 2, our reafons for not receiving *Talauma*, for the prefent at leaft, as a diftinct genus.

TALBERT's Island, in *Geography*, a fmall ifland in the Atlantic, on the coaft of Georgia, the N. point of which is in N. lat. about 30° 44′, where St. Mary's river difcharges itfelf into the ocean, between this ifland and Amelia ifland on the N. N. lat. 30° 36′. W. long. 81° 42′.

TALBOT, an ifland on the coaft of Eaft Florida, eight miles long and two wide.—Alfo, a county of Maryland, on the E. coaft of Chefapeak bay, bounded E. by Choptank river, which divides it from Carolina county, and S. by the fame river, which feparates it from Dorchefter. The foil of this county is rich and fertile; and it contains 14,230 inhabitants.

Talbot, in *Zoology*, a fort of dog, noted for its quick fcent, finding out the tracks, lodgings, and forms of beafts, and purfuing them with open mouth and continual cry, with fuch eagernefs, that if not taken off by the huntfman, he is often fpoiled.

TALC, in *Mineralogy*, *Idem*, Hauy. The name talc, in the prefent fyftomatic arrangemment of Werner, is placed both as the head of a genus and a family. Brongniart reftricts the name to thofe minerals which poffefs the following characters: they are foft and unctuous to the touch, and leave upon the nail, or on the furface of cloth on which they are rubbed, a white mark, which has fometimes a nacry luftre. The texture of talc is lamellar, or fibrous: the laminæ are flexible but not elaftic. Talc has always a fhining luftre, and is fometimes fplendent and nacry; it is tranflucent and often tranfparent; it yields eafily to the nail. The laminæ of which it is compofed, open a little by the action of fire or of the blowpipe; the fragment fwells, and the extremities of the laminæ are with difficulty fufible into a white enamel. Thefe characters, which are eafily recognifed, ferve to diftinguifh talc from chlorite and nacrite, which are very fufible; and from fteatite, ferpentine, or the unctuous clays, which are compact, have an earthy or fcaly fracture, and but little unctuofity. Talc has another remarkable property; it acquires pofitive electricity when rubbed with refin. Talc is fufceptible of cryftallization, and forms hexagonal laminæ. The primitive form of the cryftal is a right rhomboidal prifm, in which the angles at the bafe are 120° and 60°. Its fpecific gravity varies from 2.58 to 2.87. The prevailing colours are white, apple-green, and yellow.

Talc

Talc is divided by ſome mineralogiſts into three ſub-ſpecies, *viz.* common talc, indurated talc, and columnar talc.

Common talc; talc laminaire, Hauy. Its colours are thoſe before enumerated, but the green ſometimes paſſes into dark blue. The laminæ are very tender and flexible, but not elaſtic: by this they may be diſtinguiſhed from the laminæ of mica, which poſſeſs a conſiderable degree of elaſticity. In France this talc is called *craie de Briançon;* it is found in conſiderable maſſes in rocks of ſerpentine, accompanied with actinolite, granular lime-ſtone, and dolomite, along with indurated talc. The conſtituent parts are as follow:

	Vauquelin.	Klaproth.
Silex - - - - -	62	61.75
Magneſia - - - -	27	30.50
Alumine - - - -	1.50	
Potaſh - - - - -		2.75
Oxyd of iron - - -	3.50	2.50
Water - - - - -	6	2.25

It is found in Aberdeenſhire and Bamffſhire, in Scotland, and in various parts of the continent of Europe, where rocks of ſerpentine and porphyry occur. The talc which is brought from the mountains of the Tyrol is called in commerce *Venetian talc.*

Talc enters largely into the compoſition of the coſmetic named *rouge.* This ſubſtance is prepared by rubbing together in a warm mortar, generally of ſerpentine, certain proportions of carmine and finely powdered talc, with a ſmall portion of oil of benzoin. The Romans prepared a beautiful blue or purple colour, by combining this ſubſtance with the colouring fluid of the buccinum reticulatum and buccinum lapillus, teſtaceous animals abounding on the coaſts of the Mediterranean. The fleſh-coloured poliſh on figures made of gypſum is given by rubbing them with talc. The Perſians, according to Tavernier, whiten the walls of their houſes by means of lime-water, and then powder them with ſilver-coloured talc. Talc has ſometimes been uſed medicinally by the Chineſe and Europeans.

The chief uſe of the Ruſſian is as a ſcreen or cover for paintings in miniature and crayons; to which purpoſe thin ſlices of it are uſed. The Venetian is ſometimes alſo uſed for a fucus; in order to which, by reaſon of the difficulty of pulverizing it, &c. they content themſelves to raſp it with the ſkin of a ſea-dog, and to paſs the raſpings through a ſieve.

Pliny, in his Natural Hiſtory, lib. xxxvi. c. 22. obſerves, that the Romans not only uſed the Ruſſian ſort for window-lights, but they alſo paved the circus with a kind of it. See Glass.

Indurated talc is leſs flexible and leſs tranſlucent than the preceding: it occurs in maſſes, and has ſometimes a radiated ſtructure; its colours are various ſhades of green and greeniſh-grey. It forms beds of conſiderable ſize in mountains of gneiſs, mica-ſlate, and ſerpentine; it approaches nearly to pot-ſtone, and even to ſteatite, in many of its characters. It occurs in Perthſhire and Bamffſhire, in Scotland, and in France, Sweden, Saxony, Siberia, the Tyrol, and Switzerland. It is employed for drawing lines by carpenters, taylors, hat-makers, and glaziers. It is ſometimes made into culinary veſſels, like pot-ſtone, and is employed in powder for removing ſtains of greaſe from ſilk.

Columnar talc occurs in thin columnar priſmatic concretions, and it is opaque. The connection between talc, aſbeſtus, pot-ſtone, ſerpentine, chlorite, and even mica, may be traced by their apparent graduation into each other, particularly in ſome of the rock formations. See Asbestus, Pot-stone, &c.

The mixture of talc with different kinds and quantities of glaſs may be ſucceſsfully performed with a violent fire, but not with a ſmaller degree: thus three parts of talc, with one part of cryſtalline glaſs, make only a ſpongy and friable maſs in a common fire; but in a more violent one, they become a firm and ſolid maſs of a brown colour. Minium, or glaſs of lead, mixed in equal quantities with talc, and ſet in a violent fire, runs into a yellowiſh glaſs, reſembling the opaque pieces of amber; and two parts of minium to one of talc, produce a clear and tranſparent yellow glaſs, which is of a hardneſs capable of giving fire with ſteel. The alkaline earths, mixed with talc, produce a maſs ſcarcely vitrifiable by any fire: hence appears the reaſon why copels made of lime and talc are ſo very hard to vitrify. Minium, added to theſe mixtures, make them combine into a firm maſs, but without perfect fuſion; but borax added to them, melts them readily into a true glaſs. The gypſeous earths mixed with talc, will not unite into a maſs in any degree of fire; but if borax be added, the talc readily melts. Thus two parts of talc, two parts of that ſpar or gypſeous matter called *glacies Mariæ*, or the common plated ſpar, with one part of borax, run into a yellow maſs reſembling a topaz.

The argillaceous earths do not vitrify with talc; but they run into a maſs of great hardneſs, which will give fire with ſteel, and is very ſerviceable to make crucibles of, theſe veſſels not ſuffering the glaſs of lead to run through them. Talc, joined with the vitrifiable ſtones, forms no remarkable body, but the maſs remains friable; but from theſe maſſes, by the addition of proper matter to render them fluid, great variety of elegant compounds may be made. Thus if talc be mixed in equal quantities with powder of flints, on adding to the whole a fourth part of cryſtal-glaſs, the whole unites into an opaque but ſolid white maſs. Alkali-ſalt, added in equal quantity to talc and flint, gives a tranſparent yellow glaſs; and white ſand, talc, and a fixed alkali, in equal quantities, afford a green glaſs; with other mixtures of this kind, in different quantities, the reſemblances of many beautiful ſtones are produced; and what is very remarkable, ſome grains of metalline matter are often found on the ſurface of the maſſes.

Cæſalpinus, Aldrovand, and ſome others affirm, that talc melted with copper, or added to copper, while in fuſion, gave it a white colour: this being taken for granted, authors have hence agreed that talc contains an arſenical earth. But experiment ſhews this to have been a falſe aſſertion, in regard to talc; and probably it only owes its origin to the cant language of ſome of the alchemiſts, who have called the flowers of zinc talc, though theſe alone muſt render copper yellow, not white. Antimony and talc, firſt calcined with nitre, run in a violent fire into a ſort of flint, which will give fire with ſteel. With regulus of antimony and the black flux, it runs into a black maſs; and with biſmuth it calcines into a grey powder. So little is there in the propoſals of the chemiſts for the metallization of talc by antimony and biſmuth. Mem. de l'Acad. de Berlin, Ann. 1746.

In what part of Mr. Boyle's works the learned author, from whom the foregoing extract was taken, has found that talc may be reduced by common fire to a gypſum in an hour, we know not; but we find that Mr. Boyle ſays, that the calcination of talc is ſo very difficult, that eminent chemiſts have looked upon calxes of talc as counterfeits. Works abr. vol. i. p. 160.

Mr. Boyle mentions the extracting of gold from talc, as having

having ſometimes ſucceeded. See Works abr. vol. i. p. 160. but *vide ſupra.*

Talc, *Philoſophic,* a name given by ſome of the chemical writers to the flowers of zinc.

This ſubſtance, diſſolved in vinegar, affords what they have in their unintelligible language called *oil of talc,* and extolled as a thing of vaſt power in the fixing of mercury, and many other imaginary operations; and beſides this, they call it a ſovereign remedy for all diſeaſes.

TALCAGUANO, or Talcaguana, in *Geography,* a ſea-port of Chili, nine miles within the point of the ſame name, and about ſix from the town of Conception. This is the principal port in the bay of Conception, and is much the moſt frequented, as ſhips that anchor here have not only better ground than in any other part of the bay, but are in ſome meaſure ſheltered from the north winds. The town, or village, as Perouſe calls it, has been built ſince the city of Conception was deſtroyed by an earthquake in 1751: it ſtands on the river Biobin, and is ſaid to contain 10,000 inhabitants. Here are the epiſcopal cathedral, the ſeat of the biſhop, and all the religious houſes. The government of the adjacent diſtrict has been wholly military and eccleſiaſtical. The country round it is very healthy and fertile. Great numbers of cattle are annually killed for their hides and tallow, which are ſent to Lima. About 200,000 dollars' worth of gold is annually collected from the ſands in the rivers of this biſhopric. The Indians of the country have numerous herds of cattle, and plenty of horſes, and live more like the Tartars of Aſia than the ſavages of North America. Ships are here ſupplied with water, wood, and other neceſſaries. N. lat. 36° 42′. E. long. 73° 6′.

Talcaguano *Point,* a cape on the coaſt of Chili, 11 leagues N.E. of the iſland of Santa Maria, and 2 N. of Port St. Vincent.

TALCAN, a town of Aſia, in Tokariſtan, beſieged by Gengis Khan in the year 1221, and taken after a ſiege of ſeven months; 100 miles S.E. of Termed. N. lat. 36° 45′. E. long. 67° 9′.

TALCKENSTEIN, a mountain of Sileſia; 4 miles N.N.E. of Loewenberg.

TALCONAH, a town of Bengal; 30 miles E. of Goragot.

TALCOT, a town of Hindooſtan, in Concan; 25 miles N.E. of Goa.

TALCOTE, a town of the iſland of Ceylon; 20 miles W.S.W. of Candy.

TALCOUS Slate, in *Geology,* is conſidered by ſome geologiſts as a variety of clay-ſlate, but it has a nearer reſemblance to mica-ſlate. The colour is generally a greeniſh-grey, with a ſhining luſtre, like that of the finer kinds of mica-ſlate. It is ſofter than mica-ſlate, but is frequently divided into laminæ by thin ſeams of quartz, and has a twiſted or contorted form. The ſlate on ſome of the mountains of the higher Alps, as deſcribed by Sauſſure, ſeems to be of an intermediate kind between mica-ſlate and talcous ſlate. Talcous ſlate occurs on the weſtern ſide of the iſland of Angleſea, and in many alpine diſtricts, forming beds in clay-ſlate. See Slate.

TALDINGA, in *Geography,* a town of Bengal; 15 miles W. of Biſſunpour.

TALE, in *Law,* See Count and Declaration.

Tale, or Tael, in *Commerce,* a weight for gold and ſilver in China, and certain parts of the Eaſt Indies; and alſo a money of account. In China, each tale is 10 maces = 100 candareens = 1000 caſh. A tale of fine ſilver ſhould be worth 1000 caſh, which caſh is compoſed of ſix parts of copper, and four of lead, having a ſquare hole in the middle, ſo that they may be ſtrung on a ſtring or wire; but on account of their convenience for common uſe, their price is ſometimes ſo much raiſed, that only 750 caſh are given for the tale.

Gold is not conſidered as money, but as merchandize; and it is ſold in ingots of a determinate weight, called by the Engliſh "ſhoes" of gold; the largeſt of which weighs 10 tales, and the gold is reckoned 94 touch (*i. e.* 94 parts fine in 100), though it is only 92 or 93. Of late, from 100 to 110 tales of ſilver of 94 touch, have been given for 10 tales of gold of 92 or 93 touch; and ſometimes from 110 to 120 tales, or even more, of Spaniſh dollars, reckoned at 92 touch, have been paid for 10 tales of gold. When gold is exchanged for ſilver, its price is always valued by the ten-tale weight, and it is ſold either above or below touch, as follows: *viz.* if the gold be 96 touch, and ſold at 5 under touch, ſubtract 5 from 96, and 91 remains: then 91 tales of ſilver are paid for 10 of gold: if gold be ſold at 10 above touch, the fineneſs being ſtill 96, add 10 to 96, and 106 tales of ſilver are paid for 10 tales of gold. Silver ingots are uſed as money, and are from $\frac{1}{2}$ to 100 tales, their value being determined by their weight. In payment of ſmall ſums, they ſometimes lay the ingot on the fire, and by ſtriking it with a hammer, detach ſmaller pieces from it. The Engliſh reckon the tale of ſilver at 6*s.* 8*d.* ſterling, ſo that 1*l.* ſterling is = 3 tales. The catty of 16 tales weighs 19 oz. 6 dwts. 4 grs. Engliſh troy; ſo that 10 tales would weigh 5792 Engliſh grains. Upon the whole, the weight of a Chineſe tale may be taken at about 580 grains Engliſh troy; and therefore 48 tales = 58 ounces troy weight. One hundred Spaniſh dollars weigh about 722 tales. The heavieſt weight for merchandize (peculiar to the coaſt of Canton) is called pecul, and contains 100 catties or 1600 tales, with the ſame decimal diviſion as above. Hence a pecul = 132 lbs. 8 oz. 9 dr. avoirdupois: and a catty = 21 oz. $3\frac{1}{2}$dr. avoirdupois.

At Acheen, in the iſle of Sumatra, accounts are kept in tales, pardows, mace, copangs, and caſhes. A tale = 4 pardows = 16 mace = 64 copangs. The coins of the country are mace and caſhes. The mace is a ſmall gold coin weighing nine grains, and worth about 14*d.* ſterling. The caſhes are ſmall pieces of tin or lead, 2500 of which uſually paſs for a mace, ſubject to occaſional variation. In Siam, accounts are kept in catties, tales, ticals or tuals, miams, fanangs, and cowries. The catty is 20 tales: the tale = 4 ticals = 16 miams = 32 fanangs: the fanang is = 800 cowries. In Tonquin, accounts are kept in tales of 10 mace or 100 candareens. The tale weighs here 1 oz. 4 dwt. $14\frac{1}{2}$ grs. Engliſh, which is about 10 grs. more than the Chineſe tale. Kelly's Cambiſt.

TALED, in the *Jewiſh Antiquities,* a ſort of habit that the Jews wore, chiefly when they repeated their prayers in the ſynagogue. Numbers, xv. 38. Deuteronomy, xxii. 12.

It ſerved inſtead of that ſquare garment they wore heretofore, to which Moſes had appointed that they ſhould faſten borders of blue to the four quarters, and fringes or ribbands all along the borders. But at preſent, that they may not be expoſed to the laughter of the people for the too great ſingularity of their dreſs, they content themſelves with wearing a ſquare piece of cloth underneath, with four tufts at the four corners, and when they meet in the ſynagogue to ſay their prayers, they cover their heads with a ſquare woollen veil, which has four tufts at its four corners. It is this they call *thaled,* or *taled.* Calmet, Dict. & Leo of Modena, Ceremonies of the Jews, p. i. ch. 11.

TALEGONG, in *Geography*, a town of Hindooftan, in Dowlatabad; 15 miles S. of Oudighir.—Alfo, a town of Baglana; 12 miles S. of Chandor.

TALEKAN, a town and caftle of Perfia, in the province of Khoraffan; 160 miles N.E. of Herat.—Alfo, a town of Perfia, in the province of Irak; 30 miles N.E. of Hamadan.

TALENNI, a town of Japan, in the ifland of Niphon; 160 miles W.N.W. of Meaco.

TALENT, Talentum, a weight, and a coin, both very famous among the ancients; but very different in different countries.

The value of the talent it is very hard to affign in Englifh money, as being ufed among all the people throughout the Eaft, and its value, and the manner of computation, being different among each: a difficulty abundantly fhewn by Budæus, in his learned treatife "De Affe."

There were various kinds of talents, both with regard to weight and to fpecies; the value of thefe laft ftill increafing, as the metal of which they confifted was purer, though the talent weights contained the fame number of pounds and drachms. Accordingly, all talent weights are equally fixty minæ, and the mina one hundred drachmæ; but the drachma of one place exceeding that of another, there hence arofe a difference in the talents.

The common Attic talent then (the talent weight we mean) contained fixty Attic minæ, or fix thoufand Attic drachmæ; equal, according to Dr. Arbuthnot's reduction, to fifty-fix pounds, eleven ounces, feventeen and one-feventh grains, Englifh troy weight.

There was another Attic talent, by fome faid to confift of eighty, by others of one hundred minæ. The Egyptian talent was eighty minæ; the Antiochian alfo eighty; the Ptolemaic of Cleopatra eighty-fix and two-thirds; that of Alexandria ninety-fix; the Infular talent one hundred and twenty; and that of Antioch three hundred and fixty minæ. In the valuation of money, the Grecian talent, according to Dr. Arbuthnot, was equal to fixty minæ, or reckoning the mina at 3*l.* 4*s.* 7*d.* equal to 193*l.* 15*s.*; the Syrian talent in this valuation confifted of fifteen Attic minæ; the Ptolemaic of twenty; the Antiochian of fixty; the Euboic of fixty; the Babylonic of feventy; the greater Attic of eighty; the Tyrian of eighty; the Eginean of one hundred; the Rhodian of one hundred; and the Egyptian of eighty minæ. (See Arbuthnot's Tables of Ancient Coins, &c. p. 33, and Tab. 18, 19. 23, 24.) Stating the Attic drachm of filver at nine-pence of our money, the beft medium value, the mina of Athens will be worth 3*l.* 15*s.*; and the Athenian common talent, 225*l.*; and the reft may eafily be eftimated in proportion.

But Mr. Raper makes the Attic talent, which confifted of fixty minæ, or fix thoufand drachmæ, each drachm being equal to fixty-fix grains and a half troy weight, or 3*l.* 17*s.* 4$\frac{6}{10}$*d.* fterling, equal to 232*l.* 3*s.* See Drachm.

This ingenious writer alfo obferves, that hiftorians and others mention the Eginean and the Euboic talent. The former weighed ten thoufand Attic drachms; but, like other talents, contained only fix thoufand of its own; which being fo much heavier than the Attic, the Athenians called it παχειαν δραχμην, or the thick drachm. This talent was ufed at Corinth; and in a paffage of Aulus Gellius, lib.i. c. 8. it is valued at ten thoufand Attic drachms; and was probably ufed in moft of the cities of Peloponnefus. If the Attic drachm weighed fixty-fix and a half troy grains, the Eginean fhould weigh one hundred and ten and five-fixths, which Mr. Raper ftates at one hundred and eleven. This Eginean talent he concludes from the mean drachm of fix Macedonian coins, which he found to be one hundred and eleven grains and one-fourth, muft have been the ftandard of the Macedonian money, till Philip changed it. And it appears likewife to have been the ftandard of the Ptolemaic money in Egypt. Pliny indeed (Nat. Hift. lib. xxxiii. c. 3.) tells us, on the authority of Varro, that the Egyptian talent weighed eighty Roman pounds; but he fuppofes that this is a falfe reading, and that for Ægyptium we fhould read Euboicum: for Pliny is fpeaking of the riches of Afia, where the Euboic talent was ufed for weighing gold; and it is known, that the weight of that talent was fettled at eighty Roman pounds, by the treaty between the Romans and Antiochus. There is a paffage in Pollux (lib. ix. c. 6. § 86.) which makes the Egyptian talent contain fifteen hundred Attic drachms. But this, he apprehends, is an injudicious interpolation in the laft collection of that author.

The Euboic talent, fays this writer, certainly came from Afia; for Herodotus (lib. iii. fect. 89.) tells us, the kings of Perfia weighed their gold by that talent: in the fame place he informs us, that the Babylonian talent weighed feventy Euboic minæ. Pollux fays, it weighed feventy Attic minæ. Therefore the Euboic talent fhould be equal to the Attic. But Ælian (Var. Hift. lib. i. c. 22.) tells us, that it weighed feventy-two Attic minæ; and if fo, the Euboic talent fhould be heavier than the Attic, in the proportion of feventy-two to feventy. By two paffages, cited by Mr. Raper, from Xenophon, Exped. lib. i. it appears probable, that the Babylonian talent weighed above feventy Attic minæ, and above feventy Euboic minæ; and if Pollux took his value of the Babylonian talent from Herodotus, as the text now ftands, and Ælian his value of the fame from a more correct copy of that author, or from fome better authority, the Euboic talent muft have been equal to the Attic. Accordingly it contained fix thoufand Attic drachms. Phil. Tranf. vol. lxi. part ii. p. 483, &c.

There is another talent much more ancient, and much lefs than any of thofe already mentioned, which Dr. Arbuthnot calls the Homerical talent of gold, fuppofed, he fays, to be equal to three Attic aurei. Pollux fpeaks of fuch a talent. Euftathius upon Homer reckons it worth twenty-four drachmæ. That its value was fmall, whether fixed or uncertain, is conjectured from the paffage of Homer, where, defcribing the prizes at the funeral of Patroclus, two talents of gold are propofed as a more inconfiderable prize than a mare with foal, &c. Hence Mr. Raper, ubi fupra, p. 527, concludes, that it was the fame that the Dorian colonies carried to Sicily and Calabria: for Pollux tells us, from Ariftotle, that the ancient talent of the Greeks in Sicily contained twenty-four nummi, each of which weighing an obolus and a half, the talent muft have weighed fix Attic drachms, or three darics; but the daric weighed very little more than one guinea; and if two talents weighed about fix guineas, we may reckon the mare with foal worth twelve; which was no improbable price, fince we learn from a paffage in the Clouds of Ariftophanes, that, in his time, a running horfe coft twelve minæ, or above forty-fix pounds fterling; therefore this feems to have been the ancient Greek talent, before the art of ftamping money had introduced the greater talents from Afia and Egypt.

According to this ancient talent, fays Dr. Arbuthnot, fome reckon the treafure of king David, particularly that mentioned 1 Chron. xxii. 14. which, according to the common reckoning, would amount in gold talents to the value of 547,500,000*l.* and the filver to above 342,000,000*l.*; or reckoning according to the decuple proportion of gold to filver,

filver, the two fums would be equal. As David reigned in Judea after the fiege of Troy, it is not improbable but Homer and he might ufe the fame numeral talent of gold.

It is fuggefted by Mr. Pinkerton (Effay on Medals, vol. i. p. 65.) that all the ancient coins of Afia, Africa, Greece, Magna Græcia, and Sicily, were reducible to three talents or ftandards. 1. That of Egina, ufed in moft of the more ancient filver coinages; and as it would feem in even the later of Egypt, Carthage, Greece, &c. 2. The Attic, being the Afiatic gold ftandard; afterwards ufed by Phidon, king of Argos, in eftimating gold, and called Euboic, from Eubœa, one of the quarters of the city of Argos. It was afterwards ufed in Athens, and the greater part of the world, as the ftandard both of gold and filver. 3. The Doric, or Sicilian talent, of 24 nummi, each worth an obolus and a half: whence the talent is eftimated at fix Attic drachms, or three darics. Thefe weights continued to be the ftandard of money after it began to be diftinguifhed by impreffion; nay, to the fall of Greece, and prevalence of the Roman empire.

Among the Romans there were two kinds of talents, the *little* and the *great* talent; the little was the common talent; and whenever they fay fimply *talentum*, they are to be underftood of this: the *little* talent was fixty minæ or Roman pounds; the mina, or pound, eftimated at one hundred drachmæ, or denarii: it was alfo eftimated at twenty-four great fefterces, which amounted to fixty pounds.

The *great* talent exceeded the lefs by one-third part. Budæus computes, that the little talent of filver was worth 75*l.* fterling; and the greater 99*l.* 6*s.* 8*d.* fterling. The greater of gold was worth 1125*l.* fterling.

Talent, *as a fpecies, or money*, among the Hebrews, was fometimes ufed for a gold coin, the fame with the *fhekel* of gold, called alfo *ftater*, and weighing only four drachms. The Hebrews reckoned by thefe talents as we do by pounds, &c. Thus a million of gold, or million of talents of gold, among them, was a million of fhekels, or nummi; the nummus of gold being the fame weight with the fhekel, *viz.* four drachms.

But the Hebrew talent weight of filver, which they called *cicar*, was equivalent to that of three thoufand fhekels (Exod. xxxviii. 25. 28.) or one hundred and thirteen pounds, ten ounces, one pennyweight, ten grains and two-fevenths, Englifh troy weight, according to Arbuthnot's computation.

It fhould be obferved, however, that the talent was not every where the fame. The Hebrew talent weighed more than that of the Greeks, and is faid to have amounted to 341*l.* 10*s.* $4\frac{1}{4}$*d.* and $\frac{1}{7}$. The common Attic talent might be worth about 193*l.* 15*s.* which might probably have been ufed by the Jews in their commerce.

TALES, in *Law*, a fupply or addition of men for thofe impannelled on a jury of inqueft, and not appearing, or at their appearance challenged by either party as not indifferent.

In fuch cafe, the judge, upon motion, grants fupply to be made by the fheriff of one or more tales, fuch as are prefent in court, equal in reputation to thofe impannelled. For this purpofe, a writ of *decem tales*, *octo tales*, and the like, was ufed to be iffued to the fheriff at common law; and muft be ftill fo done at the trial at bar, if the jurors make default; but at the affizes, or nifi prius, by virtue of the ftatute 35 Hen. VIII. c. 6. and other fubfequent ftatutes, the judge is impowered, at the prayer of either party, to award a *tales de circumftantibus*, of perfons prefent in court, to be joined to the other jurors to try the caufe; who are liable, however, to the fame challenges as the principal jurors. This is ufually done till the legal number of twelve be completed. The *tales de circumftantibus* is in fome meafure rendered ufelefs by the ftatute for regulating juries, 3 Geo. II. c. 25. See Challenge and Jury.

TALGA, in *Geography*, a town of Hungary; 8 miles N. of Tokay.

TALGARTH, a fmall town in a hundred of the fame name, and county of Brecon, South Wales, is fituated on the banks of the river Llyfni, at one end of the Black Mountains, which ftretch hence into Herefordfhire: from its fituation it derived its name; Talgarth meaning literally the front of the hill. The town is a borough by prefcription, but without privilege, jurifdiction, or municipal officers. The parifh church is a fubftantial edifice, but has no architectural elegance, nor is it enriched by any remarkable monuments, ancient or modern: it has a tower, which forms a confpicuous object from moft parts of the furrounding country. The population of the parifh, which, befides the borough, contains five hamlets, was in the year 1811 returned to parliament as 1124, the number of houfes being 274. No lefs than eight annual fairs are held here.

In the Foreft hamlet of the parifh of Talgarth are fome veftiges of Dinas-caftle, which, at a remote period, was a fortrefs of importance, but has long fince been demolifhed. In Leland's time, it was "ruinus almoft to the hard ground." From his defcription, it muft have been of confiderable dimenfions. It confifted of three wards "waullid about," and had three parks and a foreft attached to it. From the fame writer we learn, that the caftle was deftroyed by the natives, that it might not be occupied by the favourers of Owen Glendwr.—Beauties of England and Wales, vol. xviii. South Wales, by T. Rees, F.S.A. Carlifle's Topographical Dictionary of Wales.

TALGAUTPORAM, a town of Hindooftan, in Myfore; 6 miles S. of Bangalore.

TALGRISTAN, a town of Perfia, in the province of Irak; 50 miles E. of Nehavend.

TALGUL, a town of Hindooftan, in Myfore; 10 miles S.S.W. of Sirpy.

TALHA-KIAMEN, a poft of Chinefe Tartary. N. lat. 46° 16'. E. long. 123° 44'.

TALHAM, a town of Auftria; 2 miles S.S.W. of Voglabruck.

TALI, a town on the W. coaft of the ifland of Formofa. N. lat. 23° 36'. E. long. 129° 41'.

Ta-li, a city of China, of the firft rank, in Yun-nan. This is the principal place where they make curious tables, and other ornaments of fine marble, which is got from a mountain called *Tienfung*, and is naturally beautified with different colours, in the form of mountains, flowers, trees, and rivers. Ta-li has under its jurifdiction four cities of the fecond order, and three of the third; 1205 miles S.W. of Peking. N. lat. 25° 45'. E. long. 100°.

TALIA, in *Ancient Geography*, a town of the Upper Mœfia, on the route from Viminatium to Nicomedia. Ant. Itin.

TALJARA, in *Geography*, a town of Bengal; 46 miles S. of Curruckdeah.

TALIFAY, a town on the N. coaft of the ifland of Luçon. N. lat. 14° 21'. E. long. 123° 24'.

TALIGALEA, in *Botany*, an unexplained name, Aublet Guian. 625. t. 252. Juff. 109, appears to be the fame genus, and even the fame fpecies, as Amasonia of Linnæus. (See that article.) The fruit of the latter having been examined in a drier ftate, may folve all the difficulty.

Aublet defcribes his only fpecies, *T. campeftris*, as an herb with a perennial *root*, fometimes creeping. *Stems* annual, two

two or three feet high, ſimple, leafy, downy. *Leaves* alternate, ſtalked, elliptical, pointed, from three to ſix inches long, downy, with tooth-like ſerratures. The variety with a creeping *root* has ſmooth leaves, and we ſhould preſume it may be a diſtinct ſpecies. The *flowers* are yellow, about an inch long, numerous, in a long compound *cluſter*, with ovate purple *bracteas*. *Berry* black, with two hard *ſeeds*.—This plant grows abundantly in the ſandy meadows of the iſland of Cayenne, as well as on the continent of South America, bearing flowers and fruit all ſummer long.

TALIGONG, in *Geography*, a town of Hindooſtan, in the Carnatic; 7 miles N. of Terriore.

TALIGOV, a town of Ruſſia, in the government of Riga; 24 miles N. of Dorpat.

TALIHOU, a ſmall iſland, with a lazaretto, on the coaſt of France. At low-water the land which joins to the continent is dry; 3 miles N. of La Hogue. N. lat. 49° 36′. W. long. 1° 9′.

TALINA, a town of Peru; 50 miles E.S.E. of Lipes.

TA-LIN-HO, a town of Chineſe Tartary. N. lat. 41° 10′. E. long. 120° 50′.

TALINUM, in *Botany*, a genus of Adanſon's, well ſeparated by him from the Linnæan PORTULACA. (See that article.) Its name no one, not even De Theis, has undertaken to explain; Adanſon having given ſo many barbarous, and even arbitrary ones, that the inquiry might well be deemed alike hopeleſs and unprofitable. We conjecture, however, that he muſt have had in his mind the verb θαλλω, *to be verdant*, or *flouriſhing*, and conſequently θαλος, or θαλία, *a green bough*; for he often wrote words with a *T* which in Greek begin with a θ; and the above idea is ſuitable enough to the ſucculent, and durably verdant, habit of the genus. We hence learn the true accentuation of the word, *Talinum*. Ehrhart called this ſame genus *Rülingia*, after Dr. John Philip Rülings, who publiſhed at Gottingen, in 1774, a catalogue of the genera of plants, diſpoſed in natural orders. Linnæus had formerly diſtinguiſhed it by the name of *Anacampſeros*.—Adanſ. Fam. v. 2. 245. Juſſ. 312. Willd. Sp. Pl. v. 2. 862. Ait. Hort. Kew. v. 3. 148. Purſh 365. Lamarck Illuſtr. t. 402. Gærtn. t. 128. (Rülingia; Ehrh. Beitr. v. 3. 132. Orygia; Forſk. Ægypt.-Arab. 103. Anacampſeros; Linn. Gen. ed. 1. 152. Sims in Curt. Mag. p. 1367.)—Claſs and order, *Polyandria Monogynia*. (Dodecandria Monogynia, *Willd.*) Nat. Ord. *Succulentæ*, Linn. *Portulaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of two or five oblong, rather unequal, permanent leaves. *Cor.* Petals five, ſpreading, ovate, obtuſe, as long or longer than the calyx. *Stam.* Filaments numerous, capillary, not half ſo long as the corolla; anthers incumbent, oblong. *Piſt.* Germen ſuperior, roundiſh; ſtyle ſimple, about as long as the corolla; ſtigmas three, oblong, reflexed. *Peric.* Capſule ovate, of one cell, and three, five, or ſix valves. *Seeds* numerous, roundiſh, affixed to a globular central receptacle.

Eſſ. Ch. Petals five. Calyx of two or five leaves. Capſule ſuperior, with from three to ſix valves, one cell, and many ſeeds.

Section 1. *Stipulas none. Seeds without wings.*

1. T. *triangulare*. Triangular-ſtalked Yellow Talinum. Willd. n. 1. Ait. n. 1. (Portulaca triangularis; Jacq. Amer. 147. Obſ. faſc. 1. 35. t. 23. P. racemoſa; Linn. Sp. Pl. 640. Helianthemum fruteſcens, portulacæ folio; Plum. Ic. 142. t. 150. f. 2.)—Leaves flat, channelled, wedge-ſhaped, emarginate, with a ſmall point. Cluſter ſimple, with a triangular ſtalk. Stem ſpreading.—Native of the ſea-ſhores of the Weſt Indies. Cultivated in Chelſea garden in 1739. Mr. Aiton ſays it bloſſoms in the ſtove, moſt part of the ſummer. The *ſtem* is ſhrubby, two feet high, round, ſmooth, branched, decumbent in the lower part. *Leaves* ſcattered, about one and a half or two inches long, ſucculent, ſmooth, ſhining, brittle, entire at the edges; occaſionally convex, being reflexed at the ſides, tapering at the baſe into a ſhort footſtalk. *Flowers* two or more, on a terminal triangular ſtalk, very elegant, of a brilliant yellow, without ſcent. *Calyx* of two leaves. *Capſule* with three valves.

2. T. *craſſicaule*. Thick-ſtemmed Red Talinum. (T. craſſifolium; Willd. n. 2. T. patens; Andr. Repoſ. t. 253. Ait. n. 2. Portulaca craſſicaulis; Jacq. Hort. Vind. v. 3. 29. t. 52. P. craſſifolia; Murray in Linn. Syſt. Veg. ed. 14. 446.)—Leaves flat, obovate, entire at the point. Corymbs compound, elongated. Stem erect.—Native probably of the Weſt Indies. Jacquin cultivated it at Vienna, and we have ſeen it flowering in many of the Engliſh ſtoves. This differs from the former in its more erect and thicker *ſtem*, as well as in the fine pink colour of its *flowers*. The *leaves* moreover are not emarginate. The corymboſe, or panicled, many-flowered *ſtalks*, at firſt terminal, are ſometimes overtopped by the aggregate leafy *branches*, and thus become lateral, or axillary. Murray, from mere inadvertence in tranſcribing, altered Jacquin's original name, for one which has here no appropriate meaning.—Willdenow ſeems to have copied him, without ſeeing the work of Jacquin; which from this, and ſome other inſtances, we ſuſpect he had not in his poſſeſſion. We do not think it neceſſary to perpetuate ſuch an error, any more than that of Andrews, who took this plant for Willdenow's *T. patens*, ſee n. 4.

3. T. *fruticoſum*. Shrubby White Talinum. Willd. n. 7. (Portulaca fruticoſa; Linn. Syſt. Veg. ed. 13. 371. P. paniculata; Linn. Sp. Pl. 640. P. americana latifolia erecta, floribus albis; Comm. Hort. v. 1. 7. t. 4.)—Leaves flat, obovate, ſomewhat emarginate. Corymbs compound, elongated. Stem erect. Calyx of five leaves.—Native of the Weſt Indies, or of South America. This ſpecies, a ſtranger to our gardens, appears to differ eſſentially from the two foregoing in having five leaves to the *calyx*, inſtead of two; to ſay nothing of the white *petals*. In habit, *leaves*, and *infloreſcence*, it comes very near the laſt. The *capſule* is ſaid to conſiſt of three valves in both.

4. T. *patens*. Panicled Red Talinum. Willd. n. 4. Haworth Succ. Pl. 123. (T. paniculatum; Gærtn. v. 2. 219. Portulaca patens; Linn. Mant. 242. Jacq. Hort. Vind. v. 2. 71. t. 151. P. paniculata; Jacq. Amer. 148.)—Leaves flat, obovate, obtuſe. Panicle repeatedly compound, forked, many-flowered.—Native of rocks on the ſea-coaſt of Martinico and Hiſpaniola. *Jacquin*. We have ſeen it in the Engliſh ſtoves, as Mr. Haworth likewiſe appears to have done, when he remarks that the *patens* of Andrews is a widely different plant. (See our 2d ſpecies.) That before us has an upright ſhrubby *ſtem*, one and a half or two feet high, branched; ſomewhat quadrangular below. *Leaves* ſcattered, or imperfectly oppoſite, obovate, lanceolate or oval, more or leſs obtuſe, very ſmooth and juicy; the lower ones three inches long, the reſt ſhorter; all tapering at the baſe into a ſhort *footſtalk*. *Panicles* ſolitary at the top of the ſtem and branches, erect, from ſix to ten inches long, with numerous, moſtly oppoſite, repeatedly ſubdivided, and partly forked, ſlender, ſmooth, ſpreading ſtalks, accompanied here and there by ſmall lanceolate *bracteas* at their baſe. *Flowers* numerous, ſmall, inodorous. *Calyx* of two orbicular, concave, red, widely ſpreading leaves. *Petals* five, obovate, red, thrice the ſize of the calyx, likewiſe widely ſpreading. *Capſule* globoſe, ſmaller than a pepper-corn, its three valves, which Jacquin deſcribes as double, or of

two

two layers, ſuſpended from the top of three intermediate fibres. See Gærtner's figure and deſcription, where the ſynonym of Commelin, which belongs to the foregoing, is very erroneouſly cited for the preſent ſpecies. This muſt have ariſen from Linnæus's having once called the former *Portulaca paniculata*, and Gærtner's having copied the above ſynonym without examination.

5. T. *reflexum*. Panicled Yellow Talinum. Cavan. Ic. v. 1. t. 1. Haworth Succ. Pl. 124. Curt. Mag. t. 1543. Ait. Epit. 375. (T. patens β; Willd. n. 4.)—Leaves ſomewhat convex, elliptic-lanceolate, acute. Panicle twice compound, many-flowered.—Native of South America.—An annual or biennial, ſcarcely ſhrubby, plant in our ſtoves. Mr. Haworth obſerves, it is more tender, and much taller, than the laſt, of which Willdenow thought it a mere variety. We are not ſure that the differences indicated in our ſpecific characters are ſufficient or permanent, not having had an opportunity of comparing the two plants. The *flowers* of *T. reflexum* being yellow, ſeems an important diſtinction in this genus. Both ſpecies are ſaid to be abundantly propagated by ſeed.

6. T. *cuneifolium*. Wedge-leaved Talinum. Willd. n. 5. (Portulaca cuneifolia; Vahl Symb. v. 1. 33. Orygia portulacifolia; Forſk. Ægypt.-Arab. 103.)—Leaves flat, wedge-ſhaped, obtuſe, with an occaſional point. Panicle many-flowered; its lower branches umbellate, three-flowered.—Native of Arabia Felix.—A *ſhrub* three feet high. *Leaves* eatable, alternate, ſpreading, ſeſſile, tapering at the baſe, about an inch long, thick and ſmooth. *Calyx* of two unequal leaves, deciduous. *Petals* of a violet red. *Stamens* green, with yellow *anthers*. *Capſule* three-angular, of three valves. *Seeds* black, compreſſed, ſmooth. *Forſkall.*—Vahl ſays this ſpecies is akin to *T. patens*, n. 4, but differs in having thicker *flower-ſtalks*, the lower ones bearing three-flowered umbels.

7. T. *decumbens*. Decumbent Glaucous Talinum. Willd. n. 6. (Portulaca decumbens; Vahl Symb. v. 1. 33. Orygia decumbens; Forſk. Ægypt.-Arab. 103.)—Leaves flat, obovate, pointed. Cluſters axillary. Stem decumbent. Calyx of five leaves.—Native of Arabia Felix, in ſtony places near Muſa, but not common. *Forſkall.* *Stem* ſhrubby, with angular branches, clothed, like the reſt of the plant, with a glaucous mealineſs. *Leaves* diſtant, ſtalked, thickiſh, ſomewhat wavy. *Cluſters* from the boſoms of the uppermoſt leaves, with an awl-ſhaped ſcale, or *bractea*, oppoſite to each partial ſtalk. *Capſule* of five valves. *Vahl.*—Forſkall deſcribes numerous lanceolate *petals*, about twenty, of a reddiſh violet; and five cells, as well as valves, to the *capſule*.

8. T. *teretifolium*. Cylindrical-leaved Talinum. Purſh n. 1.—"Leaves cylindrical, fleſhy. Corymbs ſtalked, terminal."—On ſunny rocks in Delaware and Virginia, flowering in July. Perennial. *Flowers* purple. *Purſh.*

Section 2. *Stipulas withinſide of the leaves, jagged. Seeds winged.*

9. T. *Anacampſeros*. Round-leaved Talinum. Willd. n. 3. Ait. n. 3. "Decand. Pl. Graſſes, t. 3." (Rülingia Anacampſeros; Ehrh. Beitr. v. 3. 133. Haworth Succ. Pl. 124. Portulaca Anacampſeros; Linn. Sp. Pl. 639. P. africana ſempervirens, flore rubicundo; Comm. Hort. v. 2. 177. t. 89. Telephiaſtrum folio globoſo; Dill. Elth. 375. t. 281.)—Leaves ovate, acute, ſmooth; convex and tumid beneath. Stipulas filamentous, many times ſhorter than the leaves. Petals obovate.—Native of the Cape of Good Hope. Cultivated by Sherard in 1732. A greenhouſe plant, flowering in July. A humble ſhrubby ſpecies, whoſe extremely thick and ſucculent *leaves*, about an inch long, give it the habit of an *Aloe*. They are ſeſſile, of a pale glaucous green, not ſhining; their upper ſide nearly flat, with a longitudinal furrow; the under very convex. *Stipulas* ſhort, in many capillary ſegments. *Flowers* crimſon, the ſize of our ſecond or third ſpecies, in long-ſtalked terminal ſimple *cluſters*, which are ſometimes two together. *Calyx* of two leaves. *Petals* ſomewhat pointed. The *ſeeds* are ſaid to be winged. Ehrhart calls them *arillata*, tunicated.—The ſpecific name, borrowed from Pliny, derived from *ἀνακάμπτειν*, *to return*, and *ἔρος*, *love*, was at firſt adopted by Linnæus as a generic appellation for the preſent plant, when he conſidered it as a diſtinct genus from *Portulaca*, in his earlier publications. But this name, and the fooliſh ſuperſtition to which it alludes, of the very touch of the herb reſtoring alienated love, rather belongs to the *Sedum Anacampſeros* of Linnæus, and its near relation *S. Telephium*. See SEDUM.

10. T. *arachnoides*. Cobweb Talinum. Ait. n. 4. (Anacampſeros arachnoides; Sims in Curt. Mag. t. 1368. Rülingia arachnoides; Haworth Succ. Pl. 125.)—Leaves elliptical, acute; ſlightly convex, and covered with cobweb-like down above; tumid beneath. Stipulas filamentous, ſhorter than the leaves. Petals elliptical.—Found by Mr. Maſſon at the Cape of Good Hope, and ſent to Kew about the year 1790. It is treated like the laſt, and agrees with that ſpecies in general habit, though ſmaller in ſize. The *leaves* are leſs glaucous; the lower ones covered with a kind of web. *Stipulas* longer and more robuſt. *Flowers* white, with a faint bluſh. *Seeds* obſerved by Mr. Haworth to be leſs winged.—The leaves are repreſented in the Botanical Magazine with a tinge of purpliſh-brown. Perhaps Mr. Haworth's *Rülingia rubens*, n. 3, may be only a higher-coloured variety.

11. T. *filamentoſum*. Thready Talinum. Ait. n. 5. (Anacampſeros filamentoſa; Sims in Curt. Mag. t. 1367. Rülingia filamentoſa; Haworth Succ. Pl. 125.)—Leaves ovate, bluntiſh, tumid and covered with cobweb-like down on both ſides. Stipulas filamentous, longer than the leaves. Petals lanceolate.—Found by Mr. Maſſon, at the Cape of Good Hope, and ſent to Kew a few years after the laſt, from which it differs in having ſmaller, blunter *leaves*, and much longer, more conſpicuous, *ſtipulas*, whoſe ſegments are linear and flattened, like ſhavings of horn. The *petals* are roſe-coloured, and elliptic-lanceolate, very fugacious, as in the two foregoing ſpecies. We have never ſeen Mr. Haworth's *Rülingia lanceolata*, n. 5, but it ſeems, by his definition, nearly akin to this.

The winged ſeeds can hardly entitle the ſpecies of this ſection to form a ſeparate genus, there being ſo little difference in habit. If they did, the name of *Rülingia* muſt certainly be preferred to *Anacampſeros*, the latter, notwithſtanding its right of priority, having been arbitrarily and erroneouſly applied to theſe Cape plants, with which the ancients were of courſe unacquainted. See our remark under the 9th ſpecies.

TALIO, *Lex Talionis*, or *Pœna Talionis*, a retaliation, or puniſhment, by which an evil is returned perfectly like that committed againſt us by another; which is what we uſually expreſs by the words, *eye for eye, tooth for tooth.*

The *pœna talionis* was enjoined by the law of Moſes, among the Jews; it was eſteemed a natural piece of juſtice, and yet the Romans ſet it aſide, inaſmuch as ſuch a parity or equality of puniſhment could not always be obſerved. For this reaſon the prætor allowed ſuch as had ſuffered an injury to make an eſtimate of it in money, that juſtice might be done him that way; only reſerving to himſelf the power of moderating the ſame. And this was what was conſtantly practiſed, and thus the *pœna talionis* became quite diſuſed with them.

TALISIA, in *Botany*, a barbarous name of Aublet's, which

which he appears to have fabricated out of the Caribbean appellation of the plant in queftion, *Toulichi*. We fhould be inexcufable in giving more than a temporary fanction to fuch a name, till the genus is either better known than at prefent, or fet altogether afide.—Aubl. Guian. 349. Juff. 247. Lamarck Illuftr. t. 310.—Clafs and order, *Octandria Monogynia*. Nat. Ord. *Sapindi*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, acute fegments. *Cor.* Petals five, ovate, inferted into the orbicular receptacle of the flower beneath the germen. Nectary of five fhort, hairy, upright fcales, one inferted into the bafe of each petal, covering the ftamens. *Stam.* Filaments eight, fhort, inferted into the orbicular receptacle; anthers oblong, of two cells. *Pift.* Germen fuperior, minute, roundifh, of four cells; ftyle one, very fhort; ftigma fimple, obtufe. *Peric.* unknown.

Eff. Ch. Calyx in five deep fegments. Petals five. Nectary of five hairy fcales, attached to the petals. Germen of four cells.

1. T. *guianenfis*. Toulichi of Guiana. Aubl. Guian. 349. t. 136.—Native of banks of rivers in Guiana, flowering in October.—A fhrub, whofe *trunk* is three or four feet high, and as many inches in diameter, with a greyifh bark, and whitifh wood; the branches long, compound, varioufly fpreading. *Leaves* alternate, pinnate, very large, each confifting of about thirty alternate, ftalked, elliptic-lanceolate, pointed, entire, fmooth, veiny *leaflets*, befides an odd one, from five to fix inches long, and above one broad. *Clufters* axillary and terminal, doubly compound, many-flowered, all over of a fine rofe-colour, with a fmall fcaly *bractea* under each fubdivifion. *Flowers* fmall, in little tufts, nearly feffile.—Nothing is known of the *fruit*, except that the germen has four cells, nor is any thing recorded concerning the qualities or ufes of this plant.

TALISKERAN, in *Geography*, a town of Perfia, in the province of Adirbeitzan; 100 miles N.N.E. of Ardebil.

TALISMANS, magical figures engraven or cut under certain fuperftitious obfervances of the characterifms and configurations of the heavens; to which fome aftrologers, hermetical philofophers, and other adepts, attribute marvellous virtues, particularly that of calling down celeftial influences.

The word is pure Arabic; though Menage, after Salmafius, thinks it may come from the Greek τελεσμα, *operation*, or *confecration*. Borel fays it is Perfian, and fignifies literally an engraven conftellation. Others derive it *a talamacis literis*, which are myfterious characters, or cyphers, ufed by forcerers, thus called from *talamafca*, a phantom, or illufion.

The author of a book, entitled, *Talifmans juftifiez*, fays, a talifman is the feal, figure, character, or image of a heavenly fign, conftellation, or planet, engraven on a fympathetic ftone, or on a metal correfponding to the ftar, &c. in order to receive its influences.

The talifmans of the Samothracians, fo famous of old, were pieces of iron, formed into certain images, and fet in rings, &c. They were held prefervatives againft all kinds of evils. There were other talifmans taken from vegetables, and others from minerals.

In the general, we may diftinguifh three kinds of talifmans. *Aftronomical*, which are known by the figns or conftellations of the heavens engraven on them, with other figures, and fome unintelligible characters. *Magical*, which bear very extraordinary figures, with fuperftitious words and names of angels unheard of. And *mixt*, which confift of figns, and barbarous words; but have no fuperftitious ones, or names of angels.

Some rabbins maintain, that the brazen ferpent, raifed by Mofes in the wildernefs, for the deftruction of the ferpents that annoyed the Ifraelites, was properly a talifman.

All the miraculous things wrought by Apollonius Tyanæus are attributed to the virtue and influence of talifmans: and that wizard is even faid by fome to have been the inventor of talifmans.

Some authors take feveral Runic medals, at leaft medals whofe infcriptions are in Runic characters, for talifmans; it being notorious, that the northern nations, in their heathen ftate, were much devoted to them. M. Keder, however, has fhewn, that the medals here fpoken of are quite other things than talifmans.

TALISSE, in *Geography*, a fmall ifland in the Eaft Indian fea, near the N. coaft of the ifland of Celebes. N. lat. 1° 40'. E. long. 124° 50'.

TALK, in *Mineralogy*. See TALC.

TALKAN, in *Geography*, a town of Perfia, in the province of Irak; 30 miles E. of Sultania.

TALKEAVE, a town of Perfia, in Khoraffan; 50 miles E. of Tabafkili.—Alfo, a town of Perfia, in Segeftan; 21 miles S.W. of Kin.

TALKHAN, a town of Grand Bucharia; 80 miles S.S.W. of Balk.

TALKING. See SPEAKING.

TALLAGH, in *Geography*, a poft-town of the county of Dublin, Ireland, where is the ancient and noble refidence of the archbifhops of Dublin; 5 miles S.W. by W. from Dublin.

TALLANO, a town of Corfica, and capital of a diftrict, in the department of the Liamone, fituated in a bay of the Mediterranean, called the "Gulf of Tallano;" 30 miles S.S.W. of Corte. N. lat. 41° 33'. E. long. 9° 11'.

TALLAPOUR, a town of Hindooftan, in Oude; 22 miles N.E. of Lucknow.

TALLARAPESCET, a town of Perfia, in the province of Mazanderan; 21 miles S. of Fehrabad.

TALLARD, a town of France, in the department of the Higher Alps, on the Durance; 9 miles S. of Gap.

TALLARO, in *Commerce*, a filver coin of Tufcany, Venice, and Ragufa. At Florence the tallaro is = 6 lire or 9 paoli, the lire being worth about 8*d.* The new tallari of Ragufa, called libertine, coined between 1791 and 1794, are of the weight of 1 oz. 10 carats, containing 9 parts of pure filver to 6 of alloy; and the value of the tallaro was reckoned at 80 groffetti. Since 1796 there have been coined ducats of 40 groffetti, containing 9 parts of pure filver and 11 of alloy. The ducat of 1796 is worth 13$\frac{1}{4}$*d.* fterling, which is nearly the value of the Turkifh piaftre of the lateft coinage.

By Mr. Bingley's affay, the mint price of filver in England being 5*s.* 2*d. per* ounce ftandard, the tallaro of Venice ($\frac{1}{2}$, &c. in proportion) is worfe than Englifh ftandard (W.) 1 oz. 3 dwts., its weight 18 dwts. 10$\frac{3}{4}$ grs., its content in pure filver 367.1 grs., and value in fterling 4*s.* 3$\frac{1}{4}$*d.* The tallaro and its divifions are marked with the head of a woman, legend, *Refpublica Veneta*; reverfe, a winged lion, and a book; legend, the reigning doge's name, thus *Paulo Rainario duca*.

The affay of the tallaro of Ragufa, or Ragufian of 1759, is W. 4 oz. 2 dwts., its weight 18 dwts. 7$\frac{1}{2}$ grs., its content in pure filver 256.4 grs., and its fterling value 2*s.* 11$\frac{3}{4}$*d.* That of 1774, W. 4 oz. 4 dwts., weight 18 dwts. 8$\frac{1}{2}$ grs., content in pure filver 253.3 grs., and value 2*s.* 11$\frac{1}{4}$*d.* That of 1794, W. 3 oz. 19 dwts., weight 18 dwts. 17$\frac{1}{4}$ grs., content 267.6 grs., and fterling value 3*s.* 1$\frac{1}{4}$*d.* The ducat of 1797, 1797, W. 5 oz. 11 dwts., weight 8 dwts. $17\frac{1}{4}$ grs., content 97 grs., and value 1*s.* $1\frac{1}{2}$*d.*

The tallaro of Ragufa is marked with the head of the chief magiftrate, called the rector; legend, *Rector Reip. Rhacufin;* reverfe, arms of the city; legend, *Ducat et Sem. Reip. Rac.* In the Levant, and other places, the term tallaro is applied to dollars in general. Kelly's Cambift.

TALLEVENDE, in *Geography*, a town of France, in the department of the Calvados, containing near 3000 inhabitants, chiefly employed in the manufacture of earthenware; 2 miles S.W. of Vire.

TALLIAGE, Tallagium, a certain rate, according to which barons and knights were anciently taxed by the king towards the expences of the ftate, and inferior tenants by their lords, on certain occafions.

That raifed to the king was on his demefnes, efcheats, and wardfhips, and upon the cities and burghs of the realm. When it was paid out of knights' fees, it was called *fcutage* (which fee); when by cities and burghs, *talliage;* when upon lands not of a military tenure, *hidage;* which fee.

This latter talliage of the cuftomary tenants was fometimes fixed and certain, and fometimes at the pleafure of the lord; and was alfo fometimes compounded for.

Talliages were anciently called *cuttings;* which name is ftill retained in Ireland, though in a different fignification.

Talliage, fays fir Ed. Coke, is a general name including all taxes; and is derived from the French *taille*, *tax*, founded on the tally of petty tradefmen; as the country people appointed to collect it, not being able to write, fcored down what they received on tallies. See Land-tax and Subsidy.

TALLIKA, in *Geography*, a town of Africa, in the kingdom of Bondou, inhabited by Foulahs of the Mahometan religion, in the road of the caravans; 70 miles W.S.W. of Fatteconda. N. lat. 13° 56′. W. long. 11° 40′.

TALLIPOUR, a town of Hindooftan, in Bahar; 10 miles S.E. of Hajypour.

TALLIS, Thomas, in *Biography*, the mafter of Bird, and one of the greateft muficians, not only of this country, but of all Europe, during the 16th century, in which many able contrapuntifts flourifhed.

He was born early in the reign of Henry VIII.; but though it has frequently been afferted that he was organift of the chapel royal during the reigns of that monarch, Edward VI., queen Mary, and queen Elizabeth, yet it would be difficult to prove that, in the three firft of thefe reigns, laymen were ever appointed to any fuch office. In the reign of Henry, and his daughter Mary, when the Roman Catholic religion prevailed, the organ, in convents, was ufually played by monks; and in cathedrals and collegiate churches and chapels, by the canons, and others of the priefthood. The firft lay organifts of the chapel royal upon record were Dr. Tye, Blithman, the mafter of Dr. Bull, Tallis, and Bird; all during the reign of queen Elizabeth.

Though the melody or plain-fong of the cathedral fervice was firft adjufted to Englifh words by Marbeck, yet Tallis enriched it with harmony. Indeed the melody ufed by Tallis is not exactly fimilar to that of Marbeck, it is only of the fame kind; confifting of fragments of the ancient ecclefiaftical canto fermo. But the harmony in which he has clothed it is admirable; and the modulation being fo antique, chiefly in common chords or fundamental harmony to each note of the diatonic fcale, often where the moderns have fixths, fevenths, and their inverfions, produces a folemn and very different effect from any mufic that has been compofed during the laft century. As all melody, in which the femitones are avoided, muft refemble that of Scotland; fo all harmony, in which neither the *tritonus* nor falfe fifth occurs, and where the fecond, third, and fixth of the key, are only accompanied with common chords, muft remind us of that which prevailed in the fixteenth century; and though fo ancient, appear new to our ears, from its long difufe.

There are two compofitions by Tallis for the organ, preferved in queen Elizabeth's Virginal Book, one of which is dated 1561, and the other 1564; both built upon a dull and unmeaning ground, or fragment of plain-chant (*fœlix namque*), and both alike dry, elaborate, and difficult, to hands formed by modern mufic. The little melody and rhythm in the compofitions of thefe times required all the harmony that could be crowded into them. Notes are multiplied without end, and difficulties created without effect. It is not by the inftrumental mufic, which had been but little cultivated, that we muft judge of the genius of old mafters; but by vocal, in parts: where the harmony and contrivance compenfate for want of accent, tafte, and invention. The Latin motets and hymns, or "Cantiones facræ," which he publifhed jointly with thofe of his difciple Bird, are perhaps the beft of his compofitions that have been preferved. Thefe appeared in 1575, under the following title: "Cantiones quæ ab Argumento facræ vocantur quinque et fex Partium. Autoribus Thoma Talliffio et Gulielmo Birdo, Anglis, Sereniffimæ Reginæ Majeftati à privato facello Generofis et Organiftis." At the time of this publication, a very arbitrary and monopolifing patent was granted by queen Elizabeth to thefe compofers, for twenty-one years, not only for the publication of their own productions, vocal and inftrumental, but thofe of all other muficians, whether Englifh, French, or Italian, as well as for the fole ruling and vending of mufic-paper.

Moft of thefe excellent compofitions, of which the words were originally Latin, were afterwards adjufted to Englifh words by Dr. Aldrich, and others, for the ufe of our cathedrals. The canons, inverfions, augmentations, diminutions, and other learned and fafhionable contrivances of the times, which were of very difficult accomplifhment, are carried to a wonderful degree of ingenuity in thefe productions.

Dr. Thomas Tudway, of Cambridge, made a very valuable collection of Englifh church mufic, in fcore, from the Reformation to the Reftoration, in fix volumes, thick 4to. for Lord Harley, afterwards earl of Oxford, which is now among the Harleian manufcripts, in the Britifh Mufeum, No. 7337. In the firft volume of this collection we have the whole fervice of Tallis in D minor, in four parts, confifting of the *Te Deum, Benedictus, Kyrie Eleifon, Credo, Magnificat, Nunc Dimittis,* and *Litany*, as printed in 1760, by Dr. Boyce; with feveral anthems in four and five parts; as, "Wipe away my fins;" "With all our hearts and mouths;" "O Lord, give thy holy fpirit;" "I call and cry;" and his anthem, "Difcomfit them, O Lord!" erroneoufly faid by Dr. Tudway to have been fet for the victory over the Spanifh Armada, 1588.

In Chrift-Church, Oxford, are manufcript fcores of his Prèces, Litany, and Anthems, among others by Bird, Farrant, Bull, Gibbons, and Child. Five of his motets and full anthems, in five parts, to Latin and Englifh words, are likewife here preferved among the works of other Englifh mafters, in Dr. Aldrich's collection. But the moft curious and extraordinary of all his labours was his "Song of forty Parts," which is ftill fubfifting, and now before us. This wonderful effort of harmonical abilities is not divided into choirs of four parts: foprano, altus, tenor, and bafe, in each, like the compofitions *a molti cori*, of Benevoli, and others; but confifts of eight trebles, placed under each other;

other; eight mezzi soprani, or mean parts; eight counter-tenors; eight tenors; and eight bases; with one line allotted to the organ. All these several parts, as may be imagined, are not in simple counterpoint, or filled up in mere harmony, without meaning or design, but have each a share in the short subjects of fugue and imitation, which are introduced upon every change of words. The first subject is begun in G, by the first mezzo soprano, or medius, and answered in D, the fifth above, by the first soprano; the second medius in like manner beginning in G, is answered in the octave below by the first tenor, and that by the first counter-tenor in D, the fifth above; then the first base has the subject in D, the eighth below the counter-tenor; and thus all the forty *real* parts are severally introduced in the course of thirty-nine bars, when the whole vocal phalanx is employed at once, during six bars more. After which a new subject is led off by the lowest base, and pursued by other parts, severally, for about twenty-four bars, when there is a general chorus of all the parts; and thus this stupendous, though perhaps Gothic, specimen of human labour and intellect, is carried on in alternate flight, pursuit, attack, and choral union to the end; when the *Polyphonic phenomenon* is terminated by twelve bars of universal chorus, in quadragintesimal harmony. The entire composition consists of one hundred and thirty-eight bars, in *alla breve* time.

This venerable musician died in November, 1585, and was buried in the old parish church of Greenwich, in Kent. The following epitaph, which Dr. Boyce has printed in the first volume of his Collection of Cathedral Music, Strype, in his Continuation of Stow's Survey, printed 1720, says he found engraved in Gothic letters, on a brass plate in the chancel.

"Enterred here doth ly a worthy wyght,
  Who for long tyme in musick bore the bell:
His name to shew was Thomas Tallis hyght,
  In honest vertuous lyff he did excell.
He serv'd long tyme in chappel with grete prayse
  Fower sovereygnes reignes, (a thing not often seene);
I mean king Henry and prince Edward's dayes,
  Quene Marie, and Elizabeth our quene,
He maryed was, though children he had none,
  And lyv'd in love full three and thirty yeres
With loyal spowse, whos name yclept was Jone,
  Who here entomb'd, him company now bears.
As he dyd lyve, so also dyd he dy,
  In myld and quyet sort, O happy man!
To God ful oft for mercy did he cry,
  Wherefore he lyves, let Deth do what he can."

The stone to which this plate was affixed had been renewed by Dr. Aldrich; but the old church having been pulled down, about the year 1720, in order to be rebuilt, no memorial remains of Tallis, or any other illustrious person, who had been interred there anterior to that period.

TALLOW, a sort of animal fat, melted down and clarified. There are scarcely any animals but a sort of tallow may be prepared from; but those which yield the most, and of which the most use is made, are the horse, bullock, sheep, hog, goat, deer, bear, and viper. Some of which tallows, or fats, are used in medicine, and called *axungiæ*.

Most of the rest are used in the making of soap, and the dressing of leather; but chiefly in making of candles. For this purpose, large quantities are annually imported from Russia in casks. (See CANDLE.) Tallow-chandlers also melt tallow, which is done by chopping the fat, as it is taken from oxen and sheep, and then boiling it for some time in a large copper; and when the tallow is extracted by this process, the remainder is subjected to the operation of a strong iron press; and the cake that is left, after the tallow is expressed from it, is called a "greave." With this dogs are fed, and most of the ducks that are reared in the vale of Aylesbury, and which supply the London markets. It is also sometimes given to oxen and pigs, but certainly without meliorating the flavour of the meat.

It has been observed, that candles should be made without any admixture of oil or grease; and when laid up, should be preserved from the action of the atmosphere. For this purpose, some persons keep their candles closely covered up in bran. If tallows are weak, a part soon becomes converted to an acid by exposure to the air; and this renders the whole, when melted together, unfit for candles. Tallows, also, that contain a large portion of sebacic acid, require much more barilla than good tallow, in the manufacture of soap, and yet produce a less quantity. Foreign tallows, which frequently contain a large portion of acid, rendering them inferior to the English, may be purified at an insignificant expence by chemical means; and by the proper application of chemical agents, other brown tallows may be rendered beautifully white, and fit for the best purposes. The mode, says a chemical writer of reputation, which naturally presents itself as the best for separating the sebacic acid from tallow, is that of melting it in water containing some alkali; but old tallows may in general be sufficiently purified from their rancidity by melting them upon lime-water, and giving a considerable agitation to the whole mixture; for when the water is again suffered to subside, it will be found to be offensive in smell, and to have subtracted most of the impurities of the tallow. If the tallow, however, should not be sufficiently purified, a repetition of this process would completely effect it. Parkes's Chemical Essays, vol. i. p. 67, &c.

TALLOW-*Tree*, in China, is a tree growing in great plenty in that country, which produces a substance like our tallow, and serving for the same purpose. See CROTON *Sebiferum*.

All the preparation they give it, is to melt it down and mix a little oil with it, to make it softer, and more pliant. It is true, their candles made of it yield a thicker smoke, and a dimmer light than ours; but those defects are owing, in a great measure, to the wicks, which are not of cotton, but only a little rod or switch of dry light wood, covered with the pith of a rush, wound round it; which being very porous, serves to filtrate the minute parts of the tallow, attracted by the burning stick, which by this means is kept burning.

TALLOW-*Chandlers' Greaves*, in *Agriculture*, the refuse of tallow-chandlery, which is found at the bottom of the pan, after the melting of tallow, in a sort of cake, and which is an excellent *manure;* which see.

TALLOW, in *Geography*, a post-town of the county of Waterford, Ireland, situated within half a mile of the river Bride, on which there is a village called Tallow-bridge. It was a borough which returned two members, previous to the Union. It is 104 miles S.W. by S. from Dublin, and 4 S. from Lismore.

TALLOW *Point*, a mark for anchoring in the harbour of Port Royal, in Jamaica.

TALLOWING, in *Rural Economy*, a term applied to the property or means of forming tallow internally in animals of some kinds, especially those of the sheep and neat cattle sorts. It has been stated in the corrected Agricultural Report of the County of Sussex, that it is by no means a settled point upon the South Downs of that district, how far a sheep, which gathers its fat upon the intestines, is or is not preferable to another which collects it upon the back and the neck,

neck. The Leicestershire graziers, it is said, contending as much for the latter as the former, is considered as a test of merit in Norfolk, and various other counties. But when it is considered, that it requires a certain portion of food to create a given quantity of fat, the question is, it is thought, which is the best part to collect it upon,—within or without? As long as the fat of the latter will sell at more than one-third of the other, it would seem, it is said, that there cannot be a doubt which of the two is preferable; and that, upon the principle of food eaten to produce the tallow or fat, that which tallows the least is the best breed. The tallow, with the major part of the fifth quarter, is all the butcher's profit, it is said, who would no doubt encourage that breed which tallows best, and yields most offal.

It is noticed, however, that the South Down sheep are not great tallowers, compared with some other sorts; but that what they lose in tallow, they make up in a disposition to fatten. The tallow of a wether, in common management, will, it is said, generally average from an eighth to a tenth part of its dead weight. In a fat wether of Mr. Ellman's, one-seventh part of the dead weight was, it is said, inside fat (caul and loose fat); and that in another which was since killed, one-sixth was inside fat. In others, too, that have been slaughtered, the variation has been found from a seventh to a tenth. The quantity of inside fat depends, it is said, much upon the age and time of fattening. It gathers itself much more in old sheep than in young ones.

The bad ill-formed breeds of sheep, for the most part, tallow in the largest and most favourable manner; and the same is mostly the case in neat-cattle stock, as those which have the best forms and dispositions for fattening have commonly the least property of tallowing well, or afford the least proof, as it is often called.

In regard to the superiority of fat meat, it may be just noticed that, in some great thoroughfares for travelling, the inn-keepers agree with the butchers to give them a penny the pound above the common price for mutton, provided it be very fat. It is likewise the same with beef. This is said to be the case at Petersfield, and to strongly shew that very fat mutton, or meat of any kind, will go much farther than that which is not equally so. It, however, makes against tallowing in animals of these kinds. See Live-*Stock* and Sheep.

TALLWATER, in *Geography*, a river of Ireland, in the county of Armagh, which runs with the Callen into Blackwater, near Charlemont.

TALLY, Taile, or *Taille*, a piece of wood on which retail traders use to score or mark, by notches or incisions, the several quantities of goods they deliver out on credit, to save the trouble of writing down so many little articles in books.

Each score consists of two pieces of wood, or rather of a single piece cleft length-wise, the parts of which falling in with one another, things delivered are scored on both at the same time; the seller keeping one, and the buyer the other.

Tallies are taken as evidences in courts of justice, as much as books. The ancient way of keeping all accounts was by tallies; the debtor keeping one part, and the creditor the other. Hence the *tallier* of the exchequer, now called the *teller*.

There are three kinds of tallies mentioned in our statutes, and long used in the exchequer; *viz*.

Tallies *of Loans*, one part of which is kept in the exchequer, and the other part given to particular persons, in lieu of an obligation for the monies they have lent to the government on acts of parliament. This last part is called the *stock*, and the former the *counter-stock*, or the counter-tail.

The tallies are numbered, and bear the person's name, and the sum lent: thus we say, the tallies, N° have been paid, or discharged; tallies are risen, fallen, 4, 5, &c.

Tallies, or *Tailes of Debt*, are a kind of acquittances for debts paid to the king.

E. gr. The university of Cambridge pays yearly 10*l.* for such things as are by charter granted them in fee-farm. He that pays this receives a *taile*, or tally, for his discharge, with which, or a note of it, he repairs to the clerk of the pipe, and there for the tally receives a full discharge on parchment.

Tallies *of Reward*, or allowance. These are made to sheriffs, for such matters as (to their charge) they have performed in their office, or by such money as is by course cast on them in their accounts, but which they cannot levy.

In the exchequer there is a *tally-court*, where attend the two deputy chamberlains of the exchequer, and the tally-cutter.

Tally-*Counter*. See Counter.

Tallies, *Cutter of the*. See Cutter.

Tally, *Petty*. See Petty.

Tallies, *Writer of*. See Writer.

Tally *the Sheets*, at sea, a word of command, when the sheets of a main-sail or fore-sail are to be hauled aft. See Sheets.

Tally *for Flowers and Plants*, in *Gardening*, that sort of mark or contrivance, either by pieces of lead or slips of wood, employed for distinguishing them.

The practice of marking flowers, trees, and plants, with tallies of some kind or other, is always highly useful and necessary in regulating their culture, as well as for many other purposes.

TALLYOOR, in *Geography*, a town of Hindoostan, in Mysore; 8 miles N.W. of Dindigul.

TALMAS, a town of France, in the department of the Somme; 9 miles S. of Dourlens.

TALMAY, a town of France, in the department of the Côte d'Or, at the union of the Vigenne and the Saône; 18 miles N.E. of Dijon.

TALMOND, a sea-port town of France, in the department of the Lower Charente, on the right side of the Gironde, with a harbour; 18 miles S.W. of Saintes.

TALMONT, a town of France, in the department of the Vendée; 6 miles E.S.E. of Sables d'Olonne.

TALMUD, or Thalmud, from תלמוד, *doctrine*, from למד, *he taught*, a Jewish book, which contains a collection of all that relates to the explication of their law.

The Talmud is the body of the Hebrew law; a compilation of expositions of the duties imposed on the people, either in scripture, or by tradition, or by authority of their doctors, or by custom, or even by superstition: to speak more plainly still, it is the course of cases of conscience, or of moral theology, in which the duties are explained, and the doubts cleared, not by reasoning, but generally by authority, by the custom of the nation, and by the decisions of the most approved of the ancient doctors.

The Talmud consists of two general parts, the one called the Mischna, the other the Gemara; which first part is also frequently called absolutely the "Talmud," the general name of the whole work.

The Jews divide their law into *written*, which is that contained in the books of Moses; and *unwritten*, which is that conveyed by tradition. This latter is, in effect, no other than a gloss or interpretation of the former, given by the ancient rabbins.

The

The Talmud then contains the traditions of the Jews, their polity, doctrine, and ceremonies, which they obferve as religioufly as the law of God itfelf: they would never put them in writing till they were compelled to it by the deftruction of Jerufalem, and till they faw themfelves difperfed throughout the world.

They had two famous fchools; the one at Babylon, and the other at Jerufalem: in thefe they made two feveral collections of thofe traditions; the firft at Jerufalem, the other at Babylon; but both called Talmud, both exceedingly reverenced, efpecially the Babylonian, though full of extravagancies. This was compiled by the Jews of Mefopotamia, about 500 years after Chrift, according to Buxtorf: but Father Morinus offers feveral reafons to prove that it was not finifhed till the year 700. The laft edition of this Talmud, at Amfterdam, is in twelve folios.

The Talmud of Jerufalem is the leaft efteemed. It was compiled by the Jews of that city, and particularly by Rabbi Jochanan, rector of the academy at Tiberias, about 300 years after Chrift, according to Buxtorf; but Father Morinus, in his "Exercitationes Biblicæ," lib. ii. exerc. 6. judges, from feveral barbarous terms found in it, of Vandalic or Gothic extraction, that it did not appear till the fifth century. This is publifhed in one large folio.

The Babylonian Talmud confifts of two parts: the one the text, the other the glofs or comment: the comment, called the *Gemara*, contains the decifion of the Jewifh doctors, and their expofitions of the text.—This we find ftuffed with dreams and chimeras; together with much ignorance, and many impertinent queftions and difputations: the ftyle is alfo very coarfe. On the contrary, the text called the *Mifchna*, is written in a tolerably pure ftyle, and the reafonings generally much more folid.

The Jews pretend that this was compofed by Rabbi Juda, furnamed the *Saint;* and that God revealed to him the doctrine, and the chief myfteries of it. But this is only to be underftood of the Mifchna, not of the Gemara, the compilation of which was not begun till the fixth century, after the deftruction of the fecond temple.

Rabbi Juda is faid to have compofed the Mifchna under the empire of Antoninus, in the fecond century; but they do not all agree about this antiquity, fome carrying it back much farther.

It is the Talmud of Babylon that is ufually read, and moft frequently confulted, among the Jews; fo that when they fay fimply "the Talmud," they always meant this; never quoting the other without the addition of Jerufalem.

Maimonides has made an abridgment of the Talmud, which Scaliger prefers to the Talmud itfelf; as being purged of many of the fables of which the other is full. It is a fyftem of the laws and cuftoms of the Jews, both of their civil and their canon law, and the beft of their traditions.

About the year 1236, a Jew of Rochelle, well verfed in the Hebrew, becoming Chriftian, made a journey to pope Gregory IX., and difcovered to him a number of errors in the Talmud: thefe the pope fent, in thirty-nine articles, to the archbifhops of France, with a letter, appointing them to feize the books of the Jews, and to burn all fuch as fhould contain thofe errors: in confequence of which order, about twenty cart-loads of Hebrew books were burnt. He wrote to the fame effect to the kings of England, France, Aragon, Caftile, &c.

His fucceffor, Innocent IV., giving commiffion to his legate, Eudes de Chateauroux, to examine the Talmud, and other Jewifh books, more carefully, and to tolerate fuch errors as were not contrary to the Chriftian religion; the legate wrote to the pope, that to tolerate them was to approve them; and the 15th of May, 1248, he alfo condemned them juridically to the flames; and Paul IV. ordered 12,000 volumes of the Talmud to be confumed; and Clement VIII. ordered all the talmudic books that could be found to be deftroyed; a zeal worthy of the Papal fee! See MISCHNA, GEMARA, CARAITES, and RABBINISTS.

TALO-CHAN, in *Geography*, a fmall ifland near the coaft of China. N. lat. 29° 57′. E. long. 122° 4′.

TALOIRE, a town of France, in the department of Mont Blanc; 8 miles S.S.E. of Annecy.

TALON, in *Ornithology*, the claw of a bird.

TALON, in *Architecture*, a kind of moulding, confifting of a cymatium, crowned with a fquare fillet; frequently found to terminate ornaments of joiners' work, as thofe of doors, &c.

The word is French, and literally fignifies *heel.*

The talon, more properly fo called, is a moulding concave at the bottom, and convex at top; having an effect juft oppofite to the doucine.

When the concave part is at top, it is called an *inverted* talon.

The talon is ufually called by our Englifh workmen *ogee*, or *O.G.* and by authors an *upright* or *inverted* cymatium.

TALOO, in *Geography*, a harbour on the N. coaft of *Eimeo;* which fee.

TALOVKA, a river of Ruffia, which unites with the Analik, and runs with it into the Irgis, 32 miles E. of Volfk, in the government of Saratov.

TALPA, the *Mole*, in *Zoology*, a genus of the Mammalia Feræ, the characters of which are, that the front teeth in the upper jaw are fix and unequal, thofe in the lower jaw are eight; the canine teeth are one on each fide, the upper ones being the largeft; and that the grinders are feven in the upper jaw, and fix in the lower. Gmelin enumerates four fpecies, befides feveral varieties.

Species.

EUROPÆA; Common Mole. Has a fhort tail, and pentadactylous or five-toed feet. The body is thick and cylindric; the fnout flender, but very ftrong and tendinous; the head not diftinguifhed from the body by any appearance of neck; the legs fo extremely fhort, as fcarcely to project perceptibly from the body; the fore-feet fituated obliquely outwards, exceffively ftrong and broad, and furnifhed with very large and ftout claws, fo as to give the animal the power of working under the furface with the utmoft eafe and readinefs; the hind-feet are fmall in proportion to the fore-feet, and are calculated for throwing back with eafe the mould from behind the creature, during his fubterraneous progrefs; the tail is fhort and fmall; the fkin is much thicker and tougher in proportion than in other quadrupeds, and the fur with which it is covered equally furpaffes that of other animals in finenefs and foftnefs. The mufcular ftrength of the mole is very great, and it is enabled to force itfelf into the ground with an extraordinary degree of celerity. The general length of the mole is about five inches and three quarters, exclufive of the tail, which meafures one inch. This animal is fuppofed to poffefs the power of hearing in an exquifite degree; and if at any time it emerges from a fubterraneous retreat, inftantly difappears on the approach of any danger. When firft taken, either by digging it out or otherwife, it utters a fhrill fcream, and prepares for defence by exerting the ftrength of its claws and teeth. According to the count de Buffon, fo lively and reciprocal an attachment fubfifts between the male and female, that they feem to dread or difrelifh all other fociety.

It has been doubted whether the mole has eyes adapted to vifion, viſion, or merely for the purpoſe of apprizing it of the approach of light, ſo as to warn it of the danger of expoſure. Galen is of the former opinion. Sir Thomas Brown refers this to the claſs of vulgar errors; but Derham, by diſſection, and the aid of a microſcope, confirmed the opinion of Galen. This animal is ſaid to feed not only on worms and inſects, &c. but on the roots of vegetables: however, it is more carnivorous than frugivorous. In particular circumſtances it is very fierce and voracious. Without damp mould for its reſidence, it is kept alive with difficulty in a ſtate of confinement. Like other animals of a black colour, the mole is ſometimes found perfectly white, or cream-coloured, and ſometimes ſpotted. Gmelin reckons four varieties, *viz.* the variegated or ſpotted mole of Edwards, the white, the yellow, and the cinereous. Of its ſurpriſing power in ſwimming, we have a curious inſtance recorded in the 3d volume of the Tranſactions of the Linnæan Society; which is that of a mole that was ſeen ſwimming towards a ſmall iſland in the middle of the loch of Clunie, in Scotland, at the diſtance of 180 yards from the land. Linnæus and Gmelin affirm that the mole paſſes the winter in a ſtate of torpidity; but this is contradicted by Buffon, and he alleges facts to prove the contrary. The mole is ſaid to be unknown in Ireland. In Siberia it attains a larger ſize than in Europe, and its fur is ſo ſoft and beautiful, that it would make the moſt elegant articles of dreſs, were it not for the difficulty of curing and dreſſing the ſkin. See Mole.

Asiatica. Has no tail, and tridactylous fore-feet. This is the Siberian mole of Pennant. It is ſomewhat ſmaller than the common mole, its length being four inches; and is a native of the Cape of Good Hope.

Longicaudata. With a tail of middling length, and pentadactylous feet, the hinder ones ſcaly. This is the long-tailed mole of Pennant: its length from noſe to tail is four inches and ſix-tenths; and it is a native of North America.

Rubra; Red Mole of Pennant. Has a ſhort tail, tridactylous fore-feet, and tridactylous hind-feet. This is ſaid to be a native of America.

Dr. Shaw mentions ſome other ſpecies, as the *T. purpuraſcens*, or black mole, with a gloſs of purple, pentadactylous feet, and white tail, firſt deſcribed by Seba, and by him ſaid to be a native of Virginia:—the *T. radiata*, or black mole, with white feet, and noſe radiated with papillæ; an inhabitant of North America:—the *Sorex criſtatus* of Linnæus; a variety, as Dr. Shaw ſays, of the *T. longicaudata*:—and the *T. fuſca*, or brown mole, with white feet and tail, the fore-feet very broad; a native of North America, and ſuppoſed to be the ſame with the *Sorex aquaticus* of Linnæus.

Talpa, (*a mole*,) in *Surgery*, a tumour, which makes its way under the ſkin, as a mole under the ſurface of the ground. Such is ſaid to be the derivation of the term. Talpa is often uſed in the language of ſurgery, to expreſs an encyſted tumour, which forms on the head, and contains a pap-like matter. See Atheroma.

TALPAR, in *Geography*, a town of Perſia, in the province of Irak; 70 miles N.W. of Hamadan.

TALPARIA, in *Surgery*, an encyſted tumour, filled with a pap-like matter. See Talpa.

TALPIA, in *Geography*, a town of Chineſe Tartary, in the country of Hami; 28 miles N.E. of Hatamtam.

TALSENGHE, a town of Hindooſtan, in Viſiapour; 10 miles S.W. of Viſiapour.

TALSHIDE. See Talwood.

TALSPERG, a town of France, in the department of the Upper Rhine; 12 miles E. of Porentrui.

TALTITZ, a town of Saxony, in the Vogtland; 4 miles S. of Plauen.

TALUS, in *Anatomy*, a name formerly given to the aſtragalus, or that bone of the foot which is articulated to the leg. (See Extremities.) This bone in the pecora has a cubic ſhape; and was employed by the ancients in their famous game, ludus talorum. (See Ariſtotle, Hiſt. Anim. lib. ii. c. 1.) For the various appellations of this well-known bone in moſt of the European and Oriental languages, and for its form in different animals; ſee Th. Hyde, Hiſtoria Talorum, in vol. ii. of his Syntagma Diſſertationum, Oxon. 1767, 4to.

Talus, or *Talud*, in *Architecture*, the inclination or ſlope of a work; as of the outſide of a wall, when its thickneſs is diminiſhed by degrees, as it riſes in height, to make it the firmer.

Talus, or *Talud*, in *Fortification*.—*Talus of a baſtion*, or *rampart*, is the ſlope or diminution allowed to ſuch a work; whether it be of earth, or ſtone; the better to ſupport its weight.

The *exterior* talus of a work, is its ſlope on the ſide towards the country; which is always made as little as poſſible, to prevent the enemy's eſcalade, unleſs the earth be bad, and then it is abſolutely neceſſary to allow a conſiderable talus for its parapet, and ſometimes to ſupport the earth with a ſlight wall, called a *revetement*.

The *interior* talus of a work, is its ſlope on the ſide towards the place.

This is larger than the former, and has, at the angles of the gorge, and ſometimes in the middle of the curtains, ramps or ſloping roads for mounting upon the terre-plain of the rampart.

Talus, *Superior*, of the *parapet*, is a ſlope on the top of the parapet, that allows of the ſoldiers defending the covert-way with ſmall-ſhot, which they could not do if it were level.

TALWOOD, Taliatura, in our *Old Writers*, fire-wood cut and cleft into billets of a certain length: it is otherwiſe written *talghwood* and *talſhide*. Stat. 34 & 35 Hen. VIII. c. 3. 7 Edw. VI. c. 7. 43 Eliz. c. 14.

TALYSIAN, in *Geography*, a town on the E. coaſt of the iſland of Borneo. N. lat. 1° 48′. E. long. 117° 40′.

TAM, a river of China, which runs into the Ta; 5 miles S.E. of Khi, in Pe-tche-li.

Tam, *El*, a town of Perſia, in Segeſtan, on the Heermund; 25 miles E. of Zareng.

TAMA, a town of Circaſſia, on the Black ſea; 60 miles E.N.E. of Theodoſia.

TAMACH. See Tainach.

TAMACHABAD, a town of Hindooſtan, in Benares; 18 miles W. of Benares.

TAMACLIPA, a town of Mexico, in the province of Guaſteca; 52 miles N. of Panuco.

TAMACUIL, a town of Mexico, in the province of Guaſteca; 40 miles S. of Panuco.

TAMAHOO, a ſmall iſland in the Eaſtern Indian ſea, near the weſt coaſt of Borneo. N. lat. 0° 7′. E. long. 109° 21′.

TAMALAMEQUE, a town of South America, in the province of St. Martha, on the river Magdalena; 160 miles S. of St. Martha. N. lat. 8° 40′. W. long. 73° 56′.

TAMALAPATRA, in the *Materia Medica*, a name by which ſome authors have called the *folium Indicum*, or Indian leaf, uſed in medicine.

The tree which produces this leaf is the *laurus caſſia* of Linnæus,

Linnæus, or *cassia lignea tree*. It is a large and lofty tree, the flowers and fruit of which resemble the cinnamon-tree. Its leaves, when full grown, are ten inches or more in length; and six or eight in breadth. The flowers stand in clusters, in the manner of umbels on the tops of the branches, and are of a greenish-white colour. The fruit is of the bigness of our currant.

The ancients recommended Indian leaf as stomachic, sudorific, and cephalic. At present, it is utterly disregarded, being only kept in the shops as an ingredient in mithridate and theriaca; and is, in its greatest perfection, far inferior to the mace which our college directs as a succedaneum to it. See CASSIA *Lignea*.

TAMALIPAN, in *Geography*, a chain of mountains in Spanish North America, called by Alcedo, in his description of New Leon, the Grand Sierra, and a branch of which is called the Eastern Tamalipa by Alzate. This last branch extends from the desarts of Jaumape to the eastern coast of the province of Santander, where it is marked in the Spanish chart of the gulf of Mexico by the names of various peaks; while the mountain of Orcasites, visible at sea at the distance of 160 miles inland, must nearly equal Orizava in height, and appears to belong to the same branch of the grand ridge of Tamalipa.

TAMALMA, a town of Africa, in the country of Kawar; 120 miles N. of Kanem.

TAMAMES, a town of Spain, in the province of Leon; 15 miles E. of Civdad Rodrigo.

TAMAN, an island at the mouth of the Kuban, and a principality belonging to it, and also a town on the same island, called *Phanagoria*, (which see.) This principality was anciently occupied by the Chazares; but it was wrested from them in the year 965 by the Russian combined with the Byzantine Greeks, who made themselves masters of the countries bordering on the sea of Azof in 1015, and completely overturned the Chazarian state, creating a distinct principality on the isle of Taman, to which both the Chazares and the Zichians were for a long time tributary. See TMUTARAKAN.

Towards the end of the 11th century, while Russia was torn by intestine broils, the principality of Taman was lost to that empire. At length, in 1221, the Mongoles made their first attack. The Komanes were expelled or subdued, but the Ziches fought for their liberty, and could not be made to submit till the year 1277, when they were overpowered by Margu-Timur-Khan and the famous Nogay. Nevertheless, they retained some degree of independence in their woody and mountainous regions. The Ottomans indeed, in 1484, conquered the cities and forts of Taman, Temryuk, and Atschuk: but they gained no sovereignty over the Tscherkassians or Circassians. At the peace of 1774, the sultan of the Ottomans relinquished his possessions in these parts; but, contrary to treaty, held Taman and Temryuk in a state of siege, till the Crimean khan, by the aid of the Russians, drove the Ottoman garrison out of them. By the treaty of the year 1783, Russia obtained, together with the Crimea and the Eastern Nogay, the northern part of the Kuban as far as the promontory of Caucasus.

The Zichians or Tschekians, called by the Russians Yasi, are the principal inhabitants of the isle of Taman. They formerly paid a small tribute to the Crimean khan, but in all other respects are governed by their own beys. The isle Atschuk or Atschuyef is likewise inhabited by Zichians. These two tribes, which, properly speaking, are only one collateral branch of the Tscherkassians, have belonged to the Russian empire, as inhabitants of the Kuban, since the year 1783.

TAMAN, the strait or channel that forms a communication between the Black sea and the sea of Azof.

TAMANAH, a sea-port town of Hindoostan, on the coast of Malabar, in the country of Concan; 25 miles S. of Gheriah. N. lat. 16° 30′. E. long. 73° 15′.

TAMANDUA, in *Zoology*, a creature called in English the ant-bear; and by the Brasilians *tamanduaguacu;* and the *tamanoir* of Buffon: different species of the same genus. See MYRMECOPHAGA.

TAMAR, in *Geography*, a considerable river, which originates in the county of Cornwall, England, and separates that county, except for the space of a few miles, from Devonshire. It rises in a moor in the parish of Morwinstow, about three miles from the North sea: passing near Whitstone, about ten miles from its source, it reaches Tamerton, which takes its name from this river; here it receives the waters of the Werrington, and about a mile and a half further its current is increased by the Attery, which runs under the walls of the town of Launceston: at Poulston-bridge it is a wide and rapid stream; a mile below Graiston-bridge it is joined by the Inney, which, rising in Alternon, passes through the parishes of Lewanick and Lezant. In the parish of Stoke-Climsland, the Tamar has a high, strong, stone bridge, called by Leland "Hawtebrig," or the High bridge, now commonly Horse-bridge. The last or lowest bridge on this river is in the parish of Calstock, and was begun, according to Leland, by sir Piers Edgcombe. Five miles farther the Tamar receives the Tavy from the east, and having made a creek into the parishes of Botesfleming and Landulph on the west, becomes a spacious harbour; and after passing near the ancient borough of Saltash, is joined by the Lynher creek and river. Increasing in importance as it winds along, it next forms, between Dock and Saltash, the noble basin called the "Hamoaze," or Plymouth Harbour, where a large proportion of the British navy rides in complete security. Having made two large creeks, one called St. John's, the other Milbrook, on the west, and Stonehouse creek on the east, the Tamar, after a course of about 40 miles nearly south, falls into the sea, having mount Edgcumbe for its western, and the lands of Stonehouse and St. Nicholas island for its eastern boundary, and produces the noble road for shipping named Plymouth Sound. The Tamar is one of the most considerable rivers in the west of England; its banks are richly diversified with rocks, woods, and meadows; and the scenery in various parts of its course is extremely interesting and beautiful. The views about the Cater-marther rocks, Tavistock-New-bridge, the Morwell rocks, Cotele and Pentilly, are peculiarly romantic, and can scarcely be equalled by any other river in the western part of the kingdom. (See PLYMOUTH *Harbour*.) Lysons's Magna Britannia, vol. iii. Cornwall. Beauties of England and Wales, vol. ii. Cornwall. By J. Britton and E.W. Brayley.

TAMAR, a town of Arabia, in the province of Hedsjas; 40 miles N.N.W. of Karac.

TAMAR *Bay*, a harbour in the straits of Magellan, E. of Cape Tamar.

TAMARA, in *Ancient Geography*, a river of Spain, which rose in the mountains W. of Lucus Augusto, and discharged itself into the sea to the W. of a small gulf, on the banks of which were Grandinirum and Acræ Sestianæ. Mela calls this river Tanaris. The Tamarisci inhabited its banks.

TAMARA, a town of the isle of Albion, assigned by Ptolemy

lemy to the Damnonii or Dumnonii. Mr. Horfley thinks it was Saltafh; but Mr. Camden and Mr. Baxter fuppofe it, more probably, to be Tamerton, which ftill retains its ancient name.

Tamara, in *Geography*, a town of Morocco, on the coaft of the Atlantic; 30 miles W. of Tarudant.—Alfo, a fea-port town on the N.W. coaft of the ifland of Socotora, and refidence of the king.

Tamara *Ifles*, or *Iflands of Idols*, a clufter of iflands near the coaft of Sierra Leone. N. lat. 8° 40′.

Tamara′, in *Botany*, the Hindoo name of a very celebrated plant. (See our article Cyamus, written by the late Rev. Mr. Wood.) The above name fhould feem to originate from the Hebrew תמר, *Tamar*, a Palm-tree, whence dates are called Támara by the Spaniards; and it may allude to the form of the feeds of the *Cyamus*, refembling dates; or to their fimilar ufe as an oriental article of food. *Támar* is alfo the Arabic name of the fame fruit. See Tamarindus.

TAMARACA, Tamarica, or *Itamaraca*, in *Geography*, a diftrict of Brafil, in the jurifdiction of Fernambuco. It has its name from an ifland on the coaft, near the mouth of the river Tamaraca, which conftitutes the principal part of its diftrict, though the territory thereof extends inland between 30 and 40 leagues, having Parayba on the north, Fernambuco on the fouth, the ocean on the eaft, and unfubdued Indians on the weft. It was reckoned one of the moft ancient and flourifhing captainfhips in Brafil; but Parayba and Fernambuco have fince exceeded it. The ifland is parted from the main land by a very narrow channel. It is fertile and pleafant enough; producing large quantities of Brafil wood, cotton, cocoa-nuts, fugar, melons, citrons, &c. befides a good deal of timber for fuel and other purpofes. It is about nine miles in length, and three in breadth, and about 22 in circuit. It has a commodious haven on the fouth fide, with fome good fprings and rivulets of frefh water. The entrance into the port is by a channel of between 15 and 16 feet water, commanded by a caftle, built on an eminence, and formerly taken by the Dutch: who alfo built Fort Orange at the mouth of the channel, which was inacceffible, by reafon of the marfhes furrounding it; fo that the veffels that failed down from the ifland were expofed to it, and they had in fome meafure ftopped all the avenues from the Portuguefe. This ifland, and the territory on the continent belonging to it, pay 3000 ducats to the governor of the captainfhip, and in it are reckoned to be about 22 fugar-mills. The French had formerly a canton or fettlement on this coaft, ftill called from them "Porto dos Francefe;" but the Portuguefe obliged them to evacuate it. The capital, called "Noftra Segnora de Conceizao," or "Da Tamaraca," ftands at the entrance into the river of the latter name; and near it is a fmall caftle with a redoubt, commanding the avenues; and about four miles N. of the mouth of the river is the famous point denominated "Punta Pedro."

Tamaraca, a river of Brafil, which runs into the Atlantic, S. lat. 7° 52′.

TAMARIL, a town of Spain, in Catalonia, fituated about a mile from the fea-coaft; 2 miles N.E. of Tarragona.

TAMARINDUS, in *Botany*, the Tamarind-tree, is fo called from *Tamar*, which is Hebrew for a Palm-tree, (and likewife the Arabic appellation of its fruit, the Date,) combined with the Latin word *Indus*, Indian. The form of the pod, and its ufe as an article of food, may well have given rife to the name. (See Tamara′.)—Linn. Gen. 23. Schreb. 450. Willd. Sp. Pl. v. 3. 577. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 134. Juff. 347. Lamarck Illuftr. t. 25. Gærtn. t. 146.—Clafs and order, *Triandria Monogynia*, Linn. *Monadelphia Triandria*, Schreb. Willd. Nat. Ord. *Lomentaceæ*, Linn. *Leguminofæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf: tube turbinate, compreffed, tapering at the bafe, oblique at the mouth, permanent; limb in four deep, ovate, acute, flattifh, reflexed, coloured, deciduous fegments; the upper and lower ones rather the broadeft. *Cor.* Petals three, ovate, acute, concave, crenate, wavy, reflexed, the length of the calyx, inferted into the mouth of the tube; the two lateral ones rather the largeft. *Stam.* Filaments three, inferted into the mouth of the calyx in the vacancy oppofite to the uppermoft petal, awl-fhaped, as long as the corolla, connected in their lower half, curved upwards; anthers ovate, large, incumbent. There are befides feven rudiments of ftamens; five of them fetaceous threads, capitate, very fhort, alternate with the above, connected in their lower part, two lower than the reft; and two minute briftles, proceeding from the calyx beneath the filaments, and lying upon them. *Pift.* Germen oblong, compreffed, incurved, feated on a ftalk, which fprings from the bottom of the calyx, and is attached longitudinally to the back of its tube within, the projecting part downy along its upper edge; ftyle awl-fhaped, afcending, downy at its lower edge, rather longer than the ftamens; ftigma tumid, obtufe. *Peric.* Legume oblong, compreffed, obtufe, with a point, fwelling at the feeds, of one cell, not burfting; its coat double; the outer dry and brittle; inner membranous; a quantity of foft pulp being lodged between the two. *Seeds* few, orbicular, fomewhat angular, flattened, hard, polifhed, with a central circumfcribed difk at each fide.

Eff. Ch. Calyx in four deep fegments. Petals three. Barren filaments feven. Style one. Legume pulpy within.

1. T. *indica.* Tamarind-tree. Linn. Sp. Pl. 48. Willd. n. 1. Ait. n. 1. Jacq. Amer. 10. t. 10. and t. 179. f. 98. Woodv. Med. Bot. t. 166. (Tamarindus; Rumph. Amboin. v. 2. 90. t. 23. Ger. Em. 1607. Balam-pulli; Rheede Hort. Malab. v. 1. 39. t. 23.)—This tree, a native of Egypt, Arabia, and the Eaft Indies, is generally preferved, rather than cultivated, in both Indies for the fake, both of its fhade, and its acid, cooling, and highly grateful, as well as falutary, fruit; the pulp of which, mixed with boiled fugar, is frequently imported into Europe, and highly efteemed. The *trunk* is lofty, and of confiderable thicknefs, crowned with wide-extended *branches*, bearing umbrageous tufts of alternate, abruptly pinnate, fmooth, bright-green *leaves*, each compofed of many pair of elliptic-oblong, feffile, entire *leaflets*, rather glaucous beneath. *Flowers* in fimple clufters, terminating the fhort lateral branches. *Petals* yellow, elegantly veined with red. *Fruit* pendulous, like large beans. Gærtner obferves that the Weft Indian Tamarind pod is fhorter than what Rheede and Rumphius reprefent, and has fewer feeds. Hence he diftinguifhes two fpecies, which appear from hiftory as well as obfervation to be mere varieties, the plant being more at home in the eaftern than in the weftern fide of the globe, though almoft perfectly naturalized in the latter. It is often feen in our ftoves, but feldom in bloffom.—As Dr. Woodville has given an original coloured plate of this interefting plant, drawn by Mr. Sowerby from a fpecimen that flowered in Kew garden, and the only one of authority extant; we conceive his work, in this inftance, if not in every other, might have been cited with advantage, by our friend Mr. Aiton, in the *Hortus Kewenfis*.

Tamarindus, in *Gardening*, contains a plant of the exotic tree kind, of which the fpecies is the tamarind-tree (T. indica);

dica); which grows to a very large ſize in the countries where it is a native: the ſtem being very large, and covered with a brown bark, dividing into many branches at the top, which ſpread wide every way; the flowers come out from the ſide of the branches, five, ſix, or more together, in looſe bunches; the pods being thick and compreſſed; thoſe from the Weſt Indies from two to five inches in length, containing two, three, or four ſeeds; but thoſe from the Eaſt Indies are almoſt twice as long, and contain five, ſix, and even ſeven ſeeds. The tree is a native of both the Indies, and of ſome other places.

Method of Culture.—This is a plant which is increaſed from ſeeds, which ſhould be ſown in the ſpring on a hot-bed, and when the plants are come up, each planted in a ſeparate ſmall pot, filled with light rich earth, plunging them into a hot-bed of tanners' bark to bring them forward, watering and ſhading them until they have taken root; and as the earth in the pots becomes dry, they muſt be watered from time to time, and have air given in proportion to the warmth of the ſeaſon, and the bed in which they are placed. When the pots in which they are planted are filled with their roots, the plants ſhould be ſhifted into pots of a larger ſize, which muſt be filled up with rich light earth, and again plunged into the hot-bed, giving them air as before, according to the warmth of the ſeaſon; but in very hot weather, the glaſſes ſhould be ſhaded with mats in the heat of the day, otherwiſe the ſun will be too violent for them through the glaſſes; nor will the plants thrive if they are expoſed to the open air, even in the warmeſt ſeaſon; ſo that they muſt be conſtantly kept in the bark-ſtove both ſummer and winter, treating them in the ſame manner as the coffee-tree. Theſe plants have a good effect in the ſtove collections.

It is the ſeed-pods of this tree which form and conſtitute the preſerve called tamarinds, which is ſold in the ſhops; and is of ſuch a pulpy acid quality, as to be of great uſe in abating and quenching thirſt, and in cooling and allaying exceſſive heat. It is brought hither from both the Eaſt and Weſt Indies; but though the pods of the trees of the former ſituation are much finer and larger, the preſerve from the latter is generally conſidered better, and of courſe moſtly preferred.

There is nothing peculiar in the making of this ſort of preſerve, exactly the ſame methods being followed as are common in the preſerving of other ſubſtances of ſimilar kinds.

Tamarindus, in the *Materia Medica.* The Eaſt India tamarinds are longer than thoſe of the Weſt; the former containing ſix or ſeven ſeeds each, the latter rarely above three or four; nevertheleſs they ſeem to be the produce of the ſame plant: the Oriental ſort is drier and darker-coloured than the Occidental, and has more pulp; the former is ſometimes preſerved without addition, but the latter has always an admixture of ſugar.

In the Weſt Indies, the pods are gathered in June, July, and Auguſt, when fully ripe; and the fruit, freed from the ſhelly fragments, is placed in layers in a caſk, and boiling ſyrup poured over it till the caſk is filled. When cool, the caſk is headed for ſale. When tamarinds are good, they are not in any degree muſty: the ſeeds are hard, flat, and clean; the ſtrings rough and entire, and a clean knife thruſt into them does not receive any coating of copper. They ſhould be preſerved in cloſely covered jars.

We owe the knowledge of the uſe of tamarinds, in medicine, to the Arabians. The ancient Greeks knew nothing of them; and Serapion, Meſue, and Avicenna, are the firſt authors who preſcribe them.

The fruit of the tamarind, which is what we uſe, is only the piſtil of the flower ſwelled into a pod; this is greeniſh at firſt, but grows browniſh or reddiſh as it ripens; its common ſize is four inches in length, and one in breadth; and it is undulated on the back, and deeply notched in three or four places at the front, which is terminated by a large rib, that runs from the pedicle on which it grows, to the end of the pod, and there frequently terminates in a ſort of hook.

This fruit is, properly ſpeaking, compoſed of two pods, the one incloſed within the other: the outer pod is fleſhy, and of the twelfth of an inch in thickneſs when freſh, and the inner one is as thin as a fine piece of parchment: between theſe two there is an intermediate ſpace of about a quarter of an inch all the way; and this ſpace is filled up with a very ſoft and pulpy ſubſtance, of a tart but very agreeable taſte, which is what we uſe in medicine. This is blackiſh, and of a viſcous texture, and is traverſed by three large veſſels, or rather bundles of veſſels, one of which runs all along the back of the pod, and the two others are placed on the oppoſite ſide, and often there are ſeveral ramifications of veſſels, which run off different ways from theſe. Theſe veſſels carry the vinous juice, which afterwards hardens into the viſcous matter of the pulp; but this is not all their office, for they alſo convey nouriſhment to the ſeeds in the inner pod.

We uſe the tamarinds only in medicine; but the Africans, and the people of many of the Oriental nations, where they are common, make them into a ſort of confection with ſugar, which they eat as a delicacy, and which cools them in the violent heats of their climates; and at the ſame time keeps their bowels in a proper ſtate of laxity. The ſour taſte of this fruit proves, that acid particles abound greatly in it; and a chemical analyſis of it gives further proof of this.

According to the analyſis of Vauquelin, the pulp contains, independently of the ſugar with which it is mixed, ſupertartrate of potaſs, gum, jelly, citric acid, tartaric acid, malic acid, and a feculent matter. The acid taſte chiefly depends on the citric acid, as its quantity exceeds that of the others ℥xvj of the prepared pulp, containing ℥iſs of citric acid, but only ʒij of tartaric acid, ℥ſs of ſupertartrate of potaſs, and ʒſs of malic acid. Annales de Chimie, vol. v. p. 92.

The eſſential ſalt of tamarinds, as Beaumé obſerves, may be obtained more expeditiouſly, by clarifying the decoction of the tamarinds with whites of eggs, than by filtering and evaporating it to a proper conſiſtence, and ſetting it to cool: the ſalt ſhoots into cryſtals of a brown colour, and very acid taſte, but in diſſolving and cryſtallizing them again, or barely waſhing them with water, they loſe almoſt all their acidity; the acid principle of the tamarind ſeeming not to be truly cryſtallizable.

The pulp of tamarinds is an agreeable laxative acid, of common uſe in inflammatory and putrid diſorders, for abating thirſt and heat, correcting putrefaction, and looſening the belly. The doſe, as a laxative, is two or three drachms; an ounce or two prove moderately cathartic. It is an uſeful addition with this intention to the purgative ſweets, caſſia and manna, in increaſing their action, and rendering them leſs liable to produce flatulencies: the reſinous cathartics are ſaid to be ſomewhat weakened by it. Lewis.

This pulp is an ingredient in confectio caſſiæ, confectio ſennæ, and in the infuſum tamarindi cum ſenna.

TAMARISCUS, in *Botany.* See Tamarix.

TAMARISK Plant, in *Agriculture*, is a plant of the large ſhrubby kind, which has lately, it is ſaid, been employed in ſome ſouthern ſituations which are much expoſed to the ſea air, and other effects of it, with great utility. It is capable of being readily raiſed and propagated by means of cuttings of the laſt year's growth, as they take root without

T A M

out any difficulty, and are, of courſe, admirably adapted as plants for forming hedges. It is the French ſort that is made up of in this way. See QUICKSET-*Hedge*.

TAMARITE, in *Geography*, a town of Spain, in Aragon; 16 miles E.S.E. of Balbaſtro.

TAMARIX, in *Botany*, *Tamariſcus* of Tournefort, and of ſome, but not all, of the older botaniſts, is ſuppoſed to derive its name from the Tamariſci, a people who inhabited a country on the other ſide of the Pyrenées, where the moſt common ſpecies of this genus abounds. Such at leaſt is the opinion of De Theis. Martyn ſays, ſome deduce this word from the Hebrew *Tamaris*, to wipe or cleanſe; but we feel no great ſatisfaction in either of theſe etymologies.—Linn. Gen. 148. Schreb. 200. Willd. Sp. Pl. v. 1. 1498. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 338. Prodr. Fl. Græc. Sibth. v. 1. 208. Ait. Hort. Kew. v. 2. 171. Juſſ. 313. Lamarck Illuſtr. t. 213. Gærtn. t. 61.—Claſs and order, *Pentandria Trigynia*. Nat. Ord. *Succulentæ*, Linn. *Portulaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, in five deep, obtuſe, erect, permanent ſegments, half the length of the corolla. *Cor.* Petals five, ovate, obtuſe, concave, ſpreading. *Stam.* Filaments five at leaſt, capillary; anthers roundiſh. *Piſt.* Germen pointed; ſtyle none; ſtigmas three, oblong, feathery, revolute. *Peric.* Capſule oblong, pointed, triangular, longer than the calyx, of one cell and three valves. *Seeds* numerous, minute, each with a ſtalked feathery crown.

Obſ. *T. germanica* has ten ſtamens, five of which, alternate with the others, are external and ſhorter; all are connected at the baſe. *Linn.*

Eſſ. Ch. Calyx inferior, in five deep ſegments. Petals five. Capſule of one cell and three valves. Seeds with a feathery crown.

1. T. *gallica*. French Tamariſk. Linn. Sp. Pl. 386. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1318. Sm. Fl. Græc. Sibth. t. 291. unpubliſhed. Mill. Ic. t. 262. f. 1. (Tamariſcus narbonenſis; Ger. Em. 1378. Lob. Ic. v. 2. 218. Myrica; Camer. Epit. 74. f. 1.)—Stamens five. Cluſters lateral. Branches ſmooth. Leaves lanceolate, imbricated, ſpurred at the baſe.—Native of rocks and banks, or of ſwampy ground, eſpecially towards the ſea, in the ſouth of Europe, and north of Africa, very abundantly. It is plentiful about the coaſts of Cornwall, Hampſhire, and Suſſex, undoubtedly wild. This ſhrub appears to have been common in the Engliſh gardens, as it ſtill is, in Gerarde's time; and yet Camden, in his life of queen Elizabeth, attributes to archbiſhop Grindall, who died in 1583, its being firſt brought into England, and made known as "exceeding good to eaſe the hard diſtemper of the ſpleen." (See our 7th ſpecies.) Mr. Hudſon has not admitted any of this genus into his *Flora*. Dr. Sibthorp found this plant common in rather moiſt ſituations in Greece, nor can there be any doubt that it is the μυρίκη of Dioſcorides. The Turks call it *Il Ghin*. On the eaſtern coaſt of Italy we have obſerved it to be the favourite food of ſheep, probably on account of a ſaltiſh flavour, perceptible to our taſte. This is an elegant, drooping, ſlender-branched *ſhrub*, with ſmooth and ſhining twigs, of a mahogany red. *Leaves* minute, rather fleſhy, lanceolate, acute, ſmooth, deciduous, with a poſterior ſpur, as in ſome ſpecies of *Sedum*; imbricated on the youngeſt ſhoots; ſcattered on the older twigs. The *flowers* appear in July, in copious, long, cylindrical *cluſters*, rather than *ſpikes*, at the ſides of the laſt year's ſhoots. *Bracteas* awl-ſhaped, ſolitary, at the baſe of each ſmooth and naked partial ſtalk. *Calyx* bell-ſhaped, acute, ſmooth. *Corolla* and *ſtamens* white or roſe-coloured.

Willdenow's variety β we ſhall next deſcribe as a diſtinct ſpecies; his γ, the *T. africana* of Poiret, gathered by this traveller in Barbary, is ſaid to have peculiarly ſhort, thick and denſe *ſpikes*, but we are not furniſhed with any further information on the ſubject.

2. T. *tomentoſa*. Downy-branched Tamariſk. (T. gallica β; Willd. n. 2. T. pentandræ varietas; Pall. Roſs. v. 1. p. 2. 72. t. 79. BCD.)—Stamens five. Cluſters lateral. Leaves imbricated, awl-ſhaped, elongated, hoary and downy as well as the branches.—Found by Pallas in ſalt ſandy deſerts about the Caſpian ſea. He ſpeaks of this plant as a ſingular very elegant variety of the preceding, about ſix feet high, with all its *branches* downy and hoary; the younger ones thicker than in the common *T. gallica*, (which he chooſes to call *pentandra*,) and the *leaves* longer, hoary, denſely imbricated; all the parts being thicker and more crowded. In the *cluſters* and *flowers* he obſerved no difference. Willdenow's ſuggeſtion, of this being probably a diſtinct ſpecies, is apparently well-founded.

3. T. *articulata*. Jointed-branched Tamariſk. Vahl Symb. v. 2. 48. t. 32. Willd. n. 2. (T. orientalis; Forſk. Ægypt.-Arab. 206. Thuja aphylla; Linn. Sp. Pl. 1422, excluding the ſynonym of Shaw.)—Stamens five. Spikes lateral. Branches jointed. Leaves ſheathing, abrupt, with a ſhort ſpreading point.—Gathered by Forſkall in Arabia. The original ſpecimen, erroneouſly conſidered by Linnæus, for want of fructification, as a *Thuja*, appears to have been brought from Egypt, or the Levant, by Haſſelquiſt. The plant of Shaw is *Thuja articulata*, which will hereafter be deſcribed under its proper genus. We find no certain evidence of the *Tamarix* before us being a native, as Vahl ſays, of the Eaſt Indies, and we imagine he confounded with it our next ſpecies. The true plant of Haſſelquiſt and Vahl has copious ſlender *branches*, appearing when young as if jointed, each joint being crowned with a minute dotted ſcale-like *leaf*, whoſe annular baſe encircles the branch, and whoſe ſhort, erect, keeled, acute point projects on one ſide. Theſe *leaves* are permanent, enlarged, and membranous on the older branches. The *flowers* are deſcribed by Vahl as forming lateral *ſpikes* about the ends of the branches, each flower being ſeſſile, accompanied by a *bractea* reſembling the leaves, but with a widely-ſpreading point. Segments of the *calyx* roundiſh and obtuſe. *Petals* the ſize of *T. gallica*, linear, or rather elliptical. *Stamens* five. *Capſule* with four angles, pyramidal.

4. T. *epacroides*. Eaſt Indian Tamariſk.—Stamens five. Cluſters lateral and terminal. Leaves ovate, acute imbricated, claſping the ſtem; gibbous at the baſe. Bracteas awl-ſhaped, longer than the flowers.—Found by Kœnig growing plentifully on the banks of a river in the Eaſt Indies, which he calls *flumen Colloram maximum*. We have the ſame from Rottler and Roxburgh. This is unqueſtionably diſtinct from the preceding, and hitherto undeſcribed. The young *branches* have no jointed appearance, nor do the *leaves* ſurround them with an annular permanent baſe. The latter are ſucculent, of a broad triangular ſhape, tapering into an inflexed point; the floral ones, or *bracteas*, much narrower, coloured, ſtrongly keeled. *Flowers* very ſmall, on ſhort partial ſtalks. Segments of the *calyx* broad and obtuſe, fringed. *Petals* elliptical. *Capſule* ſcarcely above a line in length, priſmatic, accompanied by the permanent *filaments*, which are generally rather longer. Whether the *T. chinenſis* of Loureiro be this plant, his deſcription is not ſufficient to determine. He ſays the *petals* are linear.

5. T. *mucronata*. Pointed Tamariſk.—Stamens eight or ten. Spikes lateral and terminal. Leaves ſheathing, abrupt, pointed. Bracteas taper-pointed, lanceolate.—The ſpecimens of this very diſtinct ſpecies, in the Linnæan herbarium, have

have no mark by which we can afcertain its native country, though we fufpect them to have been fent from the Eaft Indies. The jointed appearance of the young *branches*, and the fheathing abrupt form of the *leaves*, approach thofe of *T. articulata*; but the *leaves* have much more elongated and tapering points, and every part is twice the fize of that fpecies. The *foliage* moreover is much lefs evidently dotted. *Flowers* large, feffile, with lanceolate, membranous-edged *bracteas*, whofe points are longer than the calyx, and very flender. Segments of the *calyx* elliptical, obtufe, flat. *Petals* obovate. *Stamens* eight or ten, we cannot be certain which is their general number. *Capfules* prifmatic, glaucous, three-quarters of an inch long. *Seed-down* long and feathery.

6. T. *fongarica*. Songarian Tamarifk. "Pallas Nov. Act. Petrop. v. 10. 374. t. 10. f. 4." Willd. n. 3.—"Stamens eight or ten. Flowers axillary, fomewhat fpiked. Leaves flefhy, obtufe, triangular."—Gathered by Pallas, in a falt foil, on the banks of the Songari. We know nothing of this fpecies but from Willdenow. The "triangular blunt *leaves*" indicate an effential difference from the laft.

7. T. *germanica*. German Tamarifk. Linn. Sp. Pl. 387. Willd. n. 4. Ait. n. 2. Fl. Dan. t. 234. Mill. Ic. t. 262. f. 2. Pall. Rofs. v. 1. p. 2. 73. t. 80. (Tamarifcus germanica; Ger. Em. 1378. Lob. Ic. 218. Myrica; Camer. Epit. 74. f. 2.)—Stamens ten, monadelphous. Clufters terminal. Leaves linear-lanceolate, feffile, obtufe.—Native of fwamps in Germany, Siberia, Switzerland, and the mountains of Dauria and Caucafus. Common in our gardens, where it flowers in the open air from June to September. Mr. Aiton fays, on Hakluyt's authority, that this was the fpecies introduced by archbifhop Grindall; fee *T. gallica*. Gerarde fpeaks of both as profpering well in the Englifh gardens. The prefent is a more upright and glaucous *fhrub* than the *gallica*, as well as larger in all its parts. *Leaves* feffile, imbricated, channelled, dotted, entirely pointlefs, not dilated at the bafe. *Bracteas* ovate, pointed, with membranous edges. Segments of the *calyx* ovato-lanceolate, likewife membranous at the fides. *Petals* obovate, flefh-coloured, not much longer than the calyx. *Capfule* glaucous, the fize and fhape of our *T. mucronata*. *Seed-down* long and finely feathery.

Pallas figures what he conceives to be an annual herbaceous variety of this fpecies, of which, not having feen it, we do not feel ourfelves competent to give an opinion.

Tamarix, in *Gardening*, furnifhes plants of the hardy, deciduous, tree and fhrub kinds, of which the fpecies that are cultivated are, the French tamarifk (T. gallica); and the German tamarifk (T. germanica).

Though the firft in its native fituation grows to a tree of middling fize, in this climate it feldom rifes more than fourteen or fixteen feet high, fending out many flender branches, moft of which fpread out flat, and hang downward at their ends, being rather of a fhrubby nature. It is prevalent in the fouth of France, and in other fouthern countries.

But the fecond fpecies is rather a fhrub than a tree, having feveral woody ftalks arifing from the fame root, which grow quite erect, fending out many fide branches, which are alfo erect. It is found in many parts of Germany, &c.

Method of Culture.—All thefe plants may be increafed either by laying down their tender fhoots in autumn, or by planting cuttings in an eaft border, which will take root in a fhort time, if they are fupplied with water in the fpring, before they begin to fhoot in dry weather; but they fhould not be removed until the following autumn, at which time they may be either placed in a nurfery, to be trained up two or three years, or where they are defigned to remain, mulching their roots, and watering them according as the feafon requires, until they have taken root; after which, the only culture they will require is to prune off the ftraggling fhoots, and keep the ground clear about them.

The layer method is not only tedious, but unneceffary, as the cuttings grow readily, and the layers often will not ftrike at all. The cuttings fhould be of the laft fummer's fhoots, and a moift border is moft proper for them. In two years they will be good plants for the fhrubbery, and may be planted out in almoft any foil, though they like a light, moift earth beft, efpecially the latter fort, which grows naturally in low watery fituations.

Both thefe plants are of a rather hardy nature, and beautiful in their foliage and fine fpikes of flowers. They will fucceed in almoft any fort of foil and fituation.

They are very ornamental in the fhrubbery borders, clumps, and other parts of grounds.

The former fort has likewife been lately recommended as a beneficial plant for forming quick or living hedges with, in fuch fituations as are expofed much to the fea-air and blafts, as it has been found to ftand fuch expofures remarkably well, where not affected by the winter frofts, of which it is rather impatient. See Quick *Hedges*, and Tamarisk-*Plant*.

TAMARUS, in *Ancient Geography*, a river of the ifle of Albion, which ftill retains its ancient name, being called Tamar, from Tamara, a gentle river; and its mouth is Plymouth haven.

TAMASA, or Tamasi, in *Hindoo Mythology*, is a name given to the goddefs Parvati, in her *black* character; the word meaning blacknefs or darknefs. The name of Tamas, or Tamafa, was given to a dark, gloomy, aftronomical character, called *Rahu*, (fee that article,) and Ketu, the names feverally of the dragon's head and tail, or the afcending and defcending nodes of aftrologers. One of the fons of Pavaka, the Hindoo fire-king, is likewife named Tamafa. (See Pavaka.) Alfo one of thofe mythological, or hiftorical perfonages, called Menus, of whom fee under Menu. In the Sanfcrit tongue, the root *tam* is prolific of derivations indicating properties of a dark, or gloomy, or malignant tendency.

Tamasa, in *Geography*, a river of Afia, in Mingrelia, which difcharges itfelf into the Black fea.

TAMASIDAVA, in *Ancient Geography*, a town fituated in the interior of Lower Mœfia, at fome diftance from the river Hierafus.

TAMASQUI, in *Geography*, a town of Mexico, in the province of Guafteca; 36 miles W.S.W. of St. Yago de los Valles.

TAMASSUS, in *Ancient Geography*, a town fituated in the interior of the ifle of Cyprus, W. of Ledra, on one of the ftreams which formed the Pedæus.

TAMATAMQUE, or *Villa de las Palmas*, in *Geography*, a town of South America, in the kingdom of Granada, on the river St. Martha; 25 miles S. of Teneriffe.

TAMATIA, in *Ornithology*, the name of a very ftrange bird of the Brafils. It is a fpecies of *Bucco* in the Linnæan fyftem by Gmelin, and the fpotted-bellied barbut of Latham.

Its head is very large; its eyes large and black; its beak is two fingers breadth long, and one broad, fhaped fomewhat like a duck's, but pointed at the end; its upper chap is black, its under one yellow; its legs are long, and the thighs in great part naked; its toes are long; its tail is very fhort; its head is black, and its back and wings of a plain dufky brown; its belly is of the fame brown, variegated with white.

TAMATMA, in *Geography*, a town of Africa, in the kingdom of Bornou.

TAMBA, a town of Africa, in the kingdom of Benguela; 165 miles E. of Benguela.—Alfo, a town of Hindooftan, in Vifiapour; 20 miles S.W. of Sattarah.

TAMBA-AWRA, or TAMBAOURA, a town of Africa, in the kingdom of Bambouk, having in its vicinity a gold-mine; 108 miles S.E. of Gallam. N. lat. 13° 20′. W. long. 9° 25′.

TAMBAC, or TAMBAQUA, a mixture of gold and copper, which the people of Siam hold more beautiful, and fet a greater value on, than gold itfelf.

Some travellers fpeak of it as a metal found in its peculiar mines; but upon what authority we do not know.

The abbé de Choify, in his Journal of Siam, doubts whether this may not be the *electrum*, or amber of Solomon.

The ambaffadors of Siam brought feveral works in tambac to Paris in the reign of Lewis XIV., but they were not found fo beautiful as was expected. See TOMBAC and GOLD-*coloured Metal*.

TAMBACH, in *Geography*, a town of Germany, in the principality of Gotha; 6 miles N.E. of Smalkalden.

TAMBACUNDA, a town of Africa, in the country of Woolly; 30 miles E.N.E. of Medina.—Alfo, a town of Africa, in the country of Neola; 52 miles W. of Baniferile.

TAMBERCHERRY, a town of Hindooftan; 18 miles N.E. of Calicut.

TAMBILLO, a town of Peru; 56 miles N. of Oruro.

TAMBO, a town of South America, in the province of Popayan; 12 miles W. of Popayan.—Alfo, a town of Paraguay; 250 miles E. of Affumption.

TAMBO *de Oeros*, a town of Peru, in the diocefe of Cufco; 136 miles W.N.W. of Cufco.

TAMBONA, a town of Hindooftan, in the country of Travancore; 40 miles N.E. of Travancore.

TAMBOOKIES, a people of the colony of the Cape of Good Hope, fituated N.E. of the Kouffis, or the Kooffis, N. to the Orange river and tropic of Capricorn, are fuppofed by Mr. Barrow to be of Arabian extract, as they widely differ from the Hottentots and the Negroes, and are acquainted with the fmelting of iron, and fome other rude arts. He conceives that a belt of this race fpreads acrofs to the Atlantic. The Demaras on the Copper mountains are Kouffis; and their country is fo barren and fandy, that they cannot keep cattle. The Orange river, called the Groot or Great river, feems to rife about S. lat. 30°. E. long. 28°, and paffes W. by N. till it falls into the fea between the Great and Little Nemakos. It has high cataracts and inundations like the Nile. On the fhores are carnelians, calcedonies, agates, and variolites. See ORANGE-*River*.

TAMBOPALLA, a town of Peru, in the diocefe of Arequipa, at the mouth of the Nombre de Dios; 48 miles S. of Arequipa. S. lat. 17° 10′.

TAMBOS, in *Peruvian Antiquity*, buildings placed at certain diftances, for the lodging of the princes of that country, in their travels through their dominions. See M. de la Condamine, in Mem. de l'Acad. de Berlin, tom. ii. p. 435; who tells us (p. 438.) that he faw feveral remains of thefe tambos, in his journey from Quito to Lima.

TAMBOV, in *Geography*, a city of Ruffia, on the Tzna, capital of a government, and fee of a bifhop; 228 miles S.E. of Mofcow. N. lat. 52° 48′. E. long. 41° 4′.

TAMBOUR, in *Architecture*, a term applied to the Corinthian and Compofite capitals, as bearing fome refemblance to a drum, which the French call *tambour*.

Some choofe to call it the *vafe*, and others *campana*, or the bell.

TAMBOUR is alfo ufed for a little box of timber work, covered with a ceiling, withinfide the porch of certain churches; both to prevent the view of perfons paffing by, and to keep off the wind, &c. by means of folding-doors, &c.

TAMBOUR alfo denotes a round courfe of ftone, feveral of which form the fhaft of a column, not fo high as a diameter.

TAMBOUR, in the *Arts*, is a fpecies of embroidery.

The tambour is an inftrument of a fpherical form, upon which is ftretched, by means of a ftring and buckle, or other fuitable appendage, a piece of linen or thin filken ftuff; which is wrought, with a needle of a particular form, and by means of filken or gold and filver threads, into leaves, flowers, or other figures.

TAMBOUR, Fr., *a drum;* which fee.

TAMBOUR *de Bafque*, a fmall drum ufed by the Bifcayans as an accompaniment to the flageolet, or octave flute: a tabor and pipe.

TAMBOURIN, a French dance, much in favour formerly on the French ftage in all the opera dances of Lulli and Rameau. The air is gay and in common time.

TAMBOURISSA, or TAMBOURFCISSA, in *Botany*, Sonnerat's name for what is now called MITHRIDATEA; fee that article. The French appellation of this tree, Bois Tambour, or Drum-tree, might be fuppofed to allude to the lightnefs and hollownefs of the wood, or to its ufe, were not this word evidently derived from the Madagafcar name of the fame tree, *Ambora*.

TAMBOVSKOE, in *Geography*, a government of Ruffia, bounded on the north by the government of Vladimir, on the eaft by the governments of Nizegorod, Penza, and Saratov; on the fouth by the government of Saratov; and on the weft by the governments of Riazan and Voronez; about 200 miles in length, and from 80 to 100 in breadth. N. lat. 51° 36′ to 55° 20′. E. long. 38° 30′ to 48°.

TAMBRAX, in *Ancient Geography*, a town of Afia, in Hyrcania, which, according to Polybius, was large, and had a royal palace.

TAMBRAY, in *Geography*, a town of Hindooftan, in Travancore; 60 miles N.N.W. of Anjenga.

TAMBRO, a river of Spain, which runs into the Atlantic, near Muros, in Galicia.

TAMBUCO, or TABUCO, a town on the eaft coaft of the ifland of Celebes, fituated in a bay to which it gives name. S. lat. 2° 50′.

TAME, a river of England, which rifes near Winflow, in the county of Buckingham, and runs into the Thames at Dorchefter, in Oxfordfhire.—Alfo, a river of England, which rifes near Dudley, in the county of Stafford, and runs into the Trent, about 7 miles above Burton.

TAME. See THAME.

TAMEGA, a river of Portugal, which runs into the Duero, 10 miles S. of Amarante.

TAMEGAN, a town of the ifland of Ceylon; 48 miles S. of Candi.

TAMERLANE, in *Biography*. See TIMOUR.

TAMETAVE, in *Geography*, a town on the E. coaft of Madagafcar. S. lat. 18° 5′. E. long. 49° 41′.

TAMIA, in *Ancient Geography*, a town of the ifle of Albion, in the vicinity of Banatia and Alata Caftra. Ptolemy affigns it to the Vacomagi.

TAMIAGUA, in *Geography*, a river of Mexico, which joins the Tufpa at its mouth.—Alfo, a town of Mexico, in the province of Guafteca.

TAMIEH, a town of Egypt, on a canal which forms a communication between the Nile and the Birket el Kerum; 12 miles N.E. of Fayoum.

TAMINIZ, a river of Carniola, about four miles in extent; 4 miles S.E. of Veit. It has no vifible communication with any other river.

TAMINO, a river of Switzerland, which runs into the Rhine, 2 miles S. of Sargans.

TAMISRA, denoting darknefs, a name of one of the hells of the Hindoos, of which they had upwards of a fcore. Another of the Hindoo hells is named Andha Tamifra, meaning *utter darknefs;* and as thefe purgatories are differently placed, this is fuppofed to be the one fituated in the bowels of the earth, and its degree of punifhment an aggravation of the eafier penalties inflicted in Tamifra. In the Inftitutes of Menu it is ordained, that "a twice-born man, who barely affaults a Brahman with an intention to hurt him, fhall be whirled about for a century in the hell called Tamifra." (Ch. iv. v. 165.) By "a twice-born man" is meant an individual of one of the three firft tribes or fects, they being fufceptible of regeneration by the inveftiture of the *zennaar;* which fee. See alfo O'M, and SECTS *of Hindoos.*

TAMLOOK, in *Geography*, a town of Bengal; 35 miles S.W. of Calcutta.

TAMMAPUL, a town of Mexico, in the province of Guafteca; 105 miles N.W. of Panuco.

TAMMELA, a town of Sweden, in the province of Tavaftland; 22 miles S.W. of Tavafthus.

TAMMERFORS, a town of Sweden, in the province of Tavaftland; 36 miles N.N.W. of Tavafthus.

TAMMESBRUCK, a town of Saxony, in Thuringia, near the Unftrutt; 1 mile from Langen Salza.

TAMMOWISCHKEN, a town of Pruffian Lithuania; 3 miles E. of Infterburg.

TAMNUM, in *Ancient Geography*, a town of Gallia Aquitanica, upon the route from Burdigala to Auguftodunum; now *Talmon.*

TAMNUS, in *Botany*, Tourn. t. 28. Juff. 43, a more correct name, perhaps, than that of TAMUS, ufed by Linnæus, which will be found in its proper place. The word has been corrupted occafionally into *Tamarus* and *Tannus.*

TAMOATA, in *Ichthyology*, the name of an American frefh-water fifh, called by the Portuguefe *foldido.*

It is a fmall oblong fifh, with a flat head, fomewhat like that of a frog. Its mouth is fmall, and from each angle of it there hangs a long fingle filament, by way of a beard. It has no teeth, and its eyes are extremely fmall. It has eight fins; two at the gills, of one finger in length, and hard and firm like horns; two on the belly, of a fofter fubftance; and one on the middle of the back, another near the tail, and another fmall one oppofite to it on the belly; its tail is the eighth; its whole head is covered above with a hard coat like a fhell; and its body with a fort of coat of mail made up of oblong, hard, fquamofe bodies, dented at their edges; its colour is a fort of rufty iron-colour. It is accounted a very well-tafted fifh. It lives only in frefh-water rivers; and, it is faid, when the water where it is dries up, it will crawl out upon the land, and go in fearch of more. Marcgrave.

TAMOLA, in *Geography*, a town of Sweden, in the province of Tavaftland; 20 miles S.W. of Tavafthus.

TAMONEA, in *Botany*, a name of Aublet's, faid by De Theis to be in ufe among the inhabitants of Guiana, but this does not appear from any thing mentioned in the original author. Aubl. Guian. 659. t. 268. Juff. 109. Lamarck Illuftr. t. 542. *Verbena lappulacea* of Linnæus is referred by Juffieu to this genus. (See VERBENA.) We are not certain whether *Tamonea* ought to be admitted as a genus, and therefore need not ftay to object to the name.

TAMONTACA, in *Geography*, a town on the weft coaft of the ifland of Mindanao. N. lat. 7° 2'. E. long. 124° 36'.

TAMOOK, a fmall ifland in the Sooloo Archipelago. N. lat. 6° 21'. E. long. 121° 58'.

TAMOS, in *Ancient Geography*, a promontory which formed mount Taurus, in the Eaftern ocean.

TAMPASSOOK, in *Geography*, a town on the north-weft coaft of the ifland of Borneo. N. lat. 6° 21'. E. long. 116° 13'.

TAMPICO, a fea-port of Mexico, in the province of Guafteca, fituated in the bay of the gulf of Mexico; 30 miles S.E. of Panuco. N. lat. 22° 40'. W. long. 98° 36'.

TAMPICO, a name given to a river of Spanifh North America, called the *Panuco;* which fee.

TAMPING *a Hole*, in *Mining*, is ufed for filling the upper part of a hole, bored in the rock for blafting with gunpowder, upon the charge of powder, with clay or ftony matter rammed down very clofe and tight: and the clay and ftone are called the tamping. This operation is called, in the North of England, ftemming a hole.

TAMPION, TOMPION, *Tamkin*, or *Tomkin*, a kind of plug or ftopple, ferving to clofe a veffel.

The word is formed from the French *tampon*, a bung, ftopper, &c. Some derive it from the Englifh *tap.*

In *Gunnery*, the tampions are wooden cylinders put into the mouth of guns, howitzers, and mortars, in travelling, to prevent the duft or wet from getting in. They are faftened round the muzzle of the guns, &c. by leathern collars. At fea they are carefully encircled with tallow or putty, to prevent the penetration of the water into the bore, by which the powder contained in the chamber might be damaged or rendered incapable of fervice. They are alfo fometimes ufed to put into the chambers of mortars, over the powder, when the chambers are not full. Tampions are alfo iron bottoms, to which the grape-fhot defigned for fea-fervice are fixed.

TAMPISCO, in *Geography*, a river of Mexico, which runs into the Pacific ocean, N. lat. 10° 38'.

TAMPOE, in *Natural Hiftory*, the name of an Eaft Indian fruit, approaching to the figure of the mangouftan, but not near fo agreeable to the tafte. This fruit is very much of the fize, fhape, and colour of fome of our common fummer-apples; but its fkin is very thick and tough, and it has no crown. The Indians eat it in places where better fruits are fcarce, and in fome places call it the mangouftan.

TAM-SAN-HOTUN, in *Geography*, a town of Chinefe Tartary. N. lat. 40° 20'. E. long. 123° 48'.

TAMSHUC MOUNTAINS, mountains of Thibet; 30 miles N. of Dharmfaleh.

TAMSWEG, a town of the archbifhopric of Salzburg; 12 miles W. of Muehrau.

TAMUADA, in *Ancient Geography*, a river of Africa, in Mauritania Tingitana.

TAMUGADA, a town of Africa, in Mauritania, on the route from Lambefe to Cirta Coloniæ.

TAMUS, in *Botany*, an old name, fometimes written TAMNUS, fee that article, and fuppofed to be taken from the *Uva Taminia* of Pliny, which appears to have belonged to the plant now called Black Bryony. To this therefore the above name is at prefent appropriated.—Linn. Gen. 524. Schreb.

Schreb. 691. Willd. Sp. Pl. v. 4. 772. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1078. Prodr. Fl. Græc. Sibth. v. 2. 258. Ait. Hort. Kew. v. 5. 386. (Tamnus; Tourn. t. 28. Juss. 43. Lamarck Illustr. t. 817.)—Class and order, *Dioecia Hexandria*. Nat. Ord. *Sarmentaceæ*, Linn. *Asparagi*, Juss.

Gen. Ch. Male, *Cal.* Perianth in six deep, ovato-lanceolate segments, most expanded in their upper part. *Cor.* none; except the calyx be so considered, which we have recommended in a parallel case, see SMILAX. *Stam.* Filaments six, simple, shorter than the calyx (or corolla); anthers erect.

Female, *Cal.* (or *Cor.*) of one piece, bell-shaped, in six deep, lanceolate, spreading segments, superior, deciduous. Nectary an oblong depression in the base of each segment, at the inside. *Pist.* Germen inferior, large, ovate-oblong, smooth; style cylindrical, three-cleft, the length of the calyx (or corolla); stigmas three, reflexed, emarginate, acute. *Peric.* Berry ovate, of three cells. *Seeds* two in each cell, globose.

Ess. Ch. Male, Calyx (or rather Corolla) in six deep segments. Female, Calyx (or rather Corolla) in six deep segments. Style three-cleft. Berry inferior, of three cells. Seeds two in each cell.

1. T. *communis*. Common Black Bryony. Linn. Sp. Pl. 1458. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 91. Mill. Illustr. t. 89. (Bryonia nigra; Ger. Em. 871. Vitis nigra; Matth. Valgr. v. 2. 622. Camer. Epit. 988.)—Leaves heart-shaped, undivided.—Native of hedges, woods, and bushy places, in the more temperate parts of Europe, as well as in the Levant. It is common in England, not in Scotland, flowering in June, and laden with bunches of scarlet berries in autumn, till rotten with wet and frost. Dr. Sibthorp found this plant frequent in Greece, as well as in the isles of Crete and Cyprus. The young sprouts boiled are eaten in the latter, like asparagus, to which they are naturally allied. The fleshy perennial *root* is blackish externally, whence the ancient, as well as English, name. *Stems* annual, herbaceous, branched, twining round every thing in their way, and thus climbing, without tendrils, to a considerable height, till they become elegantly pendent in festoons. *Leaves* alternate, stalked, entire, acute, many-ribbed, smooth. *Stipulas* small, awl-shaped, spreading, in pairs at the base of each footstalk. *Flowers* in long, greenish, axillary clusters. *Berries* oval, the size of a large currant, bright red, insipid. The *root* is acrid. Its pulp scraped has formerly been used as a stimulating plaister.

2. T. *elephantipes*. Tuberous Cape Black Bryony. L'Herit. Sert. Angl. 29. Ait. n. 2. Willd. n. 2. Curt. Mag. t. 1347.—Leaves kidney-shaped, undivided. Root elevated, corky and tessellated.—Found at the Cape of Good Hope, near the town, by Mr. Masson, who sent it to Kew in 1774. A male plant flowered there, in the stove, in 1783, from whence l'Heritier caused a drawing to be made, but this plate never appeared. A female, originally imported by Mr. George Hibbert, flowered in Mr. Knight's greenhouse, and being published in the Botanical Magazine, has determined the genus, by its inferior germen, a point previously only guessed at. The singular appearance of the great fleshy *root*, rising out of the ground, a foot in diameter, and covered with angular, tessellated, brown knobs, more resembles the clumsy shell of some huge tortoise, than an elephant's foot. This uncouth mass sends forth in the spring a slender, twining, annual *stem*, about eight feet long, not unlike the last; but the *leaves* are very different, kidney-shaped, with strong ribs; their ends either emarginate, or abrupt with a small point. *Footstalks* tumid, or jointed, at each end. *Flowers* yellowish-green. *Germen* oblong, furrowed. *Fruit* not yet observed.

3. T. *cretica*. Cretan Black Bryony. Linn. Sp. Pl. 1458. Willd. n. 3. Ait. n. 3. Sm. Fl. Græc. Sibth. t. 958, unpublished. (Tamnus cretica, trifido folio; Tourn. Cor. 3.)—Leaves three-lobed.—Not rare in the woods and hedges of Crete and Cyprus, as well as Greece. *Sibthorp*. Miller appears to have cultivated it in 1739, but we have never met with a plant in gardens, nor is this species likely to be a popular favourite. It differs from the first chiefly in having a deep lateral sinus, on each side of the *leaves*, and twin clusters of *flowers*, one much longer than its companion. We know nothing of the *fruit*.—The young shoots are eaten boiled.

TAMUS, in *Gardening*, furnishes plants of the hardy, herbaceous, climbing, perennial kind, among which the species most generally grown are the common black bryony (T. communis); and the Cretan black bryony (T. cretica). The first sort has a very large tuberous root, which is blackish externally; the stems are smooth, twining about every thing in their way, and thus ascending, without the aid of tendrils, to the height of ten or twelve feet in hedges or among bushes, which their festoons of tawny leaves and red berries decorate in the autumnal season.

But the second species has a rounder root than the former; yet the stalks twine in the same manner.

Method of Culture.—All these plants are readily increased by sowing the seeds soon after they are ripe, under the shelter of bushes, where, in the spring, the plants will come up, and require no further care; or in beds to be afterwards planted out. The roots will abide many years, and sometimes send up suckers, from which plants may be raised by setting them out in the autumn or spring where they are to remain.

The thick fleshy root of the first sort is sometimes cultivated for use in the shops.

Both the plants are useful in thickets, and in the wilderness parts of pleasure-grounds.

TAMUSIDA, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana, between Banasa and Silda.

TAMUSIGA, a town of Africa, in Mauritania Tingitana, on the sea-coast, between the port of Hercules and the promontory Usadium.

TAMUZ, in *Chronology*, the fourth month of the Jewish ecclesiastical year, answering to part of our June and July. The 17th day of this month is observed by the Jews as a fast, in memory of the destruction of Jerusalem by Nebuchadnezzar, in the 11th year of Zedekiah, before Christ 588.

TAMWORTH, in *Geography*, is a borough and market-town, situated partly in the hundred of Offlow, county of Stafford, and partly in the hundred of Hemlingford, county of Warwick, England: at the distance of 22 miles S.E. from Stafford, 27 miles N. by W. from Warwick, and 116 miles N.W. from London. It is seated near the confluence of the rivers Tame and Anker, the former of which runs through the town, and divides it into two nearly equal parts. Tamworth appears to have been of considerable note at an early period; and was the occasional residence of the Mercian kings. Offa dates a charter to the monks of Worcester from his palace here in the year 781; and several of his successors in the next century also date their grants from the same place. At that period, a ditch, forty-five feet in breadth, protected the town and royal demesne on the north, west, and east; the river serving as a defence on the south side. Of this ditch, some vestiges can still be traced, and at two angles which it forms, are two mounts, probably raised as foundations for towers. On the invasion of this kingdom by the Danes, Tamworth was almoſt, or totally, deſtroyed. Ethelfleda, the daughter of the illuſtrious Alfred, is ſaid to have rebuilt it in 913, after ſhe had, by her prudence and valour, freed her brother's dominions from the invaders. She alſo erected a tower on an artificial mount, which forms the ſcite of the preſent caſtle; and here ſhe generally reſided till her death, in 918. The caſtle was beſtowed by William the Conqueror on Robert Marmion, whoſe deſcendants held it till 20 Edward I., when it paſſed by marriage to the Freville family; that of Ferrers ſucceeded in the reign of Henry VI.; and they were followed by the Comptons. This venerable fabric is ſtill in a good ſtate of preſervation, as to its exterior; but the inſide has ſuffered much from age and neglect. The rooms are numerous, but ill-ſuited to the liberal domeſtic manners of the preſent era; and the whole is chiefly attractive as a monument of antiquity. The town of Tamworth is large and well-built. It was incorporated by queen Elizabeth on a ſcale peculiarly liberal: the corporation conſiſts of two bailiffs, a recorder, high ſteward, under ſteward, a town-clerk, and twenty-four principal burgeſſes: one of the bailiffs is choſen from each county. Tamworth has ſent two repreſentatives to parliament ever ſince the year 1563. The right of election is in the inhabitants paying ſcot and lot: and the members are returned jointly by the ſheriffs of Warwickſhire and Staffordſhire. The church is a ſpacious edifice. The moſt ancient portion exhibits two round-headed arches, embelliſhed with zig-zag mouldings: whence it ſeems probable that the original edifice was conſtructed ſoon after the Conqueſt. The church was rendered collegiate by the Marmion family at an early period for a dean and ſix prebendaries; with ſeveral lay prebendaries, which are ſtill attached to the church. The college was granted by queen Elizabeth in 1581 to Edward Downing and Peter Aſhton. An hoſpital was eſtabliſhed in this town by Philip Marmion in the 15th year of Edward I. On its ſcite another was founded and endowed by Mr. Guy, to whom the borough of Southwark is indebted for the noble hoſpital which bears his name. A grammar-ſchool, founded by queen Elizabeth, is ſtill well ſupported. Here are ſome manufactures, the chief of which is that of ſuperfine woollen cloths: but this trade, though ſtill reſpectable, has much decreaſed. The printing of calicoes, the tanneries, the manufacture of flax, and the ſpinning of yarn, are branches of buſineſs which have conſiderably advanced. A weekly market, under queen Elizabeth's charter, is held on Saturdays: and three fairs annually. In the population return of the year 1811, the Staffordſhire diviſion of Tamworth was ſtated to contain 279 houſes, and 1327 inhabitants; the Warwickſhire diviſion 325 houſes, and 1666 inhabitants: making a total of 2993 perſons, occupying 604 houſes.

About four miles ſouth-eaſt of Tamworth is Pooley-Hall, the ſeat of the honourable colonel Finch. The lands attached to this reſidence formed part of the poſſeſſions of the Marmions; and after ſeveral intermediate tranſmiſſions, came to the family of Cokaine, in the latter part of the 14th century. It is aſcertained that ſir John Cokaine reſided at Pooley in the reign of Henry IV., and his deſcendants, for many generations, made it their principal ſeat. The preſent manſion was erected by ſir Thomas Cokaine, temp. Henry VIII., and is a fine but irregular building, varying in character between the embattled ſtyle of the previous troubled and ſuſpicious ages, and the open amplitude of conſtruction then firſt growing into practice.—Beauties of England and Wales, vol. xiii. Staffordſhire, and vol. xv. Warwickſhire, by J. N. Brewer.

TAMWORTH, a town of America, in New Hampſhire; 56 miles N. of Portſmouth; containing 1134 inhabitants.

TAMYRACA, in *Ancient Geography*, a town of European Sarmatia, near the Cærcinite gulf.

TAN, the bark of the oak, chopped, and ground by a tanning-mill into a coarſe powder; to be uſed in the tanning or dreſſing of ſkins. See TANNIN.

New tan is the moſt eſteemed; when old and ſtale, it loſes a great deal of its effect, which conſiſts in condenſing or cloſing the pores of the ſkins; ſo that the longer the ſkins are kept in tan, the greater ſtrength and firmneſs they acquire.

This bark, which is more abundant in the gummy reſinous part than any of our common indigenous aſtringents, and which, on account of its aſtringent, gummy, reſinous property, ſerves both to preſerve leather from rotting, and to render it impervious to water, is preferred to all other ſubſtances for the purpoſe of tanning. It is uſed either in the way of infuſion, which is called ooze; or the dry powder is ſtrewed between layers of hides and ſkins, when theſe are laid away in the tan-pits. The ooze is made by macerating the bark in common water, in a particular ſet of holes or pits, which, by way of diſtinction from the other holes in the tan-yard, are called letches. See TANNING.

Every part of the oak-tree, of what age or growth ſoever, is fit for the tanner's uſe, and all oaken coppice-wood, of any ſize or age, being cut and procured in barking-time, will tan all ſorts of leather; at leaſt, as well as the bark alone. When this material is got at the proper ſeaſon, it muſt be very well dried in the ſun, more than the bark alone; thence it is to be cut up, and preſerved in a covered place for uſe.

When it is to be uſed, the greater wood muſt be firſt cleft ſmall, to fit it for the beating and cutting-engine; and the ſmaller muſt be put into the engine as it is: which done, it muſt be again dried upon a kiln, and after that, ground in the ſame manner that the tanners grind their bark. Such wood as is to be uſed preſently after it is gotten, will require the better and the more drying upon the kiln; and if this is omitted, it will blacken and ſpoil all the leather it is uſed about. Where oak is ſcarce, black-thorn, or ſloe-tree, will tolerably well ſupply its place; and where that is not to be had in ſufficient plenty, the white-thorn will do. Phil. Tran. N° 108.

Birch alſo, being ordered in the ſame manner with oak, is fit for ſome uſes in tanning, particularly it does very well for tanning of ſhoe-ſole leather. All theſe ingredients will tan much better than bark alone; and that with much leſs charge; ſo that this diſcovery may very well ſave the felling of trees when the bark is wanted, at a ſeaſon when the ſap is up, which, when it is done, cauſes the outſide of the trees to rot and grow worm-eaten; whereas, if the trees had been felled in winter, when the ſap is down, they would have been almoſt all heart, as the people expreſs it, and not ſubject to worms. This manner of uſing the wood with the bark, in tanning, will alſo increaſe the value of underwoods very conſiderably. Phil. Tranſ. N° 105.

The engine neceſſary for cutting the wood conſiſts of a long ſquare wooden block, and ſome pieces of iron to be faſtened on and uſed about it, *viz.* a hammer, an anvil, an iron holding the wood to be bruiſed and cut, and a knife to cut it. The whole is a very ſimple and cheap machine, and is deſcribed at large, and figured in the above-mentioned number of the Philoſophical Tranſactions.

By M. de Buffon's experiments upon different ſkins, it was found that a decoction of young oak-wood ſucceeded perfectly well in tanning ſheep and calves' ſkins, but did not

not do equally well for ox, and the other harder ſkins. This, however, he imagines, might be only for want of knowing the beſt method of uſing the wood. And certainly theſe trials deſerve to be farther proſecuted; ſince the ſmall branches of the oak, which are of little value, might be thus made to ſupply the place of a much dearer commodity, the bark; and as in many trees the bark of the young branches is found to be of greatly more virtue than that of the larger branches, or the trunk, the uſe of theſe ſmall boughs, bark and all, might very probably be found to anſwer to all the effects of the bark of the larger kind alone. Memoirs Acad. Scienc. Par. 1736.

The Society of Arts, &c. granted a premium of 100*l.* in the year 1765, for the diſcovery of a method of tanning with oaken ſaw-duſt; but the acquiſition has not hitherto had its deſired effect; though it is ſaid that the uſe of oaken ſaw-duſt has been advantageouſly adopted in Germany. Doſſie's Mem. of Agr. vol. i. p. 227.

We are told, in Phil. Tranſ. N° 36, that the operation of tanning is performed, on leather, better in the Weſt Indies than in England. They uſe three ſorts of bark, the mangrove-bark, the olive-bark, and another; and the whole buſineſs is ſo ſoon done, that a hide delivered to them, is in ſix weeks ready to be worked into ſhoes, though they beſtow leſs labour than we do.

Mr. Albert Geſner, firſt phyſician to the duke of Wirtemberg, having made ſome experiments on the duſt of heath, dried in an oven, and afterwards pulverized, as a ſubſtitute to that of oak-bark in tanning, found that the leather prepared by this method was very good; but he obſerves, that the operation is much more tedious. (Hiſt. R. A. S. Paris, for 1756.) Others have propoſed a trial of the ſmall branches of heath, and the leaves of oak.

TAN, in *Gardening*, a ſubſtance of the oak-bark, or other ſimilar kinds, after it has been ground and ſoaked in the ooze of the tanners' vats, and properly dried, is uſed for the purpoſe of making hot-beds, for forcing many ſorts of exotic plants that require a durable ſteady heat.

It has not been of very long uſe in England, and was brought to us from Holland in the reign of king William, and then uſed for the raiſing of orange-trees; but after this period it became diſuſed; and it is of a much later date, *viz.* about the year 1719, that it has been brought into uſe again for the raiſing of the pine-apple, ſince which time it is become generally uſed, wherever it is to be had, for all the purpoſes of the hot-bed, in raiſing tender exotic plants.

Refuſe tan, made up into cakes, ſerves as fuel, in circumſtances where a gentle and continued fire is advantageous. See BARK-*Bed*, HOT-*Bed*, HOT-*Houſe*, and STOVE.

TAN, *Flower of*, is a name given by the people employed in the tanning-trade, to a yellow ſubſtance, often found upon old tan, or oak-bark broken to pieces, which has been uſed as tan, and is of no farther ſervice.

The name, however, is very improper; and though every body converſant in tan-yards muſt have ſeen the thing, yet it has always paſſed as an efflorеſcence of the bark, till the curious Mr. Marchand inquired more accurately into its nature, and found it to be a plant of itſelf, wholly different from the matter of the tan; and to which the bark, which had been often wetted and dried again, ſerved as a proper matrix. He found it to be more nearly allied to the ſpunge, than to any other genus of plants, and therefore named it *ſpongia fugax mollis flava & amœna in pulvere coriario naſcens*, ſoft, beautiful, yellow-fading ſpunge, growing on tanners' bark.

It makes its appearance moſt frequently in the ſummer-months, and is then ſeen in ſmall tufts of a beautiful yellow colour, on different parts of the old heaps of bark. It appears at firſt in form of a thin yellow ſcum, and is of a ſort of jelly-like ſtructure; but it every day grows larger and thicker, till it ſtands above half an inch out from the ſurface of the bark. As it grows, its ſurface becomes more and more cavernous and ſpungy, the pores or holes being of different diameters, and the interſticial matter forming a ſort of net-work more or leſs regular, and often interrupted by irregular prominences in ſeveral parts; and, in fine, when the growth is complete, the whole more reſembles a ſpunge than any vegetable ſubſtance, and is of a deep yellow colour, and conſiderably thick and tough conſiſtence; there are no roots to be diſcovered iſſuing from it; its ſmell is like that of rotten wood, and its taſte is ſomewhat ſtyptic. It always appears in the warm months, and always upon ſuch old tan as has begun to ferment, and is in the ſtate in which our gardeners uſe it for hot-beds. If it happens to ſtand expoſed to the ſouth ſun, it is but of ſhort duration; but if it be in a ſheltered place, it will laſt a conſiderable time, and often ſpread itſelf to a great extent, and make a very beautiful figure for many weeks. Mem. Acad. Par. 1727.

TAN-*Bed*, in *Gardening*. See BARK-*Bed*.

TAN-*Pit*. See BARK-*Pit*.

TAN-*Spud*, in *Rural Economy*, the name uſually given to a particular ſort of tool uſed for peeling of the bark from oak, and ſome other trees, in certain diſtricts; but in others they employ ſeveral different implements for effecting this purpoſe.

TAN-*Stove*. See HOT-*Houſe* and STOVE.

TANA, in *Geography*, the moſt conſiderable river in Finmark.

TANACETUM, in *Botany*, Tanſy, a barbarous Latin word, of which, like *Oſmunda*, it is ſcarcely poſſible, as Linnæus remarks, *Phil. Bot.* 160, to determine the meaning, or from what language it is derived. Of OSMUNDA we have attempted an explanation. (See that article.) De Theis cites Linnæus and Dodonæus as deducing *Tanacetum* from *Athanaſia*; but we find no ſuch etymology given by them, though ſeveral writers ſpeak of theſe words as ſynonimous, and ſome lexicographers give that explanation. Αθανασια, as expreſſing an unfading, or everlaſting, flower, is little applicable to our Tanſy.—Linn. Gen. 417. Schreb. 549. Willd. Sp. Pl. v. 3. 1809. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 862. Prodr. Fl. Græc. Sibth. v. 2. 167. Ait. Hort. Kew. v. 5. 1. Purſh 522. Juſſ. 184. Tourn. t. 261. Lamarck Illuſtr. t. 696. Gærtn. t. 165.—Claſs and order, *Syngeneſia Polygamia-ſuperflua*. Nat. Ord. *Compoſitæ diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common Calyx* hemiſpherical, imbricated, with acute compact ſcales. *Cor.* compound, tubular, convex. Florets of the diſk numerous, funnel-ſhaped, with five reflexed ſegments in the limb, all perfect: thoſe of the radius few, ſmall, three-cleft, moſt deeply divided at their inner ſide. *Stam.* in the perfect florets, Filaments five, capillary, very ſhort; anthers united into a cylindrical tube. *Piſt.* in the perfect florets, Germen oblong, ſmall; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma in two revolute ſegments: in the female ones, Germen oblong; ſtyle ſimple; ſtigmas two, reflexed. *Peric.* none, except the unchanged calyx. *Seeds* ſolitary, oblong, crowned with more or leſs of a ſlight margin. *Recept.* convex, naked.

Obſ. Sometimes the radius is wanting, all the florets being, in that caſe, perfect. The ſeeds of ſome ſpecies are ſaid to want the crown.

Eſſ.

Eff. Ch. Receptacle naked. Seeds crowned with a border. Calyx imbricated, hemifpherical. Florets of the radius three-cleft, obfolete, fometimes wanting.

1. T. *veftitum*. Leafy Cape Tanfy. Thunb. Prodr. 147. Willd. n. 1. — "Leaves flender, triangular, imbricated. Panicle terminal."—Native of the Cape of Good Hope. *Thunberg*.

2. T. *longifolium*. Long-leaved Cape Tanfy. Thunb. Prodr. 147. Willd. n. 2.—"Leaves linear-thread-fhaped. Clufter terminal, level-topped." — Found in the fame country.

3. T. *linifolium*. Flax-leaved Cape Tanfy. Thunb. Prodr. 147. Willd. n. 3. Ait. n. 1. (Athanafia linifolia; Linn. Suppl. 361.)—Leaves linear-lanceolate, channelled, taper-pointed. Clufter terminal, fimple, corymbofe. —Native of the Cape of Good Hope. Sent to Kew by Mr. Maffon in 1774. A green-houfe fhrub, flowering in Auguft. The *ftem* is fimple, round, and fmooth, clothed with alternate, fimple, linear or awl-fhaped *leaves*. *Flowers* ovate, fmooth, yellow. The length of the *leaves* is variable.

4. T. *axillare*. Axillary Cape Tanfy. Thunb. Prodr. 147. Willd. n. 4. — "Leaves linear-thread-fhaped, combined at the bafe. Flowers axillary, feffile."—Gathered by Thunberg at the Cape.

5. T. *uliginofum*. Marfh Levant Tanfy. Prodr. Fl. Græc. n. 2029. Fl. Græc. t. 855, unpublifhed. (Santolina vermiculata cretica; Tourn. Inft. 461?)—Leaves linear; the lower ones with one lateral tooth. Stalks folitary, terminal, fingle-flowered.—Gathered by Dr. Sibthorp in boggy parts of the ifle of Cyprus, intermixed with *Juncus bufonius*. The *root* is annual, fimple, tapering, with many whitifh fibres. *Stems* feveral, afcending, branched from the bottom, three or four inches high, round, fmooth, leafy. *Leaves* alternate, feffile, an inch long, acute, channelled, fmooth, moftly entire; a few of the lower ones only dilated flightly at the end, and furnifhed with a lateral tooth. *Flowers* terminal, folitary, yellow, hemifpherical, each on a fimple, naked, fmooth, erect *ftalk*, two or three inches in length, purplifh at the top. *Seed*, according to Mr. Bauer's drawing, crowned with an oblong tubular fcale, fplit on one fide.

6. T. *fuffruticofum*. Shrubby Cape Tanfy. Linn. Sp. Pl. 1183. Willd. n. 5. Ait. n. 2. Thunb. Prodr. 146. (T. africanum fruticans multiflorum, foliis tanaceti vulgaris decuplò minoribus; Comm. Hort. v. 2. 199. t. 100.)—Leaves in many pinnate, fubdivided, acute, fomewhat downy fegments. Stem fhrubby. Flowers corymbofe, level-topped.—Native of the Cape of Good Hope, from whence the Dutch obtained feeds above a century ago, and it probably foon found its way into our more curious green-houfes. The plant has little to attract general admiration, though the *leaves* are delicately divided, and the leafy branches are terminated by abundance of little golden corymbofe *flowers*, whofe *calyx* is membranous and fhining.

7. T. *fibiricum*. Long-leaved Siberian Tanfy. Linn. Sp. Pl. 1183. Willd. n. 6. (T. n. 116; Gmel. Sib. v. 2. 134. t. 65. f. 2.)—Leaves pinnate; leaflets linear-thread-fhaped, entire; undivided or three-cleft. Flowers corymbofe, level-topped. Calyx-fcales nearly orbicular, fmooth. —Gathered by Steller, in dry mountainous parts of Siberia, beyond the lake Baical, flowering in June and July. The *root* is brown, rather thick, with many fibres running deep into the ground, and apparently perennial. *Stems* about eighteen inches high, erect, round, ftriated, fmooth, fomewhat leafy; branched and corymbofe at the top. *Leaves* acute, not unlike thofe of Southernwood, but fmooth; the lower ones on long ftalks; the uppermoft feffile, at the bafe of each branch. *Flowers* bright yellow, partly drooping, encompaffed by the white membranous edges of the green orbicular fcales of the *calyx*.

8. T. *argenteum*. Silvery Armenian Tanfy. Willd. n. 7. "Ejufd. Achill. 51. t. 2. f. 4." (Achillea argentea; Lamarck Dict. v. 1. 29. Ptarmica orientalis, foliis argenteis conjugatis; Tourn. Cor. 38.)—"Leaves pinnate, clothed with filky down; leaflets lanceolate, flightly toothed at the extremity. Corymb terminal."—Gathered by Tournefort in Armenia. This is faid to bear fome refemblance to the *Achillea Clavennæ*. The *ftem* is about a foot high, fimple, channelled, covered, like the reft of the herb, with filky down. *Leaves* alternate, ftalked, with linear or lanceolate leaflets, moft of which, efpecially in the radical leaves, have two or three teeth towards the end. *Flowers* probably white. *Receptacle* conftantly naked. *Calyx* membranous at the edge of the inner fcales. *Lamarck, Willdenow*.

9. T. *angulatum*. Dropwort-leaved Tanfy. Willd. n. 8. "Ejufd. Achill. 52. t. 2. f. 3." (Achillea filipendulina; Lamarck Dict. v. 1. 27. Ptarmica orientalis, tanaceti folio et facie, flore minimo; Tourn. Cor. 38.) — Leaves pinnatifid; fegments lanceolate, ferrated. Corymb denfe. Calyx angular." — Gathered in the Levant by Tournefort. *Stem* a foot, or rather more, in height, channelled, almoft fmooth, but fparingly leafy in the upper part. *Lower leaves* two or three inches long, deeply pinnatifid, green, and fmooth; upper about half as long. *Flowers* yellow, in a fmall denfe *corymbus*. *Florets* of the radius fcarcely more than two or three, very fhort. *Receptacle* elevated, furnifhed with a very few fcales at the margin. *Willd. Lamarck*.

10. T. *microphyllum*. Small-leaved Siberian Tanfy. (Achillea n. 164; Gmel. Sib. v. 2. 198. t. 83. f. 2. Ptarmica millefolii folio tomentofo, flore luteo; Gerb. MSS. in Herb. Linn.)—Leaves pinnate; leaflets bipinnatifid, hairy, obtufe. Flower-ftalks corymbofe, hairy. Calyx fmooth.— Gathered by Gerber, in deferts, on both fides of the river Don, near upper Kundrufchewa. He remarked that the *receptacle* is devoid of fcales, which induces us to introduce this plant here, though referred to *Achillea* by Gmelin. Linnæus has paffed it over. The *root* is woody and apparently perennial. *Stem* a fpan high, more or lefs branched, leafy, angular, and downy. *Leav s* ftalked, hairy, finely fubdivided and notched. *Flowers* yellow, rather hemifpherical than cylindrical. *Calyx-fcales* oblong, ending in a fuddenly dilated white membrane; the bafe of the outward ones only occafionally hairy, or fringed. *Florets* of the radius very fhort, three-toothed.

11. T. *incanum*. Hoary Oriental Tanfy. Linn. Sp. Pl. 1183. Willd. n. 9. (Abfinthium orientale incanum tenuifolium, floribus luteis in capitulum congeftis et furfùm fpectantibus; Tourn. Cor. 34.)—Leaves pinnate, hoary; leaflets crowded, in deep finger-like fegments. Corymbs denfe, compound, fomewhat panicled.—Native of the Levant. The *ftem* is faid by Linnæus to be fimple, leafy, and very fhort. We have feen neither fpecimen nor figure.

12. T. *cotuloides*. May-weed Cape Tanfy. Linn. Mant. 282. Willd. n. 10. — Leaves deeply pinnatifid, pointed, hairy, dotted. Stem much branched. Flowers fomewhat panicled. Calyx-fcales elliptical, nearly equal.—Native of the Cape of Good Hope. *Root* fomewhat woody, with many fibres; Linnæus judged it to be annual. *Stem* about a fpan high, copioufly branched, round; branches afcending, leafy, hairy. *Leaves* numerous, fcattered, ftalked, hardly an inch long, in feven or nine deep, acute, entire fegments, clothed, on the lower fide at leaft, with very long

ftraight

ftraight loofe hairs. *Flower-ftalks* panicled, hairy, leafy, fomewhat corymbofe. *Flowers* fmall, hemifpherical, rather convex, yellow, with few or no radiant florets. *Calyx-fcales* acute, rather lax, roughifh, with thin pale edges.

13. T. *orientale.* Silky-leaved Oriental Tanfy. Willd. n. 11. (Abfinthium orientale incanum, capillaceo folio, floribus in capitulum congeftis; Tourn. Cor. 34.)—"Leaves filky and hoary; the radical ones pinnate; leaflets in three deep, linear-thread-fhaped, acute fegments; ftem-leaves in three deep, lanceolate fegments. Panicle denfely corymbofe."—Native of Armenia. *Root* perennial. *Leaves* of the root and barren ftems about three-quarters of an inch long, on ftill longer *footftalks;* thofe of the flowering ftem broader, their fegments flat, occafionally divided. *Panicle* corymbofe, terminal. *Flowers* feffile, in round heads, upon crowded ftalks. *Calyx* downy. *Receptacle* naked. *Willd.*

14. T. *annuum.* Annual Tanfy. Linn. Sp. Pl. 1184. Willd. n. 12. Ait. n. 3. (Santolina corymbis fimplicibus faftigiatis, foliis linearibus confertis; Mill. Ic. t. 227. f. 1. Elichryfon; Cluf. Hift. v. 1. 326. Elyochryfon, five Coma aurea; Ger. Em. 645.)—Radical leaves doubly pinnate; thofe of the ftem deeply pinnatifid, downy; their fegments fharp-pointed. Corymbs level-topped. Calyx-fcales oblong, hairy.—Native of Spain and Italy. Very foon introduced into our gardens, where it proves a hardy annual, flowering in July and Auguft. The *ftem* is two or three feet high, round, furrowed, much branched, clothed with innumerable fmall crowded pinnatifid *leaves*, of a rather hoary green. *Flowers* yellow, in terminal flat corymbs; the fcales of their *calyx* unequal, imbricated, keeled, hairy, tipped with a rounded membrane.

15. T. *obtufum.* Blunt-leaved Cape Tanfy. Thunb. Prodr. 147. Willd. n. 13.—"Leaves doubly pinnate, fmooth; leaflets linear, obtufe. Heads of flowers folitary, fmooth."—Found by Thunberg at the Cape of Good Hope.

16. T. *grandiflorum.* Large-flowered Cape Tanfy. Thunb. Prodr. 147. Willd. n. 14.—"Leaves doubly pinnate, villous; leaflets linear, acute. Heads of flowers folitary, downy."—From the fame country.—We have not feen either of the two laft fpecies. Willdenow underftands Thunberg's expreffion, *capitulis folitariis*, as meaning *floribus folitariis;* but the fuppofition of fo great an inaccuracy is fcarcely warrantable. We therefore preferve the original fenfe; whether it be accurate or not muft remain with the author.

17. T. *multiflorum.* Many-flowered Cape Tanfy. Thunb. Prodr. 147. Willd. n. 16.—"Leaves doubly pinnate, villous; leaflets acute. Panicles compound, level-topped."—Found by Thunberg at the Cape.

18. T. *myriophyllum.* Millfoil Tanfy. Willd. n. 17. "Ejufd. Achill. 50." (Achillea bipinnata; Linn. Sp. Pl. 1265. Ptarmica orientalis incana, foliis pennatis, femiflofculis florum vix confpicuis; Tourn. Cor. 38.)—Leaves doubly pinnate, downy; leaflets ovate; thofe of the ftem toothed; of the radical leaves entire.—Native of the Levant. Only to be feen perhaps in Tournefort's herbarium, or in collections extracted from thence.

19. T. *vulgare.* Common Tanfy. Linn. Sp. Pl. 1184. Willd. n. 18. Ait. n. 4. Fl. Brit. n. 1. Engl. Bot. t. 1229. Woodv. Med. Bot. t. 115. Fl. Dan. t. 871. (Tanacetum; Ger. Em. 650. Matth. Valgr. v. 2. 259. Camer. Epit. 650.)—β. T. crifpum anglicum; Ger. Em. 650.—Leaves doubly pinnatifid, fharply ferrated, naked.—Native of banks, hedges, and borders of fields, in moft parts of the middle of Europe; very frequent in England, flowering in July and Auguft. *Root* perennial, creeping. *Herb* two feet high, leafy, dark green, with a ftrong balfamic fcent, and bitter tafte. It was formerly more ufed than at prefent to give a flavour, as well as a green colour, to a rich kind of pudding. The *leaves* are copious, feffile, a fpan long, fometimes a little hairy underneath; clafping the ftem with their dilated bafe. *Flowers* compofing a large, flattifh, terminal, golden *corymbus*. The *radius* is fcarcely remarkable but in hot feafons, though its rudiments may generally be detected. The curled-leaved variety is efteemed moft aromatic and wholefome.

Willdenow's fifteenth fpecies, *T. monanthos*, Linn. Mant. 111, having a fcaly receptacle, is referred to SANTOLINA, (fee that article,) in the Prodr. Fl. Græca, by the fpecific name of *S. rigida*. This is a depreffed annual plant, with doubly-pinnatifid pointlefs *leaves;* fingle-flowered afcending hairy *ftalks;* and a hairy *calyx*, whofe fcales are nearly equal. The *flowers* are yellow. This is a native of Cyprus, and very nearly akin to *S. anthemoides*, Linn. Sp. Pl. 1180; whofe *calyx* is imbricated on all fides, and its *leaves* have briftle-pointed fegments.

TANACETUM, in *Gardening*, furnifhes plants of the herbaceous and fhrubby perennial kinds, among which the fpecies moft commonly cultivated are, the common tanfy (T. vulgare); the annual tanfy (T. annuum); the coftmary tanfy (T. balfamita); the Siberian tanfy (T. fibiricum); the fhrubby tanfy (T. fuffruticofum); and the fan-leaved tanfy (T. flabelliforme).

In the firft fort there are varieties with curled leaves, called double tanfy; with variegated leaves; and with larger leaves, which have little fcent.

Method of Culture.—All the different herbaceous fpecies are increafed by parting the roots, and by feed.

In the firft mode the bufinefs is effected by flipping or dividing the roots in autumn or winter, when the ftalks are decayed; or early in fpring, before new ftalks fhoot forth; planting the flips at once where they are to remain; thofe for the kitchen-garden, as the common tanfy, &c. in any bed or border a foot and a half afunder; and thofe intended for variety in the pleafure-ground, fingly here and there, at fuitable diftances, to effect a proper diverfity.

The feed faved in autumn fhould be fown in the fpring following, in beds of light earth, broad-caft and raked in, when the plants will foon come up, and in July be fit to prick out in beds, in rows a foot afunder; fome to remain, and others to be planted out in autumn where they are to grow.

All the fhrubby forts are eafily increafed by cuttings of the branches, which fhould be planted any time in fpring and fummer, choofing the young and moft robuft fhoots, which fhould be cut off in proper lengths, and if early in fpring, &c. be planted in pots of good earth, feveral in each, plunging them in a hot-bed, where they will be rooted, and fit for potting off feparately in fix weeks; or if in fummer, the young fhoots may be planted in the full ground, in a fhady border, or where they may be fhaded with mats from the fun; or in pots, and placed in the fhade, or under a garden-frame, &c.: in all of which methods, giving plenty of water, they will readily take root; but thofe in the hot-bed will be forwardeft: they, however, will all be well rooted the fame feafon, and fhould then be tranfplanted into feparate pots, and managed as other fhrubby greenhoufe plants. See GREEN-HOUSE *Plants*.

Moft of the former forts require to be afterwards kept free from weeds, cutting down the decayed ftalks annually in autumn; and as the roots increafe faft into large bunches,

fpreading

ſpreading widely round, they ſhould be cut in, or be ſlipped occaſionally, otherwiſe they are apt to overrun the ground; and to have the ground dug between the plants annually.

All the latter ſorts are ſomewhat tender, but only require ſhelter from froſt, being kept in pots, and depoſited among the greenhouſe plants, and treated as other ſhrubby exotics of that collection. They effect a very agreeable variety at all times of the year, but particularly in ſummer and autumn, when in flower.

The common tanſy has been long cultivated in the garden as a culinary and medicinal herb; the leaves being uſed occaſionally while young and tender, in ſallads during the ſpring ſeaſon, as well as for making cakes, puddings, and many other ſimilar articles. The powder of the dried leaves, the ſeeds, and the flowers, have alſo been ſometimes employed as a remedy againſt worms.

The curled and variegated ſorts or varieties are principally made uſe of for ornamental purpoſes.

The earl of Dundonald has propoſed the cultivation of the tanacetum, or tanſy, for the production of potaſs, aſſerting that it will yield more of this alkali than can be procured from an equal weight of any other vegetable.

Tanacetum, in the *Materia Medica*. See Tansy.

TANADASSA, in *Ancient Geography*, a town of Africa Propria, on the route from the Grand Leptis to Tacapæ.

TANÆCIUM, in *Botany*, ſo named by Dr. Swartz, on account of its very long climbing ſtem and branches, from ταναηκης, *ſtretched out*, or rather *having an elongated point*.—Swartz Prodr. 91. Ind. Occ. 1049. t. 20. Schreb. Gen. 412. 834. Willd. Sp. Pl. v. 3. 312. Mart. Mill. Dict. v. 4.—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Luridæ*, or perhaps *Putamineæ*, Linn. Swartz. Akin to *Solanaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, undivided, abrupt, nearly or quite entire. *Cor.* of one petal, long; tube cylindrical, dilated upwards, limb ſpreading, in five, ſomewhat unequal, or two-lipped, deep ſegments. *Stam.* Filaments four, ſhorter than the tube of the corolla, two of them rather ſhorter than the reſt, with an intermediate rudiment of a fifth; anthers two-lobed. *Piſt.* Germen ſuperior, roundiſh, ſeated on an annular receptacle; ſtyle ſimple, about the length of the ſtamens; ſtigma of two thick ſpreading lobes. *Peric.* Berry very large, globoſe or oblong, on a ſhort ſtalk, of two cells, with a hard coat. *Seeds* ſmall, numerous, oblong, angular, inſerted into a central globoſe receptacle.

Eſſ. Ch. Calyx cylindrical, undivided, abrupt. Corolla tubular, rather unequal, five-cleft. Rudiment of a fifth ſtamen. Berry coated, of two cells, with many ſeeds.

Obſ. This genus ſurely belongs to the *Luridæ* of Linnæus, and is conſiderably akin to another genus of Swartz's, the Solandra, ſee that article, though he does not appear to advert to this affinity.

1. T. *paraſiticum*. Simple-leaved Tanæcium. Willd. n. 1. Swartz Ind. Occ. 1053. Jacq. Hort. Schoenbr. v. 1. 61. t. 115.—Leaves ſimple, ovate, coriaceous. Stem ſhrubby, climbing paraſitically.—Native of woods in the weſtern part of Jamaica. *Stem* when young cloſely attached by fibrous radicles to the trunks of trees, round, with a grey rugged bark; when full-grown, it often decays below, ſupporting itſelf altogether paraſitically, and ſending out round, ſpreading, ſmooth, leafy branches. *Leaves* oppoſite, on ſhort thick ſtalks, five or ſix inches long, entire, acute, ſcarcely pointed, ſmooth, of a fine ſhining green, with one rib, and many oblique veins. *Flower-ſtalks* axillary, ſhort, each bearing about four elegant drooping *flowers*, about an inch and a half long. *Calyx* ſwelling, purpliſh-red, contracted at the mouth, quite entire. *Corolla* with a pale yellowiſh tube, and crimſon, ſpreading or reflexed, border, whoſe ſegments are rounded, and nearly uniform, the lowermoſt only a little the largeſt, and folding over the mouth like a lid, before the flower expands. *Berry* globoſe, as big as a ſmall apple, with a brown brittle coat. Swartz once found a fruit with three cells.

2. T. *Jaroba*. Three-leaved Tanæcium. Willd. n. 2. Swartz Ind. Occ. 1050. t. 20. f. 1. (Jaroba; Marcgr. Braſil. 25. Pis. Braſil. 173. Cucurbitifera fruticoſa trifolia ſcandens; Sloane Jam. v. 2. 175.)—Lower leaves ternate; upper in pairs, with an intermediate terminal tendril. Stem climbing.—Native of woods, on the banks of rivers, in the weſtern part of Jamaica. Swartz found it in flower in February, climbing to the top of a tree of the *Bignonia leucoxylon*. The ſhrubby *ſtem* mounts to a great height, where it has an opportunity of ſupport, ſending out long, pendulous, round, ſlightly ſtriated, herbaceous branches. *Leaves* oppoſite, ſtalked; the lower ones with three ovate, pointed, entire, ribbed, ſmooth, ſcarcely coriaceous, leaflets, each half a foot long; upper of two rather ſmaller ones, with a ſlender rigid tendril in the place of a third leaflet, by which the branches are ſupported on thoſe of neighbouring trees. *Cluſters* axillary, of few flowers, with thick, round, oppoſite ſtalks. *Flowers* white, ſhort-lived. *Calyx* gibbous at the baſe; ſometimes very minutely five-toothed at the margin. *Corolla* funnel-ſhaped; its tube ſix or ſeven inches long, ſwelling at the top, downy both within and without; ſegments of the limb ovate, wavy or plaited, about three-quarters of an inch in length, all nearly equal, though the two uppermoſt are, as in the former ſpecies, leſs deeply ſeparated. *Berry* very large, a foot long, oval, pendulous, ſmooth, brittle when ripe. *Seeds* large, broad, compreſſed, lying cloſely over each other. The Portugueſe call this plant *Caſca amargoſa*, on account of its bitterneſs.

3. T.? *pinnatum*. Pinnate Tanæcium. Willd. n. 3. (Creſcentia pinnata; Jacq. Coll. v. 3. 203. t. 18.)—Leaves pinnate. Stem arboreous, erect.—Native of Mozambique, where it is called *Kigelikeia*, and from whence it was carried to the iſles of Mauritius or Bourbon, and thus got into the imperial gardens at Schoenbrun, being accompanied by a diſſected drawing of the *flower*, which is all that Jacquin has exhibited of the plant. The young tree, about ſeven feet high, and four inches in the diameter of its trunk, bore in the ſtove ſeveral branches, with alternate pinnate *leaves*, each of four pair of oblong leaflets with an odd one, all coriaceous, obtuſe with a point, undulated, ſparingly and ſharply ſerrated; ſmooth above; roughiſh to the touch beneath; the largeſt near ſix inches long; the odd one on a conſiderable partial ſtalk. The *flowers* are ſaid to grow on the trunk and older branches, but of their mode of inſertion or infloreſcence we have no account. The *calyx* is ovate, tubular, ſmooth, paleiſh-green, about an inch long, with five acute, rather deep, red ſegments. Tube of the *corolla* cylindrical, pale, the length of the calyx; limb very large, bell-ſhaped, three inches long, with five acute, unequal, reflexed, marginal lobes; its outſide ſtrongly and copiouſly ribbed, pale, with a tinge of red; the whole inſide of a fine crimſon. The fifth *ſtamen* is apparently perfect, with an anther, though but half the length of the others; all the filaments hairy. *Germen* accompanied at the baſe by five glands. *Stigma* of two lanceolate plates. *Berry* as large as a man's head, coated, full of pulp, in which the ſeeds are lodged.—Jacquin was doubtful of the genus of this magnificent

ficent and curious plant, which is faid to form, in its native country, a very large tree. There feems as much reafon to refer it to *Crefcentia* as to *Tanæcium*, the *calyx* not anfwering well to either, and the internal ftructure of the *fruit* being unknown.

TANAEIM, or Tenaiem, in *Geography*, a town of Arabia, in the province of Yemen, famous among the Arabian Jews, who had anciently their chief feat, and many confiderable fynagogues in it; at prefent it is almoft defolate; 30 miles S.E. of Sana.

TANAGA, one of the Fox iflands, in the North Pacific ocean, about 40 miles in circumference. N. lat. 53° 20'. E. long. 182° 14'.

TANAGER, *Il fiume Negro*, in *Ancient Geography*, a river of Italy, in Lucania, according to Virgil. It has its fource in a mountain called Albufnus, now monte Poftiglione, and difcharges itfelf into the Silanus.

TANAGRA, a confiderable town of Bœotia, towards the weft, feated on an eminence, at fome diftance from the mouth of the Afopus. In a temple of Bacchus at this town was a fine ftatue of this god, and above, a triton of admirable workmanfhip. Befides the temple of Bacchus, here were temples of Themis, Venus, Apollo, and Mercury. In the moft confpicuous place of this city was the tomb of Corinna, fo famous for her beauty and poetical talents, fo that at Thebes fhe gained a prize in preference of Pindar. Here was alfo the tomb of Orion. Paufanias.

Tanagra, *Tanager*, in *Ornithology*, a genus of the order Pafferes; the characters of which are, that the bill is conic, acuminated, emarginated, fubtrigonous at the bafe, and inclining at the apex. Gmelin enumerates forty-fix

Species.

Jacapa. Black; the forehead, neck, and breaft, crimfon-coloured. This is the jacapu of Marcgrave, the red-breafted blackbird of Edwards, and the red-breafted tanager of Latham. It is found in America.

Brasilia. Crimfon, with black tail and wings. This is the cardinal of Buffon, and the Brafilian tanager of Latham. Found in South America. Of this bird there are two varieties, one of which is the rumplefs blue, red, and black Indian fparrow of Willughby.

Rubra. Red, with black wings and tail, and tail-feathers white at the apex. This is the Canada tanager of Pennant, and the red tanager of Latham. Found in Canada. Of this the fcarlet fparrow of Edwards, or merula brafilienfis of Ray and Willughby, is a variety.

Jacarina. Violet-black, with wings whitifh beneath, and tail of two divaricated branches. This is a bird of Brafil and Guiana, the jacarini of Marcgrave.

Violacea. Violet, and the under part very yellow: the teitei of Marcgrave, the golden titmoufe of Edwards, and golden tanager of Latham. A variety of this, found in Brafil, Surinam, and Cayenne, is fhining black, with the abdomen, breaft, and front pale yellow, and the outer tail-feather having on its inner fide a white fpot.

Olivacea. Olive; the throat and breaft yellow, the abdomen white, the quills and tail-feathers brown, with a white margin. This is the olivet of Buffon, and found in Cayenne.

Gyrola. Green, red-headed, yellow collar, and ceruleous breaft: the rouvardin of Buffon, the red-headed greenfinch of Edwards, and red-headed tanager of Latham. Found in various parts of South America.

Cayana. Yellow, green back, red cap, and black cheeks. A bird of Cayenne, of which there is a variety, underneath golden-coloured, back green and yellow, head ceruleous, wings and tail green.

Atrata. Shining black: the black tanager of Latham. Found in India.

Mexicana. Black, underneath yellowifh, breaft and rump blueifh: the black and blue titmoufe of Edwards, and black and blue tanager of Latham. The tangara barbadenfis cerulea of Briffon is a variety. Found in Cayenne, Guiana, and New Spain.

Tatao. Violet, black back, yellow rump, green head, and violet breaft and wings: the titmoufe of paradife of Edwards, the paradife tanager of Latham, and the tangara of Briffon, Ray, Willughby, and Buffon. Found in Guiana.

Albirostris. Black, with a fpot on the wings, and tail yellow, and a white beak: the white-billed tanager of Latham. Of this there is a variety. It is an American bird.

Gularis. Black, beneath white, red head, and purple throat: the rouge-cap of Buffon, and red-headed tanager of Latham. Found in Cayenne and Guiana.

Cayennensis. Black, both fides of the breaft and under part of the wings yellow. Found in Brafil, Guiana, and New Spain.

Brasiliensis. Black, under part white, throat and rump blueifh, face and breaft black: the guira-genoia of Marcgrave, the turquin of Buffon, and turquoife tanager of Latham. A Brafil fpecies.

Dominica. Black-fpotted, above brown, and below whitifh: called from the place of its refidence, by Latham, the St. Domingo tanager.

Militaris. Brown; breaft, neck, throat, and fhoulders fanguineous: the military tanager of Latham, and greater bulfinch of Edwards. Found in South America.

Grisea. Grey-olive, under grey, with wings and tail black, grey at their margin. Found in Guiana and Louifiana.

Episcopus. Cinereous, with wings and tail externally blueifh: the bifhop tanager of Latham. Found in Cayenne.

Sayaca. Hoary, with blueifh wings: the fayacu of Marcgrave. Found rarely in Cayenne.

Punctata. Green, pointed with black; under yellowifh-whitifh: the fyacoa of Buffon, fpotted green titmoufe of Edwards, and fpotted tanager of Latham. Found in Cayenne.

Virens. Green, under yellowifh, cheeks and throat black: the green tanager of Latham. Found in New Spain, Peru, and Brafil.

Mississipensis. Wholly red: the Miffiffippi tanager of Latham. Of this fpecies there are two varieties; one found on the river Miffiffippi, and the other in New Spain.

Cristata. Blackifh, golden creft, throat and rump yellow: the houppette of Buffon, and crefted tanager of Latham. Found in Guiana.

Æstiva. Red, bill yellowifh: the fummer red-bird of Catefby and Edwards, and fummer tanager of Pennant and Latham. Found in Carolina and Virginia.

Magna. Olive-brown; under reddifh; legs, front, and temples blueifh; vent-feathers and throat red, and the middle of the throat white: the grand tanager of Latham. Found in Guiana and Cayenne.

Cærulea. Blueifh, black bill, and light-red legs: the blue tanager of Latham. A Cayenne bird.

Variabilis. Green, partly blueifh and partly brown, black band about the eye, quills and tail-feathers black, with green margins: variable tanager of Latham.

 Tricolor.

Tricolor. Green; head, chin, throat, and breaſt pale ſea-colour; black neck-band, head and ſides of the neck golden-green, a large ſpot on the throat, and back black, the breaſt-band blueiſh, the abdomen and vent-feathers yellowiſh-green: the green-headed tanager of Latham. Of this there is a variety.

Guianensis. Green, head cinereous-grey, front and head-band on both ſides from the front to the nape red: the grey-headed tanager of Latham. Found rarely in the foreſts of Guiana.

Nigricollis. Olive, beneath yellow, black throat, golden breaſt, feathers of the wings and tail-feathers brown, with olivaceous margins: the black-throated tanager. Found in Guiana.

Ruficollis. Black and blue, with a large red ſtreak on the throat, and black wings and tail: the rufous-throated tanager of Latham. Found in Jamaica.

Leucocephala. Black and brown, white front, reddiſh throat, purple breaſt and wings, and yellowiſh abdomen and vent-feathers: the quatoztli of Seba. Found in the mountains of Braſil.

Flava. Yellow throat, breaſt and ſpots of the abdomen black, quills and tail-feathers black, ſea-coloured at the margin. This is the guiraperea of Ray and Willughby, and the yellow tanager of Latham. Found in Braſil, of the ſize of a lark.

Amboinensis. Varied with black and blue, black vertex, blueiſh-green rump; cheeks, chin, throat, and breaſt blueiſh; abdomen and vent-feathers white. Found in Amboina, and called calatti.

Canora. Blueiſh, varied with yellow; black tail, white at the apex; and wings partly blueiſh and partly yellow: the xiuhtototl of Fernandes. Found in New Spain.

Sinensis. Olivaceous, beneath yellow, with the quills and tail-feathers black, yellow at their margin: the Chineſe tanager of Latham.

Bonariensis. Black and violet, with a ſlight greeniſh tint in the wings and tail: the violet tanager of Latham.

Atra. Cinereous, with the face, chin, and throat black, (thoſe of the female yellow:) the camail or cravatte of Buffon, and black-faced tanager of Latham. Found in Guiana.

Pileata. Blueiſh-cinereous, beneath ſilvery, with the vertex, temples, and ſides of the neck black, and the ocular ſpot white; the hooded tanager of Latham. Of this the tijepiranga of Ray and Willughby is a variety. Found in Guiana and Braſil.

Melanictera. Above ferruginous, beneath very yellow, head and nape black, wings ſtreaked with white, and tail brown: the black-crowned tanager of Latham. Found on the Caucaſus and in Georgia.

Sibirica. Black, the tips of the down between the ſhoulders and the rump ciliated with white. A Siberian ſpecies.

Atricapilla. Reddiſh and rufous; head, tail, and wings ſhining black, with a roundiſh tail: the mordoré of Buffon, and black-headed tanager of Latham. Found in Guiana.

Striata. Beneath yellow, with a head ſtriated with black and blue, back above blackiſh and beneath golden, quills and tail-feathers black, with a blue margin: the onglet of Buffon, and furrow-clawed tanager of Latham. Found in South America.

Nigerrima. Black, with a white ſpot within the wings: the Guiana tanager of Latham.

Capensis. Above ferruginous-brown, beneath ferruginous, varied with white; the middle of the tail black, its ſides ferruginous-rufeſcent, the bill yellowiſh, the legs black. Found at the Cape of Good Hope.

TANAH, in *Geography*. See San.

TANAIS, the *Don*, in *Ancient Geography*, a large river which had its riſe towards the eaſt, in the territory of the Thyrſagetes, traverſed the country of the Sarmatians, turned its courſe to the ſouth, and diſcharged itſelf in the lake of Mæotis. Its courſe was ſo rapid, that it never froze. Its borders were inhabited by the Sarmatians. The two mouths of the Tanais were diſtant 70 ſtadia from one another, according to Strabo.—Alſo, a town of European Sarmatia, ſituated between the mouths of the river of the ſame name.—Alſo, a river of Africa, which ran into the Mediterranean, towards the ſouth-weſt, at five miles from Thena.

Tanais, in *Mythology*, a divinity peculiar to the Armenians, to whom were conſecrated the ſlaves of both ſexes; and it is alſo ſaid, that the people of better rank offered to him their daughters, who, as ſoon as they were conſecrated to this god, were authoriſed by the law to proſtitute themſelves to the firſt comer, until the time of their marriage. Nor did this conduct by any means prevent the addreſſes of ſuitors.

TANAK Point, in *Geography*, a cape on the north coaſt of Java. S. lat. 6° 24′. E. long. 108° 36′.

TANAKAKA, a ſmall iſland near the ſouth-weſt coaſt of Celebes, belonging to the Dutch. S. lat. 5° 30′. E. long. 119° 42′.

TANALITZKAIA, a fortreſs of Ruſſia, in the government of Upha, at the conflux of the Urdaſim and Ural; 120 miles E. of Orenburg.

TANAMBE, a town on the eaſt coaſt of Madagaſcar. S. lat. 16° 20′. E. long. 50° 20′.

TANAON, a town on the eaſt coaſt of the iſland of Leyta. N. lat. 11° 10′. E. long. 125° 1′.

TANAOSIMA, one of the Japaneſe iſlands, about 100 miles in circumference. N. lat 30° 20′. E. long. 132° 30′.

TANARGUE, a mountain of France, which gives name to a diſtrict in the department of the Ardêche; 20 miles S.W. of Privas.

TANARO, one of the ſix departments of Piedmont, after its union with the French republic, Auguſt 26, 1802, formerly Acqui and Aſti, in N. lat. 44° 45′, weſt of Marengo, containing 197 ſquare leagues, and 311,458 inhabitants. It was divided into three circles, *viz.* Aſti, including 131,910; Acqui, 82,914; and Alba, 96,634 inhabitants. The ſoil is broken by torrents, which form many lakes and marſhes. The ſouth-weſt diſtrict conſiſts of barren ſpots and fruitful vallies; the northern part is fertile, and the hills yield abundance of wine of an inferior quality. The principal products of the department are grain, fruits, and paſtures, with quarries of ſtone, mineral ſprings, &c.

Tanaro, a river of France, which riſes in the mountains near Tenda, paſſes by Coni, Cheraſco, Alba, Aſti, Alexandria, &c. and joins the Po, 3 miles E. of Valenza.

TANARUS, the *Tanaro*, in *Ancient Geography*, a river of Italy, in Liguria, which having been formed by the confluence of many rivers, diſcharged itſelf into the Padus, north-weſt of Dertona.

TANASSERIM, in *Geography*. See Siam.

TANAVELLE, a town of France, in the department of the Cantal; 4 miles W.S.W. of St. Flour.

TANAW, a town of Napaul; 45 miles S.W. of Catmandu.

TANBAY, a town on the E. coaſt of the iſland of Negros. N. lat. 10° 3′. E. long. 123° 1′.

TANCACA, a town of Mexico, in the province of Guaſteca; 50 miles W.S.W. of St. Yago de los Valles.

TANCALE, a town of Mexico, in the province of Guaſteca; 50 miles N.W. of St. Yago de los Valles.

TANCANCHY, a town of Hindooſtan, in Madura; 8 miles S. of Vadagary.

TANCARVILLE, a town of France, in the department of the Lower Seine; 10 miles S.E. of Montevilliers.

TANCHOY, a town of Mexico, in the province of Guaſteca; 35 miles N. of Panuco.

TANCICUY, a town of Mexico, in the province of Guaſteca; 15 miles S.W. of Panuco.

TANCOA, a town of Abyſſinia; 40 miles N.N.E. of Miné.

TANCOBANCA, a river of Perſia, which runs into the ſea, 69 miles W.N.W. of Port Jaques.

TANCOS, a town of Portugal, in Eſtremadura, at the conflux of the Zezare and the Tagus; 21 miles N.E. of Santarem.

TANCUYLABO, a town of Mexico, in the province of Guaſteca; 30 miles S.S.E. of St. Yago de los Valles.

TANCYTOWN, a poſt-town of Maryland; 27 miles N.E. of Frederickſtown.

TANDA, a town on the eaſt coaſt of the iſland of Mindanao. N. lat. 8° 48′. E. long. 126° 12′.

Tanda, or *Tanrah*, a town of Hindooſtan, called ſometimes *Chawaſpour Tanda*, from the original name of the diſtrict in which it was ſituated. It was a ſhort time, in the reign of Shere Shaw, about the year 1540, the capital of Bengal, and became the eſtabliſhed capital under Acbar, about 1580. It is ſituated very near to the ſcite of Gour, on the road leading from it to Rajemal. There is little remaining of this place, ſave the rampart; nor do we know for certain when it was deſerted. In 1659 it was the capital of Bengal, when that ſubah was reduced under Aurungzebe.

TANDAH, a town of Bengal; 12 miles S.E. of Calcutta.

TANDAM, a town of Bootan; 57 miles N. of Dinagepour.

TANDAMORGONG, a town of Hindooſtan, in Goondwanah; 25 miles E. of Nagpour.

TANDEGO, a town of Africa, on the St. Domingo river; 25 miles E. of Farim.

TANDERAGEE, a poſt-town of the county of Armagh, Ireland, which has a good linen market. It is near the Newry canal, and 61 miles N. by W. from Dublin.

TANDLA, a town of Hindooſtan, in Malwa; 72 miles W. of Ougein. N. lat. 23° 5′. E. long. 74° 30′.

TANDOO Baas, a ſmall iſland in the Sooloo Archipelago. N. lat. 5° 8′. E. long. 120° 15′.

Tandoo *Battoo*, a ſmall iſland in the Sooloo Archipelago. N. lat. 5° 9′. E. long. 120° 12′.

TANDORF, a town of Bohemia, in the circle of Konigingratz; 20 miles E. of Konigingratz.

TANE, a river of Finmark, which runs into the Frozen ſea, N. lat. 70° 48′.

Tane. See Taroataihetoomo.

TANG, in *Geography*, a town of Sweden, in Weſt Gothland; 30 miles E.N.E. of Uddevalla.

TANGA, in *Commerce*, a money of account at Goa, in the Eaſt Indies; ſome of which are good, and others bad. A pardo is worth 4 good tangas or 5 bad; 16 good vintins, or 20 bad, are equal to 300 good baſaruccos, or 360 bad. The coins are the St. Thomas, a gold piece of money of nearly the weight of a ducat, which paſſes for 11 good tangas, more or leſs. The ſilver coins are the pardo xeraphin of 5 good tangas, and the common pardo of 4 good tangas. The copper and tin coins are the good and bad baſaruccos. Venetian ſequins are worth 16 good tangas; pagodas, 10 good tangas; and Spaniſh dollars, 550 good baſaruccos, all more or leſs. A good tanga is worth about $7\frac{1}{2}d$ ſterling; a pardo, 2*s*. 6*d*.; and a xeraphin, 3*s*. $3\frac{1}{2}d$. ſterling nearly. Kelly's Cambiſt.

TANGALA, in *Geography*, a ſmall iſland in the Eaſt Indian ſea, near the S. coaſt of Java. S. lat. 8° 20′. E. long. 111° 45′.

TANGALE, a town of the iſland of Ceylon; 92 miles S. of Candy.

TANGARAC, in *Botany*, a poiſonous Braſilian plant; but the root, ſays Piſo, is an antidote to the leaves, flowers, and fruit. Boyle's Works, Abr. vol. i. p. 14.

TANGAWA, in *Geography*, a town of Japan, in the iſland of Ximo; 30 miles S.E. of Kokura.

TANGE, a town of Sweden, in Weſt Gothland; 21 miles N. of Gotheburg.

TANGEN, a town of Norway, in the province of Aggerhuus; 2 miles E. of Stromſoe.

TANGENE, a town of Sweden, in Weſt Gothland; 26 miles E. of Uddevalla.

TANGENT, in *Geometry*, a right line which touches a circle, that is, meets it in ſuch manner, as that, though infinitely produced, it would never cut the ſame; that is, never come within the circumference.

Thus the line A D (*Plate* XV. *Geometry*, *fig*. 3.) is a tangent to the circle in D.

It is demonſtrated in geometry; 1. That if a tangent, A D, and a ſecant, A B, be both drawn from the ſame point, A; the ſquare of the tangent will be equal to the rectangle, under the whole ſecant A B, and that portion of it, A C, which falls without the circle.

2. That if two tangents, A D, A E, be drawn to the ſame circle from the ſame point A, they will be equal to each other.

As a right line is the tangent of a circle, when it touches the circle ſo cloſely, that no right line can be drawn through the point of contact between it and the arc, or within the angle of contact that is formed by them; ſo in general, when any right line touches any arc of a curve, in ſuch a manner that no right line can be drawn through the point of contact, betwixt the right line and the arc, or within the angle of contact that is formed by them, then is that line the tangent of the curve at the ſaid point.

The tangent of an arc is the right line that admits the poſition of all the ſecants that can paſs through the point of contact, though, ſtrictly ſpeaking, it is no ſecant. Macl. Flux. art. 181. 505.

Tangent, in *Trigonometry*.—*A tangent of an arc* is a right line, raiſed perpendicularly on the extreme of the diameter, and continued to a point, where it is cut by a ſecant, that is, by a line drawn from the centre through the extremity of the arc of which it is a tangent.

A tangent of an arc A (*Plate* II. *Trigonom. fig*. 13.) is a part of a tangent of a circle (that is, of a right line, which touches a circle without cutting it), intercepted between two right lines drawn from the centre C, through the extremes of the arc E and A.

Hence the tangent F E is perpendicular to the radius E C.

And hence the tangent F E is the tangent of the angle A C E, as alſo of that of A C I; ſo that two adjacent angles have only the ſame common tangent.

TANGENT, *Co*, or *Tangent of the Complement*, is the tangent of an arc, which is the complement of another arc to a quadrant.

Thus a tangent of the arc A H, is the co-tangent of the arc A E, or the tangent of the complement of the arc A E.

To find the length of the tangent of any arc, the ſine of the arc being given: ſuppoſe the arc A E, the given ſine A D, and the tangent required E F. Since both the ſine and tangent are perpendicular to the radius E C, they are parallel to each other. Wherefore as the coſine D C is to the ſine A D, ſo is the whole ſine to the tangent E F. See SINE.

Hence, a canon of ſines being had, a canon of tangents is eaſily conſtructed from it.

TANGENTS, *Artificial*, are the logarithms of the tangents of arcs.

TANGENTS, *Line of*, is a line uſually placed on the ſector, and Gunter's ſcale; the deſcription and uſes of which, ſee under SECTOR.

TANGENT *of a Conic Section*, as of a parabola, is a right line, which only touches or meets the curve in one point, and does not cut or enter within the curve. See CONIC *Sections*.

TANGENTS, *Method of*, is a method of drawing tangents to any algebraical curve, or of determining the magnitude of the tangent and ſub-tangent, the equation to the curve being given.

The method of tangents is nearly related to that of *maxima et minima*; and the ſame authors, who in the early ſtate of algebra attempted one of thoſe caſes, never failed of touching alſo on the other. Hence we have the methods of Deſcartes, Fermat, Roberval, Hudde, &c. We have already explained under the article MAXIMA *et Minima*, the ſeveral methods of theſe authors relating to the latter ſubject; and as their methods of tangents differ in no reſpect from this, we ſhall not repeat them again in this place, but merely explain the principle which led to ſo intimate a connection between the two problems.

Deſcartes' Method of Tangents.—It has been ſhewn under the article above referred to, that Deſcartes' method of maxima and minima, depended upon his making two roots of his equation equal to each other, and the ſame principle led him alſo to his problem of tangents.

Let us conceive, for example, a curve A B b, (*Plate* XIV. *Analyſis*, *fig.* 16.) deſcribed on an axis A C; and from any point in this axis, C, as a centre, let there be deſcribed a circle, which ſhall cut the curve at leaſt in two points, as B, b; from theſe draw two ordinates, which will neceſſarily be common both to the circle and curve: let us now imagine the radius of this circle to decreaſe, while its centre remains fixed; and it is obvious that thus the two points of interſection will approach each other, and finally coincide, in which caſe the circle will touch the curve at the point E, and the tangent at that point will be common to both, and perpendicular to the radius of the circle at that point. Thus the problem of determining the tangent to a curve, is reduced to finding the poſition of a perpendicular to the curve, drawn from any point in its axis. In order to effect this, Deſcartes ſought, in a general manner, the points of interſection in the curve made by a circle deſcribed with a given radius from a given point in the axis. He thus arrived at an equation, which, in the caſe of two interſections, ought to contain two unequal roots, expreſſing the diſtance of the two ordinates from the vertex of the curve. But when the two points of interſection are united in one, as in the caſe of the circle touching the curve, then the two roots of the equation are neceſſarily equal to each other. His object, therefore, was, in the equation firſt obtained, and of which the co-efficients were indeterminate, to give them ſuch values, that the two roots ſhould be equal; for which purpoſe, he compared the propoſed equation with an equation of the ſame degree, having two equal roots; and hence, by equating the co-efficients, obtained the value of thoſe in his firſt equation.

In order to illuſtrate this, let A B b (*fig.* 16.) be a parabola, and B b a circle. Make C A $= a$, A D $= x$, the radius C B $= r$, then C D $= a - x$; and ſince the ordinate B D belongs to the circle, we have

$$y^2 = r^2 - \mathrm{CD}^2 = r^2 - (a - x)^2 = r^2 - a^2 + 2ax - x^2.$$

But the ſame ordinate belonging alſo to the parabola, we have from the known property of that curve, $y^2 = px$, p being the parameter; therefore

$$r^2 - a^2 + 2ax - x^2 = px, \text{ or}$$
$$x^2 + (p - 2a)x + (a^2 - r^2) = 0,$$

which, being an equation of the ſecond degree, muſt neceſſarily have two roots, or values, of x, anſwering to the two abſciſſes A D, A d: for we ſhould arrive at the ſame concluſion, if our equation had been deduced with reference to the point b; and it is obvious that theſe roots depend entirely upon the relation of the co-efficients $(p - 2a)$ and $(a^2 - r^2)$, or upon the ratio of the quantities a, p, and r, to each other; and, conſequently, ſuch values may be given to theſe quantities, that the two values of x may be equal.

In order to find this ratio, Deſcartes formed an equation of the ſecond degree, having two equal roots, as $x^2 - 2ex + e^2 = 0$, *viz.* $(x - e)(x - e) = 0$; and comparing this with that found above, he obtained the equation $x - a =$ C D $= \frac{1}{2}p$, which ſhews that in the parabola, the ſubnormal is equal to half the parameter; whence it alſo follows, that the ſub-tangent is equal to double the abſciſs, which is the known property of the curve.

Deſcartes had alſo another method for tangents, a little different from the above in practice, although it was the ſame in principle; thus he conceived a right line to revolve about a fixed point in the axis of the curve produced, which at firſt ſhould cut the curve in a certain number of points, but by its revolution, theſe points of interſection approaching each other would finally coincide, and thus the revolving line become a tangent to the curve. For this purpoſe he alſo firſt obtained the general equation, which he afterwards equated with another having two equal roots, and thus determined the ſeveral relations of his indeterminate co-efficients, exactly as in the caſe above given.

Fermat's Method of Tangents.—It will be found by comparing the above method of tangents of Deſcartes, with that of his maxima and minima, that the two ultimately depend upon the ſame principle, *viz.* of making two roots of an equation equal to each other; and the coincidence of Fermat's methods for theſe two problems is ſtill more obvious; in fact, he ſcarcely treats of them as diſtinct caſes, but refers immediately for the ſolution of the caſe of tangents to that of his maxima and minima. In order, ſays this author, that a line may be a tangent to a curve, as for example to the parabola A B b, at the point b, (*fig.* 17.) it is evident that every ordinate, except B C, will meet that tangent beyond the curve, as in C. Thus the ratio of B C^2 : ce^2, which is the ſame as C D^2 : c D^2, will be leſs than that of C B^2 : cb^2, or than that of C A to c A; but if we ſuppoſe theſe ratios to be the ſame, and conſequently the diſtance c C to vaniſh, the points B, b, will coincide, and we ſhall have an equation, which, treated in the ſame manner as in his method *de maximis et minimis*, will give the ratio of C D : C A.

As

As to the methods propoſed by Hudde, Roberval, Huygens, &c. they differ from thoſe given above, only in the ſame manner as in their methods of maxima and minima; it would therefore be uſeleſs to deſcribe them in this place.

Barrow's Method of Tangents.—It is obvious from what is ſaid above, and what has been ſtated under the article MAXIMA *et Minima*, that both the method of tangents, and that for the greateſt and leaſt ordinates, were very nearly related to the preſent fluxional way of treating the ſame ſubjects; but with regard to tangents, a ſtill nearer approach was made by Dr. Barrow.

This accurate geometer conſidered the little triangle formed by the difference of the two ordinates, their diſtance from each other, and the indefinitely ſmall part of the curve, as ſimilar to that which is formed by the ordinate, the tangent, and ſub-tangent. He then ſought by the equation of the curve, the ratio of the two ſides ba, Ba, (*fig.* 18.) of the triangle Bba, when the difference of the ordinates is infinitely little; and then ſaid, as $ba : Ba ::$ ordinate BP : the ſub-tangent TP.

In the caſe of the parabola, for example, whoſe equation is $y^2 = px$; ſuppoſing Pp the increaſe of the abſciſs $= e$, and ba the correſponding increaſe of the ordinate $y = a$; then the equation for the ordinate pb becomes

$$(y + a)^2 = p\,(x + e), \text{ or}$$
$$y^2 + 2ay + a^2 = px + pe.$$

Subtracting from both ſides $y^2 = px$, there remains
$$2ay + a^2 = pe.$$

Alſo a being itſelf infinitely ſmall, its ſquare a^2 may be entirely neglected, and there reſults $2ay = pe$; therefore $a : e :: p : 2y$; but $a = ba$, and $e = Ba$, alſo $y = \sqrt{px}$; therefore, from the propoſition ſtated above, *viz.*

$$ab : aB :: \text{ordinate} : \text{ſubtangent},$$

we have

$$p : 2\sqrt{px} :: \sqrt{px} : 2x, \text{ the ſubtangent required.}$$

Such were the principles employed in the ſolution of this intereſting problem prior to the brilliant diſcovery of the fluxional calculus, which from its generality ſupplanted them all, and they are now therefore merely matters of hiſtorical curioſity; but as they exhibit the flow and progreſſive advances of genius and ſcience towards an ultimate ſtate of perfection, they are highly deſerving of the attention of the mathematician, who will find in them much to admire; they will at the ſame time enable him duly to appreciate the tranſcendant talents of that great philoſopher, who formed out of them one general and comprehenſive principle of ſolution, which will apply with equal facility to algebraical curves of every order.

The Method of Tangents according to the Doctrine of Fluxions.—Its uſe is very great in *Geometry;* becauſe in determining the tangents of curves, we determine at the ſame time the quadrature of the curvilinear ſpaces: on which account it well deſerves to be here particularly inſiſted on.

To find the Sub-tangent in any algebraic Curve.—Let the propoſed curve be AMO (*Plate* XIV. *Anal. fig.* 19.), and the right line TMQ a tangent to it at the point M; let the ſemiordinate pm be infinitely near another PM, and MR parallel to AH; then the relative celerities of the point M, moving along the curve from A towards O, in the directions MR and PM, with which AP and PM increaſe in this poſition, will be truly expreſſed by MR and Rm; but the celerities by which quantities increaſe are as the fluxions of thoſe quantities; therefore (Mm being the fluxion of the curve line AM) MR and Rm are the correſponding fluxions of the abſciſs AP, and the ordinate PM; and, becauſe the triangles MmR and TMP are ſimilar, we have Rm : MR :: PM : PT. Let, therefore, the abſciſs AP be put $= x$, and the ordinate PM $= y$, and we ſhall have $\dot{y} : \dot{x} :: y : \frac{y\dot{x}}{\dot{y}} = $ PT. By means of this general expreſſion for the ſub-tangent, and the equation of the curve expreſſing the relation between x and y, the ratio of the fluxions $\dot{x}$ and $\dot{y}$ will be found, and from thence the length of the ſub-tangent; whence the tangent itſelf may be eaſily determined and drawn. This we ſhall illuſtrate in the following examples:

I. The equation defining a circle is $ax - xx = y^2$; and by taking the fluxions of theſe quantities, $a\dot{x} - 2x\dot{x} = 2y\dot{y}$; conſequently $\frac{\dot{x}}{\dot{y}} = \frac{2y}{a - 2x} = \frac{y}{\frac{1}{2}a - x}$; and, multiplying both ſides by y, we have $\frac{y\dot{x}}{\dot{y}} = \frac{y^2}{\frac{1}{2}a - x} =$ the ſub-tangent PT (ſee *fig.* 20.); whence $(\frac{1}{2}a - x)$, or AC − AP, *i.e.* CP : (y) PM :: (y) PM : PT; a property of the circle deduced from the principles of common geometry.

II. The equation defining the common parabola is $ax = y^2$, a being the parameter, x the abſciſs, and y the ordinate; hence $a\dot{x} = 2y\dot{y}$, and $\frac{\dot{x}}{\dot{y}} = \frac{2y}{a}$; conſequently, $\frac{y\dot{x}}{\dot{y}} = \frac{2y^2}{a} = \frac{2ax}{a} = 2x$; therefore the ſub-tangent PT (*fig.* 19.) is the double of its correſponding abſciſs AP; which is a well-known property of the parabola.

III. The general equation for parabolas of any kind being $a^m x^n = y^{m+n}$; we have $n a^m x^{n-1}\dot{x} = \overline{m+n} \times y^{m+n-1}\dot{y}$; and, therefore, $\frac{\dot{x}}{\dot{y}} = \frac{\overline{m+n} \times y^{m+n-1}}{n a^m x^{n-1}}$; whence $\frac{y\dot{x}}{\dot{y}} = \frac{\overline{m+n} \times y^{m+n}}{n a^m x^{n-1}} = \frac{\overline{m+n} \times a^m x^n}{n a^m x^{n-1}}$ (becauſe $y^{m+n} = a^m x^n$) $= \frac{\overline{m+n}}{n} \times x =$ the true value of the ſub-tangent; which, therefore, is to the abſciſs in the conſtant ratio of $m + n$ to n.

IV. The equation defining an ellipſis is $b^2 \times \overline{ax - x^2} = a^2 y^2$, AP (*fig.* 21.) being $= x$, MP $= y$, AB $= a$, and the leſſer axis $= b$; for by the property of the ellipſis, we have $a^2 : b^2 :: \overline{ax - x^2}$ (AP × PB) : y^2 (MP²); and, therefore, $b^2 \times \overline{ax - x^2} = a^2 y^2$; whence $b^2 \times \overline{a\dot{x} - 2x\dot{x}} = 2a^2 y\dot{y}$, and $\frac{\dot{x}}{\dot{y}} = \frac{2a^2 y}{b^2 \times \overline{a - 2x}}$; and, conſequently, the ſub-tangent PT $\left(\frac{y\dot{x}}{\dot{y}}\right) = \frac{2a^2y^2}{b^2 \times \overline{a - 2x}} = \frac{a^2y^2}{b^2 \times \overline{\frac{1}{2}a - x}} = \frac{b^2 \times \overline{ax - x^2}}{b^2 \times \overline{\frac{1}{2}a - x}} = \frac{\overline{ax - x^2}}{\overline{\frac{1}{2}a - x}}$: whence the point T being given, through which the tangent muſt paſs, the tangent itſelf may be drawn.

V. Becauſe the equation, exhibiting the nature of all

kinds

kinds of ellipſes, (putting a and c for the two principal diameters) is $\overline{a-x}|^m \times x^n = \frac{c}{a} \times y^{m+n}$, we ſhall have $-m\dot{x} \times \overline{a-x}|^{m-1} \times x^n + n\dot{x}x^{n-1} \times \overline{a-x}|^m = \frac{c}{a} \times \overline{m+n} \times y^{m+n-1}\dot{y}$; and, therefore, $\frac{y\dot{x}}{\dot{y}} =$

$$\frac{\frac{c}{a} \times \overline{m+n} \times y^{m+n}}{-m \times \overline{a-x}|^{m-1} \times x^n + nx^{n-1} \times \overline{a-x}|^m} =$$

$$\frac{\overline{m+n} \times \overline{a-x}|^m \times x^n}{-mx^n \times \overline{a-x}|^{m-1} + nx^{n-1} \times \overline{a-x}|^m}$$ (becauſe $\frac{c}{a} \times y^{m+n} = \overline{a-x}|^m \times x^n$) $= \frac{\overline{m+n} \times \overline{a-x} \times x}{-mx + n \times \overline{a-x}} = \frac{\overline{m+n} \times \overline{ax-x^2}}{na - \overline{n+m} \times x}$ = the ſubtangent required.

VI. The equation defining the hyperbola is $c^2 \times \overline{ax + x^2} = a^2y^2$, a and c being uſed to denote the two principal diameters; whence we have, $c^2 \times \overline{a\dot{x} + 2x\dot{x}} = 2a^2y\dot{y}$; conſequently $\frac{\dot{x}}{\dot{y}} = \frac{a^2y}{c^2 \times \overline{\frac{1}{2}a + x}}$; and $\frac{y\dot{x}}{\dot{y}} = \frac{a^2y^2}{c^2 \times \overline{\frac{1}{2}a + x}} = \frac{c^2 \times \overline{ax + x^2}}{c^2 \times \overline{\frac{1}{2}a + x}} = \frac{\overline{ax + x^2}}{\frac{1}{2}a + x}$ = the ſubtangent; whence the diſtance of the point of interſection of the tangent and axis from the vertex, which is equal to the difference of the ſub-tangent and abſciſs, may be found; for $\frac{ax + x^2}{\frac{1}{2}a - x} - x = \frac{\frac{1}{2}ax}{\frac{1}{2}a - x}$; and, therefore, that point being given, the tangent may be eaſily drawn.

The manner of drawing tangents to all ſorts of hyperbolas univerſally, will be the ſame as in the ellipſes, the equations of the two kinds of curves differing in nothing but their ſigns.

After the manner above explained, the ſubtangent, in curves whoſe abſciſſes are right lines, may be determined; but if the abſciſs, or line terminating the ordinate, on the lower part, be another curve, then the tangent may be drawn as in the following example.

VII. Let the curve B R F (*Plate* XIV. *Anal. fig.* 22.) be a cycloid; whoſe abſciſs is here ſuppoſed to be the ſemicircle B P A, to which let the tangent P T be drawn, as above. Moreover, let r R H be a tangent to the cycloid, at the correſponding point R, and let G R e be parallel to T P v; putting the arc, or abſciſs, B P $= z$, its ordinate P R $= y$, A F $= b$, and B P A $= c$; then, by the property of the cycloid, we ſhall have c (B P A) : b (A F :: z (B P) : y (P R)); therefore $y = \frac{bz}{c}$, and $\dot{y} = \frac{b\dot{z}}{c} = re$. But by ſimilar triangles, re ($\dot{y}$) : R e (= P v $= \dot{z}$) :: P R (y) : P H $= \frac{y\dot{z}}{\dot{y}} = z$ (becauſe $y = \frac{bz}{c}$); conſequently, if in the right line P T, there be taken P H equal to the arc P B, we ſhall have a point H, through which the tangent of the cycloid muſt paſs.

The preceding examples relate to curves, whoſe ordinates are parallel to each other. We ſhall now briefly illuſtrate the method of drawing tangents to curves of the ſpiral kind, all whoſe ordinates iſſue from a point: ſuch as the ſpiral B A G (*Plate* XV. *Anal. fig.* 1.) whoſe ordinates, C B, C A, C G, are referred to the point C, called the centre of the ſpiral. Let S A N be a tangent to the ſpiral at any point A, and let C T be perpendicular to it, and let the arc C B A (conſidered as variable by the motion of A towards G) be denoted by z, and the ordinate C A by y. Then $\dot{z} : \dot{y}$ :: A C (y) : A T $= \frac{y\dot{y}}{\dot{z}}$. Hence, if upon C A, as a diameter, a ſemicircle be deſcribed, and in it, from A, a right line equal to $\frac{y\dot{y}}{\dot{z}}$ be inſcribed, that right line will be a tangent to the ſpiral at the point A.

VIII. Let the nature of the curve C B A be ſuch, that the arc C B A may be, always, to its correſponding ordinate C A in a conſtant ratio, *viz.* as a to b: then, becauſe $z : y :: a : b$, we have $z = \frac{ay}{b}$, and $\dot{z} = \frac{a\dot{y}}{b}$; and, conſequently, A T $\left(\frac{y\dot{y}}{\dot{z}}\right) = \frac{by}{a} = \frac{b}{a} \times$ A C: therefore A C and A T being in a conſtant ratio, the angle C A T muſt alſo be invariable; which is a known property of the logarithmic ſpiral.

IX. Let B A A (*fig.* 2.) be the ſpiral of Archimedes; whoſe nature is ſuch, that the part E A of the generating ordinate, intercepted by the ſpiral, and a circle, B E D, deſcribed about the ſame centre C, is always in a conſtant ratio to the correſponding arc B E of that circle. Suppoſe A n perpendicular to A C; B C $= c$, C A $= y$, and the given ratio of A E to B E, that of b to c; then $b : c :: y - c$ (A E) : $\frac{cy - cc}{b}$ = B E; whoſe fluxion is $= \frac{c\dot{y}}{b}$. If the right line C E A a be ſuppoſed to revolve about the centre C, the angular celerity of the generating point A, in the perpendicular direction A n, will be to that of E, as A C to E C; and as the latter of theſe celerities is expreſſed by $\frac{c\dot{y}}{b}$, the former will be expreſſed by $\frac{y}{c} \times \frac{c\dot{y}}{b}$, or $\frac{y\dot{y}}{b}$; which is to $\dot{y}$, the celerity of A in the direction A a, as $\frac{y}{b}$ to unit, or as y to b. Conſequently, C T and A T are in the ſame ratio, and A C : C T :: $\sqrt{yy + bb}$: y; and A C : A T :: $\sqrt{yy + bb} : b$; whence C T and A T are given, equal to $\frac{y^2}{\sqrt{yy + bb}}$, and $\frac{by}{\sqrt{yy + bb}}$ reſpectively; from either of which expreſſions the tangent A T may be drawn; and, in the ſame manner, may the poſition of the tangent of any other ſpiral be determined. Simpſon's Flux. vol. i. ſect. 3.

As to the method of inveſtigating tangents by fluxions, ſee Macl. Flux. book i. c. 7. where it is demonſtrated independently of infiniteſimals.

To

To determine the tangents of curves, fuppofed to be defcribed by the interfections of right lines revolving about given poles, fee Mr. Maclaurin's Fluxions, art. 210, feq. In finding the tangents of curves by the method of infinitefimal differences, it has been objected that the conclufion is found by a double error. 1. By taking the curve for a polygon of an infinite number of fides. 2. By the falfe rule for taking the differential of a power. But there is no need of fuch fuppofitions in the method of fluxions, for it may be geometrically demonftrated, that the fluxions of the bafe, ordinate, and curve, are in the fame proportion to each other, as the fides of a triangle refpectively parallel to the bafe, ordinate, and tangent. When the bafe is fuppofed to flow uniformly, if the curve be convex towards the bafe, the ordinate and curve increafe with accelerated motions; but their fluxions at any term are the fame as if the point which defcribes the curve had proceeded uniformly from that term in the tangent. Any farther increment which the ordinate or curve acquires, is to be imputed to the acceleration of the motions with which they flow. See Maclaurin's Fluxions, book i. chap. vii. and viii.

Any two arcs of curve lines touch together, when the fame right line is the tangent of both at the fame point. But when they are applied to each other in this manner, they never perfectly coincide, unlefs they be fimilar arcs of fimilar and equal figures.

In the Philofophical Tranfactions, we have the following method of drawing tangents to all geometrical curves, without any labour or calculation, by M. Slufius.

Suppofe a curve, as D Q (*Plate* XV. *Anal. fig.* 3.) whofe points are all referrible to any right line given, as E A B, whether that right line be the diameter or not; or whether there be more given right lines than one, provided their powers do but come into the equation. In all his equations, he puts v for the line D A, y for B A; and for E B, and the other given lines, he puts b, d, &c. that is, always confonants only.

Then, fuppofing D C to be drawn touching the curve in D, and meeting with E B produced in C, he calls the fought line, C A, by the name of a.

To find which, he gives this general method. 1. Reject out of the equation all members which have not either v or y in them; then put all thofe that have y on one fide, and all thofe which have v on the other; with their figns + or −; and the latter, for diftinction and eafe fake, he calls the right, the former the left fide. 2. On the right fide, let there be prefixed to each member the exponent of the power, which v hath there; or, which is the fame thing, let that exponent be multiplied into all the members. 3. Let the fame be done alfo on the left fide, multiplying each member there by the power of the exponent of y; adding this moreover, that one y muft, in each part, be changed into a. This done, the equation thus reformed will fhew the method of drawing the required tangent to the point D; for, that being given, as alfo y, v, and the other quantities expreffed by confonants, a cannot be unknown. Suppofe an equation $by - yy = vv$, in which E B is called b; B A $= y$, D A $= v$, and let a, or A C, be required fo as to find the point C, from whence C D being drawn, fhall be a true tangent to that curve Q D in D. In this example, nothing is to be rejected out of the equation, becaufe y or v are in each member: it is alfo difpofed, as required by the rule 1; to each part, therefore, there muft be prefixed the exponent of the powers of y or v, as in the rule 2; and on the left fide, let one y be changed into a, and then the equation will be in this form, $ba - 2ya = 2vv$, which equation reduced, gives eafily the value of $a = \frac{2vv}{b - 2y} =$ A C. And fo the point C is found, from which the tangent D C may be drawn.

To determine which way the tangent is to be drawn, whether towards B or E, he directs to confider the numerator and denominator of the fraction. For, 1. If in both parts of the fraction all the figns are affirmative; or if the affirmative ones are more in number; then the tangent is to run towards B. 2. If the affirmative quantities are greater than the negative in the numerator, but equal to thofe in the denominator, the right line drawn through D, and touching the curve in that point, will be parallel to A B; for in this cafe a is of an infinite length. 3. If in both parts of the fraction the affirmative quantities are lefs than the negative, changing all the figns, the tangent muft be drawn now alfo towards B; for this cafe, after the change, comes to be the fame as the firft. 4. If the affirmative quantities are greater than the negative in the denominator, but in the numerator are lefs, or *vice verfâ*, then changing the figns in that part of the fraction where they are lefs, the tangent muft be drawn a contrary way; that is, A C muft be taken towards E. 5. But whenever the affirmative and negative quantities are equal in the numerator, let them be how they will in the denominator, a will vanifh into nothing: and, confequently, the tangent is either A D itfelf, or E A, or parallel to it; as will eafily be found by the data. This he gives plain examples of, in reference to the circle, thus: let there be a femicircle, whofe diameter is E B; in which there is given any point, as D (*fig.* 4.), from which the perpendicular D A is let fall to the diameter. Let D A $= v$, B A $= y$, B E $= b$: then the equation will be $by - yy = vv$, and drawing the tangent D C, we have A C, or $a = \frac{2vv}{b - 2y}$. Now, if b be greater than $2y$, the tangent muft be drawn towards B; if lefs, towards E; if it be equal to it, it will be parallel to E B, as was faid in the firft, fecond, and fourth rules.

Let there be another femicircle inverted, as N D D (*fig.* 5.), the points of whofe periphery are referred to the right line B E, parallel and equal to the diameter. Let N B be called d, and all things elfe as before; then the equation will be $by - yy = dd + vv - 2dv$; which being managed according to his rules, you have $a = \frac{2vv - 2dv}{b - 2y}$.

Now, fince v here is fuppofed to be always lefs than d; if b be greater than $2y$, then the tangent muft be drawn towards E; if equal, it will be parallel to B E; if lefs, changing all the figns, the tangent muft be drawn towards B, as by rules fourth, fifth, and third. But there could be no tangent drawn, or at leaft E B would be it, if N B had been taken equal to the diameter. Let there be another femicircle, whofe diameter N B (*fig.* 6.) is perpendicular to E B, and to which its points are fuppofed to be referred.

Let N B be called b, and all things elfe as above; the equation will be $yy = bv - vv$, and $a = \frac{bv - 2vv}{2y}$. If, now, b be greater than $2v$, the tangent muft be drawn towards B; if lefs, towards E; if equal, D A will be the tangent, as appears by rules fourth and fifth.

Tangents, *Inverfe Method of*, is a method of finding the equation, or the conftruction, of any curve; from the tangent

gent of any other line, whose determination depends on the tangent given.

This method is also one of the great results of the new *calculus integralis*.

Its application we shall give in what follows. The fluxional expressions of the tangent, sub-tangent, &c. being delivered under the last article, if you make the given value equal to the fluxional expression, and either sum up the fluxional equation, or, if that cannot be, construct it, the curve required is had. For example:

1. *To find the curve-line, whose sub-tangent* $= \frac{2y^2}{a}$.

Since the sub-tangent of an algebraic line is $= \frac{y\dot{x}}{\dot{y}}$; we have $\frac{y\dot{x}}{\dot{y}} = \frac{2y^2}{a}$, and $ay\dot{x} = 2y^2\dot{y}$, and $a\dot{x} = 2y\dot{y}$; therefore (taking the fluents by the inverse method of fluxions) $ax = y^2$.

The curve sought, therefore, is a parabola; whose construction is shewn under PARABOLA.

2. *To find the curve, whose sub-tangent is a third proportional to* $\frac{1}{2}a - x$ and y. Since $\frac{1}{2}a - x : y :: y : \frac{y\dot{x}}{\dot{y}}$, we have $\frac{1}{2}a - x : y \; (:: y\dot{y} : y\dot{x}) :: \dot{y} : \dot{x}$; consequently $\frac{1}{2}a\dot{x} - x\dot{x} = y\dot{y}$, and, taking the fluents, $\frac{1}{2}ax - \frac{1}{2}x^2 = \frac{1}{2}y^2$, i. e. $ax - x^2 = y^2$. The curve sought is, therefore, a circle.

3. *To find a line, wherein the sub-tangent is equal to the semiordinate.* Since $\frac{y\dot{x}}{\dot{y}} = y$; $y\dot{x} = y\dot{y}$, and $\dot{x} = \dot{y}$; therefore $x = y$.

Hence it appears, that the line sought is a right line, which respects the cathetus of an equicrural triangle, as an axis, or the hypothenuse of an equicrural rectangled triangle. If x had been taken for the arc of a circle, the line sought had been a cycloid.

TANGER, in *Geography*, a river of Westphalia, which runs into the Elbe at Tangermunde.

TANGERE, *Noli me*. See NOLI.

TANGERMUNDE, in *Geography*, a town of Westphalia, in the Old Mark of Brandenburg, situated on the Elbe, where vessels pay a toll: the chief trade of the town is brewing; 24 miles N. of Magdeburg. N. lat. 52° 32′. E. long. 12° 2′.

TANGHOO, or TENHOA, a capital of a province of Tonquin, situated on a small river near the W. coast of the gulf of Cochinchina. Rice and cattle constitute the chief riches of the province. The town is called "Cuabang." N. lat. 19° 40′.

TANGIA, a town of Arabia, in the province of Hedsjas; 50 miles W.N.W. of El Catif.

TANGIBLE. See TACTILE.

TANGIER ISLANDS, in *Geography*, several islands of the Chesapeak, near the coast of Maryland, opposite to the mouth of the Potomack. N. lat. 38° 12′. W. long. 76° 12′.

TANGIERS, anciently called *Tinjis* and *Tingia*, and now by the Arabs *Tinjiah*, a town of Africa, in Fez, situated at the western mouth of the straits of Gibraltar, about a day's journey from Tetuan. This town was first possessed by the Romans, who took it under Sertorius; next by the Goths; and it was surrendered by count Julian to the Saracens. It was taken in 1471 by Alonso, king of Portugal; and given to Charles II., king of England, in 1662, as a marriage portion with the princess Catherine of Portugal. The English abandoned it in 1684, after destroying the mole and fortifications. Although now almost in ruins, it still retains some batteries, in tolerable condition, facing the bay; at the bottom of which are a river, and the remains of the bridge of Old Tangiers; but on account of the accumulated sand, the bridge, if it had continued, as well as the river, would be useless. The bay of Tangiers, independently of Ceuta, is so situated, being the narrowest part of the straits, that it must be favourable to Moorish piracy; but Tangiers can never be a commercial town, as it has few productions in its vicinity; the Spaniards, however, formerly shipped in this place, eggs, vegetables, and some fruits; and the English at present obtain supplies for their garrison at Gibraltar. The bay of Tangiers is not very safe when the wind is in the west, having been encumbered by the ruins of the mole and fortification, as the cables are liable to be rent, and the ships to be driven on shore. The best anchorage for frigates and the larger vessels, is at the eastern point, whence they may easily sail whatever way the wind sets: however, the bay is only dangerous in winter; 108 miles N.N.W. of Fez, and 38 W.S.W. of Gibraltar. N. lat. 35° 42′. W. long. 5° 50′. Chenier's Morocco.

TANGLAKE, in *Ichthyology*, the viviparous blenny of Pennant; the mustela vivipara of Willughby, Ray, &c.; and the blennius viviparus of the Linnean system.

TANGMEW, in *Geography*, a town of the Birman empire, on the right bank of the Ava; 10 miles N.W. of Prome.

TANGO, a town of Japan, in the island of Niphon; 65 miles S.W. of Meaco.

TANGOLOTANGO, a seaport town of Mexico, in the province of Guaxaca, near the gulf of Mexico; 100 miles S.S.E. of Guaxaca. N. lat. 16° 8′. W. long. 97° 36′.

TANGONE, a town of New York; 9 miles W. of Kingston.

TANGOUZI, a town on the east coast of Madagascar. S. lat. 19° 5′. E. long. 49° 12′.

TANGOUZLIO, a town of Asiatic Turkey, in Natolia; 70 miles E.S.E. of Smyrna.

TANGU, a city of Pegu, and capital of a province which was formerly a kingdom; situated a considerable distance to the north of Pegu.

TANGUEY, or TONGUEY, a town of Chili, on the coast. S. lat. 30° 30′.

TANGUIA, a river of Chinese Tartary, which rises near mount Ilha, and running nearly south, falls into the river Ya-lou-kiang.

TANGULAW, a small island in the Spanish Main, near the Mosquito shore. N. lat. 13° 35′. W. long. 83° 55′.

TANGUT. See THIBET.

TANG-YANG, a lake of China, about thirty miles in circumference; 32 miles N. of Hoai-ngan.

TANIALA, a town of Hindoostan, in Palnaud; 25 miles E.N.E. of Timerycotta.

TANIBOUCA, in *Botany*, a Caribæan name, to be tolerated only till the genus is properly understood.—Aubl. Guian. 448. Juss. 76.—Class and order, *Decandria Monogynia*. Nat. Ord. *Elæagni?* Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, bell-shaped, internally downy; its limb in five deep, roundish, acute segments. *Cor.* none. *Stam.* Filaments ten, thread-shaped, inserted into the tube of the calyx, as long as its limb; anthers oval, of two lobes. *Pist.* Germen inferior, roundish; style solitary, thread-shaped, curved; stigma simple. *Peric.* . . . .

Eff. Ch. Calyx bell-fhaped, five-cleft, fuperior. Corolla none. Fruit . . . . .

1. T. *guianenfis.* Aubl. t. 178.—Native of marfhes in Guiana, flowering in May. A *tree*, whofe trunk is twenty feet, or more, in height, and two feet in diameter, with a whitifh, light and brittle wood; the bark greyifh. *Branches* fpreading every way; their young fhoots leafy at the ends. *Leaves* deciduous, alternate, ftalked, obovate, pointed, entire, coriaceous, fmooth; the largeft feven inches long, and three broad. *Spikes* axillary, folitary, ftalked, about three or four inches long, of many fmall, alternate, greenifh, fragrant *flowers*, clothed internally with white hairs. Aublet not having met with the *fruit*, nor having been able to determine any thing of the internal ftructure of the minute *germen*, we are left in great doubt as to the effential character of this genus, and even its natural order. Nothing is recorded of its ufe or qualities.

TANICHI, in *Geography*, a town of Hindooftan, in the Carnatic; 16 miles S.S.W. of Tritchinopoly.

TANILA, a river of Mexico, which runs into the gulf of Mexico, N. lat. 18° 10′. W. long. 95° 6′.

TANINGE, a town of France, in the department of the Leman; 24 miles S.E. of Geneva.

TANJONG *Currang*, a town on the weft coaft of the ifland of Lombock. S. lat. 8° 31′. E. long. 115° 48′.

TANJONG *Putus*, a town of Malacca, on the north fide of the river Pera, where the Dutch have a factory.

TANJORE, a country of Hindooftan, included in the Carnatic; bounded on the north and weft by part of the Carnatic, and on the eaft and fouth by the gulf of Bengal: about ninety-five miles in length from north to fouth, and fifty in breadth from eaft to weft; watered by the river Cauvery, which divides itfelf into feveral ftreams. Though forming a part of the Carnatic, it is governed by a prince or rajah, and pays an annual fubfidy to the Englifh of 160,000*l.* fterling.

TANJORE, a town of Hindooftan, and capital of a country to which it gives name, fituated in a plain between two branches of the Cauvery; including the fuburbs, about two leagues in circumference; a double wall and a large ditch are the only defence. The palace is fituated to the eaft of the town, and is a grand fquare, fortified with a wall and a wet ditch, abounding in crocodiles. It was originally only a pagoda. In 1773, this city was taken by the Britifh under general Jofeph Smith; 176 miles S.E. of Seringapatam. N. lat. 10° 46′. E. long. 79° 10′.

TANIS, in *Ancient Geography*, a town of Egypt, fituated between the Mendefian mouth of the Nile towards the weft, and the Pelufian mouth to the eaft. It lay on a fmall branch of the Nile, and gave its name to one of the mouths of the river. This town was the capital of the nome called Tanites.

TANISTRY, TANISTRIA, an ancient municipal law, or tenure, which allotted the inheritance of lands, caftles, &c. held by this tenure, to the oldeft and moft worthy and capable perfon of the deceafed's name and blood, without any regard to proximity. This, in reality, was giving it to the ftrongeft; and this naturally occafioned bloody wars in families; for which reafon it was abolifhed under king James I.

Sir John Davies defcribes it thus: " Quant afcun perfon moruft feifie des afcuns caftles, manors, terres ou tenements del *nature et tenure de teniftry*; que donques mefmes le caftles, &c. doent defcender, et de temps dont memory ne court ont ufe de defcender, *Seniori et digniffimo viro fanguinis et cognominis* de tiel perfon," &c.

TANITICUM OSTIUM, in *Ancient Geography*, the name of the fixth mouth of the Nile, in paffing from the weft to the eaft.

TANKABAT, in *Geography.* See TANTABEE.

TANKARD TURNIP, in *Agriculture*, the common Englifh name of a particular fort of this kind of root, which has the property of ftanding high above the ground. It is a good fort for feeding off before the froft fets in, in the winter feafon; but after that has taken place, it is not fo valuable or ufeful, as being more liable to be injured and affected by it than the other forts, in confequence of ftanding expofed fo much above the furface of the land. See TURNIP.

TANKERDSONG, in *Geography*, a town of Thibet; 230 miles E. of Laffa. N. lat. 29° 50′. E. long. 100°.

TANKESIR, a town of Perfia, near the gulf; 9 miles N. of Bufheer.

TANKISA, a town and fortrefs of Thibet, at the foot of a mountain, which is faid to exhale fuffocating fumes; 120 miles N.W. of Taffafudon. N. lat. 28° 23′. E. long. 87° 20′.

TANKROWAL, a town of Africa, in the kingdom of Kaen, with a factory belonging to the Englifh African company, near the river Gambia. The Portuguefe have a church there. The chief trade is in wax. N. lat. 13° 10′. W. long. 14° 27′.

TANKUNNY, a town of Hindooftan, in Berar; 20 miles W. of Ellichpour.

TANLAY, a town of France, in the department of the Yonne; 6 miles E. of Tonnerre.

TANLOCOM, a town of Mexico, in the province of Guafteca; 40 miles S.W. of St. Yago de los Valles.

TANNA, an ifland in the South Pacific ocean, and one of thofe called *New Hebrides*, difcovered by captain Cook in the year 1774; about twenty-two miles in length, and ten in breadth. The inhabitants would not fuffer captain Cook, or any of his company, to advance far into the ifland. The produce, as far as could be feen, is bread-fruit, plantains, cocoa-nuts, a fruit like a nectarine, yams, tarra, a fort of potatoe, fugar-cane, wild figs, a fruit like an orange, which is not eatable, and fome other fruits and nuts. Captain Cook doubts not but nutmegs likewife grow in this ifland. The bread-fruit, cocoa-nut, and plantains, are neither fo plentiful nor fo good as at Otaheite; on the other hand, fugar-canes and yams are not only in great plenty, but of fuperior quality, and much larger. One of the latter weighed fifty-fix pounds, every ounce of which was good; hogs did not feem to be fcarce; but they faw not many fowls. Thefe are the only domeftic animals they have. Land-birds are not more numerous than at Otaheite, and the other iflands; but they faw fome fmall birds, with a very beautiful plumage, which they had never feen before. There is a great variety of trees and plants. The inhabitants of this ifland, as well as thofe of Erromango, were at firft thought to be a race between the natives of the Friendly Iflands and thofe of Mallicollo; but upon further acquaintance, it was found that they had little or no affinity to either, except in their hair, which is generally black and brown, growing to a tolerable length, and very crifp and curly. Their beards, which are ftrong and briftly, are generally fhort. One of the languages which they fpeak is nearly, if not exactly, the fame with that of the Friendly Iflands: the other, which is alfo that of Erromango and Annatom, is properly their own. Thefe people are of the middle fize, rather flender than otherwife; many are little, but few tall or ftout; moft of them have good features and agreeable countenances, are, like all the

the tropical race, active and nimble, and feem to excel in the ufe of arms, but not to be fond of labour. Both fexes are of a very dark colour, but not black; nor have they the leaft characteriftic of the negro about them. They make themfelves blacker than they really are, by painting their faces with a pigment of the colour of black lead. They alfo ufe another fort, which is red; and a third fort, brown, or a colour between red and black. All thefe, but efpecially the firft, they lay on with a liberal hand, not only on the face, but on the neck, fhoulders, and breaft. The men wear nothing but a belt, and the wrapping-leaf, as at Mallicollo. The women have a kind of petticoat, made of the filaments of the plaintain-tree, flags, or fome fuch thing, which reaches below the knee. Both fexes wear ornaments, fuch as bracelets, ear-rings, necklaces, and amulets. The bracelets are chiefly worn by the men; fome made of fea-fhells, and others of thofe of the cocoa-nuts. The men alfo wear amulets; and thofe of moft value being made of a greenifh ftone, the green ftone of New Zealand is valued by them for this purpofe. Necklaces are chiefly ufed by the women, and made moftly of fhells; ear-rings are common to both fexes, and thofe valued moft are made of tortoife-fhell. Thefe people, befide the cultivation of ground, have few other arts worth mentioning. They know how to make a coarfe kind of matting, and a coarfe cloth of the bark of a tree, which is chiefly ufed for belts. The workmanfhip of their canoes is very rude; and their arms, with which they take the moft pains in point of neatnefs, come far fhort of fome others. Their weapons are clubs, fpears, or darts, bows and arrows, and ftones. The clubs are of three or four kinds, and from three to five feet long. Captain Cook knew no more of their cookery, than that it confifts of roafting and baking; for they have no veffels in which water can be boiled. Nor did he know that they had any other liquor but water, and the juice of the cocoa-nut. They were utter ftrangers to their religion, and but little acquainted with their government. They feem to have chiefs among them, at leaft fome were pointed out to him by that title; but they appeared to have very little authority over the reft of the people. They gave intimations that they practifed circumcifion, and that they allowed themfelves to eat human flefh; but captain Cook fays, that it admits of doubt whether they are cannibals. The ifland contains a very confiderable volcano, and fome hot fprings were difcovered, which raifed the thermometer from 80° to 170°, and in one place to 202°. Captain Cook named the harbour where he lay, *Port Refolution*, from the name of the fhip, which was the firft that had ever entered it: which is fituated in S. lat. 19° 32′ 25″. E. long. 169° 44′ 35″. The variation of the needle was 7° 14′ 12″ E.; and the dip of its fouth end 45° $2\frac{1}{3}$′. The time of high water on full and change days was about 5^h 45^m, and the tide rofe and fell three feet.

TANNA, a town of Hindooftan, in the ifland of Salfette, on the eaft coaft; 15 miles N.E. of Bombay. N. lat. 19° 13′. E. long. 72° 53′.

TANNA, or *Thann*, a town of Saxony, in the county of Reuffen; 17 miles S.W. of Greitz. N. lat. 50° 25′. E. long. 11° 57′.

TANNA *Balloo*, a fmall ifland in the Eaft-Indian fea, near the eaft coaft of Borneo. N. lat. 4° 52′. E. long. 118° 21′.

TANNA *Mera*, a fmall ifland in the Eaft-Indian fea, near the eaft coaft of Borneo. N. lat. 3° 45′. E. long. 117° 5′.

TANNAR, a town of Bengal; 35 miles E.S.E. of Moorfhedabad.

TANNAS, a town of Sweden, in Harjedalen; 15 miles N.W. of Langafchantz.

TANNASER, a town of Hindooftan, in the fubah of Delhi. This place was formerly held facred by the Hindoos. In 1011 it was taken by Mamhood, king of Gizni; 45 miles N.E. of Hiffar. N. lat. 29° 31′. E. long. 76° 20′.

TANNAY, a town of France, in the department of the Nievre; 16 miles S.S.E. of Clamecy.

TANNDORF, a town of the principality of Culmbach; 8 miles S. of Culmbach.

TANNEBERG, a town of Auftria; 8 miles S. of Aigen.

TANNED HIDE. See HIDE and LEATHER.

TANNENBERG, in *Geography*, a town of Pruffia, in the province of Oberland; 6 miles S.S.W. of Hohenftein. —Alfo, a town of Saxony, in the circle of Erzgebirg; 6 miles S.W. of Wolkenftein.

TANNER, THOMAS, in *Biography*, an Englifh prelate, and eminent antiquary, was the fon of a clergyman, who was vicar of the parifh of Market Levington, in Wiltfhire, where he was born in the year 1674. He entered into Queen's college, Oxford, in 1689, and having graduated as B.A., he removed to All-Souls college in 1694, of which he became a fellow in 1696. At the univerfity he devoted himfelf very much to the ftudy of antiquities, and in 1695 publifhed his "Notitia Monaftica," or "A fhort Account of the religious Houfes in England and Wales," which attracted notice; and foon after Dr. Moore, bifhop of Norwich, appointed him his chaplain, and in 1701 made him chancellor of his diocefe; which office led him to acquire an extenfive and correct acquaintance with municipal and ecclefiaftical law, fo that he was often confulted by the dignitaries of the church. Having married the bifhop's daughter, he obtained in fucceffion various preferments; and in 1710 he took the degree of D.D. In 1723 he became canon of Chrift-church, Oxford; in 1727, prolocutor of the lower houfe of convocation; and in 1732, bifhop of St. Afaph. He died at Chrift-church, in 1735, where he was buried. He was thrice married, but left only one fon. He was diftinguifhed by the exemplary difcharge of his clerical functions, and by the liberality of his charities. Availing himfelf of papers prefented to him by Wood, he publifhed a fecond edition of his "Athenæ Oxonienfes," much corrected and enlarged, with the addition of more than five hundred lives from the author's MS. Lond. 1721. 2 vols. fol. A pofthumous work, founded on his Notitia, and entitled "Notitia Monaftica; or, an Account of all the Abbies, Priories, and Houfes of Friars, heretofore in England and Wales, and alfo of all the Colleges and Hofpitals founded before 1540," was publifhed by his brother, the Rev. John Tanner, Lond. 1744. fol. Another elaborate work, on which he had beftowed the application of forty years, entitled "Bibliotheca Britannico-Hibernica; five, de Scriptoribus qui in Anglia, Scotia, et Hibernia, ad Sæculi xvii. initium floruerunt, literarum ordine juxta familiarum nomina difpofitis Commentarius, &c." was publifhed in 1748, fol. under the care of Dr. Wilkins, who prefixed to it a learned preface. He had alfo made collections for the hiftory of his native county of Wilts, but by removal to a diftance he was prevented from profecuting his defign. To the Bodleian library he bequeathed many valuable papers, tending to illuftrate the hiftory of thefe iflands, and he made feveral communications of a fimilar nature to the Society of Antiquaries, of which he was a member. His various labours in this way rank him among the moft valuable contributors to Britifh literature and ecclefiaftical hiftory. Biog. Brit. Gen. Biog.

TANNER, a perfon who manufactures hides and fkins by tanning.

It is only within a few years paft, that the tanners of this country have been liberated from a variety of penalties and prohibitions, which were extremely oppreffive, and long retarded the progrefs of the manufacture.

In the reigns of Elizabeth and James I. when *patents of monopoly* were in exiftence—when the true principles of trade were not well underftood—and when the leather manufacture was conducted by unfkilful perfons, fome rules and regulations as to the mode and manner of tanning, the materials to be employed, and the time to be confumed in the procefs, might, perhaps, be in fome degree neceffary: but fuch prohibitions and reftrictions were wholly inapplicable to the prefent enlightened age. It was not, however, till 1808, after a long parliamentary inveftigation, that the act 1 James I. c. 22, and others of a fimilar tendency which had long difgraced our ftatute-book, were at length repealed by the 48 Geo. III. c. 60. By this act, the tanner is now allowed, like all other manufacturers, to exercife his ingenuity in the difcovery of new materials or new methods, in abridging the time or improving the procefs. Nor can any injury thereby arife to the community; for the competition which in this country exifts in every branch of trade, combined with the credit and the intereft of the parties, will always infure to the public the production of the beft articles which can be manufactured. See LEATHER, TAWING, and VELLUM.

TANNER'*s Bark*, is the bark of the oak or other tree, which, after it has been ground in a mill into a coarfe powder, is ufed in tanning of leather. When the tanning principle has been wholly exhaufted, it is taken out of the pits, and called *tan*. It is then fold to the gardeners, who ufe it in hot-houfes to produce an artificial heat, for the purpofe of raifing pine-apples, &c. After a certain time the tan ceafes to caufe fermentation: it is then taken out of the hot-houfe, and, when entirely rotted, becomes a vegetable mould, and is employed as a manure in kitchen-gardens and on grafs-land.

With refpect to its advantages as a manure, different opinions are entertained. Miller, Mortimer, and others, have reprefented it as highly nutritious, while more modern agriculturalifts confider it of very little value. When, however, it is blended and incorporated with other vegetable fubftances, or with lime or earthy matter in certain proportions, cautioufly employed, and laid on foon after Michaelmas, it will be found a good top-dreffing for ftiff and cold grafs-land.

TANNETE, in *Geography*, a town on the W. coaft of the ifland of Celebes. S. lat. 4° 14'. E. long. 120° 4'.

TANNEWANG, a river on the S. coaft of the ifland of Celebes, which runs into the fea, 5 miles W. of Bonthain.

TANNHAUSEN. See THANNHAUSEN.

TANNIN, in *Vegetable Chemiftry*, a peculiar fubftance which is naturally formed, and exifts in a great number of vegetable bodies, fuch as oak bark, galls, fumach, catechu, &c. Its name is derived from the effect it has in converting the gelatine into leather.

Several proceffes have been given to obtain pure tannin, which have been fo various in their refults, as to induce chemifts to fufpect the identity of tannin.

The procefs recommended for procuring pure tannin, is to powder nutgalls, and make an infufion in water, which will be of a deep brown colour. Evaporate the infufion with a gentle heat till it is very ftrong, but ftill retaining its humidity. Add to this a faturated folution of carbonate of potafh. A yellowifh-white precipitate is formed, which is faid to be pure tannin. When the liquid part is poured off, a little cold water muft be added to wafh the precipitate, as a large quantity would diffolve it again. When the precipitate is feparated and dried, it affumes the appearance of refin, having a vitreous fracture. It is of a brown colour. Its tafte is bitter, and ftrongly aftringent. It is very foluble in water. The folution becomes frothy by agitation, as if it contained foap. It diffolves ftill more plentifully in alcohol. The folution is of a dark-brown colour, differing little in its properties and appearance from what has been termed tincture of galls.

For our firft knowledge of this fubftance in a definite ftate, we are indebted to Deyeux. Seguin afterwards feparated it by means of a folution of gelatine, the matter which was precipated being a fubftance, having the fmell and many other properties of leather. Thefe facts led to the great improvements he made in the procefs of tanning, of which no true theory was known before his time.

For a more minute inveftigation of the properties of tannin, we are indebted to Prouft. He obtained his tannin by adding an acid to a concentrated infufion of nutgalls. A precipitate is obtained of the confiftency of pitch. This precipitate is to be wafhed with a little cold water, with the fame caution obferved in the laft procefs. The precipitate is now to be diffolved in boiling water, and carbonate of potafh added, which takes up the acid and precipitates the tannin.

Prouft recommends the following procefs for procuring pure tannin. Drop into an infufion of nutgalls, a folution of muriate of tin. This gives a yellow precipitate, which being feparated, wafhed, and dried, is of a buff-colour. This is a compound of oxyd of tin and tannin. He then mixes this powder with water, and paffes through it fulphuretted hydrogen gas. The fulphur combines with the tin, and becomes infoluble, while the tannin diffolves in the water. When the fulphuret is feparated, and the folution of tannin evaporated with a gentle heat, a brown fubftance is left behind, which he confidered as pure tannin.

Another procefs for obtaining tannin from infufion of nutgalls, has been given by Merat Guillot. This confifts in mixing pure water with an infufion of galls. If to this mixture dilute nitric or muriatic acid be added, a deep brown precipitate is formed, which, when dry, becomes black. This he fuppofes to be pure tannin.

Trommfdorff has fhewn that all thefe proceffes are infufficient to produce pure tannin. As the fubftance called extract was contained in all the above precipitates, and more or lefs gallic acid, he made a great number of experiments to obtain pure tannin; and although he obtained it nearer to a ftate of purity than any of his predeceffors, his labours were not completely fuccefsful. He evaporated the infufion of galls with a gentle heat to one-fourth its bulk. The liquid became muddy from the precipitation of extractive matter, and was feparated by ftraining. It was now further evaporated to the confiftence of jelly, and ultimately dried by a gentle heat. He now digefted the mafs with pure alcohol, till no more gallic acid could be taken up. He then confidered the mafs left behind as pure tannin, or nearly fo. In order to afcertain if it ftill contained extract, he re-diffolved it in pure water, and evaporated this and future portions of water from it, judging that if any extract ftill remained it would become infoluble by oxygenation, and thus be precipitated, but no depofition took place. Sufpecting it might contain mucilage, he left the folution in a warm place for fome time. It became covered with mould, which he attributed to the prefence of mucilage. The mould was feparated by filtration, and the folution evaporated

rated to dryneſs, which left the tannin in a ſtate of conſiderable purity.

He ſtill, however, found that it contained a portion of ſulphate of lime. In order to ſeparate this ſalt, he diſſolved the tannin in water, to which he added carbonate of potaſs: this cauſed a precipitation, which has been already noticed. The clear liquor being ſeparated, a ſolution of acetite of lead was added to it. A precipitate fell down, which conſiſted of tannin, combined with oxyd of lead, and probably ſulphate of lead. The lime alſo combined with the tannin, forming an inſoluble compound. He then ſeparated this precipitate, mixed it with water, and paſſed a ſtream of ſulphuretted hydrogen gas through it. The lead and ſulphur became ſeparated, and the combination of lime and tannin unchanged, while the pure tannin remained in ſolution, which was obtained by evaporating the ſeparated liquid to dryneſs. The tannin thus obtained, approaches much nearer to purity than that obtained by any of the former proceſſes. But we ſhall ſhew further on, that, even in this ſtate, its purity is doubtful.

Tannin obtained by the above proceſs does not differ much from that formed by the other proceſſes. We have already ſtated it to be ſoluble in alcohol: when, however, both the tannin and alcohol are pure, the tannin does not diſſolve.

Moſt of the metallic oxyds form inſoluble compounds with tannin. There is, however, great reaſon to believe that the gallic acid, which is difficult to ſeparate from it, has a much greater effect upon theſe bodies. It is ſuppoſed that when the metallic oxyds are precipitated by tannin, the latter combines with the oxygen, and, in ſome inſtances, converts the tannin into extract.

The common method of detaching the preſence of tannin is by a ſolution of gelatine in water. Iſinglaſs is moſtly uſed for this purpoſe. The ſolutions both of the tannin and the gelatine ſhould be in a conſiderably concentrated ſtate; as weak ſolutions of either rediſſolve, to a certain extent, the precipitate which the tannin forms with the gelatine.

The gelatine ſhould be quite freſh, as the precipitate is imperfect when it has the leaſt ſigns of putridity.

Sir Humphrey Davy ſtates that the proportion of the gelatine to the water ſhould be 120 grains of the former to 20 ounces of the latter.

According to the authority of the ſame chemiſt, the compound formed by the tannin and gelatine dried at 150°, is compoſed of

Gelatine - - - - -	54
Tannin - - - - -	46
	100

Potaſh, ſoda, and ammonia, combine with tannin, forming compounds which are leſs ſoluble in water than pure tannin. Theſe alkalies have a ſtronger attraction than gelatine for tannin; as the alkaline ſolutions do not precipitate gelatine till the alkali is ſaturated by an acid.

The combinations of the earths with tannin are moſtly inſoluble. Thoſe with barytes and lime are ſlightly ſo, and do not precipitate gelatine till an acid is added.

Moſt of the acids form inſoluble compounds with tannin; but when extract is preſent, it is alſo precipitated: hence the imperfection of the proceſs for ſeparating tannin by acids.

When perfectly free from gallic acid it has no action upon ſulphate of iron; but it produces a deep blue precipitate from the oxyſulphate: hence its effect in common writing-ink and black dye. The black is not complete without expoſure to the air. The precipitate which the tannin forms is very heavy, and almoſt immediately ſeparates from the water; while that formed by the gallic acid remains longer ſuſpended, and certainly, on that account alone, is an eſſential ingredient in writing-ink.

Tannin exiſts in a great number of vegetables in ſome proportion, but is the moſt abundant in nutgalls; and of them, the Aleppo galls afford the moſt. Sir Humphrey Davy has given the following analyſis of the Aleppo galls. He extracted, by infuſion with water, all the ſoluble part from 500 grains of powdered galls. This ſolution he ſubmitted to ſlow evaporation, from which he obtained, in ſolid matter, 185 grains. Theſe he found to conſiſt of

Tannin - - - - - - -	130

We are indebted to the ſame diſtinguiſhed chemiſt for bringing into notice a new ſubſtance, which contains a large proportion of tannin. This ſubſtance is brought from the Eaſt Indies, and is known by the names of catechu, or terra Japonica. It is produced by the evaporation of a vegetable fuſion from the wood of a ſpecies of *mimoſa*, which grows in India.

There are two varieties of this ſubſtance, one brought from Bengal, and the other from Bombay. The former is of a chocolate colour, of the ſpecific gravity 1.28; the latter of a lighter colour, of the ſpecific gravity 1.39. Both have an aſtringent taſte, leaving an impreſſion of ſweetneſs. They are not changed by expoſure to the air.

Sir Humphrey procured an infuſion from this ſubſtance by long decoction, the ſpecific gravity of which was 1.102: 500 grains of this infuſion yielded, by evaporation, 41 grains of ſolid matter; 34 of which were tannin, and 7 of a peculiar extractive matter.

This ſubſtance, in its original ſtate, ſeems to contain a very large proportion of tannin. The above chemiſt found that 100 grains of the powdered catechu required 18 ounces of water for its infuſion. The reſiduum, or undiſſolved part, is ſeldom more than $\frac{1}{14}$th of the original weight, and conſiſts of calcareous and aluminous earth, with a little fine ſand: 200 grains of the Bombay catechu gave

The

The great uncertainty which has prevailed refpecting the definite nature of tannin, feems to have been completely removed by the very important difcovery made by Mr. Hatchett, who has fucceeded in forming artificial tannin. An account of his experiments may be found in three papers in the Philofophical Tranfactions for 1805 and 1806.

The moft direct procefs which is given for obtaining it, is by pouring an ounce of nitric acid, diluted with two parts of water, upon 100 grains of charcoal, in a matrafs. This is to be placed in a fand-heat. Great effervefcence takes place, and much nitrous gas is difengaged. At the end of two days he added a fecond ounce of acid, and fometimes even a third. The digeftion is continued till the whole is diffolved. This folution is of a reddifh-brown colour. It is then to be flowly evaporated to drynefs, which produces a brown gloffy fubftance, exhibiting a refinous fracture.

This fubftance has the following properties:

1. It diffolves in cold water and alcohol.

2. The flavour is highly aftringent.

3. Expofed to heat, it fmokes a little, fwells up, and affords a bulky coal.

4. The folution in water reddens litmus paper.

5. It copioufly precipitates the metallic falts, efpecially the muriate of tin, acetite of lead, and oxyfulphate of iron. The precipitates are commonly of a brown colour.

6. It precipitates gold in the metallic ftate.

7. It precipitates the earthy falts; fuch as the nitrates of lime, barytes, &c.

8. When the alkalies are added to this folution, the colour becomes deeper, and ultimately turbid.

9. A folution of ifinglafs added to the fame folution produces a precipitate, which is infoluble in boiling water, refembling in its effential properties the precipitate formed by the natural tannin.

Mr. Hatchett produced the fame fubftance by treating various kinds of coal in the fame way, fuch as pit-coal, coke, and animal charcoal. What may feem very curious, he formed it from the coal of one portion of ifinglafs to precipitate another portion diffolved in water; and hence afferts that one portion of the fkin of an animal may be employed to convert the other into leather.

Of the different fubftances employed, he found thofe the beft which confifted of carbon unmixed with other vegetable matter, which always reduced the quantity; and that thofe vegetable fubftances which contained gum or mucilage, produced the leaft tannin.

When he fucceeded in producing tannin from other vegetable fubftances, fuch as indigo, refin, lac, and many other bodies, it was by repeatedly adding frefh nitric acid; by which he very properly fuppofes that the carbon becomes feparated, fo as to put it under fimilar circumftances to the charcoal itfelf. Indigo produced the moft in this way. At the commencement of his paper he mentions the fact of Mr. Chenevix having found that coffee-berries acquired, by roafting, a portion of tannin. He made fome experiments which, although not very fuccefsful, convinced him that the chief characteriftic properties of tannin may be formed or developed at fome particular temperature and under favourable circumftances, by very fimple means.

He ingenioufly conjectures, that the tannin found in fome varieties of peat has been produced in this way.

In making ufe of fulphuric acid to char various fubftances, he found that, in fome inftances, the artificial tannin, or a fubftance nearly refembling it, was formed. He firft diffolved 100 grains of camphor in an ounce of concentrated fulphuric acid. The camphor firft diffolved, without producing much change of colour. In a little time it became brown, and ultimately black. During this change, fulphurous acid gas was difengaged. After two days, during which time the alembic had not been heated, the difengagement of gas diminifhed, and the veffel was placed in a moderately heated fand-bath. This increafed the action. At the end of two days, fix ounces of cold water were added; the liquid changed to a reddifh-brown colour; the difengagement of gas ceafed, and was fucceeded by a fmell refembling a mixture of the oils of lavender and peppermint. By gradual diftillation, the water came over impregnated ftrongly with the above odour, and accompanied by an effential oil, which weighed three grains.

When the whole water had come over, two ounces more were added. The fmell before mentioned did not return, and the evaporation was continued to drynefs. The blackifh-brown refiduum was not acted upon by water, but by feveral digeftions with alcohol, leaving behind a compact coaly refiduum, which, when dried and heated to a red heat in a clofe veffel, weighed 53 grains. The alcohol was then drawn off from the folution by diftillation in a water-bath, leaving a blackifh-brown mafs, of the appearance of a gum refin, and the fmell of calomel. Its weight was 49 grains. The whole of this therefore confifted of

The effential oil above-mentioned - - - - -	3
A compact hard coal in fmall fragments - -	53
And the blackifh-brown mafs above-mentioned -	49
	105

This increafe of five grains Mr. Hatchett attributes to the oxygen united to the carbon by the acid, or the water combined with the blackifh-brown fubftance.

This latter fubftance had the following properties:

1. It had an aftringent tafte, and when diffolved in cold water, formed a dark-brown folution.

2. It yielded a dark-brown precipitate with fulphate of iron, acetite of lead, muriate of tin, and nitrate of lime.

3. It precipated gold in its metallic ftate.

4. It formed fo complete a precipitate with a folution of ifinglafs, that the liquid became colourlefs as water.

The precipitate was nearly black, and was, like the other compounds of tannin and gelatine, infoluble in hot water.

Mr. Hatchett obferves that although this fubftance poffeffes the general character of that obtained by the nitric acid with charcoal, yet it feems to act lefs powerfully upon fkin. The precipitate, at the time of its formation, is more flocculent and lefs tenacious than that produced by the other procefs.

Mr. Hatchett fuppofes this difference may arife from the want of azote, which feems to exift in that produced by nitric acid and charcoal.

He afcertained this by fubjecting to analyfis a portion which had been prepared from vegetable charcoal. He expofed in a retort fome of this tannin in the dry ftate, to the heat of a lamp connected with a jar, to obtain the gafeous product.

Firft a fmall quantity of water rofe; then a little nitric acid, which had not been expelled in the evaporation. Next a fmall quantity of yellowifh liquor, which ftained the neck of the retort. The fire was then raifed, when a quantity of gas was explofively difengaged, and upfet the jar. This gas he judged from the fmell to be ammonia. He alfo obferved obſerved ſome white fumes, which reſulted from the nitric acid uniting with the ammonia.

On replacing the jar, he continued the proceſs. The future gas which came over was carbonic acid, and a little of another, which he ſuppoſed to be nitrogen.

Although the artificial tannin appears in almoſt every reſpect ſimilar to the natural tannin, it might be expected that each would have been ſimilarly affected by nitric acid, yet Mr. Hatchett found that the one was deſtructible by that acid, while the other was not in the leaſt affected by it. He frequently diſtilled nitric acid from the artificial tannin, without producing any change upon it.

The ſame acid being added to infuſion of galls, ſumach, Pegu cutch, and kaſcutti, completely deſtroyed the tannin. The common catechu and oak bark treated in the ſame way, had not the whole of their tannin deſtroyed. He then made infuſions of equal ſtrength of nutgalls, ſumach, ſhavings of oak wood, oak bark, and the artificial tanning ſubſtances. To half an ounce of each of theſe, one drachm in meaſure of ſtrong nitric acid was added. The tannin of all were deſtroyed, with the exception of the oak bark and the artificial tannin. Mr. Hatchett obſerves that the tannin of thoſe bodies containing much mucilage is the moſt liable to deſtruction by the nitric acid; and that in the caſes where the tannin is deſtroyed, the oxalic acid is moſtly formed. The oak bark and the common catechu contain little or no mucilage, and hence have leſs of their tannin deſtroyed.

Theſe facts ſeem to prove that pure tannin, unmixed with other matter, is not affected by nitric acid, and that in thoſe inſtances in which it is deſtroyed, the effect muſt ariſe from ſome new ſubſtance being formed by the action of the acid upon the extraneous matter, and alſo that mucilage contributes the moſt to this change.

Mr. Hatchett has not given us any preciſe analyſis of this ſubſtance, but concludes, from its formation, that it has carbon for its baſe. From the circumſtance of its being formed with greater facility when the nitric acid is diluted, he thinks that the water is decompoſed, and that the hydrogen enters into its compoſition.

In the caſe of its decompoſition by heat, the formation of ammonia led him to believe that azote was alſo one of its elements.

This, however, does not agree with the fact of its being formed with ſulphuric acid and vegetable matter only. Although this objection ſeems partly to be removed by the circumſtance of the tannin from ſulphuric acid being different in ſome of its properties from that produced from the nitric acid and charcoal, it may, however, be here obſerved that the natural tannin, which is not known to contain azote, more nearly reſembles that formed with nitric acid, than that from the ſulphuric acid.

It does not appear probable that azote is a component part, even of the natural tannin. The ammonia which Mr. Hatchett obtained might be in combination with the tannin, and may perhaps always be formed when the tannin is formed. The circumſtance of the tannin not being changed by repeatedly digeſting it with nitric acid, would ſeem to favour the idea of its conſiſting of carbon and oxygen only. The importance of this ſubſtance in the art of tanning, ought to be a ſufficient ſtimulus to future experiments.

If in the proceſs of forming artificial tannin, the nitric acid is decompoſed merely into nitrous gas, it might be practicable to bring it back to its original ſtate by the oxygen of the atmoſphere only, and thus produce a valuable product, which is now obtained at conſiderable expence from certain vegetables.

The following table ſhews the proportions preſent of natural tannin in a variety of ſubſtances.

Catechu from Bombay - - -	54.5

Huntingdon or Leiceſter willow	10.1	109
Sumach - - - - -	16.2	158

It appears from this table that ſimilar barks, when taken from trees at different ſeaſons of the year, differ as to the quantities of tannin contained in them. In the winter they contain the leaſt, and in the ſpring (which is the uſual time of felling oak-timber), if the ſeaſon is very cold and ungenial, the quantity is diminiſhed. This is well known to practical men, as likewiſe that all barks contain the greateſt proportion of tannin; at the time when the buds of the trees begin to germinate. It is found by experience that, on an average, four or five pounds of good oak bark are required to form one pound of leather.

Sir Humphrey Davy obſerves that the aſtringent principles in barks vary conſiderably, according as their age and ſize are different. That in every aſtringent bark, the interior white bark (which is the part next to the alburnum) contains the largeſt quantity of tannin. The proportion of extractive matter is generally greateſt in the middle; but the epidermis ſeldom furniſhes either tannin or extractive matter. The white cortical layers are, comparatively, moſt abundant in young trees; and hence their barks contain, in the ſame weight, a larger proportion of tannin than the barks of old trees. (Phil. Tranf. 1803, p. 264.) From thefe obfervations, founded on experiments, Mr. Hatchett infers that there is an intimate connection between the formation of new wood and the formation of tannin in fuch vegetables as afford the latter; and this idea is corroborated by the chemical nature of thofe fubftances.

It has been fuggefted that the extractive matter found in barks, or in fubftances ufed in tanning, affects the colour, if not the quality of leather. Thus, fkin tanned with gall-nuts is much paler than fkin tanned with oak bark, which contains a brown extractive matter. Leather made from catechu is of a reddifh tint.

It is found that the precipitates obtained from infufions containing this principle or tannin by ifinglafs, when dried, contain at a medium rate about 40 *per cent.* of vegetable matter; and that it is eafy to obtain the comparative value of different fubftances for the ufe of the tanner, by comparing the quantities of precipitate afforded by infufions of given weights mixed with folutions of glue or ifinglafs. In order to make experiments of this kind, an ounce or 480 grains of the vegetable fubftance in coarfe powder, fhould be acted upon by half a pint of boiling water: the mixture fhould be frequently ftirred, and fuffered to ftand twenty-four hours; the fluid fhould then be paffed through a fine linen cloth, and mixed with an equal quantity of folution of gelatine, made by diffolving glue, jelly, or ifinglafs in hot water, in the proportion of a drachm of glue or ifinglafs, or fix table fpoons full of jelly, to a pint of water. The precipitate is to be collected by paffing the mixture of the folution and infufion through folds of blotting paper, and the paper expofed to the air until its contents are quite dry. If pieces of paper of equal weights are ufed, in cafes in which different vegetable fubftances are employed, the difference of the weights of the papers when dried, will indicate, with tolerable accuracy, the quantities of this principle or tannin contained in the fubftances, and their relative value for the purpofes of manufacture.

TANNING, the art of converting the gelatinous part of the fkins of animals into the fubftance called leather, by impregnating it with tannin or the tanning principle, in fuch a manner as to render it tenacious, durable, and impermeable to water.

It is difficult to fay at what period the art of tanning was difcovered. It was doubtlefs known to the ancients in fome degree of perfection; and it is highly probable that the fkins of animals were employed by man as a covering long before the art of tanning was known: but they would require in this ftate to be conftantly kept dry, as moifture would foon bring them into a ftate of putrefaction.

The aftringent matter, which converts the fkin into leather, abounds in fo many vegetables in every country, that accident would foon lead to fome method of producing the change. Independent, however, of vegetables, many earthy and metallic fubftances have the property of rendering fkins incorruptible to a certain extent; and fome mineral waters containing copper or iron will occafion this change. Hence we may conclude that fome means of giving prefervation to the fkins of animals muft have been known at a very early period.

Though there has been no radical alteration or any great practical improvements in the art of tanning, yet for the laft twenty or thirty years it has attracted the attention of many celebrated chemifts and philofophers in all countries, who have inveftigated the fubject with great accuracy and precifion. Previous to this period we occafionally find fome experiments and obfervations by men of fcience on the materials of tanning, as by the Hon. Charles Howard in 1674, (Phil. Tranf. vol. ix.) by the abbé Nollet, Gefner, Gleditfch, Buffon, de la Lande, and others, in Mem. Acad. Sc. Paris and Berlin.

In the year 1765, the Society of Arts and Sciences in London granted a premium of 100*l.* for the difcovery of a method of tanning with oak faw-duft; and in 1795 the Rev. G. Swayne fuggefted the ufe of oak leaves. It is unqueftionably true that all thofe fubftances, and indeed every part of almoft every vegetable in nature, poffeffes a certain portion of the tanning principle; but, exclufive of oak bark and two or three other well-known articles, the quantities of all the reft added together would be fo inconfiderable, and the proportion of tannin contained in them fo inadequate to the purpofes of manufacture, that, except for philofophical curiofity and chemical experiment, they are unworthy of notice. As the theories of fpeculative minds they are ingenious and amufing, but they afford very little ufeful information on the nature and properties of tannin, and have produced no beneficial refults in practice.

Deyeux, about 1793, (Annales de Chimie, vol. xvii.) appears to be the firft chemift who fuccefsfully explained the true principles of tanning; which afterwards, with more practical application, were ftill further developed by the labours of M. Seguin in 1795. Before his inveftigation of this fubject, the theory of tanning was ftrictly mechanical. The aftringency of vegetables, which produced the change in the fkin, was confidered as a refinous body, which had the effect of giving firmnefs to the fibres of the fkin, and rendering it infoluble.

Seguin faw the operation in a chemical point of view: he examined the nature of the procefs fcientifically, and difcovered that the change which the fkin underwent in the operation of tanning, was the refult of a chemical union between a fubftance furnifhed by the vegetable employed, and the gelatinous part of the fkin. Thefe principles he confirmed, by combining the vegetable fubftance in queftion with the gelatine of a folution of ifinglafs.

It will be feen, from our article TANNIN, that the compound difcovered by Seguin, and which is precipitated when an infufion of nutgalls is added to a folution of ifinglafs, is an infoluble fubftance, having many properties common to leather. See Nicholfon's Journal, vol. i. p. 271. 4to.

The practice which M. Seguin founded upon his theory was generally admired. He firft extracted the tannin from the vegetable, which was oak bark, and applied it to the prepared fkin in a more concentrated form, with a view to impregnate it as fpeedily as poffible with the tannin. This was faid to be done with great fuccefs in one-third of the ufual time, and to have produced fuperior leather. The fame of this difcovery foon fpread throughout Europe, and Mr. Defmond, a man of education and intelligence in this country, took out a patent for the exclufive right of ufing M. Seguin's method of tanning.

Although this procefs of fufpending the hides vertically in a very ftrong folution of bark faved much time, yet it was foon found to be adapted only to the thickeft hides ufed for fole leather, and quite unfit for the lighter kind of fkins which required flexibility and tenacity. This method, therefore, of Seguin's, however chemical and philofophical it might appear, did not anfwer in the refult; and as it was attended with much additional expence, has never been generally practifed in England.

It was not, however, till 1803, when fir Humphrey Davy (a name ever to be recorded in the annals of fcience with gratitude and admiration) began to inveftigate the fubject,

ject, that the art of tanning was thoroughly underftood, and reduced to fcientific principles. He inftituted a feries of experiments on the various fubftances employed—examined their chemical affinities and agencies—their action upon animal matter, and combination with other bodies—and developed and explained the whole with a fimplicity and perfpicuity which forcibly elucidated the effential principles on which the art depends. If this elucidation has not been productive of any material improvements in the mode of manufacturing leather, it may perhaps be attributed more to the prejudices arifing from long habit, than to any defect in the theory and demonftrations of that enlightened philofopher. And here it may be remarked, that thefe demonftrations and that theory derive additional importance, and are entitled to peculiar attention, from having been ftrongly confirmed and fuccefsfully practifed by an intelligent and refpectable manufacturer (now retired from bufinefs), to whom we are chiefly indebted for this article.

From thefe and other fources of information now open to the public, and from the general diffufion of knowledge among all claffes, the man of fcience and the manufacturer are daily becoming more affimilated to each other; and if the latter fhould be taught to difcard all unfounded prejudices, and to adopt more fcientific principles, there is reafon to believe that the various proceffes of the art of tanning may yet be capable of great practical improvement.

In the two valuable papers which fir Humphrey Davy has given in the Philofophical Tranfactions for 1803, he confiders the procefs of tanning as depending fimply on the chemical union of the tanning principle with the matter of fkin, fo as to form an infoluble compound. He has fhewn that Seguin's quick method of tanning is not the beft; becaufe the exterior ftrata of fkin being perfectly combined with tannin, before the interior ftrata are materially acted upon, thereby prevent the latter in fome degree from imbibing the full action of the folution. This renders the texture of the leather lefs equable, makes it harfh and brittle, liable to crack, and of courfe lefs durable.

Sir Humphrey thinks it probable that another fubftance, befides tannin, combines with the fkin, namely, the extract, to which it owes much of its fupplenefs and tenacity—that the leather gets more of this fubftance from weak infufions of bark, than from the ftrong ones recommended by Seguin—that it is equally infoluble in water—and that, upon the whole, the methods now generally in ufe, may, with a few alterations, be confidered the beft.

The various difcoveries pretended to have been made, and the numerous patents obtained for their ufe and application, have hitherto tended very little to the advancement of fcience or the progrefs of the art. This may fairly be inferred from the conclufion of the celebrated chemift above-mentioned. Indeed it appears by the fpecifications annexed to the patents, that moft of thefe projected improvements purport to be either for the different conftruction and arrangement of the various pits—for the application of mechanical apparatus to diminifh labour—or for extracting the tannin and warming the infufion by artificial heat, with a view to accelerate the procefs. Thefe fancied improvements are only the idle theories and vifionary projects of fpeculative minds: but as it may afford information to the curious, and furnifh hints for future difcovery, we fubjoin

A Lift of Patents for Tanning.

1790. Anthony Fay, efq. of London, for a mechanical apparatus to diminifh the labour of *handling*, to grind the bark very fmall, and to concentrate it, by boiling, into a ftrong extract.

1794. Samuel Afhton of Sheffield, for tanning hides and fkins with certain mineral productions. As fuch materials were prohibited by the ftatute of James I. an act of parliament was paffed to legalize the ufe of them.

1795. Mr. Tucker of Wickham, Hants, for triple pits compofed of wood, metal, and bricks, to keep up a conftant fire at the bottom, to warm the infufion and expedite the procefs.

1796. William Defmond, efq. of London, for a new mode of tanning, according to M. Seguin's method, as before ftated.

1797. Robert Crofs of Lancafter, for pits on a new conftruction, to enable him to apply artificial heat and to tan quickly.

1799. Francis Brewin, efq. of London, for a peculiar conftruction and arrangement of pits, and for the ufe of machinery, &c.

1802. John Lawrence, for the ufe of oak faw-duft in tanning.

1802. Thomas Martin of London, for conftructing pits on a new plan, &c.

1802. John Cant and John Miller of Montrofe, for boiling the bark, &c. fo as to extract the tanning principle more effectually.

1807. Robert John Stanley of Lincolnfhire, for tanning light leather without bark, for a peculiar preparation previous to the application of ooze, and for boiling the materials of tanning.

1813. Sparks Moline, for the ufe of the folid extract of bark.

1815. Thomas Afhmore, efq. for the ufe of all kinds of foot, whether from coal, wood, peat, or bones, and the oils and empyreumatic liquors arifing from them by diftillation or combuftion, to be applied to the purpofes of tanning.

Of the utility of the laft-named patent, we fhall give no opinion at prefent; but of the remainder it may be affirmed that none of the methods therein recommended have ever been much practifed: fome of them which were adopted by a few individuals, were attended with confiderable lofs; and as moft of them are now laid afide, we may reafonably conclude that they have not proved beneficial to the projectors or to the public.

Before we defcribe the prefent method, it may be neceffary to premife, that in different parts of the kingdom, the fame terms and denominations are fometimes employed to defignate diftinct kinds of leather: but all tanned leather is technically claffed and univerfally known under two general denominations; namely, *hides* and *fkins*. The former term being commonly applied to the larger animals, as bulls, oxen, cows, &c. which are chiefly intended for the foles of ftout fhoes, and other purpofes requiring very thick and folid leather; while the latter term is ufed for calves, feals, &c. which, being thinner and more flexible, are intended for the upper leathers of fhoes and boots, for faddles, harnefs, &c.

The heavieft and ftouteft of the bull and ox hides are generally felected to make what are technically called *butts* or *backs*, and are manufactured in the following manner.

When the horns, &c. have been removed, the raw hides are laid on a heap for two or three days, and are then fufpended on poles in a clofe room, called a fmoke-houfe, which is heated fomewhat above the common temperature by a fmouldering fire: this occafions incipient putrefaction, which

which loosens the epidermis, and renders the hair and other extraneous matter easy of separation from the true skin. This is effected by extending the hide on a wooden horse or beam of a convex form, and scraping it with a large two-handled knife, called a *fleshing-knife*, which is bent, to suit the convexity of the beam.

The hides are then immersed in a pit containing water slightly impregnated with sulphuric acid. This operation, which is called *raising*, by distending the pores and swelling the fibres, prepares the hide for the reception of the tannin, and renders it more susceptible of its action.

When the hides are sufficiently *raised*, they are removed into a pit, in which they are lain smooth with a stratum of oak bark ground to a coarse powder between each.

The pit is then filled with the tanning lixivium or ooze, prepared from oak bark and water, and the hides remain a month or six weeks without being moved. At the end of this time, the tanning principle being exhausted, the ooze and spent bark are taken out of the pit, and the hides put in again, stratified with fresh bark, and covered with fresh ooze as before. Here they remain about three months, when the same process is repeated, at about the same intervals, three several times or more, according to the strength of the lixivium and the substance of the hides. When sufficiently tanned, they are taken out of the pit, hung up in a shed to dry gradually, and being compressed with a steel instrument, and beaten smooth to render them firm and dense, the operation is complete; and having been numbered, weighed, and stamped by the excise officer, to ascertain the amount, and denote the payment of the duty (which will be noticed at the end of this article), they are ready for sale, and are termed *butts* or *backs*. These form the thickest and most substantial sole leather for very strong shoes, and are chiefly intended for exportation.

Crop hides are thus manufactured. The horns having been removed, the hides are immersed in pits containing a mixture of lime and water, where they remain three or four days, being occasionally moved up and down, that each part may be uniformly exposed to the action of the lime-water. They are then taken out of the lime-pits, and the hair and other extraneous matter being scraped off on a wooden beam, as before described, are washed in water, to free them from the lime and filth adhering. They are now immersed in a weak ooze, and by degrees are removed into other pits, containing solutions gradually increasing in strength, during which time they are taken up and put down (technically termed *handling*) at least once in every day, that all parts of the hide may be acted upon by the tanning principle equally and uniformly. This is continued for about a month or six weeks, when they are put into other pits with stronger ooze and a small portion of ground bark; from whence, as the tannin becomes exhausted, they are removed to other pits in regular succession, with fresh ooze and fresh bark, for two or three months.

At the end of this period, the hides are put into larger vats, called *layers*, in which they are stratified, or lain smooth, in a lixivium of greater strength, and with a larger quantity of ground bark between each fold. Here they remain about six weeks, when they are taken up and relaid in the same manner, with fresh bark and strong ooze, for two months. This process is repeated, with little variation, once, twice, or thrice, at the discretion of the manufacturer, till the hides are thoroughly tanned; when they are taken out of the pits, suspended on poles to dry, and being compressed and smoothed, nearly in the manner before described, are called *crop hides*, and form the principal part of the sole leather which is used in England.

The process of tanning *skins* (calves, seals, &c.) is somewhat different from *hides*. They are continued in the lime-pits for ten or fifteen days; they are then depilated and washed in water, after which they are immersed in an infusion of pigeon's dung, called a *grainer*, having the property of an alkali. Here they remain for a week or ten days, according to the state of the atmosphere and other circumstances, during which time they are frequently *handled*, and scraped on both sides upon a convex wooden beam. This scraping, or *working*, as it is termed, with the action of the *grainer*, helps to discharge all the lime, oil, and saponaceous matter, and renders the skin soft and pliant, fitted to imbibe the tanning principle. They are now removed into pits containing a weak solution of bark, where they undergo nearly the same process of handling, &c. as *crop hides*; but they are seldom stratified in *layers*; and the time occupied in tanning them is usually from two to four months, according to their nature and substance. The skins are then dried, and sold to the currier, who dresses and blacks them for the upper leathers of boots and shoes, for harness, and various other purposes.

The light and thin sort of cow-hides and horse-hides undergo nearly the same process in tanning as calf-skins, and are applied to similar uses.

These processes are such as are now commonly practised, varying, however, with the nature and condition of the peculiar kind of hides and skins—with local habits and circumstances—and with the skill and experience of the manufacturer. The greatest defect in the common methods appears to exist in the means of extracting the tannin from the bark. Cold water is chiefly used for that purpose; but some persons conceiving that this does not entirely exhaust the tanning principle, subject the bark, as before observed, to the action of boiling water, &c. If, however, as sir Humphrey Davy has stated, the extract as well as the tannin combines with the skin, the extraction of the tannin by heat would tend to oxygenate the former, and render it insoluble in the liquid.

The late ingenious Dr. Macbride of Dublin invented and published in 1778 a new method of tanning, the leading feature of which was the use of lime-water, which he conceived would extract the virtues of oak bark more completely than plain water.

It has, however, been observed, that both natural and artificial tannin form compounds with the alkalies and the alkaline earths, and these compounds are not decomposable by skin. Lime forms with tannin a compound not soluble in water, and therefore Dr. Macbride's system is founded on erroneous principles, as so much of the tannin as combined with the lime contained in the water was lost. It was also found, by the practical experience of tanners, that this method was in all respects injurious rather than beneficial; and as it has long been universally rejected, it is not necessary to enter into the detail. The reader who is desirous of further information on this point, may refer to Phil. Trans. vol. lxviii. part i. art. 8.

The application of some new and cheap substitute for oak bark has been long a desideratum in tanning. Catechu, the substance we have spoken of under the article Tannin, has been recommended, and its powerful tanning properties have been fully ascertained by experiment and actual practice: but it is not likely that the article can be procured in sufficient quantity, or at an adequate price, for the purposes of manufacture. The bark of elm, willow, larch, and other trees, together with *vallonia* (the acorn of a peculiar species of oak in Turkey), have all been employed in tanning with considerable effect.

The greatest hope which chemical science presents, is the pro-

probability that the tanning principle will, at some future period, be formed artificially in such quantities and at such expense as will admit of its general application to practical purposes. The important discovery of Mr. Hatchett already goes far towards the accomplishment of this object. He has distinctly ascertained that a substance very analogous to tannin may be produced by exposing carbonaceous matter, whether vegetable, animal, or mineral, to the action of nitric acid; and has actually converted skin into leather by deal saw-dust, asphaltum, pit-coal, wax-candle, and even by a part of the same sort of skin itself. The changes produced in these bodies, by disuniting and recombining their elementary principles, may by further developement lead to a more economical process of tanning, and thus render essential service to the arts and manufactures.

Tanned leather is subject to a very heavy excise duty. In the ninth year of queen Anne, a duty of 1*d. per* lb. was laid on all hides and skins tanned in Great Britain. In the following year an additional ½*d. per* lb. was imposed. Thus it remained, amidst all the financial difficulties of successive chancellors of the exchequer, till 1812, when, by the act 52 Geo. III. c. 94. a further duty of 1½*d. per* lb. was added, making the whole duty on tanned hides and skins 3*d. per* lb. The annual revenue arising therefrom now amounts to upwards of 500,000*l.*

It may not be improper here to remark, that the excise duty on leather tanned in Ireland, is levied and collected in a different manner.

The act 40 Geo. III. c. 9. passed in Ireland in 1800, instead of imposing a certain duty *per* pound weight, as in England, on all hides and skins tanned with oak bark, imposes a duty of nine pence by the year, for every cubic foot contained in all the pits in the yard of the tanner, allowing a deduction of two-ninths for certain pits called *latches*, which are used solely for the purpose of preparing the lixivium or ooze. By this act the tanner was permitted, on giving certain notice, to discontinue not less than one-fourth, and by 43 Geo. III. c. 97. not less than one-eighth for six months, receiving a proportionate deduction from his monthly payments of the duty. By the 48 Geo. III. c. 62. those acts were made perpetual.

Previous to the passing the Irish act 40 Geo. III. the writer of this article was consulted by the then chancellor of the exchequer in Ireland, on the relative amount of the intended duty of nine pence *per* cubic foot; and upon accurate calculation it was found to bear a fair proportion to the duty then existing in England. If the present duty on leather tanned in this part of the united kingdom were proportionably commuted on a similar plan, it would materially tend to the progress of the manufacture.

The chief obstacle to great practical improvement is the excise duty—not so much from its amount (though that is very considerable), as from the mode in which it is now levied and ascertained, namely, by weight, when the leather is dry and fit for sale. This mode necessarily requires a system of rules and regulations, which, from their multiplicity and complicated nature, subject the manufacturer to daily inconvenience, and to occasional hardships. For, notwithstanding the repeal of the oppressive act 1 James I. cap. 22, and other subsequent statutes, the tanner is still restricted, by various excise laws, from advantageously shaving and reducing his hides and skins—from mixing and removing them at his discretion—and also from exercising the trades of a currier, &c.

Those restrictions, it must be acknowledged, are in some degree necessary for the protection and security of the revenue, while the duties are imposed and collected upon the present system. But if a different mode of taxation and collection (as in Ireland, on the admeasurement of the pits; or on the raw material, or any other plan) could be adopted, the benefits which would result, both to the manufacturer and to the community, are incalculable. It would leave the tanner at full liberty to conduct his business entirely according to his skill and judgment, and to unite with it the trades of currier and leather-cutter, which are so naturally connected with his own. It would enable him to facilitate the process; to save much superfluous labour; to economize the materials of tanning, which are now unavoidably wasted on useless or inferior leather; to shave, divide, select, and appropriate certain hides and skins, or parts of hides and skins, at the proper time for their peculiar purposes; to prevent the injury which leather often receives in drying at particular seasons; and ultimately to improve the quality and reduce the price of one of the most useful articles of general consumption.

These are matters well worthy the consideration of the executive government and the legislature. Some attention has already been given to this subject by the house of commons in the sessions of 1815 and 1816, and we have no doubt that by further investigation, intelligent and unprejudiced persons might easily arrange and complete a plan which would afford perfect security to the revenue, would simplify the collection, would prevent the possibility of fraud, and at the same time prove extremely beneficial to the manufacture and to the public.

TANNRODA, in *Geography*, a town of the principality of Weimar; 9 miles S.S.W. of Weimar.

TANORE, a town of Hindoostan, in the country of Calicut; 25 miles S.S.E. of Calicut. N. lat. 10° 58′. E. long. 75° 54′.

TANOS, in *Ancient Geography*, a town of the island of Crete.

TANOT, in *Geography*, a river of North Wales, which rises in the county of Montgomery, and runs into the Severn, 7 miles below Welshpool.

TANOUMDAIN, a town of the Birman empire; 30 miles N.E. of Pagahm.

TANREC, in *Zoology*, a name given by Buffon to the ERINACEUS *Ecaudatus*; which see.

TANSA, in *Geography*, a branch of the river Mobile.

TANSCHA. See TANGIA.

TANSE, a town of Brasil, in the jurisdiction of St. Paul.

TANSIFT, or TENSIFT, vulgarly called Wed Marakosh, or the river of Morocco, because it passes through the district of that name, a river that rises in mount Atlas, E. of Morocco, and taking its course about five miles N. of that city, proceeds through the territory of Morocco, and Rahamana, and nearly divides the two maritime provinces of Shedma and Abda; discharging itself into the Atlantic ocean, about 16 miles S. of the town of Saffy. In its course it receives some tributary streams issuing from the Atlas, the principal of which is the Wed Niffis. In many places it is very deep; and about six miles from Morocco it is crossed by a bridge, erected by Muley El Mansor, which is very strong, but flat, with many arches. At the mouth of this river, on the N. side, amid some sands and marshes, are the ruins of a small town, called by the Moors Suera, from which the insalubrity of the air, or the inundations of the Tansif, have driven the inhabitants. On the other side of the river, which is passed by fording, or on rafts made of reeds tied to leathern bags inflated with wind, is a square castle, built in the reign of Muley Ishmael, to defend the passage of the river, during the time of the intestine disturbances of the empire. This castle at present only contains a few families; and the country round it is uncultivated.

TANSILLO, Luigi, in *Biography*, an Italian poet, was a native of Nola, and born about the year 1510. The firſt ſpecimen of his talents in Tuſcan poetry, when he was twenty-four years of age, was his " Il Vandemmiatore," firſt printed in 1734, and it afterwards paſſed through ſeveral editions, under the title of " Stanze amoroſe ſopra gli orte della Donne." This poem was ſucceeded by another of the ſame licentious character, entitled " Stanze in lode della Menta." His reputation was ſo much ſunk by theſe publications, that all his poems and other pieces were conſigned by pope Paul IV. to the liſt of prohibited books. The author, deeply mortified by this circumſtance, addreſſed a penitential letter to the pope, ſupplicating forgiveneſs, and informing him that he had made reparation by compoſing a devout poem, entitled " Le Lagrime di San Pietro," or, " The Tears of St. Peter." The apology was admitted, and his name was eraſed from the liſt. In 1569 he was judge-royal at Gæta, and being then declining in health, he probably did not long ſurvive. His " Tears of St. Peter" was publiſhed, after his death, in fifteen cantos, and much applauded. It was tranſlated into French by Malherbe, and alſo into Spaniſh. His other poems have been often printed; but the moſt complete edition is that of Venice in 1738. Two other elegant poems, entitled " La Balia" and " Il Podera," were publiſhed in the year 1767 and 1769. Some perſons have repreſented Tanſillo as equal to Petrarch; but though this degree of praiſe ſhould not be allowed, he is conſidered by the beſt judges as one of the moſt elegant and ſpirited poets of his age. Moreri. Gen. Biog.

TANSITARO, in *Geography*, a town of Mexico, in the province of Mechoacan.

TANSOR, a town of Africa, in the kingdom of Fez, 30 miles N. of Fez.

TANSOU, a town on the E. coaſt of Madagaſcar. S. lat. 15° 40′. E. long. 50° 8′.

TANSUCHE, a town of Mexico, in the province of Guaſteca; 83 miles N.W. of Panuco.

TANSY, or Tanzy, in *Botany*. See Tanacetum.

Tansy, in the *Materia Medica*. The leaves and flowers of tanſy have a ſtrong, not very diſagreeable ſmell, and a bitter ſomewhat aromatic taſte. They give out their virtue both to water and ſpirit, but moſt perfectly to the latter: the tincture made from the leaves is of a fine green; from the flowers, of a bright pale yellow colour. Diſtilled with water, they yield a greeniſh-yellow eſſential oil, ſmelling ſtrongly of the herb, and probably containing camphor; the remaining decoction, inſpiſſated, affords a ſtrong, bitter, ſubſaline extract.

According to Bergius, the virtues of tanſy are tonic, ſtomachic, anthelmintic, emmenagogue, and reſolvent, qualities uſually attributed to bitters of the warm or aromatic kind. Tanſy has been much uſed as a vermifuge, and its efficacy has been aſcertained by the teſtimonies of many reſpectable phyſicians.

The ſeeds have been chiefly recommended in this laſt intention, and ſubſtituted for thoſe of the *ſantonicum*, from which they differ not a little in quality as well as in appearance, being much leſs bitter, and of a more aromatic flavour.

Dr. Clark informs us (Eſſ. and Obſ. Phyſ. and Lit. vol. iii.) that in Scotland tanſy was found to be very beneficial in various caſes of gout, and Dr. Cullen ſays, that he has known ſeveral who have taken it without any advantage, and ſome others who reported that they had been relieved from the frequency of their gout. Tanſy is alſo recommended in the hyſteria, eſpecially when this diſeaſe is ſuppoſed to proceed from menſtrual obſtructions.

The leaves of this plant may be given in powder to the quantity of ℈j to ʒj, for a doſe twice a day; but it has been more commonly taken in infuſion, or drank as tea. It is now ſcarcely ever uſed, except as an anthelmintic for expelling lumbrici, to which it has certainly ſome pretenſions. Lewis. Woodville. Thomſon.

Tansy, *Wild*. See Cinquefoil.

TANT, in *Natural Hiſtory*, an Engliſh name for a ſmall ſpider of the *phalangium* kind, having only two eyes, and eight very long legs, and commonly ſuppoſed to be very poiſonous.

It is all over of an elegant ſcarlet colour, reſembling that of the flowers of the red poppy when full blown, except that the belly has a whitiſh caſt. Four of its legs are inſerted in the upper part of the breaſt, and the other four near the belly; and near the origin of each leg there is a ſmall black ſpot. Its body is round and full, and it is all over covered with a fine, ſhort, velvety down. It is not unfrequent in dry paſtures in the ſpring-ſeaſon. It is terribly dreaded by our farmers, who ſuppoſe that an ox will die who chances to ſwallow it. Ray's Hiſt. Inſects, p. 44.

TANTABEE, or Tankabast, or *Lop*, in *Geography*, a town of Little Bucharia, on the river Yarkan; 100 miles S. of Tourfan.

TANTALAM. See Ligor.

TANTALITE, in *Mineralogy*, the ore of a newly diſcovered metal called tantalium, or tantalum. (See Tantalium.) This ore has been called columbite by Mr. Hatchett, who obtained a ſpecimen of it from Maſſachuſetts bay, in North America, and diſcovered the metal which he denominated columbium, and which is now found to be the ſame with tantalium. The colour of tantalite is iron-black, ſometimes with a tinge of blue. It occurs imbedded in angular pieces, from the ſize of a pea to that of an hazle-nut. It is alſo cryſtallized in acute octohedrons, with ſquare baſes. The ſurface of the angular pieces is uneven; that of the cryſtals is ſometimes ſmooth, and ſometimes ſtreaked; it has a ſhining metallic luſtre, inclining to reſinous. The fracture is uneven and granular, inclining to compact or conchoidal. The fragments are irregular, ſharp, and angular. It ſcratches glaſs, and gives a few ſparks with ſteel. The ſtreak is dull, and the powder a browniſh-black. The ſpecific gravity varies from 7.15 to 7.953. The columbite, according to Hatchett, is 5.918. Tantalite is infuſible before the blow-pipe, without addition; and it ſuffers no change but a diminution of luſtre.

The conſtituent parts of tantalite from Finland are, according to

	Wollaſton.	Vauquelin.	Klaproth.	Berzelius.
Oxyd of tantalium	85	83	88	83.2
Oxyd of iron	10	12	10	7.2
Oxyd of mangancſe	4	8	2	7.4
Oxyd of tin -	0	0	0	0.6

The North American columbite contained, according to an analyſis of Dr. Wollaſton, 80 parts of oxyd of tantalium, 15 of oxyd of iron, and 5 of oxyd of manganeſe.

Tantalite occurs in the pariſh of Kemito, in Finland, diſſeminated in coarſe red granite. It bears a conſiderable reſemblance to ſeveral other minerals, particularly to magnetic iron-ſtone, tin-ſtone, wolfram, yttryotantalite, and gadolinite. It is diſtinguiſhed from magnetic iron-ſtone by its greater ſpecific gravity, and by not affecting the magnetic needle; from compact black tin-ſtone, by its metallic luſtre, and by the action of the blow-pipe, which reduces tin-ſtone on charcoal; from wolfram, by the abſence of the foliated fracture; from yttryotantalite, by the form of the

cryſtals,

cryſtals, and by reſiſting the action of the blow-pipe, by which yttryotantalite is melted into a greeniſh-yellow ſlag; laſtly, tantalite is diſtinguiſhed from gadolinite, by its greater ſpecific gravity, uneven fracture, and infuſibility. Yttryotantalite, another ore of tantalium, contains the newly diſcovered earth called yttria, from Ytterby, near Roſlagen, in Sweden, where it was firſt diſcovered. See Tantalium and Yttryotantalite.

TANTALIUM, or Tantalum, the metal obtained from tantalite and yttryotantalite. The method of reduction conſiſts in boiling the ores with alkalies, and adding nitro-muriatic acid to the ſolution. The oxyd of tantalium is thrown down in white powder: this muſt be waſhed, dried, and ſtrongly ignited in a crucible lined with charcoal.

Berzelius preſſed the oxyd into a cavity of the ſize of a gooſe-quill, made in a lump of well-burned charcoal, and expoſed it to a violent heat, in a Heſſian crucible. The reduced metal was not melted, but the particles of it firmly adhered together, and formed a maſs, through which water would not penetrate. The grains were hard enough to ſcratch glaſs. The ſpecific gravity, as aſcertained by Dr. Wollaſton, was 5.61; but as the maſs had not been melted, the weight of tantalium muſt be ſomething heavier. Its colour is dark grey; and when ſcratched with a knife, it aſſumes the metallic luſtre, and has the appearance of iron. It may be reduced to powder by trituration; the powder is of a dark brown colour, without the ſmalleſt metallic luſtre. This powder is not in the leaſt altered by muriatic or nitric acids, nor by aqua regia, though it be digeſted with them for ſeveral days. In this reſpect it agrees with chromium, titanium, oſmium, iridium, and rhodium.

When heated to redneſs, it takes fire, burns feebly without flame, and goes out directly if it be removed from the fire. By this means it is converted into a greyiſh-white matter, which may again be reduced to the metallic ſtate by heating it with charcoal: 100 parts of tantalium, treated in this manner, combine with 8.5 or 4.5 of oxygen. But by this proceſs it is ſcarcely poſſible to oxydize tantalium completely.

If tantalium, when pulverized, is mixed with nitre, and thrown into a red-hot crucible, a feeble detonation takes place. The maſs is ſnow-white, and is a compound of potaſh and oxyd of tantalium.

The mean of four experiments on the reduction of the oxyd of tantalium to the metallic ſtate, makes it a compound of 100 metal with 5.485 oxygen. The ſuppoſition that the oxygen in the water, which converts the oxyd into a hydrate, is twice as great as that in the oxyd, would make it a compound of 100 metal with 5.5 oxygen. Muriatic acid throws down oxyd of tantalium, from its combinations with potaſh: it is then a hydrate of a white colour; and when waſhed and dried, it is compoſed of 100 of oxyd of tantalium and 12.5 water. From experiments of Berzelius, it appears that the oxyd of tantalium poſſeſſes acid properties. He ſucceeded in alloying ſeveral metals with tantalium, as tungſten and iron. Thomſon's Annals, September, 1816, p. 233.

TANTALUS, in *Ancient Geography*, a town in the iſle of Leſbos.—Alſo, a town in Aſia Minor, upon the bank of the Meander.

Tantalus, one of the many names given by chemiſts to mercury.

Tantalus, in *Mythology*, a king of Lydia, Phrygia, or Paphlagonia, according to ſome, but, according to others, the ſon of Jupiter by the nymph Plota, who is ſaid to have preſented the mangled members of his ſon Pelops, whom he murdered, to the gods, at a feaſt, in order to prove their divinity; or, according to the modern explication of this fable, he offered up his ſon as a ſacrifice to the gods. Others, however, have charged him with revealing the ſecrets of the gods, *i. e.* the myſteries of their worſhip, of which he was the high-prieſt. But whatever was the nature of his crime, the poets repreſent him as condemned to hell, and tormented there with perpetual hunger and thirſt in the midſt of plenty of both meat and drink. Some repreſent him as ſtanding up to the chin in water, which he was incapable of reaching; or as ſtanding under a tree, ſome of the branches of which, loaded with the fineſt ripe fruits, hung down juſt before his mouth, which, the moment he endeavoured to take, always waved out of his reach. Others repreſent him as ſtanding under a heavy ſtone, which was ſuſpended over his head, and which he ſuſpected would every moment fall and cruſh him.

Horace (lib. i. ſat. i. v. 71.) ſeems to make Tantalus only an emblem of the covetous: as Lucretius (lib. iii. v. 1015.) makes Siſyphus, who is repreſented as bending under the weight of a great ſtone, or labouring to heave it againſt the ſide of a ſteep mountain, and which always rolls precipitately down again before he can fix it on the top, as an emblem of the ambitious.

Tantalus, in *Ornithology*, a genus of the order of Grallæ. Its characters are, that the bill is long, thick at the baſe, and ſomewhat incurvated; the face naked; the tongue ſhort and broad; the noſtrils linear; and the feet, with four toes, palmated at the baſe. Linnæus enumerates twenty-one

Species.

Loculator. With a blueiſh face, reddiſh bill, quills and tail-feathers black, and white body: the curicaca of Marcgrave, the wood pelecan of Cateſby, and wood ibis of Pennant. It is found in New Holland and South America.

Falcinellus. With a black face, blueiſh legs, wings and tail violet, and cheſnut body: the bay ibis of Pennant and Latham, and green courlis of Buffon. A variety is the numenius caſtaneus of Briſſon. It is found in flocks about the lakes of Italy, ſouth of Germany, Denmark, the Ural deſert, and the Caſpian and Euxine ſeas.

Minutus. With face, bill, and legs greeniſh, ferruginous body, beneath white: the leſſer ibis of Edwards and Latham. Found in Surinam.

Ibis. With red face, luteous bill, grey legs, black quill-feathers, and reddiſh-white body: the Egyptian ibis of Latham. Found plentifully in Egypt. See Ibis.

Ruber. With face, bill, and legs red, ſanguineous body, and the apices of the wings black: the guara of Marcgrave, Willughby, Ray, &c. and the ſcarlet ibis of Pennant and Latham. Found gregarious in the Bahama iſlands, in parts of America between the tropics, particularly Eaſt Florida.

Albus. With red face, bill, and legs, white body, and the tips of the wings green: the white curlew of Cateſby, and white ibis of Pennant and Latham. Found in the Braſils and in Carolina.

Fuscus. With red face, bill, and legs, brown body, beneath white: the brown curlew of Ibis, and brown ibis of Pennant and Latham. Found in the warmer parts of America, and in ſummer in Carolina.

Viridis. With black face and legs, green and cyaneous wings, neck cinereous-black, beneath faſciated with white, upper part of the body and tail green-golden, beneath and rump brown-blackiſh: the green ibis of Latham.

Igneus. With black head and neck, green legs, body cyaneous, reſplendent with green, beneath blackiſh-red, with the quills and tail-feathers green-golden: the gloſſy ibis of Latham.

Leuco-

Leucocephalus. With white head, neck, and body, bill and face yellow, legs pale, and rump with very long rufous feathers: the white-headed ibis of Latham. Found in Ceylon.

Calvus. With white head, the hinder part of the neck tuberculated, with the jugular bag bare, the crown, bill, and legs black, and body black: the bald ibis of Latham. Found in the weftern parts of Africa.

Manillensis. With the bill and orbits greenifh, legs vermilion-coloured, and body red-brown: the Manilla ibis of Latham. Found in the ifland of Luçon.

Cristatus. With pale face, head, part of the neck, tail, and vent black, the creft on the hinder part of the head long with feathers partly white and partly black, ferruginous body, and whitifh wings: the crefted ibis of Latham. Found in Madagafcar.

Niger. With face, bill, and legs red, and black body: the black ibis of Latham. Found in Egypt, near Damietta.

Coco. With face and bill yellow-flefhy, legs flefhy pale, body white, wings as far as the apex white, the three outer quill-feathers black above at the apex. Found in the Caribbee iflands.

Pillus. With face, bill, and legs brown, body white, quill and tail-feathers black. Found near the rivers and lakes of Chili.

Cayennensis. With face obfcurely reddifh, obfcure bill, body black and fhining green: the Cayenne ibis of Latham.

Mexicanus. With blueifh bill, reddifh face, head and neck obfcure and white, a little varied with green and yellow, back, rump, and legs black, breaft and abdomen brown, tail and quill-feathers braffy-green: the acalotl of Ray and Willughby, the acalot of Buffon, and the Mexican ibis of Latham. Found near the lakes of New Spain.

Melanopis. With bill, face, and nails black, crown yellow, neck and breaft yellowifh, the feathers of the back, the fcapulars, and tail-feathers, and pectoral band, cinereous, brown at the margin, the eyes and tail green and black, and the legs red: the black-faced ibis of Latham.

Albicollis. With black bill, head and neck rufous-white, body brown with grey waves and fhining green, and red legs: the white-necked ibis of Latham. Found in Cayenne.

Griseus. With fpadiceous bill, face and nails black, hind part of the head and neck grey, body whitifh, back, rump, quills, and tail greenifh-black, and reddifh legs: the grey ibis of Latham, and matuiti of Willughby and Buffon. Found in Brafil.

Tantalus's *Cup*, in *Hydraulics*, is a cup, as A (*Pl.* VIII. *Hydraulics*, *fig.* 6.) with a hole in the bottom, and the longer leg of the fiphon B C E D cemented into the hole; fo that the end D of the fhorter leg D E, may almoft touch the bottom of the cup within. Then, if water be poured into this cup, it will rife in the fhorter by its upward preffure, extruding the air before it through the longer leg; and when the cup is filled above the bend of the fiphon at F, the preffure of the water in the cup will force it over the bend of the fiphon; and it will defcend in the longer leg C B G, and even through the bottom, until the cup be emptied. The legs of this fiphon are almoft clofe together, and it is fometimes concealed by a fmall hollow ftatue, or figure of a man placed over it; the bend F being within the neck of the figure as high as the chin. So that poor thirfty Tantalus ftands up to the chin in water, according to the fable, imagining it will rife a little higher, and he may drink; but, inftead of that, when the water comes up to his chin, it immediately begins to defcend, and therefore, as he cannot ftoop to follow it, he is left as much tormented with thirft as ever.

TANTAMOUNT, fomething that amounts to, or is equivalent to, fome other.

TANTANEH, in *Geography*, a mountain of Africa, which forms the fouth boundary of Berdoa.

TAN-TCHING, a town of Corea; 33 miles W.S.W. of Tfin-tcheou.

TANTECO, a town of Mexico, in the province of Guafteca; 25 miles N. of Panuco.

TAN-THOUI-TCHING, a town on the W. coaft of the ifland of Formofa. N. lat. 25° 8′. E. long. 120° 49′.

TANTRA, the name of a branch of literature among the Hindoos, of which we have hitherto received but very imperfect information. The books bearing this title appear to contain directions for certain religious ufages adopted by fome fects and condemned by others. (See Sakta.) The name Tantra, or Yantra, is alfo given to myfterious hieroglyphics, facred to particular deities. See Mantra, Yantra, and Parusha.

TANTUM Decies. See Decies.

TANTUMQUERI, in *Geography*, a town of Africa, in the country of Fantin, on the Gold Coaft, with two forts, one belonging to the Englifh, the other to the Dutch. N. lat. 5° 20′. W. long. 2° 54′.

TANTUR. See Tortura.

TANUM, a town of Sweden, in Weft Gothland; 31 miles N.W. of Uddevalla.

TANUO, a town of Peru, in the archbifhopric of Lima, and jurifdiction of Cagnete.

TANURI, a town of Sweden, in the government of Bahus; 30 miles N.N.W. of Uddevalla.

TANUS, in *Ancient Geography*, a river of Greece, in the Peloponnefus, which had its fource in mount Parnon, traverfed the Argolide, and difcharged itfelf into the gulf of Thyræa.

TANXIPA, in *Geography*, a town of Mexico, in the province of Guafteca, at the foot of a mountain; 70 miles N.N.W. of Panuco.

TANYGONG, a town of Hindooftan, in Berar; 36 miles W. of Nagpour.

TANZIPAO, a river of Louifiana, which runs into Pontchartrain lake, N. lat. 30° 18′. W. long. 90° 10′.

TANZU, a town of Africa, in Angola, near the coaft; 20 miles S.W. of Loando.

TANZY, in *Botany*, &c. See Tanacetum and Tansy.

TAOCE, in *Ancient Geography*, a town of Afia, in the interior of the Perfide, near the town of Orebatis.—Alfo, a promontory of Afia, on the coaft of the Perfide, 500 ftadia from the mouth of the river Oroatis, and 700 ftadia from that of the river Rhogomagus.

TAOCENA, a country of Afia, in the Perfide.

TAOCHI, a people of Afia, in the mountains of Armenia.

TAO-LOU-SAC, or Ta, in *Geography*, a town of Lower Canada. N. lat. 48° 5′. W. long. 69° 30′.

TAONABO, in *Botany*. See Tonabea and Ternstromia

TAONEROA, in *Geography*. See Poverty *Bay*.

TAOO Island, one of the Friendly iflands, in the South Pacific ocean, about 24 miles in circumference.

TAOOK, a town of Curdiftan, fituated in a barren country, N. of an extenfive vale, which is about 20 miles over, and has a chain of mountains on each fide, running E. and W.

TAORMINA, the ancient *Tauromenium*, a town of Sicily, in the valley of Demona, fituated on the E. coaft, on on a narrow level above a precipice of mount Taurus, and overhung by immenfe maffes of rocks. According to Swinburne it contains 3000 inhabitants. It has been much celebrated for its coftly marble and excellent wine. The ancient Tauromenium was much more extenfive than the prefent town, and comprehended within its walls the town of the promontory of St. Andrew, where was a theatre placed between two high rocks, and commanding a full view both of Ætna and of the plains. This theatre is reckoned the moft beautiful monument of antiquity extant. A confiderable portion of this building has efcaped the ravages of time, and affords the antiquary, as well as the architect, an opportunity of examining that divifion of a theatre on which the actors ftood; a part that is wanting in almoft all other ruined theatres. The arcades are all compofed of brick, the reft of the walls of pebbles, and covered with cafings of marble. The whole range of the vomitoria and galleries that encircled the feats is yet ftanding as high from the ground as the bottom of the fecond order; the profcenium, which formed the chord of the arch, is almoft entire; it is a thick wall, with a large opening in the centre, and three niches; a fmall door, and a fourth niche on each fide; between each of thefe apertures, or receffes, are marks in the wall, where columns were placed. According to the plan deduced from thefe ruins, the ftage was a parallelogram of 138 feet by 58; on each fide was a lofty fquare building, confifting of a bafement and two upper ftories, from the higheft of which a communicating gallery was carried along the back fcenes: the diameter of the femicircular part of the theatre, where the audience fat, was 142 Englifh feet. The ftreets of the modern town, the courts and houfes, are every where interfperfed with fragments of antique walls, aqueducts, and mofaic pavements. The afcent to Taormina is very fteep and difficult; but the charms of the landfcape amply recompenfe the labour of attaining the height. Every thing belonging to it is drawn in a large fublime ftyle; the mountains tower to the clouds; the caftles and ruins rife on weighty maffes of perpendicular rock, and feem to defy the attacks of mortal enemies; Ætna, with all its fnowy and woody fweeps, fills half the horizon; the fea is ftretched out upon an immenfe fcale, and occupies the remainder of the profpect. The beach is confined by high cliffs, that are calcareous and confifting generally of a fpecies of red and white marble, which was in high efteem among the ancients. The houfes in the vicinity are inhabited by peafants, who occupy them with their children and cattle. Thefe feveral monuments are undoubtedly coeval with the Romans; that is, pofterior to Cæfar, who, having expelled the inhabitants of Tauromenium, placed in it a Roman colony. The origin of this city is loft in the obfcurity of ages. It is known that it was confiderably augmented, when Dionyfius, in the 94th Olympiad, 443 years B.C., having taken and deftroyed Naxos, caufed it to be deferted by its inhabitants, who fettled here. This proud city was at length deftroyed by the Venetians, and fortified by the Norman conquerors; and it ftill exifts in a reduced ftate. When it was taken by the Saracens from the Greek emperor in the 10th century, it was one of the ftrongeft places in the ifland, and called by them "Al Moezzia," which name it retained for a confiderable time; 27 miles S.S.W. of Meffina. N. lat. 37° 51'. E. long. 15° 23'.

TAOS Lapis, the *peacock-ftone*, a name given by fome of the ancient writers to a very beautiful variegated agate, refembling, in fome degree, the great variety of colours in the peacock's tail.

TAOSANLU, in *Geography*, a town of Afiatic Turkey, in Natolia; 20 miles N.W. of Kiutaja.

TAOUKA, one of the Society iflands, in the South Pacific ocean. S. lat. 14° 30'. W. long. 145° 9'.

TAP, among *Hunters*. A hare is faid to tap, or beat, when fhe makes a particular noife at rutting-time.

Tap. See Tapping.

Tap-*Root*, that fort of root which fhoots directly downwards to a great depth. There are many roots of this nature, which are in conftant ufe by the farmer, fuch as the carrot, parfnip, beet, &c.; and there are many plants of the tree kind which have tap-roots, as the oak, &c. See Tapping.

In the vegetable kinds of tap-rooted plants, they all require a deeply broken-down and prepared foil, in order to grow them with any fuccefs, and to any confiderable fizes. And, as in the tree forts, they muft always rife from the feeds where they are fown; as they cannot be tranfplanted out with any kind of propriety or advantage. Where the land is not properly prepared to a fuitable depth, they are ufually fhort, forked, and of aukward growth; and when raifed by tranfplanting, very fmall and ftunted; but fome of them cannot be at all grown in the laft method.

Tap-*Rooted Turnip*, in *Agriculture*, that fort which grows much with this kind of root. It is not a favourable kind of growth for this fort of crop. See Turnip.

TAPACRI, in *Geography*, a town of Peru; 20 miles N.E. of Cochabamba.

TAPAJOS, a river of Brazil, in the Capitania of Matto Groffo, which runs N. between the Madeira and the Chingu for 300 leagues, flowing into the Amazons, in lat. 2° 24' 50" and long. 55°, the geographical pofition of the town of Santarem fituated at its mouth. This river rifes in the plains of the Parexis, fo called from an Indian nation which inhabits them. From thefe elevated plains defcend the two greateft rivers of South America, *viz.* the Paraguay, and the Madeira, the largeft river that flows into the Amazons on the fouth. The Tapajos flows in a contrary direction from thefe mountains. Its wefternmoft branch is the river Arinos, which entwines its fources with thofe of the Cuiaba at a fhort diftance from thofe of the Paraguay. The largeft and wefternmoft branch of the Tapajos is the Juruena, which rifes in lat. 14° 20', 20 leagues N.N.E. of Villa Bella, and running N. 120 leagues, flows into the Arinos, and with it forms the bed of the Tapajos. The Juruena may be navigated to its upper fall, within two leagues of its own fource. From the geographical pofition of the Tapajos, it is evident that this river facilitates navigation and commerce from the maritime city of Peru to the mines of Matto Groffo and Cuiaba, by means of its large branches, the Juruena and Arinos. The Tapajos is known to be auriferous through a great part of its courfe.

TAPANA, a name of the Hindoo regent of the fun. It means the *inflamer*. (See Surya.) One of the five arrows with which the Hindoo Kama, or cupid, wounds his votaries, is named Tapana. Its head is formed of a flower of a fuppofed inflaming quality.

TAPARICA, in *Geography*, an ifland at the entrance of All Saints' bay, on the coaft of Brafil, about 25 miles long, and 5 broad. S. lat. 13°.

TAPAS, the name of a fpecies of devotion, to which great merit and efficacy are afcribed by the Hindoos. It confifts of intenfe contemplation, accompanied by aufterities. See Jap.

The performance of the Tapas, or, more correctly written, Tapafya, is ftrongly recommended in Hindoo books; and numerous inftances are there given of benefits conferred on the fuppliants by the gods fo propitiated. An individual, while in the performance of the penances of Tapafya, is called

called Tapafwi: he is much revered, and his prayers are earneftly folicited by the fuperftitious as neceffarily efficacious. (See RAVENA.) Among his aufterities he went through the following feries, each of the eleven fpecific mortifications enduring one hundred years.

1. He ftood on one foot, holding the other and both hands up toward heaven, with his eyes fixed on the fun. 2. He ftood on one great toe. 3. He took as fuftenance nothing but water. 4. He lived fimilarly on air. 5. He remained in the water. 6. He was buried in the earth, but continued, as in the other inflexions, in inceffant adoration. 7. The fame in fire. 8. He ftood on his head, with his feet upwards. 9. He ftood on one hand. 10. He hung by his hands on a tree. 11. He hung on a tree with his head downwards.

Some of the Puranas, or books of divine authority, contain a feries of eighteen fpecific mortifications. One is now lying before us, and we give their denominations, with fome explanatory obfervations.

1. *T'hedefir*, is an elevation of the head, as the word denotes, during life: in this penance fome devotees profefs never to fit. 2. *Akas-muni:* this means etherial contemplation: the afpirant in this cafe looks conftantly on the heavens. 3. *Med'ha-muni*, indicates felf-examination: the arms are ufually croffed over the breaft, and the penitent preferves a thoughtful pofture or gait, with downcaft looks. 4. *Pherfabahu*, with arms projected horizontally. 5. *Dhamr-pana*, inverfion; by fufpenfion on a tree, &c. head downwards, over a fire. 6. *Patala-muni:* this is the reverfe of Akasmuni, meaning fubterrene contemplation; Patala being the name of the lower regions, and Yama the lord thereof. The Patala-muni conftantly looks downwards to the earth. 7. *Muni*, preferving continued filence in aid of abftraction. The word means a wife man, a fage, or faint, as well as wifdom and contemplation. We know of no difference between this fpecies of devotion and that called *Jap*, which fee. 8. *Chourafi-afin:* the meaning of this compound word is eighty-four fitting pofitions; but it may have fome other more myfterious and lefs obvious meaning. It would feem to be the reverfe of fome other penances, the merit of which confift in preferving one pofture; whereas this implies an inceffant variation to the extent of eighty-four changes. 9. *Kaffali:* the Areka or betle-nut penance. This confifts in ftanding foles upwards, the head refting on the nut placed on the ground. This is done at ftated times; but cannot, one would think, be long continued. 10. *Patali*, the earthly or fubterrene penance. This is defcribed to be a partial burying of the body up to the breaft, head downwards, and of courfe under ground, with the feet in the air, as in the laft. One can fcarcely fee at firft how this can be done; but probably the earth is placed very loofely about the head, &c. with the body or legs fupported againft a tree or wall. 11. *Urd'ha-bahu*, with elevated hands, keeping them above the head. This is a common penance, perfevered in fometimes till the arms become mere fkin and bone, the fore-arms fixed immoveably, croffing horizontally, and the finger-nails perhaps perforating the palms. A moft eminent Urdha-bahu is defcribed, with a portrait, in the fifth volume of the Afiatic Refearches, art. ii. 12. *Bäitfiri*, fitting pofture, never rifing or lying. 13. *Nyas-d'hean*, retaining the breath. To this practice great merit is afcribed, and it is perfevered in to a very extraordinary extent; till at length no refpiration is vifible. In this ftate impoftors pretend to beatific vifions, and the credulous of courfe admire the wonders they relate. 14. *Chourangi-afin*, a quadrupedal pofition, obtained by refting on the elbows and knees, putting the hands backwards over the fhoulders, and keeping hold of the toes. This muft be a very aukward and uneafy pofture, and not obtainable without much practice. 15. *Brahm-hanfa:* this is a ftage of aufterity much venerated, and eafily practicable, at leaft oftenfibly. The devotee profeffes total indifference to every thing fublunary: he provides or afks for no food or clothing: he wanders or fits naked: if any one bring him food, he eats: his whole time, in fhort, is occupied in divine contemplation. 16. *Panch-agni*, five fires. The devotee fits on the ground, with a fire to the cardinal points, intenfe and near in proportion to his ability to bear them. The fun over head is the fifth fire. (See PANCH-AGNI.) 17. *Tirbanghi*, ftanding on one foot. This Lakfhmi is related to have done for 100,000 years in the flower of the lotos, during one of her terreftrial incarnations, that fhe might be reunited to her lord Vifhnu. (See PAVAKA.) 18. *Surya-varti*, propitiating Surya, or the fun. This is done in various ways. Sometimes by abftinence merely till he is rifen, or until other prefcribed ceremonies have been performed. Fixing the eyes conftantly on the fun is another mode. See SURYA.

TAPASSANT, among *Hunters*, denotes *lurking*, or *fquatting*. Hence alfo, *to tappy*, is to lie hid, as deer may do.

TAPA-TACSO, in *Geography*, a town of Thibet; 45 miles N.E. of Laffa.

TAPAUACA, a town of South America, in the province of Darien; 40 miles E.S.E. of St. Maria de Darien.

TAPAYAXIN, in *Zoology*, the name of a very remarkable fpecies of lizard, called by Hernandez the *lacertus orbicularis*.

It is not of the long and flender fhape of the common lizards, but as broad as it is long, and much refembling the ray-fifh in fhape, though feldom exceeding four inches in length or breadth. It is a cartilaginous lizard, of a very beautiful variety of colours, always very cold to the touch, and fo fluggifh a creature, that it often will not move out of its place even on touching it. Its head is exceedingly hard and elate, and has a fort of crown of prickles for its defence; yet it is a perfectly harmlefs animal, and fo far from having the fear of man, and fhynefs that other beafts have, that it loves to be taken up and played with, and will ftand perfectly ftill, and feem very happy while played with. Hernandez, lib. ix. cap. 16.

TAPE-WORM, a fpecies of worm breeding in the human bowels, and called by authors *tænia*, and *lumbricus latus*, or the broad worm. See TÆNIA.

The Greek and Roman phyficians, as well as thofe of our own time, have defcribed thofe forts of worms to which the human bowels are fubject. The common long worms, which refemble earth-worms; the afcarides, or fmall worms; and this tape-worm, which they have alfo called *vermis cucurbitinus*, or the gourd-worm, from its refembling, in fome degree, the feeds of that fruit.

The interpreters of fome of the Greek phyficians have, however, been guilty of a great error, in confounding the gourd-worms and the afcarides together, though nothing can be more unlike. The ancients feem to have had a very juft opinion of this animal in calling it *vermis cucurbitinus*, fince it is plain by this, that they underftood every joint, as we call them, of this creature, to be a diftinct worm; and what we call a fingle worm, to be a long feries of thefe worms, joined together end to end.

The true hiftory of this animal is, that it is fhort and broad. What is called a link of the long worm is really a diftinct worm; and when one of thefe multiplies in the bowels, its young adhere to it, and to each other endwife, fo as to form a fort of chain, which lengthens as they continue

tinue to increafe, and in fine becomes immoderately long. Hence it is that the breaking, as it is called, of this worm, does not deftroy it, and that the voiding large pieces of it is no cure, fince it ftill recovers that length again by new young ones. Every feparate link of fuch a chain, if examined, is found to be entire, lively, and brifk, and not at all injured by the feparation.

Dr. Tyfon, in the Phil. Tranf. N° 146, gives a curious account of this worm: it is always fingle; it lies varioufly convoluted, being fometimes as long as all the guts, and fometimes it very much exceeds that length. Olaus Borrichius affures us, that a patient of his, in a year's time, voided eight hundred feet in meafure of this worm, though in that length he did not meet with the head; in voiding, the patient always obferved it to break off.

Dr. Tyfon parallels this cafe with that of a patient of his, who difcharged vaft quantities of this worm for feveral years, but in various pieces, of two, three, four, fix, or more yards long, but all put together, would (he fays) much exceed the length of that of Borrichius.

The joints in this worm are very numerous. In one of twenty-four feet long, Dr. Tyfon numbered five hundred and feven joints. Above the middle of the edges of each joint, he obferved a protuberant orifice. Thofe orifices he takes for fo many mouths; the beft microfcopes difcovering no mouth in that part which ufually paffes for the head. This worm is common in moft kinds of animals, as dogs, oxen, crabs, herrings, pikes, &c.

Some authors have afferted, that it is not one, but many worms linked together, and included in a fpolium of the inteftines; and that this fpolium is not animated, but receives its fenfe and motion from a fort of vermiculi cucurbitini enclofed in it. This Gabucinus, de Lumb. Com. fays, he has plainly difcovered; but Dr. Tyfon abundantly evinces the contrary.

Authors who have treated of thefe worms as a difeafe, have given a canine appetite, or unnatural appetite to food, as one of the fymptoms; but this is wrong, for it has never been found, in reality, that thefe worms, even where moft numerous, have at all increafed the natural appetite; and indeed it is very difficult to judge of their being in the body by fymptoms, fince they occafion none which are not alfo common in many other difeafes. Many people have had them a long courfe of time, without being fenfibly hurt by them; and there has never been known an inftance of their occafioning any one's death, or indeed any confiderable diforder.

Fern-root has been long known as a remedy againft worms. See *Difeafes of* INFANTS, and WORMS.

However, it was funk into neglect till a few years ago, when it again came into notice, by being difcovered to be the remedy which had become greatly celebrated in Switzerland as a fpecific in the cure of the *tænia* or tape-worm. The fecret was purchafed by the king of France, after its efficacy had been attefted upon trial by fome of the principal phyficians at Paris.

The following has been publifhed as the mode of its exhibition. After the patient has been prepared by an emollient clyfter, and a fupper of panada with butter and falt, he is directed to take in bed in the morning a dofe of two or three drachms of the powder of male fern-root. The dofe to infants is only one drachm. The powder muft be wafhed down with a draught of water, but nothing elfe muft be taken till two hours after, when a bolus of calomel, joined with fome of the ftrongeft cathartics, is to be given. If this does not operate, it muft be followed by a dofe of purging falts. By this method the worm is commonly expelled in a few hours. If the trial does not fucceed, the procefs muft be repeated at due intervals. Lewis's Mat. Med. by Aikin, 1784.

TAPEANDURIAN, in *Geography*, a town on the E. coaft of the ifland of Borneo. N. lat. 1° 24'. E. long. 117° 54'.

TAPEANTAN, a fmall ifland in the Sooloo Archipelago. N. lat. 6° 15'. E. long. 122° 9'.

TAPECON, in *Ichthyology*, a name given by fome to the fifh generally called the *uranofcopus*, or ftar-gazer.

TAPEINIA, in *Botany*, a little plant of the ftraits of Magellan, fo named by Commerfon, from ταπεινος, *humble*, or *low*; Juff. 59. This is the *Ixia pumila* of Forfter, Pl. Magell. 11. t. 2, referred by Vahl to WITSENIA. See that article.

TAPER, TAPERING, is underftood of a piece of timber, or the like, when broad at one end, and gradually diminifhing to the other; as is the cafe in pyramids, cones, &c.

To meafure taper timber, &c. fee SLIDING-*Rule*.

TAPER-*Bored* is applied to a piece of ordnance, when it is wider at the mouth than towards the breech.

TAPER alfo denotes a kind of tall wax-candle, placed in a candleftick, and burnt at funeral proceffions, and in other church folemnities.

Tapers are made of different fizes; in fome places, as Italy, &c. they are cylindrical; but in moft other countries, as England, France, &c. they are conical or taper; whence poffibly the name; unlefs we rather choofe to derive taper in the adjective fenfe from the fubftantive *taper*, in the Saxon *tapen* or *tapon*, *cereus*, *wax-candle*.

Both kinds are pierced at bottom, for a pin in the candleftick to enter.

The ufe of lights in religious ceremonies is of a long ftanding; the ancients, we know, ufed flambeaux in their facrifices, and particularly in the myfteries of Ceres; and they had tapers placed before the ftatues of their gods.

Some fuppofe that it was in imitation of this heathen ceremony, that lights were firft introduced into the Chriftian church; others take it, that the Chriftians borrowed the practice from the Jews; but recourfe need not be had to the one or the other. Doubtlefs, as in the firft ages of Chriftianity, they had their meetings in obfcure fubterraneous vaults, there was a neceffity for tapers, &c.; and there was even occafion for them after they had the liberty of building churches, thofe being contrived in fuch a manner as only to receive very little light, that they might infpire the greater awe and refpect by the obfcurity.

This original of tapers in churches is the moft natural; but it is now a long time fince the ufe of tapers, which neceffity firft introduced, is become a mere ceremony. St. Paulinus, who lived at the beginning of the fifth century, obferves, that the Chriftians of his days were fo fond of tapers, that they even painted them in their churches.

There are two ways of making tapers, the firft with the ladle, the fecond by hand.

In the firft, after the wicks (which are ufually half cotton, half flax) have been well twifted, and cut of the due length, a dozen of them are hung, at equal diftances, around an iron hoop, directly over a large copper bafon full of melted wax.

Then taking an iron ladleful of the wax, they pour it gently over the wicks, a little below the tops of them, one after another; fo that, the wax running down them, they become foaked and covered with it, and the furplus returns into the bafon, under which is a pan of coals to keep it in fufion.

Thus they continue to caft on more and more wax for ten or or twelve times, till the tapers be brought to the required dimenfions. The firft caft only foaks the wick, the fecond begins to cover it, and the reft give it the form and thicknefs; in order to which, they take care that every caft, after the fourth, be made lower and lower below the wicks to make them taper. The tapers, thus formed, are laid, while yet hot, one againft another, in a feather-bed, folded double, to preferve them foft; and afterwards taken out thence, one after another, to be rolled on a long fmooth table, with an oblong inftrument of box, polifhed at the bottom, and furnifhed with a handle above.

The taper thus rolled and polifhed, a piece of its larger end is cut off, and a conical hole bored in it, with a boxen inftrument, into which the pin or point of the candleftick is to be received.

While the broach is yet in the hole, they ufe to ftamp the maker's name and the weight of the taper, with a boxen ruler, on which proper characters are cut. The taper is then hung up to harden, after which it is fit for ufe.

Making of Tapers by Hand.—The wicks being difpofed, as in the former manner, they begin to foften the wax, by working it in hot water, in a narrow, deep, copper veffel. They then take a quantity of this wax out with the hand, and apply it gradually on the wick, which is faftened to a hook in the wall, at the end oppofite to the collet; fo that they begin to form the taper by the large end, and proceed, ftill leffening the thicknefs to the neck or collet.

The reft is performed after the fame manner as in tapers made with the ladle, except that they do not lay them in the feather-bed, but roll them on the table as faft as they are formed.

Two things there are to be obferved in the two kinds of tapers; the firft, that, in the whole procefs of tapers with the ladle, they ufe water to moiften the table, and other inftruments ufed therein, that the wax may not ftick; and that, in the other, they ufe oil of olives, or lard, for the fame end.

Taper, *Pafchal*, among the *Romanifts*, is a large taper, on which the deacon applies five bits of frankincenfe, in holes made for the purpofe, in form of a crofs; and which he lights with new fire in the ceremony of Eafter-Saturday.

The Pontifical makes pope Zofimus the author of this ufage; but Baronius will have it more ancient; and quotes a hymn of Prudentius to prove it. That pope he fuppofes to have only eftablifhed the ufe of it in parifh-churches, which till then had been reftrained to greater churches.

F. Papebroch explains the original of the pafchal taper more diftinctly in his "Conatus Chronico-Hiftoricus," &c. It feems that, though the council of Nice regulated the day on which Eafter was to be celebrated, the patriarch of Alexandria was enjoined to make a yearly canon of it, and to fend it to the pope. As all the other moveable feafts were to be regulated by that of Eafter, a catalogue of them was made every year; and this was written on a taper, *cereus*, which was bleffed in the church with much folemnity.

This taper, according to the abbot Chaftelain, was not a wax-candle made to be burnt; it had no wick, nor was it any thing more than a kind of column of wax, made on purpofe to write the lift of moveable feafts on; and which would fuffice to hold that lift for the fpace of a year.

For, among the ancients, when any thing was to be written to laft for ever, they engraved it on marble or fteel; when it was to laft a long while, they wrote it on Egyptian paper; and when it was only to laft a fhort time, they contented themfelves to write it on wax. In procefs of time, they came to write the moveable feafts on paper, but they ftill faftened it to the pafchal taper; which practice was obferved for a long time at Notre Dame, in Rouen, and throughout the order of Cluny. Such is the original of the benediction of the pafchal taper.

TAPERA, in *Ornithology*, a fpecies of fwallow. See Hirundo.

Tapera *dos Bocas*, in *Geography*, a town of Brafil, in the government of Para, on the Guanapu; 90 miles S.W. of Para.

TAPERI, a town of Peru; 16 miles N.E. of Cocha.

TAPESTRY, or Tapistry, a curious kind of manufacture, ferving to adorn a chamber, or other apartment, by hanging or lining the walls of it.

Some ufe tapeftry as a general name for all kinds of hanging, whether woven or wrought with the needle; and whether filken, woollen, linen, leathern, or of paper, (in which they are countenanced by the etymology of the word, formed from the French *tapiffer, to line;* of the Latin *tapes*, a cover of a wall or bed, &c.) But, in the common ufe of our language, the term is now appropriated to a kind of woven hangings of wool and filk, frequently raifed and enriched with gold and filver, reprefenting figures of men, animals, landfcapes, &c.

The invention of tapeftry feems to have come from the Levant; and what makes this the more probable is, that formerly, the workmen concerned in it were called, at leaft in France, *Sarazins*, or *Sarazinois.*

Some have fuppofed that the Englifh and Flemifh, who were the firft that excelled in it, might bring the art with them from fome of the croifades or expeditions againft the Saracens. Accordingly they fay, that thofe two nations were the firft who fet on foot this noble and rich manufacture in Europe, which afterwards became one of the fineft ornaments of palaces and churches, &c. At leaft, if they be not allowed the inventors, they have the honour of being the reftorers, of this curious and admirable art, which gives a kind of life to wools and filks, in fome refpects not inferior to the paintings of the beft mafters. However, it does not appear at what precife era this manufacture was introduced into Europe; nor is it certain to whom it was owing.

Guicciardin, in his "Defcription and Hiftory of the Netherlands," printed at Antwerp in 1582, afcribes the invention of the art of making tapeftry hangings to the Netherlanders, but he does not affign the time of the invention.

The art of weaving tapeftry was brought to England by William Sheldon, efq. about the end of the reign of Henry VIII. See Dugdale's Warwickfhire in Stemmate Sheldon, p. 584.

In the reign of king James, the manufacture of tapeftry was fet up at Mortlake, in Surrey. Aubrey, indeed, in his hiftory of that county, dates its inftitution in the fubfequent reign; but Lloyd (State Worthies, p. 953.) is not only pofitive for the former era, but affirms, that at the motion of king James himfelf, who gave two thoufand pounds towards the undertaking, fir Francis Crane erected the houfe at Mortlake for the execution of the defign; and this is confirmed by authentic evidence; for, in Rymer's Fœdera, vol. xviii. p. 66, there is an acknowledgment from king Charles in the firft year of his reign, *viz.* 1625, that he owes fix thoufand pounds to fir Francis Crane for tapeftry; and he grants to him two thoufand pounds yearly, for ten years, towards the maintenance of the faid work.

Thefe works at Mortlake, which at firft had been conducted after old patterns, were afterwards formed from defigns, deſigns, both in hiſtory and groteſque, furniſhed by Francis Cleyn, and thus carried to ſingular perfection.

From the deed above recited, it is plain that the manufacture was then arrived at great perfection. See Mr. Walpole's Anecdotes of Painting in England, vol. ii. p. 36.

In the year 1663, a ſtatute was enacted (cap. 15.) for the encouragement of the linen and tapeſtry manufactures of England, and diſcouragement of the very great importation of foreign linen and tapeſtry.

The firſt eſtabliſhment of a tapeſtry manufacture at Paris was under Henry IV., in the year 1606 or 1607, by means of ſeveral excellent artiſts, whom he invited from Flanders.

But this fell with the death of that prince. Under Lewis XIV. the manufacture was retrieved by the care and addreſs of the great M. Colbert, to whom is owing the eſtabliſhment of the Gobelins, a royal tapeſtry manufactory, which has produced works of this kind ſcarcely inferior to the fineſt Engliſh or Flemiſh tapeſtry, either with regard to the deſign, the colours, or the ſtrength.

In this manufactory both wool and ſilk are uſed, and ſometimes gold and ſilver. The fineſt paintings may be copied in this work, and the greateſt maſters have been employed in draughts for the tapeſtry weavers.

The weavers of the Gobelins work behind, or on the wrong ſide of the loom, which ſtands upright, and the pattern is placed on either ſide of the workman.

As the tapeſtry of the Gobelins is made of pieces of a certain breadth only, there are other workmen, called rentrayeurs, or fine-drawers, who are employed in ſewing or fine-drawing the ſeveral parts together, ſo that no ſeam is diſcernible, but the whole appears as one deſign, like a piece of ſilk from a loom. Theſe workmen are alſo uſeful in mending and cleaning tapeſtry when damaged or ſullied.

The tapeſtry-men diſtinguiſh two kinds of work; *viz.* tapeſtry of the *high* and the *low warp*, though the difference is rather in the manner of working, than in the work itſelf, which is, in effect, the ſame in both, only the looms, and conſequently the warps, are differently ſituated; thoſe of the *low warp* being placed flat, and parallel to the horizon, and thoſe, on the contrary, of the *high warp*, erected perpendicularly.

The French have had three conſiderable tapeſtry manufactories beſides that of the Gobelins; the firſt at Aubuſſon, in Auvergne; the ſecond at Felletin, in the Upper Marche; and the third at Beauvois: they were all equally eſtabliſhed for the high and the low warp; but all laid aſide the former, excepting that of the Gobelins.

There are admirable low warps in Flanders, generally exceeding thoſe of France; the chief and almoſt only Flemiſh manufactories were at Bruſſels, Antwerp, Oudenard, Liſle, Tournay, Bruges, and Valenciennes.

At Bruſſels and Antwerp they ſucceeded both in human figures and animals, and in landſcapes: and that both with reſpect to the deſigning and the workmanſhip. At Oudenard their landſcapes and animals were good, but their human figures not well executed. Liſle, and the other cities named, came behind Oudenard. The French manufacture of Felletin has done tolerably well in landſcapes, Aubuſſon in figures, and Beauvois in both.

The uſual widths of tapeſtries were from two ells to three ells and a half, Paris meaſure.

The manufacture of tapeſtry of each kind (though leſs faſhionable and in uſe than formerly) is too curious to be here paſt over without a ſhort deſcription. We ſhall give each under its ſeparate article.

Manufacture of Tapeſtry of the High Warp.—The loom on which this is wrought is placed perpendicularly: it conſiſts of four principal pieces; two long planks or cheeks of wood, and two thick rollers or beams. The planks are ſet upright, and the beams acroſs, one at top, and the other at bottom, a foot diſtance from the ground. They have each their trunnions, by which they are ſuſpended on the planks, and are turned with bars. In each roller is a groove, from one end to the other, capable of containing a long round piece of wood, faſtened in it with hooks. Its uſe is to tie the ends of the warp to. The warp, which is a kind of worſted, or twiſted woollen thread, is wound on the upper roller; and the work, as faſt as woven, is wound on the lower.

Withinſide the planks, which are ſeven or eight feet high, fourteen or fifteen inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at one end, ſerving to ſuſtain the coat-ſtave: the pieces of iron have alſo holes pierced in them, by putting a pin in which, the ſtave is drawn nearer, or ſet farther off; and thus the coats or threads are ſtretched and looſened at pleaſure. The coat-ſtave is about three inches diameter, and runs all the length of the loom; on this are fixed the coats, or threads, which make the threads of the warp croſs each other. It has much the ſame effect here as the ſpring-ſtave and treddles have in the common looms. The coats are little threads faſtened to each thread of the warp, with a kind of ſliding-knot, which forms a ſort of maſh or ring. They ſerve to keep the warp open, for the paſſages of broaches wound with ſilks, woollens, or other matters uſed in the piece of tapeſtry.

Laſtly, there is a number of little ſticks, of different lengths, but all about an inch diameter, which the workman keeps by him in baſkets, to ſerve to make the threads of the warp croſs each other, by paſſing them acroſs: and that the threads thus croſſed may retain their proper ſituation, a packthread is run among the threads above the ſtick.

The loom thus formed, and mounted with its warp, the firſt thing the workman does, is to draw, on the threads of this warp, the principal lines and ſtrokes of the deſign to be repreſented on the piece of tapeſtry; which is done by applying cartoons made from the painting he intends to copy, to the ſide that is to be the wrong ſide of the piece; and then with a black-lead pencil following and tracing out the contours of them on the thread of the right ſide; ſo that the ſtrokes appear equally both before and behind. As to the original deſign the work is to be finiſhed by, it is hung up behind the workman, and wound on a long ſtaff, from which a piece is unrolled, from time to time, as the workman proceeds.

Beſides the loom, &c. here deſcribed, there are three other principal inſtruments required for working the ſilk, or wool of the woof within the threads of the warp. Theſe are a broach, a reed, and an iron needle.

The broach is of hard wood, ſeven or eight inches long, and two-thirds of an inch thick, ending in a point, with a little handle. It ſerves as a ſhuttle, the ſilks, woollens, gold, or ſilver, to be uſed in the work, being wound on it. The reed, or comb, is alſo of wood, eight or nine inches long, and an inch thick at the back; whence it uſually grows leſs and leſs, to the extremity of the teeth, which are more or leſs apart, according to the greater or leſs degree of fineneſs of the intended work.

Laſtly, the needle is in form of a common needle, only bigger and longer. Its uſe is to preſs cloſe the wool and ſilks, when there is any line or colour that does not ſit well.

All things being prepared for the work, and the workman

man ready to begin, he places himfelf on the wrong fide of the piece, with his back towards the defign; fo that he works, as it were, blindfold, feeing nothing of what he does; and being obliged to quit his poft, and go to the other fide of the loom, whenever he would view and examine the piece, to correct it with his preffing-needle.

To put any filk, &c. in the warp, he firft turns and looks at his defign; then taking a broach full of the proper colour, he places it among the threads of the warp, which he brings acrofs each other with his fingers, by means of the coats or threads faftened to the ftaff: this he repeats every time he is to change his colour.

The filk, or wool, being placed, he beats it with his reed, or comb; and when he has thus wrought in feveral rows over each other, he goes to fee the effect they have, in order to reform the contours with his needle, if there be occafion.

As the work advances, they roll it up on the lower beam, and unroll as much warp, from the upper beam, as fuffices them to continue the piece: the like they do of the defign behind them. When the pieces are wide, feveral workmen may be employed at once.

We have but two things to add: the firft, that this high-warp tapeftry goes on much more flowly than the low-warp, and takes almoft double the time and trouble. The fecond, that all the difference the eye can obferve between the two kinds confifts in this, that in the low warp there is a red fillet, about one-twelfth of an inch broad, running on each fide from top to bottom; which is wanting in the high warp.

Manufacture of Tapeftry of the Low Warp.—The loom, or frame, on which the low warp is wrought, is much like that of the weaver's: the principal parts of it are two ftrong pieces of wood forming the fides of the loom, and bearing a beam, or roller, at each end: they are fuftained at bottom with other ftrong pieces of wood, in manner of treftles; and to keep them the firmer, they are likewife faftened to the floor with a kind of buttreffes, which prevent any fhaking, though there are fometimes four or five workmen leaning on the fore-beam at once.

The rollers have each their trunnions, by which they are fuftained: they are turned by large iron pins three feet long. Along each beam runs a groove, in which is placed a *wich*, a piece of wood of about two inches diameter, and almoft of the length of the roller: this piece fills the groove entirely, and is faftened in it, from fpace to fpace, by wooden pins. To the two wiches are faftened the two extremities of the warp, which is wound on the farther roller; and the work, as it advances, on the nearer.

Acrofs the two fides, almoft in the middle of the loom, paffes a wooden bar, which fuftains little pieces of wood, not unlike the beam of a balance: to thefe pieces are faftened ftrings, which bear certain fpring-ftaves, with which the workman, by means of two treddles, under the loom on which he fets his feet, gives a motion to the coats, and makes the threads of the warp rife and fall alternately. Each loom has more or fewer of thefe fpring-ftaves, and each ftaff more or fewer coats, as the tapeftry confifts of more or fewer threads.

The defign or painting, the tapeftry-man is to follow, is placed underneath the warp; where it is fuftained from fpace to fpace with ftrings, by means of which the defign is brought nearer the warp.

The loom being mounted, there are two inftruments ufed in working of it: *viz.* the reed, and the flute. The flute does the office of the weaver's fhuttle; it is made of an hard polifhed wood, three or four lines thick at the ends, and fomewhat more in the middle, and three or four inches long. On it are wound the filks, or other matters, to be ufed as the woof of the tapeftry. The comb or reed is of wood or ivory; it has ufually teeth on both fides; it is about an inch thick in the middle, but diminifhes each way to the extremity of the teeth: it ferves to beat the threads of the woof clofe to each other, as faft as the workman has paffed and placed them with his flute among the threads of the warp.

The workman is feated on a bench before the loom, with his breaft againft the beam, only a cufhion or pillow between them; and, in this pofture, feparating, with his fingers, the threads of the warp, that he may fee the defign underneath, and taking a flute, mounted with a proper colour, he paffes it among the threads, after having raifed or lowered them, by means of the treddles moving the fpring-ftaves and coats.

Laftly, To prefs and clofe the threads of the filk or yarn, &c. thus placed, he ftrikes each courfe (*i. e.* what the flute leaves in its paffing and coming back again) with the reed.

What is very remarkable in the manufacture of the low warp, is, that it is all wrought on the wrong fide; fo that the workman cannot fee the right fide of his tapeftry, till the piece be finifhed and taken out of the loom.

M. Le Blon, in endeavouring to fix the true harmony of colouring in painting, found that all vifible objects may be reprefented by the three primitive colours, red, yellow, and blue; becaufe out of thefe, all others, even black itfelf, may be compounded.

From the principle of producing any vifible object with a fmall number of colours, and from obferving the compounded colours which were reflected from two pieces of filk of different colours, placed near to one another, he arrived at the fkill of producing in the loom all that the art of painting requires. In weaving, indeed, he hath been obliged to make ufe of white and black threads, befides red, yellow, and blue; and though he found that he was able to imitate any picture with thefe five colours, yet for cheapnefs and expedition, and to add a brightnefs where it was required, he found it more convenient to make ufe of feveral intermediate degrees of colours.

In his new way of weaving tapeftry in the loom with a draw-boy, it may be performed almoft as expeditioufly as fine brocades; for when the loom is once fet and mounted, any common draught-weaver, unacquainted with drawing or painting, and indeed hardly knowing what figure he is about, may exactly produce what the painter hath reprefented in the original pattern: and thus a piece of tapeftry may be woven in a month or two, which, in the common way of working, would take up feveral years; and what in the common way cofts a thoufand pounds, may, by this means, be afforded finer and better for a hundred.

The main fecret of this confifts in drawing the patterns, from which any common draught-weaver can mount the loom; and when that is done, the piece may be made of any fize, by only widening the reeds and the warp; and a reverfe may be made with the fame eafe; which is done by the boy's pulling the lafhes up again in the fame order in which he pulled them down before: by which contrivance the tapeftry may be fuited to any room, whether the light comes in on the right, or on the left. The patterns are painted upon paper, on which are printed fquares from copper-plates, and thefe fubdivided by as many lines as anfwer to the threads of the warp, which run lengthwife of the piece; then they try how many threads of the fhoot anfwer in breadth to every fubdivifion of the fquares. Every thread of of the warp goes through a fmall brafs ring called a *male*, or through a loop in the leifh, and hath a fmall long weight or lingoe hung below, to counterbalance the packthreads, which going from the top of the rings or loops, are paffed over the pullies in the table directly over the loom, and are continued nearly in an horizontal pofition on one fide of the loom to a convenient diftance; where they are all fpread on a crofs piece faftened to two ftaples: thefe are called the *tail of the mounture;* and from each of thefe packthreads, juft by the fide of the loom, are faftened other packthreads, called *fimples,* which defcend to the ground; fo that by pulling thefe fimple cords, you raife any of the threads of the warp at pleafure: wherefore they faften a loop or potlart to as many of thefe fimple cords as there are threads of the warp to be pulled up at every fhoot, or every throw of the fhuttle; by which means the fhoot fhews itfelf on the right fide, where the warp is pulled up: and in ordering this, they are guided by the pattern, on which they count the diftances of the fubdivifions, which contain the fame colours in the fame line, and can be fhot at once: then they faften potlarts to the feveral fimple cords that draw up the rings, through which thofe threads of the warp run, which are to lie behind this colour; they tie all thefe loops together, and faften a piece of worfted or filk to the knot, of the fame colour that the workman is to throw; and the boy, when he pulls each loop, names the colour, that the weaver may take the proper fhuttle, and fo on for every colour to be thrown. Phil. Tranf. abr. vol. vi. p. 469, &c.

In connection with this fubject, we are naturally led to give a brief account of the manufacture of carpets. This is faid to have been introduced into France from Perfia, in the reign of Henry IV., where it has been diftinguifhed by extraordinary encouragement. The moft confiderable manufactory of this kind was that of Chaillot, or the royal manufactory of La Savoniere, or the Soap-houfe, about a league from Paris. This manufacture was altogether of wool, and worked in the manner of velvet. All forts of figures of animals may be imitated in this work, but fruits and flowers anfwer beft; and it is moft fuccefsfully applied to the manufacture of carpets and all forts of fcreens.

The carpets are, in fome refpect, wrought by the upright way of tapeftry. The two rollers are placed the fame way: the warp is braced from the top downward; the chain, with its loops, keeps all the threads of the warp equally perpendicular; the ftick, which facilitates their croffing, runs through them in the fame manner, and feparates the foremoft threads from the reft; the lizier-pole holds all the ftrings, which ferve to draw the fore-threads in their turns, and then the oppofite threads, in order to infert the fpindles of wool. But the method of working in this manufactory differs from the upright way of tapeftry in the following particulars.

The warp is divided, both before and behind, into parcels of ten threads, nine white and one blue; which is regularly continued through the whole width of the piece. The weaver works on the fore-fide, and confequently fees what he does. The defign or pattern is traced in its proper colours on cartons, tied about the workman, who looks at it every moment, becaufe every ftitch is marked upon it, as it ought to be in his work. By this means he always knows what colours and fhades he is to ufe, and how many ftitches of the fame colour. In this he is affifted by fquares, into which the whole defign is divided; each fquare is fubdivided into ten vertical lines, correfponding with each parcel of ten threads of the warp; and befides, each fquare is ruled with ten horizontal lines, croffing the vertical lines at right angles. The workman having placed his fpindles of thread near him, begins to work on the firft horizontal line of one of the fquares. Thefe lines marked on the carton are not traced on the warp, for this would be endlefs; becaufe an iron-wire, which is longer than the width of a parcel of ten threads, fupplies the place of a crofs line. This wire is managed by a crook at one end, at the workman's right hand; towards the other end it is flatted into a fort of knife, with a back and edge, and grows wider to the point. The workman fixes his iron wire, or rod, horizontally on the warp, by twifting fome turns of a fuitable thread of the woof round it, which he paffes forward and backward, behind a fore-thread of the warp, and then behind the oppofite thread, drawing them in their turn by their leifhes. Afterwards, if it be neceffary, he brings his woof-thread round the wire, in order to begin again to thruft it into the warp. He continues in this manner to cover the iron rod or wire, and to fill up a line to the tenth thread of the warp, which is the blue one. He is at liberty either to ftop here, or go on with the fame crofs line in the next divifion. According as he paffes the thread of the woof round the iron wire, and into the warp, the threads of which he caufes to crofs one another at every inftant; when he comes to the end of the line, he takes care to ftrike in, or clofe again all the ftitches with an iron reed, whofe teeth freely enter between the empty threads of the warp, and which is heavy enough to ftrike in the woof he has ufed. This row of ftitches is again clofed and levelled, by a dweet of blue thread doubled, which the workman puts into the warp, fliding his hand over the whole length of line he has wrought. He croffes the fame threads of the warp, and then ftretches through them another fingle blue thread. He beats in thefe two threads, one after another, with his reed; thefe dweets of crofs-thread, which are a fupport to each line, will be hid by the pile on the fore-fide, and they indeed diminifh the beauty of the wrong fide; but this is of no confequence. This done, the workman draws the iron rod or knife out of the loops of the woof that covered it; and as it is wider towards its end, thefe loops refift its paffage; but being edged at its fore part, it cuts them through. Then the workman with his left hand lays a ftrong pair of fhears along the finifhed line, cuts off the loofe hairs, and thus forms a row of tufts perfectly even, which, together with thofe before and after it, form the fhag. One line of this fort comprehending the row of ftitches and woollen pile, with the two blue threads which fupport them, fomewhat furpafs in thicknefs the fpace between the firft and fecond crofs line of a fquare. By this means the workman always fees what he is doing. He follows, ftitch for ftitch and colour for colour, the plan of his pattern which he is at, and paints magnificently, without having the leaft notion of painting or drawing.

The manufacture of carpets, after the manner of Chaillot, was introduced into London in the year 1750, by two workmen who left the manufactory in difguft, and came here to procure employment. They were encouraged and furnifhed with materials by Mr. Moore, to whofe affiduity and zeal the eftablifhment of this fort of manufacture has been principally owing. However, thefe men afterwards connected themfelves with a Mr. Peter Parifot, who, under the patronage, and by means of the pecuniary affiftance of his royal highnefs the duke of Cumberland, purfued the manufacture of a carpet already begun at Paddington. This undertaking was foon removed to Fulham, and, under the munificence of the duke, promifed to be durable and advantageous. In 1752, Parifot, the undertaker, propofed a plan of fubfcription, the nature of which it is now needlefs to recite; as the whole fcheme, as far as he was concerned in it, foon came to nothing. But Mr. Moore, being provided

vided with the neceffary materials, and engaging proper workmen, and rifking a very confiderable expence, fucceeded in eftablifhing this important and ufeful manufacture, infomuch that, in 1757, he obtained a premium from the Society of Arts, &c. for the beft carpet in imitation of the Turkey carpets; and by his ingenuity and perfeverance in bringing this manufacture to perfection, it is now arrived at a very high degree of reputation.

Mr. Whitby and Mr. Paffavant were alfo honoured with premiums for carpets of their manufacture by the Society of Arts in 1757 and 1758. We have alfo manufactories for carpets that are much efteemed at Axminfter and Wilton; not to mention thofe of Kidderminfter and other places.

TAPETI, in *Zoology*, the name of an animal common in the Weft Indies, and called by fome *cuniculus Americanus*, the American rabbit. In the Linnæan fyftem, this animal is a fpecies of hare, or *lepus Brafilienfis*. (See LEPUS.) It has large ears like the common hare; a white ring round the neck, though fome have not this ring; the face of a reddifh colour; the chin white, the eyes black; colour of the body like that of the common hare, but darker; the body whitifh, without a tail. Thefe animals inhabit Brafil, live in woods, do not burrow, are very prolific, and afford good meat. The tapeti is found alfo in Mexico, where it is called *citli*. Pennant.

TAPHICESIUS LAPIS, a name given by Pliny and the ancients to a fpecies of ætites, or eagle-ftone, found in a place of that name near Leucadia.

TAPHNEUS, a word ufed by fome writers to exprefs any thing when depurated or purified to the greateft degree, as the falts, by repeated folutions and cryftallizations, and the like. Paracelfus ufes it for a fpecies of earth, the things produced from which, he fays, never alter their nature by calcination or reverberation, or the like operations.

TAPHNIS, in *Ancient Geography*, a town of Egypt, mentioned by the prophet Jeremiah, to which he and the Ifraelites that were with him retired.

TAPHRA, a town fituated in the ifthmus of the Tauric Cherfonefus, mentioned by Pliny and Strabo.

TAPHROS, a name which was given to the ftrait that feparates the ifland of Sardinia from that of Corfica.

TAPHRURA, or TAPHRA, a town of Africa Propria, upon the gulf of Numidia.

TAPHUA, a town of Paleftine, in the tribe of Juda. —Alfo, a town of Paleftine, which belonged to the tribe of Ephraim, and was fituated upon the frontier of that of Manaffeh.

TAPIA, in *Botany*, an American name, adopted by Plumier from Pifo. See CRATEVA.

TAPIA, in *Geography*, a town of South America, in the kingdom of New Granada, and province of St. Martha.

TAPIAN POINT, a cape on the W. coaft of Mindanao. N. lat. 7°. E. long. 124° 30′.

TAPIAU, a town of Pruffia, in Samland, on the Pregel; 20 miles E.S.E. of Konigfberg. N. lat. 54° 36′. E. long. 21° 13′.

TAPICURU, a river of Brafil, which runs into the fea, S. lat. 12° 20′.

TA-PI-HOTUN, a town of Corea; 690 miles E. of Peking. N. lat. 40° 20′. E. long. 125° 22′.

TAPINOSIS, ταπεινωσις, in *Rhetoric*, the fame with *diminution;* which fee.

TAPION, LE, in *Geography*, a town on the W. coaft of Hifpaniola; 10 miles E. of St. Marc.

TAPIR, or TAPIJERETE of Marcgrave, in *Zoology*, the name of an animal found in fome parts of America, and called by the Portuguefe *anta*, by others *danta*, by Dampier *vache montagnarde*, and by others *elan*, and *fus aquaticus*, and in the tenth edition of the Linnæan Syftem, *hippopotamus terreftris*. Gmelin makes it a diftinct genus; and his generic characters, amended by Dr. Shaw, are as follow; *front teeth* in both jaws ten; *canine teeth* in both jaws fingle, incurvated; *grinders* in both jaws five on each fide, very broad; *feet* with three hoofs, and a falfe hoof on the fore-feet. This animal (*Tapir Americanus*) is of the fize of a young calf, or heifer, and in fhape fomewhat approaching to the figure of the hog, and the back arched; its head is thicker than a hog's, and ends in a fharp ridge at top; and the male has a fnout, or fort of probofcis, hanging over the opening of the mouth, in which he has a very ftrong mufcle, ferving to retract it at pleafure; the nofe of the female is deftitute of the probofcis, (this circumftance is doubted by Sonnini,) and the jaws are of equal length; its eyes are fmall, and very like thofe of the hog; its ears roundifh, bordered with white; and thefe he can draw forward at pleafure; its legs are thick, and not longer than thofe of our hogs; its fore-hoofs are divided into three portions; and a fort of falfe hoof behind; but its hind-hoofs into three; its tail is very fmall; the fkin is hard and folid; and the hair fhort, and of a pale brown, and when young, variegated with white fpots; and along the neck is a briftly mane, an inch and a half high. It lives in thick woods, on the eaftern fide of South America, from the ifthmus of Darien to the river of the Amazons; and fleeps all day, but at night, or early in the morning, goes out for its prey: it feeds on vegetables, and is particularly fond of the ftalks of the fugar-cane; it often takes the water, and fwims excellently: the natives, in places where it is common, eat its flefh, which is faid to be good: the Indians fhoot it with poifoned arrows, and cut the fkin into bucklers. This animal is falacious, flow-footed, and fluggifh, and makes a kind of hiffing noife; but perfectly harmlefs: the young are eafily tamed, and may be rendered domeftic, which is faid to be the cafe in fome parts of Guiana. When attacked by dogs, it makes a vigorous refiftance. The tapir produces but one young at a birth, of which it is very careful, leading it at an early age to the fea, and inftructing it to fwim. Ray and Pennant.

TAPIRIA, in *Botany*, Juff. 372, flightly altered from the ftill more barbarous *Tapirira*, Aubl. Guian. 470. t. 188, which is itfelf an alteration of the Caribbean name *Tapiriri*, by which this tree is known in Guiana. See JONQUETIA.

TAPIR-TALA, in *Geography*, a town of Chinefe Tartary. N. lat. 43° 15′. E. long. 120° 39′.

TAPIS. See TUNICA.

TAPL, in *Geography*. See TOPEL.

TAPLAKEN, a town of Pruffia, in Samland, on the Pregel; 24 miles E. of Konigfberg.

TAPLEYS, a town of North Carolina; 12 miles N.E. of Hillfborough.

TAPLINGS, in the *Englifh Salt-Works*, the name given to certain bars of iron which fupport the bottom of the pan in which the brine is boiled.

Thefe pans are very large, and cover a wide furnace; but as their width would make them apt to bend in the middle, which would fpoil the working of the falt, there is a fort of wall of brick carried along the middle of the furnace, and on the top of this are placed thefe taplings: they are about eight inches high, and from four to fix in thicknefs, being fmalleft at the top. Thefe are placed at about three feet diftance one from another, and the wall which fupports them, and which is called the *mid-feather*, is broad at the bafe, and fo narrow at the top, as barely to give room for the bafes of the taplings.

TAPOAMANAO, in *Geography*. See *Sir Charles* SAUNDERS's *Iſland*.

TAPOANA, a river of Brafil, which runs into the fea, S. lat. 21° 10'.

TAPOCOROI, a river of Brafil, which runs into the fea, S. lat. 27°.

TAPOGOMEA, in *Botany*, from the Caribbean name of one of the fpecies, *Tapogomo;* Aubl. Guian. 157. Juff. 208. See CALLICOCCA.

TAPOOKAS, in *Geography*, a town of the ftate of Georgia, on the Yazoo. N. lat. 35° 57'. W. long. 89° 51'.

TAPOOL, a fmall ifland in the Sooloo Archipelago. N. lat. 5° 37'. E. long. 120° 52'.

TAPOOR, a town of Hindooftan, in the Myfore; 15 miles S.S.W. of Darampoory.—Alfo, a river of Hindooftan, which runs into the Cauvery, 4 miles N. of Caveripatam.

TAPOSIRIS, in *Ancient Geography*, a town of Egypt, at fome diftance from the fea, between Cynoffema and Pinthyna.—Alfo, another town, called *Parva Tapoſiris*, on a tongue of land between the fea and the canal which paffed from Canopus to Alexandria.

TAPPA, in *Geography*, one of the fmall Molucca iflands; feparated by a narrow channel from Latalatta: on it is a pool of frefh water; a little to the north of the line. E. long. 127° 5'.

TAPPAHANOCK, a town of the United States of America, in Virginia, on a fmall river, which runs into the Rappahanock; 43 miles N.E. of Richmond. N. lat. 37° 58'. W. long. 76° 55'.

TAPPALANG, a town on the weft coaft of the ifland of Celebes. S. lat. 2° 25'. E. long. 119° 5'.

TAPPAN. See ORANGE-TOWN.

TAPPANOOLY, a fea-port town of the ifland of Sumatra, fituated on the weft coaft, in the country of Batta, on a fmall ifland called Punchongcacheeie. The bay is very deep, capable of containing the united navies of Europe, and confifting of a number of harbours within one another. The bay ftretches into the heart of the Batta dominions, and its borders are inhabited by that people, who barter here the produce of their country for fuch articles as they want. The Englifh Eaft India company have a factory here. N. lat. 1° 40'. E. long. 98° 12'.

TAPPI, or TAPI, called by the Moors *Chedder*, a river of Hindooftan, which, as Thevenot fays, has its fource ten miles from the little town of Brempore, in the kingdom and mountains of Deccan, and runs into the fea about 2½ leagues below Surat. The Banians and Gentoos efteem this a very holy river.

TAPPING, the act of piercing a hole in a veffel, and applying a tube, or cannula, in the aperture, for the commodious drawing off the liquors contained therein.

TAPPING, in *Agriculture*, is the making an incifion in the bark of a tree, and letting out the juice.

To tap a tree at the root, is to open it round about the root.

Ratray, the learned Scot, affirms, that he has found by experiment, that the liquor, which may be drawn from the birch-tree in the fpring-time, is equal to the whole weight of the tree, branches, roots, and all together.

In the tapping of trees, the juice, taken in from the earth, afcends from the root; and, after it is concocted and affimilated in the branches, &c. it defcends, like a liquor in an alembic, to the orifice or incifion where it iffues out.

One of the moft effectual ways of tapping, fo as to obtain the greateft quantity of fap in the fhorteft time, is not only to pierce the bark, or to cut the body of the tree almoft to the pith, with a chiffel (as fome have directed), but to bore it quite through all the circles, on both fides of the pith, leaving only the outermoft and the bark on the north-eaft fide unpierced.

This hole is to be bored floping upwards, as large as the largeft auger will make; and that alfo through and under a large arm near the ground. So will it not need any ftone to keep open the orifice, nor tap to direct the fap into the receiver.

By this method the tree will, in a fhort time, afford liquor enough for brewing; and with fome of this fweet fap, one bufhel of malt will make as good ale as four bufhels of malt with ordinary water. The large maple, which we call the fycamore, is faid to yield the beft brewing fap, its juice being very fweet and wholefome. See BETULA.

To preſerve the Sap for Brewing.—Infolate it by a conftant expofure to the fun in proper veffels, till the reft be gathered and ready, otherwife it will contract an acidity: when there is enough, put into it as much very thin cut and hard-toafted rye-bread, as will ferve to ferment it; and when it works, take out the bread, and bottle up the liquor. A few cloves in each veffel that receives the fap, as it oozes from the tree, will alfo, certainly, preferve it a twelvemonth. See Dr. Tonge's Obf. in the Philofophical Tranfactions, N° 43, 44. 46. 68. or Abr. vol. ii. p. 673, &c.

TAPPING *of Oaklings and other Trees*, the practice of cutting off the tap-roots of young oaks and other trees or plants of that kind.

It has been noticed by Mr. Nicol, in his work on planting, that thofe who are in favour of this method, rather than that of fowing the feeds of thefe forts of trees, fuppofe that tapping the downward roots of the young plants while they are in the nurfery plantation, has the power and capability of making their roots ever afterward have a horizontal tendency in the earth or foil; that in confequence of it they are not liable to injury by infinuating themfelves downwards into bad foil; and that by a plentiful planting of nurfing plants, to draw them upright, the neceffity of heading them down is prevented. But that thefe are correct and folid arguments, he thinks, it is much to be queftioned. No doubt, he fuppofes, exifts that tapping is of infinite advantage to all taprooted plants of the tree kind, previous to their removal, fince it caufes them to put forth fibres on the upper part of the root, which they otherwife would not have done; fitting them thereby for being tranfplanted into fhallow foils, and for feeking pafturage for the fuftenance of the plants. But that the roots will, ever afterwards, have a horizontal tendency, may, it is believed, be fairly denied. Every plant, unlefs conftrained, it is maintained, will follow its own natural inclinations and habits of growth. Nor can all the art of man prevent a downward tendency in the roots of thefe forts of tree-plants, and at the fame time allow them *depth* of foil. See TAP-*Root*.

TAPPING *of Springs*, the practice of boring through the furface covering materials of land with the auger, and letting off the hurtful water which is pent up, confined, and contained in the clayey bed or ftratum below. See SPRING-*Drain*.

TAPPING, a term applied to an operation which is fometimes performed on fheep for removing a difeafe of the local dropfical kind in the head. It is executed either by means of a very large pin, or a trocar made for the purpofe. See STURDY.

TAPPING, in *Mechanics*, a term applied to the making and rectifying of female fcrews by means of a tap, *i. e.* a fcrew prepared and referved for this purpofe. The procefs, which

 confifts

confifts of various manipulations, is minutely defcribed in Nicholfon's Journal, vol. i. p. 160—163. See SCREW.

TAPPING, in *Surgery*. See PARACENTESIS.

TAPPOOS, in *Geography*, a town on the W. coaft of Sumatra; 25 miles N. of Tappanooly.

TAPROBANA, or TAPROBANE, in *Ancient Geography*, a name anciently given to the ifland of *Ceylon;* which fee.

TAPSAGUN, a town in the interior of Africa, and one of thofe which were fubjugated by Cornelius Balbus.

TAPSAS, a river of Africa, which ran near the town of Rufìcada.

TAPSON, in *Geography*, a town of Thibet; 50 miles E. of Tchontori.

TAPSUS, or THAPSUS, in *Ancient Geography*, a peninfula on the eaftern coaft of Sicily, between Hybla parva and Syracufe.—Alfo, a promontory of Africa, 12 leagues E. of the promontory Tritum. This formed the eaftern extremity of the Sinus Numidicus.

TAPTEE, in *Geography*, a river of Hindooftan, formed by the union of feveral fmaller rivers in the Candeifh country, which runs into the gulf of Cambay, about 12 miles below Surat. See TAPPI.

TAP-TOO. See TAT-TOO.

TAPUI-TAPERA, in *Geography*, a town of Brafil, on the coaft; 15 miles N.W. of St. Luis de Marannon.

TAPURA, in *Botany*, an unexplained name of Aublet's. See ROHRIA.

TAPURA, in *Ancient Geography*, a town of Afia, in the mountains of Leffer Armenia.

TAPURI, or TAPYRI, a people of Afia, in Media.

TAPURI *Montes*, mountains of Scythia, on this fide of mount Imaus. Ptolemy.

TAPUYAS, in *Geography*, a river of Brafil, which runs into the river of the Amazons; the banks of which are inhabited by Indians, independent of the Portuguefe.

TAQUARI, a river of Brafil, having the largeft of its many mouths in the Paraguay, in lat. 19° 15', and long. 54°.

TAR. See PAMLICO.

TAR, or *Tarr*, a thick dark-brown or black refinous adhefive juice, iffuing from the wood and bark of old pines or firs, either naturally, or by burning. See PINUS.

Some modern writers inform us, that tar flows from the trunks of pines and firs, when they are very old, through incifions made in the bark near the root; that pitch is only tar infpiffated; and both are the oil of the tree grown thick and black with age and the fun. The trees, like old men, being unable to perfpire, and the fecretory ducts obftructed, they are, as one may fay, choaked and ftuffed with their own juice. But the method ufed by our colonies in America of making tar and pitch, is, in effect, the fame with that of the ancient Macedonians; as appears from the account given in the Philofophical Tranfactions. And the relation of Leo Africanus, who defcribes, as an eye-witnefs, making of tar on mount Atlas, agrees in fubftance with the methods ufed by the Macedonians of old, and the people of New England of this day. The greater part of the tar imported into Britain is brought from the Baltic, and is ftill prepared in nearly the fame method which is defcribed by Diofcorides as having been practifed by the ancients. The branches of the trees are cut into billets, and piled up in large ftacks, which are covered with turf. Fire is then applied to the wood, and it is fuffered to burn with a flow fmothered flame, during which procefs the tar is formed by the decompofition of the refinous juice, which flows to the bottom, and runs out through a fmall channel cut for the purpofe. The ftacks are generally built on the flope of a hill, fo that the tar is eafily collected, and put into barrels; in which ftate it is brought into this country. The procefs now defcribed is termed "diftillatio per defcenfum." See PINE.

A more expeditious and economical method of obtaining tar is practifed in France and Switzerland. The wood is heated in large brick ovens, conftructed for the purpofe, and thus it is charred more equally, and the tar is of a more uniform and better quality. In the Vallais the pines are felled in the preceding year, that the wood may be fufficiently dry, and when the outer bark and twigs are ftripped off, the remainder of the tree is cut into billets of tolerably equal fize. The oven is conftructed of ftone or brick, of the fhape of an egg placed on its fmall end: the floor is made either of a flat ftone, fcooped out into a hollow, or of feveral ftones accurately joined together. On one fide of it, about five inches above the loweft part, is a hole, in which a gun-barrel is thruft, and this ferves to convey off the liquid tar that is collected. A large iron grate is laid at the bottom of the oven. The largeft of thefe ovens are about ten feet high, and five or fix feet in the largeft diameter. In charging the oven, bundles of billets are thrown in and fpread as evenly as poffible, the interftices being filled with chips, till the charge nearly reaches the top. The whole is then covered with a layer of chips, and the top of the furnace is clofed with flat ftones heaped upon one another, gradually leffening the opening, and forming a kind of vaulted chimney, the mouth of which is four or five inches acrofs. The dry chips at the top of the furnace are then fet on fire, and the heat fpreads downwards, till the whole charge is fufficiently kindled. The chimney is then entirely clofed with a large ftone, and wet earth is heaped on the ftones at top, and thrown on wherever the fmoke is obferved to burft out too ftrongly. The melting then begins, and the tar falls to the bottom, fills the hollow of the floor (which detains any bits of wood and other impurities), and runs off through the gun-barrel into cafks placed for receiving it. The fire muft be occafionally refrefhed by letting in a fmall draught of air through fmall holes left for the purpofe in the fides of the kiln. When the procefs is finifhed, the wood, completely charred, is taken out, and the oven, after having been cleared out, is again filled. The red wood and knots, being the richeft in refin, are found to yield about one-fourth of their weight of tar; but the general average product is about 10 or 12 *per cent.* of the weight of the whole charge. After each procefs, a quantity of "lamp-black" is collected beneath the ftones that form the vault of the temporary chimney.

According to Theophraftus, not only the turpentine-trees, the pines, and the firs yield refin or tar, but alfo the cedars and palm-trees; and the words *pix* and *rofin* are taken by Pliny in fo large a fenfe, as to include the weepings of the lentifcus and cyprefs, and the balms of Arabia and Judæa; all which perhaps are near of kin, and in their moft ufeful qualities concur with common tar, efpecially the Norwegian, which is the moft liquid and beft for medicinal ufes. Thofe trees that grow on mountains, expofed to the fun or north wind, are reckoned to produce the beft and pureft tar; and the Idæan pines were diftinguifhed from thofe growing on the plain as yielding a thinner, fweeter, and better fcented tar. Every part of the tree, which is at all refinous, is fit for yielding tar; but the red wood and the hard roots yield the beft in quality as well as the greateft in quantity.

Every kind of wood will produce the *pyroligneous* acid (which fee), and tar by the deftructive diftillation. Peat alfo will yield it in abundance.

There

There is alſo a kind of tar, the project of making which was ſuggeſted by Becher, the celebrated chemiſt, in the time of king Charles II., which has for ſeveral years been prepared from coal in the biſhopric of Liege, and in other parts of Germany: we alſo make conſiderable quantities in England, eſpecially near Broſeley, in Shropſhire, and at Briſtol. In the biſhopric of Liege the coal is diſtilled in a kind of ſtill, compoſed of two large caſt-iron pots. In England the coal is put into ovens, which are heated by fires lighted under their bottom, and the liquid matter is forced through an iron pipe inſerted into the top of the oven, and which communicates with proper condenſing veſſels. Watſon's Chem. Eſſ. vol. ii. p. 346, &c.

The earl of Dundonald, in Scotland, has lately invented the art of extracting tar and pitch from pit-coal, by a new proceſs of diſtillation. See Addreſs and Propoſals by ſir John Dalrymple, 1784.

A ſubſtance reſembling tar, called "brai-gras," and much uſed by the French for careening ſhips, is made in the following manner. The oven, deſcribed in the preceding part of this article, is charged with alternate layers of chips of green wood, and billets of dry, and all the refuſe matter of turpentine, &c. Over the whole is laid a ſtratum of "braihee," or roſin, and the gun-barrel pipe is ſtopped up, and not tapped till the whole of the wood is reduced to charcoal. The vault of the oven is alſo covered more carefully after the charge is ſufficiently kindled, and the whole proceſs is carried on more ſlowly, and the heat of the fire melts the roſin at the top, which mixes with the reſinous ſap, and the whole concretes into a dark reſinous liquid at the bottom. When it is ſufficiently cooled, it is drawn off and barrelled. This "brai-gras" is of an intermediate conſiſtence between tar and roſin. Aikin's Dict.

Tar is properly an empyreumatic oil of turpentine, and has been much uſed as a medicine both internally and externally.

Tar in ſubſtance, mixed with honey, has been found an excellent medicine for coughs.

The ancients eſteemed tar good againſt poiſons, ulcers, the bites of venomous creatures; alſo for phthiſical, ſcrofulous, paralytic, and aſthmatic perſons. But the method of rendering it an inoffenſive medicine, and agreeable to the ſtomach, by extracting its virtues in cold water, was unknown to them. Siris, ſect. 9. 16, 17. 21. 28. See TAR-*water*, infra.

Tar is ſometimes given in ſubſtance, mixed with ſo much powdered liquorice, or other ſuch powdery matter, as is ſufficient to render it of a fit conſiſtence to be formed into pills. An ointment of tar has been directed in the pharmacopeias, which has been chiefly employed in cutaneous diſorders. See UNGUENTUM *è Pice*.

Dr. Cullen mentions an empirical practice, with reſpect to tar, which is as follows. A leg of mutton is laid to roaſt, and whilſt it is roaſting it is baſted with tar. Whilſt the roaſting is continued, a ſharp ſkewer is frequently thruſt into the ſubſtance of the mutton, ſo that the gravy may run out: with a mixture of the tar and gravy found in the dripping-pan, the body is to be anointed for three or four nights ſucceſſively, and during the time the ſame linen is to be worn. This is alleged to be a remedy in ſeveral caſes of lepra; and Dr. Cullen knew one inſtance of its having been employed in a lepra icthyoſis with great ſucceſs; but he had no opportunities of repeating the practice.

But the chief uſe of tar is for paying the ſides of ſhips and boats, and their rigging, in order to preſerve them from the effects of the weather, which would otherwiſe crack or rot them.

The tar obtained from the depoſition of pyroligneous acid has been recommended as the beſt preſervative for every kind of wood-fence. For this purpoſe, it ſhould be gently heated in an iron pot, and laid on with a bruſh. It ſoaks into the wood, and ſeems to leave no body, as the artiſts expreſs it; but after ſome days' expoſure to the ſun, the ſurface and texture of the wood will be much altered; for it will be found ſo impervious and hard, that it will be very difficult to make any impreſſion upon it. If a ſecond, and eſpecially if a third coat of this tar be put upon wood, it will then *bear out*, as the painters call it, ſufficiently well; and Mr. Parkes is of opinion that it will preſerve all outſide wood-work much more effectually than any other means that have hitherto been employed for the purpoſe. For ornamental paling, and all outſide work, a firſt, and perhaps a firſt and ſecond coat of this tar might be uſed with great advantage; and when theſe are dry, white lead and oil might be uſed to finiſh the work. This ſubſtance not only hardens the wood, but effectually preſerves it from worms and from all other inſects. It will ſtop the progreſs of decay, when wood has become worm-eaten. It is obſerved, however, that this tar is very different from that which is diſtilled from mineral coal, but which the earl of Dundonald recommended for a ſimilar purpoſe. The appearance of the application may be very conſiderably improved by the following preparations; *viz.* 1 gallon of tar, 1 oz. of tallow, 2 oz. of pulverized roſin, melted together and put on warm; — or, 1 gallon of the tar and 2 oz. of pulverized ſulphate of iron, uſed as the other. This tar has alſo been found an uſeful varniſh for articles made of rolled iron, or of caſt-iron. A beautiful varniſh for theſe purpoſes may be formed by intimately mixing in a gentle heat one gallon of the wood-tar with half a pint of rectified ſpirits of wine. If this be laid on hot and properly hardened, it will prove a beautiful and durable black varniſh. Parkes's Chem. Eſſ. vol. ii.

Tar may ſometimes be found uſeful as an application for cuts in ſheep by clipping, and alſo to the parts affected by the fly; as well as in thoſe of many other ſorts of animals. It is likewiſe applied to the axles of wheel-carriages, in order to prevent friction, and might probably be ſtill more beneficially made uſe of in this intention, by having a portion of black-lead incorporated with it, as it would laſt longer, and be, at the ſame time, more powerful in obviating the effects of friction.

It is a material which has alſo been recommended for being applied to the parts of trees from which boughs are taken; in which caſes, the faces of the wounded parts and the edges of the bark are to be made perfectly ſmooth by means of a proper knife; and in a few hours afterwards, or as ſoon as the parts are become quite dry, they are to be carefully plaiſtered over with the tar, which is ſimilar to that employed for ſmearing of ſheep; or they may be laid over with white or blue lead paint, well mixed with oil, and made rather thicker than that commonly uſed in painting. The tar is, however, certainly preferable, being of a more adhering, healing nature; and, when laid on in a thin ſtate, is not ſo apt to fall off in a ſcaly manner by the action and effects of the weather, as is the caſe with the other ſubſtances.

As the component parts of vegetable tar have been found to conſiſt of oil, reſinous matter, pyroligneous acid, and water; that which is of the fineſt brown colour, has the leaſt acridity, and which is the freeſt from a dark black appearance, is probably the beſt and moſt proper for uſe in applications as dreſſings to animals; though the other kinds may be equally or more beneficial in different other intentions.

Tar, when in intimate mixture and union with butter or lard, and the different precipitates of mercury or ſulphur, forms an excellent application in different difeafes of various kinds of animals, efpecially thofe of the fkin.

Tar, *Barbadoes*. See Bitumen, and Petroleum *Barbadenfe*.

Tar, *Mineral*. See Bitumen.

Tar-*Water*. As the cold infufion of tar has been formerly much in vogue, and has been recommended by one of the moft learned and ingenious writers of the age, it may not be improper to give fome account of its virtues from the bifhop of Cloyne's Siris, or chain of reflections concerning the virtues of tar-water.

In fome parts of America, tar-water is made by putting a quart of cold water to a quart of tar, and ftirring them well together in a veffel, which is left ftanding till the tar finks to the bottom. A glafs of clear water being poured off for a draught, is replaced by the fame quantity of frefh water, the veffel being fhaken, and left to ftand as before. And this is repeated for every glafs, fo long as the tar continues to impregnate the water fufficiently, which will appear by the fmell and tafte.

But as this method produces tar-water of different degrees of ftrength, the author fays he chufes to make it in the following manner: Pour a gallon of cold water on a quart of tar, and ftir and mix them thoroughly with a ladle or flat ftick, for the fpace of three or four minutes; after which the veffel muft ftand eight-and-forty hours, that the tar may have time to fubfide; when the clear water is to be poured off, and kept for ufe, no more being made from the fame tar, which may ftill ferve for common purpofes.

This cold infufion of tar hath been ufed in fome of our colonies as a prefervative or preparative againft the fmall-pox, which foreign practice induced the bifhop to try it in his own neighbourhood, when the fmall-pox raged with great violence. He fays the trial fully anfwered his expectation; all thofe within his knowledge, who took the tar-water, having either efcaped that diftemper, or had it very favourably. Several were preferved from taking the fmall-pox by the ufe of this liquor; others had it in the mildeft manner; and others, that they might be able to take the infection, were obliged to intermit drinking tar-water. He fays, he has found it may be drank with great fafety and fuccefs for any length of time, and this not only before, but alfo during the aforefaid diftemper.

The general rule for taking it is, about half a pint night and morning, on an empty ftomach, which quantity may be varied according to the cafe and age of the patient; provided it be always taken on an empty ftomach, and about two hours before or after a meal.

It has been found, that feveral perfons infected with cutaneous eruptions and ulcers were immediately relieved, and foon after cured, by the ufe of this medicine. It is faid, that even in the fouleft diftempers, it proved much more fuccefsful than falivations and wood-drinks had done. It alfo fucceeded, beyond expectation, in a tedious and painful ulceration of the bowels, in a confumptive cough, and (as appeared by expectorated pus) an ulcer in the lungs, in a pleurify and peripneumony. And when a perfon who had been for fome years fubject to eryfipelatous fevers, perceived the ufual forerunning fymptoms to come on, the drinking of tar-water prevented the eryfipelas.

Tar-water cures indigeftion, and gives a good appetite. It is an excellent medicine in an afthma; it imparts a kindly warmth, and quick circulation to the juices, without heating, and is therefore ufeful, not only as a pectoral and balfamic, but alfo as a powerful and a fafe deobftruent in cachectic and hyfteric cafes. As it is both healing and diuretic, it is very good for the gravel. The bifhop fays he believes it to be of great ufe in a dropfy, having known it cure a very bad anafarca in a perfon whofe thirft, though very extraordinary, was in a fhort time removed by the drinking of tar-water. From the fuccefs of this medicine in five or fix inftances, the bifhop believes it to be the beft and fafeft, either for preventing the gout, or for fo ftrengthening nature againft the fit, as to drive it from the vitals.

It may likewife be fafely ufed in inflammatory cafes; and, in fact, hath been found an admirable febrifuge, at once the fafeft cooler and cordial.

The falts and more active fpirits of tar are got by infufion in cold water; but the refinous part is not to be diffolved thereby. Hence the prejudice which fome, perhaps, may entertain againft tar-water, the ufe of which might inflame the blood by its fulphur and refin, as a medicine, appears not to be well grounded. It is obferved by chemifts, that all forts of balfamic wood afford an acid fpirit, which is the volatile oily falt of the vegetable. Herein is chiefly contained their medicinal virtues; and this author affirms, that by the trials he has made, it appears that the acid fpirit in tar-water poffeffes the virtues, in an eminent degree, of that of guaiacum, and other medicinal woods.

It is certain tar-water warms, and therefore fome may perhaps ftill think it cannot cool. The more effectually to remove this prejudice, let it be farther confidered, that, as on one hand, oppofite caufes do fometimes produce the fame effect; for inftance, heat by rarefaction, and cold by condenfation, do both increafe the air's elafticity; fo, on the other hand, the fame caufe fhall fometimes produce oppofite effects. Heat, for inftance, in one degree thins, in another coagulates, the blood. It is not therefore ftrange, that tar-water fhould warm one habit and cool another; have one good effect on a cold conftitution, and another good effect on an inflamed one; nor, if this be fo, that it fhould cure oppofite diforders.

A medicine of fo great virtue in fo many different diforders, and efpecially in that grand enemy the fever, muft needs be a benefit to mankind in general. There are neverthelefs three forts of people to whom the bifhop fays he would peculiarly recommend it; fea-faring perfons, ladies, and men of ftudious and fedentary lives. See Two Letters from the Bifhop of Cloyne, &c. publifhed in 1747.

If it be afked, what precife quantity, or degree of ftrength, is required in tar-water? It is anfwered, that the palate, the ftomach, the particular cafe and conftitution of the patient, the very feafon of the year, will difpofe and require him to drink more or lefs in quantity, ftronger or weaker in degree. Precifely to meafure its ftrength by a fcrupulous exactnefs, is by no means neceffary.

It is to be obferved, that tar-water fhould not be made in unglazed earthen veffels, thefe being apt to communicate a naufeous fweetnefs to the water.

The fame ingenious author recommends tar-water in the plague, and for the diftemper among the horned cattle; with what fuccefs, muft be left to experience.

Though this medicine, fays Dr. Lewis, is undoubtedly very far inferior to the character that hath been given of it, it is apparently capable of anfwering important purpofes, as a deobftruent balfamic folution, moderately warm and ftimulating. It fenfibly raifes the pulfe, and increafes either perfpiration or the groffer evacuations. He adds, "I have been informed of fome late inftances of its good effects in diforders of the leprous kind." Mat. Med.

Dr. Cullen thinks that the acid principle gives the virtue to tar-water, and on this account the bifhop of Cloyne properly preferred the Norway tar to that of New England, as the former contains more acid than the latter. This eminent

phyfician

phyſician acknowledges that he found this preparation in ſeveral caſes to be a valuable medicine; and that it appeared to ſtrengthen the tone of the ſtomach, to excite appetite, to promote digeſtion, and to cure all ſymptoms of dyſpepſia. At the ſame time, it manifeſtly promotes the excretions, particularly that of urine. From all theſe operations, it will be obvious, as the doctor thinks, that in many diſorders of the ſyſtem this medicine may be highly uſeful. Lewis. Woodville.

It has been lately obſerved by Dr. Darwin, that the watering of ground with tar-water is capable of deſtroying the white ſlug, which is ſo highly deſtructive to vegetables.

Tar-*Kettle*, in *Rope-Making*, is made of copper, and holds from ten to twenty barrels of tar. It is ſet in ſtrong brick-work, and over it is faſtened, from ſide to ſide, in the direction of the nipper, a bridge, made of three-inch oak-plank, thirteen inches broad, through the middle of which is a mortiſe for the ſtep to go through, to keep the yarn down and clear of the bottom, when drawing through the kettle. On the ſide of the kettle next the capſtern, is an upright poſt, twelve inches ſquare, in which is fixed a nipper to preſs the tar out of the yarn; and a ſtaff, with a weight ſuſpended at the end, is fixed on the ſide of the nipper to keep it down, that the yarn may imbibe no more tar than is neceſſary.

Tar-*Rope*, a term uſed to ſignify tarred rope, or rope-yarn, ſuch as the thread of old cables, &c. This ſort of tar-rope is uſeful for a great number of different purpoſes, ſuch as thoſe of tying up the wads or ſheaves of beans in the field, and many other ſimilar articles; the faſtening of plants and trees to various kinds of ſupports; and for being applied to a variety of other little uſes of the more domeſtic kind, as being cheap and readily procured.

Tar, in *Commerce*, a ſmall ſilver coin on the coaſt of Malabar.

Tar, in *Sea Language*, a figurative expreſſion for a ſailor of any kind.

TARA, in *Geography*, a town of Ruſſia, in the government of Tobolſk, on the Irtiſch; 220 miles E.S.E. of Tobolſk. N. lat. 57°. E. long. 74° 43′.—Alſo, a town of Japan, in the iſland of Xicoco; 28 miles N.N.E. of Ovutſi.

Tara *Hill*, a mountain of Ireland, in the county of Wexford, near the ſea-coaſt; 4 miles N. of Newborough. See Taragh.

Tara, the name of a ſimian hero renowned in the Hindoo epic the Ramayana, for mighty deeds in battle with the hoſts of the tyrant Ravena, for the recovery of Sita, the raviſhed ſpouſe of Rama.

TARAAN, in *Geography*, a town of Grand Bucharia; 50 miles E. of Samarcand.

TARABAD, a town of Hindooſtan, in Baglana; 13 miles E. of Saler Mooler.

TARABE, in *Ornithology*, the name of a Braſilian parrot, larger than the common green parrot. Its general colour is green; but its head, breaſt, and the origin of its wings, are red; its beak and legs are of a duſky grey. Marcgrave. See Psittacus.

TARACASSA, in *Geography*, a diſtrict of South America, in the viceroyalty of Buenos Ayres, part of the juriſdiction of Carangas.

TARAE Lapis, the name given by the writers of the middle ages to a ſtone which they ſay had the power of ſtopping all ſorts of fluxes. They have left us no deſcription of it, and it ſeems to have been loſt even in their times; for they obſerve that the phyſicians uſed the *ſanguis draconis*, or dragon's-blood, in its place.

TARAGH, in *Geography*, a ſmall town or rather village of the county of Meath, Ireland, on the noted hill of Taragh; where the ſtates of Ireland are ſaid to have aſſembled, and where ſome pretend that there was a magnificent palace belonging to the kings of Ireland; but as no trace of any ſuch palace is to be found, its having exiſted muſt be regarded as improbable. General Vallancey accounted for there being no trace of it, by ſuppoſing it to have been made of mud and ſtraw. A Daniſh invader is alſo ſuppoſed to have taken up his abode here, and to have built the fine Daniſh fort, or rath, on the ſouth-eaſt ſide of the hill, which is now beautifully planted. It is 5 miles N. by W. from Dunſhaghlin, and 19 miles from Dublin, on the road to Cavan. There are two other hills of the ſame name, one in the county of Down, and the other in the county of Wexford, both of them near the ſea.

TARAGOT, or Taragale, a town of Africa, in the country of Darah; 130 miles S.E. of Morocco.

TARAGUICO Aycuraba, in *Zoology*, the Braſilian name for a ſpecies of lizard, much approaching to the nature of the taraguira; but its tail is covered from its beginning with ſmall triangular ſcales, and very regularly marked with four brown ſpots; the back alſo, particularly that part which is next the head, is variegated with undulated brown lines. Ray.

TARAGUIRA, the name of an American lizard. It grows to about a foot long; its body is rounded, and every where covered with ſmall triangular duſky grey ſcales; its back is ſmooth, and it has not that falſe gullet under the throat which the iguana has.

This is the ſpecies of lizard of which it is reported, that it will wake a ſleeping perſon, if it ſee him in danger of being bitten by a ſerpent. It is very common about houſes and gardens in South America, and runs very ſwiftly, but with a waddling motion; and when it ſees any thing at a diſtance, has an odd way of nodding its head very ſwiftly. Ray.

TARAGUPALA, in *Geography*, a town of Hindooſtan, in Tellingana; 25 miles N.W. of Warangole.

TARAKLI, a town of European Turkey, in Beſſarabia; 24 miles S.S.W. of Bender.

TARALEA, in *Botany*, a barbarous name of Aublet's. See Dipteryx, ſpecies 2d.

TARAMA, in *Geography*, a juriſdiction of Peru, in the audience of Lima. The air is healthy, and the ſoil fertile.

TARAMAMON, a name given by Loubere to a ridge of mountains that paſſes E. and W. in Siam, not far to the north of Yuthia.

TARAMANDAHU, a river of Braſil, which runs into the Atlantic, S. lat. 30° 40′.

TARAMEH, Al, a town of Egypt, in ruins; 2 miles N.E. of Tineh.

TARAMUNDE, a town of Spain, in Aſturia; 45 miles W. of Oviedo.

TARANCON, a town of Spain, in New Caſtile; 33 miles S.E. of Madrid.

TARANDUS, in *Entomology*, a ſpecies of *Lucanus*; which ſee.

Tarandus, in *Zoology*, a name given by Agricola, and ſome other authors, to the rein-deer. See Cervus *Tarandus*.

TARANIOLO, in *Ornithology*, a name by which the whimbrel, or ſmall curlew, called the *arquata minor* by authors, is known in the markets of Italy.

TARANIS, probably from *taran*, thunder, in *Ancient Mythology*, a name given by the Gauls to Jupiter, under which appellation they ſacrificed human victims to him.

Taranis correfponded to the Jupiter Tonans of the Romans. See Thor.

TARANNON, in *Geography*, a river of North Wales, which runs into the Severn; 4 miles W. of Newtown in Montgomeryfhire.

TARANSA, one of the Weftern iflands of Scotland, about four miles in length, and two in breadth, where wideft, but in fome places fcarcely half a mile acrofs; 5 miles N.E. from Toe-Head. N. lat. 57° 52′. W. long. 6° 59′.

TARANTA, the name of mountains of Abyffinia, that lie on the eaft of the kingdom.

TARANTARA, according to Ennius, the military trumpet's flourifh of the Romans.

TARANTELLA, a rapid tune played to perfons in Calabria, fuppofed to be bitten by the tarantula, in order to excite them to dance, which has been thought, while the difeafe was believed, to be the only fpecific.

TARANTISMUS, in *Medicine*, the difeafe or affection of thofe bit by the tarantula.

The patients under this malady are denominated *tarantati*.

Dr. Cornelio, in the Philofophical Tranfactions, reprefents this as an imaginary difeafe; and tells us, that the tarantati, or thofe that think themfelves feized with it, (excepting fuch as for particular ends feign themfelves fo,) are moft of them young wanton girls, fuch as the Italian writers call *Donne di fale*, who, falling from fome particular indifpofition, into melancholy madnefs, perfuade themfelves, according to vulgar prejudice, that they have been bitten by a tarantula.

But the evidence, on the other fide of the queftion, has gained confiderable credit, as will appear from the article Tarantula.

TARANTOLA, in *Geography*, a town of Naples, in Abruzzo Citra; 10 miles E.N.E. of Sulmona.

TARANTULA, or Tarentula, in *Natural Hiftory*, a venomous infect, whofe bite gives name to a new difeafe, called *tarantifmus*.

The tarantula is a kind of fpider, the *aranea tarantula* of Linnæus, fo denominated from the city of Tarentum, in Apulia, near which it is chiefly found. It is alfo called *phalangium Apulium*. Valetta, a monk of Apulia, who had always refided about the places where this mifchievous animal is moft frequent, and had many opportunities of tracing its feveral qualities, publifhed a fuccinct, but very accurate hiftory of it in the year 1706, under this name.

It has its name *phalangium*, from the three phalanges or joints of its legs, and this name equally fuiting many other fpiders, as well as this, it ceafed to be its appropriated name, and was applied as a generical term to feveral other fpiders of the larger kind, among which this fpecies was always diftinguifhed by the epithet *Apulian*, from the place where it was fo frequently found.

The tarantula, or Apulian phalangium, is frequent in all parts of this country, in uncultivated places, but more efpecially it breeds moft in funny dry hills, and particularly in fuch parts of them as are expofed to the fouth.

It is faid not to be found any where except in Apulia, but probably it is an inhabitant of many other places, though its poifon may not be violent enough any where elfe to bring on the effects it does there: as we find in vipers and many other poifonous creatures, that the ftrength of their poifon differs greatly in degree in different places.

M. Geoffroy fays, that it is the opinion of fome that the tarantula is never venomous but in the coupling feafon; and Baglivi fays, that it is never fo but in the heat of fummer; particularly in the dog-days, when, becoming enraged, it flies on all that pafs by.

As this fpider is very tender, and eafily injured by cold winds and rain, it always digs itfelf a cave in the fide of a hill for its habitation; and ufually chufes for this purpofe the hardeft ground it can find, which is better able to defend it, and which it eafily works into, with its forceps and claws. This always is hollowed upward in the hill, and by that means is fafe from wet, all the water in rainy feafons running down over its top. Sometimes it burrows itfelf a cave in a valley or plain, but then it always chufes a dry, ufually a chalky foil. In this cafe, the entrance into its cave is fmall, and within, there are feveral winding paffages: if it happens to be furprifed with wet in this place, from hard rains, it quits the floor and hangs by its feet againft the top of the cave. It preys upon a number of fmall infects, with which the fields of Apulia abound, and feldom appears in the day-time, but creeps out about the time of fun-fet, and preys at large upon the animals which are then betaking themfelves to reft; without the danger it would be expofed to from its own enemies by day-light. If at any time he remains the whole evening in his cave or den, it is only to practife another method of hunting his prey. In this cafe, he comes forward to the mouth of the hole, and there lies in wait; his fore-legs are placed at the extremity of the hole, and his eyes have a clear view all round. The other infects are not aware of this trick, but as they walk near his hole he burfts out upon them, and feizing them, he conveys them into his habitation; where, as foon as he has eaten them, he retires back into his cell to difpofe of the wings and other fragments, till he can carry them out at a more convenient time, and then places himfelf in his former pofture for another prey.

The peafants of Apulia have a method of getting him out of his hole in the day-time, in order to deftroy him. This they do by making a foft hiffing noife through an oat ftraw: whether it be that the creature loves this found, or rather that he takes it for the voice of fome infect that he is ufed to prey upon, he always comes out, and falls a facrifice to his greedinefs.

The creature has eight legs, and walks very well; his legs have each three joints, and are covered with a fine downy hairinefs; they are of a whitifh colour at the bottom, and variegated with black lines, and are wholly black in their upper part, where they are joined to the breaft: thefe all arife from a kind of oval fhield, which is placed upon the breaft, and is black, hairy, and very hard: this is called by fome the *fpeculum* of the tarantula. From the fhoulders there grow a pair of horns, at leaft they are ufually called fo, though they feem much better to deferve the name of *arms*; the ufe of thefe is to hold faft the prey, that it may not be able to efcape while he is killing it with his forceps: thefe horns or arms have the fame number of joints that the legs have, but they greatly differ from the legs, in that they are fhorter, and of a yellowifh colour; they are alfo covered with a longer and thicker hair, for the more certainly holding the prey, and are terminated by black claws, and they are much fmaller and more capable of motion every way. The belly is either white, or of a pale yellow, and is marked with a tranfverfe black ftreak: this is furrounded with feveral other fmall fpots of the fame colour, and is clothed with a very fine and fhort down; the whole body befide is covered with longer hairs, and is of a whitifh or brownifh colour; the apex of the head, the fhield of the breaft, and the ends of the forceps, are as hard as a crab's claws; but the reft of the body is covered with a tender fupple fkin: the eyes are very large, and of a fine ſhining black; they are continually in motion, and, when ſeen in the night, or in a duſky place, they ſhine like the eyes of a cat. In the place where the mouth is placed in other animals, there ariſes in this a black hard forceps; the upper part of this inſtrument is covered with a yellow hairineſs, and it is terminated by extremely fine and ſharp claws, which the creature can open or cloſe up at pleaſure. While the arms hold the prey in a proper poſition, theſe ſharp points make wounds in the body, and the other parts of the forceps ſqueeze the body till all its juices are preſſed out, and the creature feeds on them: the mouth is placed much below theſe, and ſtands exactly in the proper place to receive the juices expreſſed by this operation. The tarantula ſleeps in his cave the whole winter, and a great part of the autumn and ſpring; and if during this time he is ploughed up, as is often the caſe, or is any other way taken out of his hole, he is found quite torpid and numbed, and is unable to do any miſchief by biting.

The hole or mouth of a tarantula's cave always gives ſome idea of the ſize of the creature within: he makes it ſmall if he enters it while young; and as he grows larger, he eats away more and more of the earth to widen it ſtill more, ſo that the diameter of it is uſually about equal to the diameter of the body. The ſize of a cheſnut is about the ſtandard of a full-grown tarantula; but there are ſome old ones found much larger and more hairy. The female is known from the male by having longer legs and a larger belly. They copulate in June and July, and at that ſeaſon the females are often met with in the fields carrying the males upon their backs. In Auguſt and September they lay their eggs, which remain the whole winter; and in the ſummer after are hatched.

Pliny tells a ſtory of the young ones always eating up their mother for the firſt food, which is countenanced by the relation of the peaſants in thoſe parts, who ſay that they all ſwarm about her and ſuck her juices from many places at once, till they leave her a lifeleſs carcaſe on the field, and then go each their ſeveral ways in ſearch of other food. The bite of the tarantula, as it is called, is not properly a bite, but a wound inflicted in a very peculiar manner. The creature pierces the ſkin with its forceps, and at that inſtant injects from its mouth a poiſon into the wound. The time in which their wounds are fatal, is that of their copulation; at this time they are in their utmoſt vigour and power of hurting. People of faſhion are rarely hurt by them, but principally the poor labourers, who ſleep half naked in the field, and the women who travel the country with naked feet, gathering medicinal herbs.

The bite occaſions a pain, which at firſt ſeems much like that felt on the ſtinging of a bee, or an ant: in a few hours the patient feels a numbneſs, and the part affected becomes marked with a little livid circle, which ſoon after riſes into a very painful tumour; a little after this he falls into a profound ſadneſs, breathes with much difficulty, his pulſe grows feeble, and his ſenſes fail; at length he loſes all ſenſe and motion; and dies, unleſs relieved. But theſe ſymptoms come ſomewhat differently, according to the nature of the tarantula, and the diſpoſition of the patient. An averſion for black and blue; and, on the contrary, an affection for white, red, and green; are other of the unaccountable ſymptoms of this diſeaſe.

All the aſſiſtance medicine has been able to diſcover by reaſoning, conſiſts in ſome chirurgical applications on the wound, and in cordials and ſudorifics; but theſe are of little efficacy: a thing that avails infinitely more, is, what reaſon could never have diſcovered—muſic.

As ſoon as the patient has loſt his ſenſe and motion, a muſician tries ſeveral tunes on an inſtrument; and when he has hit on that, the tones and modulations of which agree with the patient, he is immediately ſeen to make a faint motion: his fingers firſt begin to move in cadence, then his arms, then his legs, by degrees his whole body; at length he riſes on his feet, and begins to dance; his ſtrength and activity ſtill increaſing. Some will continue the dance for ſix hours without intermiſſion.

After this he is put to bed, and when he is judged ſufficiently recruited from his firſt dance, he is called out of bed, by the ſame tune, for a ſecond.

This exerciſe is continued for ſeveral days, ſix or ſeven at leaſt; in which time the patient finds himſelf exceedingly fatigued, and unable to dance any longer; which is the characteriſtic of his being cured; for as long as the poiſon acts on him, he would dance, if one pleaſed, without any diſcontinuance, till he died of the mere loſs of ſtrength.

The patient, on this, perceiving himſelf weary, begins to come to himſelf; and awakes as out of a profound ſleep; without any remembrance of what had paſſed in his paroxyſm, not even of his dance.

Sometimes the patient, thus recovering from his firſt acceſs, is quite cured; if he be not, he finds a melancholy gloom hanging on him; he ſhuns the ſight of men, and ſeeks water; and, if he be not carefully looked to, throws himſelf into ſome river. If he do not die, the fit returns at that time twelvemonth, and he is driven to dancing again. Some have had returns regularly for twenty or thirty years.

Every tarantula has his particular and ſpecific tune; but, in the general, they are all very briſk, ſprightly ones, that work cures.

This account was given in the Royal Academy of Sciences, by M. Geoffroy, at his return from Italy, in 1702, and confirmed by letters from F. Gouye. The like hiſtory is given by Baglivi, in an expreſs diſſertation on the tarantula, publiſhed in 1696.

Authors are divided about the nature of the poiſon of the tarantula. Cardan ſays it is a cold one, and Scaliger ſays it is a hot one; but, be this as it will, Valetta informs us, that its effect is very ſudden; it is no ſooner received into the fleſh, but the veins take it up and carry it to the heart, where it becomes diffuſed through the whole maſs of blood, and gives an immediate trembling of the limbs, and a difficulty of breathing. The next part it ſeizes is the brain, where it produces different effects in different ſubjects; and, according to their ſtate of health, and the condition of their juices, brings on various ſpecies of phrenſies. The patient ſees a thouſand phantoms, ſometimes all jovial and merry ones, and ſometimes imaginary ſcenes of blood and cruelty. Some are fond of ſeeing little ſtreams of water trickling down into a baſon; others are never eaſy unleſs they have green leaves before them. this indeed is almoſt an univerſal ſymptom. Some are delighted with various colours, and ſome are fond of violent motion, ſuch as dancing, leaping, and the like; and ſome are in love with ſlow and graceful movements, as walking majeſtically, bowing, and dancing ſlow dances. Some are military mad, and call out for the noiſe of drums and trumpets, and the claſhing of ſwords; but all of them, as well the briſk and noiſy, as the lethargic and dull, are pleaſed with muſic.

They will get up and dance to any inſtrument; and the moment it ceaſes playing, they will fall down to the ground as if apoplectic, and not ſtir again till the muſic is renewed. Many people have laughed at the whole hiſtory of the bite of a tarantula, from this one accident of its poiſon being

cured

cured by muſic; but all who have been upon the ſpot atteſt it. Valett. de Phaleng. Apulo.

To ſuch extraordinary facts, it is no wonder a few fables ſhould be added; as, for inſtance, that the patient is no longer infected than while the inſect lives; and that the tarantula itſelf dances, all the while, to the ſame air with the perſon bitten.

Dr. Dominico Cirillo, profeſſor of natural hiſtory at the univerſity of Naples, poſitively contradicts the teſtimonies above recited. Having had an opportunity of examining the effects of this animal, in the province of Taranto, where it is found in great abundance, he affirms that the ſurpriſing cure of the bite of the tarantula by muſic, has not the leaſt truth in it; and that it is only an invention of the people, who want to get a little money, by dancing when they ſay the tarantiſm begins. He makes no doubt but the heat of the climate contributes very much to warm their imagination, and to throw them into a delirium, which may be in ſome meaſure cured by muſic: but ſeveral experiments have been tried with the tarantula; and neither men nor animals, after the bite, have had any other complaint, except a very trifling inflammation on the part, like that produced by the bite of a ſcorpion, which goes off by itſelf without any danger at all. In Sicily, where the ſummer is ſtill warmer than in any part of the kingdom of Naples, the tarantula is never dangerous, and muſic is never employed for the cure of the pretended tarantiſm. It is without doubt very extraordinary, ſays this writer, that a man of ſenſe, and a phyſician of great learning, as Baglivi was, ſhould have been ſatisfied with the account of this diſorder; and that, inſtead of examining the facts by experiments, he ſhould rather have tried to explain it: but even philoſophers like very much to meet with wonderful and extraordinary things, and though they are againſt all reaſon, ſtill they want them to be true, and endeavour to find out the cauſe of them. Every year this ſurpriſing diſorder loſes ground; and he is perſuaded, that in a very little while it will entirely loſe its credit. The Neapolitan phyſicians all look upon the tarantula in the ſame light, particularly after the ingenious book publiſhed on this ſubject by the learned Dr. Serao; who, by various experiments, has proved, that the bite of the tarantula never produced any bad effects, and that muſic never had any thing to do with it. Phil. Tranſ. vol. lx. art. 22.

The bite of the tarantula, and the method of its cure, were, however, for many years ſubjects of elaborate diſcuſſion; and different theories were propoſed for explaining them, ſome account of which it may not be improper to preſerve.

Theory of the Tarantula's Bite, by M. Geoffroy. The poiſonous juice injected by the tarantula, M. Geoffroy conceives, may give the nerves a degree of tenſion greater than is natural to them, or than is proportionate to their functions: and hence may ariſe a privation of knowledge and motion. But, at the ſame time, this tenſion, equal to that of ſome ſtrings of an inſtrument, puts the nerves in uniſon to certain tones, and obliges them to ſhake, after being agitated by the undulations and vibrations of the air proper to thoſe tones. And hence this wonderful cure by muſic: the nerves, thus reſtored to their motion, call back the ſpirits thither, which before had abandoned them.

It may be added, with ſome probability, and on the ſame principles, that the patient's averſion for ſome colours ariſes hence, that the tenſion of his nerves, even out of the paroxyſm, being ſtill different to what it is in the natural ſtate, the vibrations thoſe colours occaſion in the fibres of the brain, are contrary to their diſpoſition, and occaſion a kind of diſſonance, the effect of which is pain.

Theory of the Effects of the Tarantula's Bite, by Dr. Mead. The malignity of the poiſon of the tarantula ſeems to conſiſt in its great force and energy, whereby it immediately raiſes an extraordinary fermentation in the whole arterial fluid, by which its texture and craſis are conſiderably altered: the conſequence of this alteration, when the ebullition is over, muſt neceſſarily be a change in the coheſion of its parts, by which the globules, which did before with equal force preſs each other, have now a very differing and irregular niſus, or action; ſo that ſome of them do ſo firmly cohere together, as to compoſe moleculæ, or ſmall cluſters: upon this account, as there is now a greater number of globules contained in the ſame ſpace than before, and the impulſe of many of theſe, when united together, differing according to the conditions of their coheſion, as to magnitude, figure, &c. the impetus with which this fluid is driven towards the parts, will not only be ſeen at ſome ſtrokes greater than ordinary, but the preſſure upon the blood-veſſels muſt be very unequal and irregular; and this will be particularly felt in thoſe which are moſt eaſily diſtended, as thoſe of the brain, &c.

Upon this, the nervous fluid muſt neceſſarily be put into various undulatory motions, ſome of which will be like thoſe, which different objects, acting upon the organs or paſſions of the mind, do naturally excite in it; upon which ſuch actions muſt follow in the body, as are uſually the conſequences of the ſeveral ſpecies of ſadneſs, joy, deſpair, or the like determinations of thought.

This, in ſome degree, is a coagulation of the blood, which will, the more certainly, when attended with uncommon heat, as is the caſe in thoſe countries where theſe creatures abound, produce ſuch like effects as theſe: becauſe the ſpirits ſeparated from the blood thus inflamed, and compounded of hard, fixed, and dry particles, muſt unavoidably ſhare in this alteration; that is, whereas their fluid conſiſts of two parts, one more active and volatile, the other more viſcid and glutinous, which is a kind of vehicle to the former; their active part will bear too great a proportion to the viſcid; and conſequently they muſt have more than ordinary volatility and force; and will, therefore, upon the leaſt occaſion imaginable, be irregularly determined to every part.

Whereupon will follow tremblings, anger, or fear, upon a light cauſe; extreme pleaſure at what is trivial, as particular colours, or the like; and, on the other hand, ſadneſs at what is not agreeable to the ſight; nay laughter, obſcene talk and actions, and ſuch other ſymptoms as attend perſons bit; becauſe, in this conſtitution of nervous fluid, the moſt ſlight occaſion will make as real a reflux and undulation of it to the brain, and preſent as lively ſpecies there, as the ſtrongeſt cauſe and impreſſion can produce in its natural ſtate and condition: nay, in ſuch a confuſion the ſpirits cannot but ſometimes, without any manifeſt cauſe at all, be hurried towards thoſe organs, to which, at other times, they have been moſt frequently determined; and every one knows which theſe are in hot countries.

The effect of muſic on perſons touched with this poiſon confirms the doctrine above delivered. For muſcular motion, we know, is no other than a contraction of the fibres, from the arterial fluid's making an effervefcence with the nervous juice, which, by the light vibration and tremor of the nerve, is derived into the muſcle.

Thus there is a twofold effect and operation of the muſic, that is, upon the body and the mind: a briſk harmony excites

cites lively ſpecies of joy and gladneſs, which are always accompanied with a more frequent and ſtronger pulſe, or an increaſed impulſe of the liquor of the nerves into the muſcles; upon which ſuitable actions muſt immediately follow.

As for the body, ſince it was ſufficient to put the muſcles into action, to cauſe thoſe tremors of the nerves, by which their fluid is alternately dropped into the moving fibres, it is the ſame thing whether it be done by the determination of the will, or the outward impreſſions of an elaſtic fluid: ſuch is the air; and that ſounds are the vibrations of it, is beyond diſpute: theſe, therefore, rightly modelled, may ſhake the nerves as really as the *imperium voluntatis* can do; and, conſequently, may produce the like effects.

The benefit of muſic ariſes not only from their dancing to it, and ſo evacuating by ſweat a great part of the inflammatory fluid; but, beſides this, the repeated percuſſions of the air hereby made, by immediate contact, ſhaking the contractile fibres of the membranes of the body, eſpecially thoſe of the ear, which, being contiguous to the brain, communicate their tremblings to its membranes and veſſels: by theſe continued ſucceſſions and vibrations, the coheſion of the parts of the blood is perfectly broken, and the farther coagulation prevented; ſo that the heat being removed by ſweating, and the coagulation by the contraction of the muſcular fibrillæ, the wounded perſon is reſtored to his former condition.

If any one doubts of this force in the air, he may conſider, that it is demonſtrated in mechanics, that the ſmalleſt percuſſion of the ſmalleſt body may overcome the reſiſtance of any the greateſt weight, which is at reſt; and that the languid tremor of the air, which is made by the ſound of a drum, may ſhake the largeſt edifices.

But, beſides this, we muſt allow a great deal to the determinate force, and particular modulation of the trembling percuſſions; for contractile bodies may be acted upon by one certain degree of motion in the ambient fluid, though a greater degree of it, differently qualified, may produce nothing at all of the like effect. This is not only apparent in two common-ſtringed muſical inſtruments, tuned both to the ſame height; but alſo in the trick which many have of finding the tone or note peculiarly belonging to any wine-glaſs, and, by accommodating their voice exactly to that tone, and yet making it loud and laſting, make the veſſel, though not touched, firſt to tremble, and finally to burſt; which it will not do, if the voice be either too low, or too high.

This makes it no difficult matter to conceive, why different perſons, infected with this ſort of venom, do require a different ſort of muſic, in order to their cure; inaſmuch as the nerves and diſtractile membranes have different tenſions, and conſequently are not all alike to be acted upon by the ſame vibrations.

Tarantula, in *Zoology*, is alſo the name given by the Italians to a peculiar ſpecies of lizard, called by Aldrovand, and ſome others, *lacertus facetanus*.

It is of a grey colour; its ſkin is extremely rough; and it is thicker and rounder bodied than the other lizards. It is found, like our common eft, under old walls, and among the ruins of buildings, particularly in the neighbourhood of Rome, in great plenty; its colour looks dead and ghaſtly, and it is as odious to the ſight among the Italians, as the toad is with us, being never ſeen without a ſort of natural horror. It is eſteemed alſo a poiſonous creature, as the toad is with us; though it is not eaſy to find well-atteſted ſtories of any body's ever having been hurt either by the one or the other of theſe creatures. Ray.

TARAPACA, in *Geography*, a town of Peru, in the biſhopric of Arequipa, on a river which ſoon after runs into the Pacific ocean, S. lat. 20° 10′.

TARAPILLY, a town of Hindooſtan, in Coimbetore; 20 miles N.E. of Damicotta.

TARARE, a town of France, in the department of the Rhône and Loire; 18 miles W.N.W. of Lyons.

TARAS, in *Ancient Geography*, a ſmall river of Italy, which paſſed to Tarentum, and probably gave it its name.—Alſo, a river of Italy, in Japygia.—Alſo, a river of Epirus.—Alſo, a town of Aſia Minor.—Alſo, a river of Scythia.

Taras, in *Geography*, a town of the duchy of Wurzburg; 2 miles N.W. of Haſfurt.

TARASCO, in *Ancient Geography*, a town of Gallia Narbonnenſis, on the left of the Rhone, and weſt of Arelate.

TARASCON, in *Geography*, a town of Spain, in New Caſtile; 22 miles S.W. of Huete.—Alſo, a town of France, and principal place of a diſtrict, in the department of the Mouths of the Rhône, on the Rhône, with a caſtle, fortified in the ancient manner. It is ſituated oppoſite Beaucaire, with which it communicates by means of a bridge of boats. The number of inhabitants is about 7000; 3 poſts E. of Niſmes. N. lat. 43° 48′. E. long. 4° 44′.—Alſo, a city of France, and capital of the department of the Arriege, on the river Arriege. In it are ſeveral manufactures of iron; 48 miles S. of Toulouſe. N. lat. 42° 50′. E. long. 1° 41′.

TARASOVA, a town of Ruſſia, in the government of Irkutſk, on the Lena; 12 miles S. of Tutura.

TARATATO, a town on the eaſt coaſt of Fortaventura, one of the Canary iſlands.

TARAUMARA, a large province of North America, in the north-eaſt part of New Biſcay, bounded on the weſt by Sonora, on the eaſt by New Mexico, its limit being the Rio Bravo. On the ſouth-weſt it borders on Cinaloa. Alcedo computes the extent at 100 Spaniſh leagues from eaſt to weſt, and as much from north to ſouth. This province was diſcovered in 1614, and derives its name from a ſavage nation found there, of pacific diſpoſitions. This province contains 48 pueblos, or villages, or ſtations of Franciſcan miſſionaries, excluſive of the capital of St. Felippe de Chiguaga. It is chiefly rich in mines, the minerals being ſmelted at the Real, or royal ſtation of St. Eulalia, or probably the Real Nueva in the maps, in N. lat. 29° 36′.

TARAXACUM, or Taraxacon, in *Botany*, a name uſed by the Arabians, ſuppoſed by Ambroſini to have been derived from the Greek τρωξιμος, *eatable*, becauſe the plant to which it was applied, (our Dandelion, or ſomething nearly akin,) was uſed for food. De Theis derives it, with more appearance of probability, from ταρασσω, *to move*, or *trouble*, becauſe of the laxative and diuretic quality of the plant in queſtion, commemorated in its vulgar Engliſh, as well as French, appellation. See Leontodon; at the end of which botanical article, we muſt obſerve, *genus* of *Leontodon* is printed by miſtake for *gender*.

TARAXIPPUS, formed of ταρασσω, *I frighten*, and ιππος, *horſe*, a kind of evil genius, the ſtatue of which was erected in the Grecian hippodromes, in order to alarm and frighten the horſes in their courſe. The ſhape and form of this ſtrange deity are not deſcribed; but he certainly anſwered the end for which he was deſigned: it frequently happening, that the horſes were ſo feared at his appearance, as to turn away with the utmoſt violence, and expoſe the lives of their riders or drivers to the moſt imminent danger. Many conjectures have been formed concerning this ſtrange deity, and the means he uſed to frighten the horſes: but the moſt probable

bable

bable conclufion will be, perhaps, to fuppofe that fome tricks and artifices were practifed under the difguife of this figure, either with a defign to render the victory more honourable in proportion to the difficulty of gaining it, or elfe that this horfe-frightening deity was placed in the courfe as a touch-ftone, to prove the refolution and temper of the horfes; and to oblige the candidates to bring none into the field but fuch as by exercife and difcipline were fo affured and fteady, as not to let their obedience be fhaken upon the moft trying occafions. Berenger's Hift. and Art of Horfemanfhip, vol. i. p. 54. See STADIUM.

TARAXIS, from ταράσσω, *to difturb*, in *Surgery*, a flight ophthalmy, or inflammation of the eye. See OPHTHALMY.

TARAZ, in *Geography*, a river of Independent Tartary, which runs into the Sirr or Jaxartes at Otrur. Some fuppofe this to be the fame with the river Tulas; but others reprefent it as a much more inconfiderable ftream.

TARAZ, or *Turkeftan*, a city of Afia, and capital of the country of Turkeftan, fituated on a fmall river which runs into the Sirr, 250 miles N. of Samarcand. N. lat. 44° 45'. E. long. 69° 42'.

TARAZONA, a town of Spain, in New Caftile; 15 miles S. of Alarçon.—Alfo, a city of Spain, in Aragon, the fee of a bifhop, fuffragan of Saragoffa. This town is ancient, and was deftroyed by the Moors in the year 724, and by the fame people rebuilt in the beginning of the 12th century; 43 miles N.W. of Saragoffa. N. lat. 42°. W. long. 1° 43'.

TARBA, in *Ancient Geography*, a town fituated on the fouthern coaft of the ifle of Crete.

TARBASON, a word ufed by fome chemical writers as a name of antimony.

TARBASSUS, in *Ancient Geography*, a town of Afia, in Pifidia.

TARBAT, in *Geography*, a town of Scotland, in the county of Cromarty. This parifh originally belonged to the county of Rofs, but was feparated from it and annexed to Cromarty, in 1693; 6 miles E. of Tam.

TARBAT *Nefs*, a cape of Scotland, on the eaft coaft of the county of Rofs, between the friths of Dornoch and Murray. N. lat. 37° 50'. W. long. 3° 40'.

TARBE, a city of France, and capital of the department of the Upper Pyrenées, built on the ruins of the ancient Bigorre: before the revolution it was the fee of a bifhop, and refidence of a governor. It confifts principally of one ftreet along the Adour, and is defended by a caftle; 7½ pofts S. of Auch. N. lat. 43° 14'. E. long. 0° 8'.

TARBELLI, in *Ancient Geography*, a people of Gaul, in Aquitania, whofe territory extended along the Aquitanic gulf.

TARBERT, in *Geography*, a poft-town of the county of Kerry, Ireland, on the river Shannon, where there is a charter-fchool. It is 124 miles S.W. from Dublin. There is alfo a fmall ifland of this name off the coaft of Galway.

TARBIDO, or MARAZZO, a river of Naples, which runs into the Mediterranean, 13 miles S.W. of Cofenza.

TARBOU, a town of Hungary, on the river Theyfe; 14 miles N.N.E. of Kifwarda.

TARBURGH, or TARBOROUGH, a town of North Carolina, on the Tar; 45 miles N.N.W. of Newbern. N. lat. 35° 52'. W. long. 77° 44'.

TARBUT, a city of Perfia, in Khoraffan, eight furfungs diftant from Turfhifh; with a population of about 8000 perfons, defended by a ftrong wall, and flanked with towers. Provifions are here plentiful and cheap; it has 220 dependent villages, and is poffeffed by Ifa Khan, a powerful chief, who can bring into the field an army of 10,000 men.

TARCHI, in *Biography*, a Neapolitan compofer, who arrived in England in 1786, at the fame time as Rubinelli. He was young at that time, but though he remained here only one feafon, he difcovered confiderable abilities, and feemed advancing rapidly into fame. He had fire, tafte, and invention. If he ftill lives, we make no doubt but that he ranks high among the dramatic compofers of his country.

TARCHONANTHUS, in *Botany*, fo called from *tarcon*, or *taracon*, the Arabic name of *Artemifia Dracunculus*, our Taragon, and ἄνθος, *a flower*, becaufe its flowers refemble thofe of that plant. Vaillant contrived this name in the Mem. de l'Acad. des Sciences, for 1719, but it is not one of his happieft.—Linn. Gen. 416. Schreb. 547. Willd. Sp. Pl. v. 3. 1792. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 515. Juff. 185. Lamarck Illuftr. t. 671. Gærtn. t. 166.—Clafs and order, *Syngenefia Polygamia-æqualis*. Nat. Ord. *Compofitæ Nucamentaceæ*, Linn. *Corymbiferæ*, Juff.

Gen. Ch. *Common Calyx* turbinate, of one leaf, cut half way down into (for the moft part) feven rather acute fegments, coloured internally, fhorter than the corolla, permanent. *Cor.* compound, uniform, of about twenty florets, all perfect, equal, each of one petal, funnel-fhaped, with five teeth. *Stam.* in each floret, Filaments five, capillary, very fhort; anthers united into a cylindrical tube, as long as their own partial corolla, with a filamentous appendage at the bafe. *Pift.* in each floret, Germen inferior, oblong; ftyle twice the length of the floret; ftigmas two, divaricated. *Peric.* none, except the permanent calyx. *Seeds* folitary, ovate-oblong, compreffed. *Down* woolly, invefting every part of the feed. *Recept.* minute, clothed with woolly hairs, the length of the calyx.

Obf. The *feed-down* is very remarkable, as not crowning but entirely invefting the feed. *Linnæus.*

Eff. Ch. Receptacle villous. Seeds invefted with hairs. Common calyx of one leaf, turbinate, cut half way down into feveral fegments. Anthers fpurred at the bafe.

1. T. *camphoratus.* Shrubby African Fleabane, or Aromatic Taragon-bloffom. Linn. Sp. Pl. 1179. Suppl. 361. Willd. n. 1. Ait. n. 1. (Elichryfo affinis africana arborefcens, floribus purpuro-violaceis, foliis Salviæ, odore Rofmarini; Herm. Lugd.-Bat. 228. t. 229. Pluk. Phyt. t. 174. f. 1.)—Leaves elliptic-oblong, nearly entire; denfely downy beneath. Native of the Cape of Good Hope, from whence it was brought very early into the gardens of Europe. This is a greenhoufe evergreen *fhrub*, or fmall *tree*, flowering from June to October. The *branches* are angular, tuberculated, denfely downy and hoary. *Leaves* fcattered, ftalked, two or three inches long, more or lefs acute, fomewhat wavy, entire or minutely toothed; their upper fide of a dark dull green, quite fmooth, reticulated with fine veins; the under white and cottony, with a prominent rib and veins. When bruifed they fmell like rofemary, but lefs agreeably. *Panicles* terminal, many-flowered, with numerous lanceolate *bracteas*, all together hoary, like the branches. Segments of the *calyx* from five to feven, or more. *Florets* dark dull purple, with whitifh *anthers*. *Seeds* enveloped in copious white wool, like thofe of an ERIOCEPHALUS; fee that article.

2. T. *ellipticus.* Oval-leaved Taragon-bloffom. Thunb. Prodr. 145. Willd. n. 2.—"Leaves elliptical, finely toothed; denfely woolly beneath."—Gathered by Thunberg at the Cape. We have feen no authentic fpecimen from him, but there are fome in the Linnæan herbarium which anfwer to the

the ſpecific character, though they are obviouſly a mere variety of the foregoing.

3. T. *racemoſus*. Cluſter-flowered Taragon-bloſſom. Thunb. Prodr. 145.—"Leaves elliptical, pointed, finely toothed; denſely woolly beneath."—From the ſame country. This is perhaps but another variety. The *leaves* of *T. camphoratus* vary in acuteneſs. Willdenow ſeems accidentally to have omitted this in tranſcribing. It ſhould have been his n. 3.

4. T. *lanceolatus*. Lanceolate Taragon-bloſſom. Thunb. Prodr. 145. Willd. n. 4.—"Leaves elliptical, entire, ſmooth."—Gathered at the Cape by Thunberg. His ſpecific name is exceptionable, when compared with the characters of this and the reſt of the ſpecies. We muſt rely on him for the ſynonyms of the following, it being his own diſcovery; or we ſhould have preſumed, without ſeeing ſpecimens, that the plant before us might be *T. glaber* of Linnæus.

5. T. *dentatus*. Toothed Taragon-bloſſom. Thunb. Prodr. 145. Willd. n. 5. (T. glaber; Linn. Suppl. 360, according to Thunberg.)—"Leaves oblong, entire or toothed; ſlightly downy beneath."—Gathered by Thunberg at the Cape. We have ſeen no ſpecimen. Linnæus deſcribes his plant as extremely like *T. camphoratus*, but quite ſmooth, and without any ſmell. It varies with narrower or broader *leaves*, ſometimes entire, ſometimes toothed.

6. T. *ericoides*. Heath-like Taragon-bloſſom. Linn. Suppl. 360. Willd. n. 6.—Leaves oblong, ſmooth, imbricated in four rows. Calyx in four deep ſegments.—Native of the Cape of Good Hope. A rigid *ſhrub*, with copious, round, irregular *branches*, whoſe points ſometimes taper into a ſpinous point. *Leaves* like thoſe of many *Ericæ*, minute, ſcarcely a line in length, elliptic-oblong, obtuſe, entire, concave, ſmooth on both ſides, dotted, aromatic when rubbed, imbricated in four rows on the very ſhort, oppoſite, lateral ſhoots. *Flowers* ſolitary at the end of thoſe ſhoots, each on a ſhort ſilky ſtalk. They are erroneouſly termed "*conferti*" in the *Supplement*, being no otherwiſe crowded than becauſe the little branches which bear them are ſo. *Calyx* in four very deep, elliptical, ſmooth, reddiſh diviſions, very aromatic. *Florets* few, minute, concealed in the copious woolly hair, which is twice the length of the calyx.

Linnæus juſtly obſerves of this laſt ſpecies, that its genus is rather doubtful. We conceive it might as readily be ſuppoſed an *Eriocephalus*, and if the *leaves* could by any means be called filiform, we might gueſs it to be *E. glaber*, Thunb. Prodr. 168, a ſpecies not adopted in our account of that genus; (where Lamarck Illuſtr. t. 717, ought to have been quoted after Juſſ. 186.) The above conjecture is ſtrengthened by Thunberg's having mentioned no *Tarchonanthus ericoides*, nor, as far as we can diſcover, has he deſcribed the ſhrub in queſtion under any other name. We beg leave to remark that the ſpecies of this whole genus, except the original one, are involved in much uncertainty, nor are the materials with which we are furniſhed ſufficient to enable any botaniſt to form an opinion about them.

Tarchonanthus, in *Gardening*, contains a plant of the ſhrubby evergreen exotic kind, of which the ſpecies that is moſt commonly cultivated is the ſhrubby African fleabane, (T. camphoratus,) which has a ſtrong woody ſtem, that riſes to the height of twelve or fourteen feet, ſending out many woody branches at the top, which may be trained to a regular head.

Method of Culture.—This is a plant that may be increaſed by cuttings, which ſhould be planted out in the ſpring or early ſummer ſeaſons, in pots filled with light mould, giving them ſhade and water occaſionally. They ſoon ſtrike root, and in three or four months may be potted off into ſeparate pots, affording them ſhade and water as before, and placing them under ſhelter. They alſo ſtrike root in the ſummer ſeaſon, when planted in a common border, and covered with hand-glaſſes, and may in theſe caſes be potted off in the autumn.

Afterwards they require the management of other hardy greenhouſe plants. The plants do not produce ripe ſeeds in this climate.

They afford variety in theſe different ſituations.

TARDA Avis, in *Ornithology*, a name given by many to the buſtard, more commonly known among authors by the name *otis*.

TARDETS, in *Geography*, a town of France, in the department of the Lower Pyrenees; 6 miles S. of Mauleon.

TARDIGRADUS, or Sloth, in *Zoology*. See Bradypus.

TARDO, in the *Italian Muſic*, is uſed to denote a ſlow movement, being much the ſame as *largo*.

TARDOIRE, or Tardouere, in *Geography*, a river of France, which runs into the Charente, near Rouchefoucault.

TARDOU, El, a town of Spain, in the province of Cordova; 28 miles W. of Cordova.

TARDSONG, a town of Thibet; 250 miles E. of Laſſa. N. lat. 29° 54′. E. long. 95° 34′.

TARE, in *Botany*. See Vetch.

Tare, in *Agriculture*, a well-known plant of the vetch kind, of which there are two ſorts; the common purple-flowered ſpring or ſummer tare, and the purple-flowered wild or winter tare; the latter of which ſort is by much the hardieſt.

Numerous experiments in the culture of theſe different kinds of tares, were made by the Rev. Mr. Laurents, in order to aſcertain their differences in hardineſs, for which we refer to the Corrected Agricultural Survey of the County of Suffolk.

It is evident from the tall, cloſe, hardy growth and ſucculent quality of the winter tare, that it muſt be a plant of much value to the farmer, as affording an abundant produce of green food for animals; and by being alternated with thoſe of the grain kind, in ameliorating or preventing the exhauſtion of the land that muſt otherwiſe take place. It has been ſuggeſted by the writer of the Agricultural Survey of the County of Middleſex, that it may be the means of enabling the arable farmer to ſupport as much live-ſtock as the grazier, as while crops of this ſort remain upon the ground, they afford larger ſupplies of the beſt kind of green food on the acre than the moſt rich and fertile graſs lands; and they may be taken from the ground at ſo early a period in the ſummer ſeaſon, as on the friable loamy ſoils to admit of a clean crop of turnips, &c. being obtained from the ſame land in the ſame year; and of thoſe of the more heavy kinds being prepared and ſown with wheat. And while they are capable of being raiſed with ſucceſs on moſt ſorts of ſoils and ſituations, they ſupport and fatten cattle and ſheep of different ſizes and breeds in an expeditious manner. And further, they afford a good preparation for other ſorts of green crops, and in that way keep up the ſucceſſion of ſuch ſorts of food for the fattening of additional numbers of animals, and in that manner afford abundance of manure in ſituations where it could not otherwiſe be procured. On the

the whole, he fuppofes, that by a judicious combination of this plant with thofe of turnips, clover, and fainfoin, the poor downs, fheep-walks, and other wafte lands may be rendered from ten to thirty times more valuable than they are in their prefent ftate.

The tare in all its varieties is a plant which, in refpect to foil, according to the author of the Prefent State of Hufbandry, admits of confiderable latitude, growing without difficulty or trouble on all the varieties, from that of the thin gravelly, to thofe of the deep and ftiff clayey kinds, but flourifhing in the moft vigorous and perfect manner on thofe of the gravelly, loamy defcriptions, that are not too moift or wet at particular feafons.

With regard to the preparation of the land for this fort of crop, there is lefs care neceffary than for many other kinds of graffy forts of crops, as it will fucceed well where the foil has not been fo much broken down, or reduced into fine mould; but it always grows in the moft perfect and vigorous manner where a good degree of pulverization and finenefs has been produced in the land by proper tillage. But in common, two or three ploughings, with occafional good harrowings in the intermediate times, may be fully fufficient for the purpofe, at whatever feafon the crop is to be put into the ground.

As to the fowing of the feed of this crop, it has been obferved, that as the feed of the fpring tare does not fucceed well when fown for the winter crop, nor that of the winter kind when put in for the fummer product, care fhould be taken to keep the feeds of the two forts as perfectly diftinct as poffible. And that as they are, from their being both of nearly the fame colour and fize, as well as their agreeing in other particulars, extremely liable to be mixed in the feed-fhops, it may be the beft practice for the cultivator to preferve his own feed, as by that means he may not only be certain of having the feed good in its quality, but of the right forts, and, of courfe, may depend more fully on his crops. And it has been fuggefted by the writer of the Middlefex Report on Agriculture, that fteeping the feed in dry feafons may be of utility in promoting the quick vegetation of the crop in many fituations of land and peculiarities of feafon. With regard to the quantity of feed that fhould be employed, it fhould, of courfe, vary according to the nature of the foil, and the time as well as manner of fowing. But from two bufhels to two and a half are the proportions moft commonly recommended in the broad-caft method of fowing. But on poor forts of land, where the feed is fown late, and the climate is backward, three bufhels may not be too much. And it has been alfo obferved by a late writer, that where the crops are either to be cut for foiling, or to be fed down by live-ftock, the proportion of feed fhould be confiderably increafed, as not only a greater produce is thereby provided, but the growth of the crops rendered more quick and full. In the drill method of fowing, when at the diftance of fix inches, two bufhels of feed will be quite fufficient; and where the diftances are larger, ftill fmaller proportions of feed will anfwer the purpofe.

In regard to the periods and manner of fowing thefe forts of crops, it is evident that the former muft vary with the intentions of the cultivator; but the winter fowings fhould be performed fome time between Auguft and October; and in expofed fituations and poor foils, more early than in thofe of the contrary defcription. As for the fpring fowings of thefe crops, they may be executed from the beginning of March to the end of April, or even earlier, with fuccefs. In fome places, as on the down lands in Suffex, they find great advantage from fowing fpring tares in June with a light mixture of rape or cole feed, as about a quart to the acre, on the fame land, as furnifhing a good and nutritious feed for weaned lambs in the autumnal feafon.

With regard to the mode of fowing crops of this nature, it is moftly that of the broad-caft, which fhould be performed as evenly as poffible over the furface of the well-prepared land; the feeds being afterwards well covered in by proper harrowing, in order to prevent their being picked up by birds, and to enfure their perfect vegetation and growth. It has been fuggefted, however, that in rich clean foil, it is probable the row method would fucceed well with this fort of crop, as is the practice in fome of the fouthern diftricts of the ifland, according to a late practical writer. And with fome it has been the cuftom to fow a little rye with their winter tare crops, and a fmall quantity of barley with thofe of the fpring, on which, however, it has been well obferved, that as plants of different forts never fucceed well together, it is probable that little advantage can be derived from the practice, efpecially as the tare is not a plant that ftands much in need of protection in the early ftages of its growth, and may be injured by too much fhade and clofenefs. The former of thefe forts of feed, and fome others, may, however, be occafionally blended with it, and fown as a good green feed for fome forts of young animals, as already noticed.

It has been fuggefted in the firft volume of the Farmer's Magazine, that the moft productive method of fowing this crop, when intended for feed, is to mix them amongft beans when drilled, at the rate of one firlot of tares to one boll of beans.

It is further ftated, however, as obvious, that when tares are intended for green food, there is no neceffity for mixing them with beans. But that when fuch is the purpofe, they require to be fown tolerably thick, fo as the furface may be early covered; and if the ground is good, and recently dunged, an acre of them will afford as much keep for horfes and cows, as can be gained from a full clover crop; at leaft the writer has found them fully as beneficial.

It has been found that crops of this fort are capable of being grown well after wheat or barley, but that they may be grown after almoft any fort of crop where the land is in good heart, and properly prepared for the purpofe.

In regard to the after-management of thefe forts of crops, from their covering the land in a very complete manner, when they are fufficiently full, they do not require any great attention during their growth.

And in the procefs of making tare-crops into hay, more attention is found neceffary than in thofe of moft of the artificial graffes, as wet is more injurious to them, and they require more fun and air; but in other refpects they demand the fame cautious management, in order to prevent the foliage from being loft.

The moft proper time for cutting for this purpofe is, according to the author of the Synopfis of Hufbandry, when the bloffoms have declined, and the crops begin to fall flat on the ground. When well made, the hay is of the beft and moft nutritious quality or properties, being extremely ufeful in many intentions.

The writer of the Report of the State of Agriculture in Middlefex, ftates the produce as the refult of experience, in having frequently weighed green tares, to be ten or twelve tons *per* acre, which is a large crop. And when made into hay, at about three tons the acre, which fhews the vaft difadvantage of making thefe crops into hay. The value of the produce, eftimating it as if the whole were made into hay, being in that diftrict from twelve to fifteen guineas the acre; and in fituations where other forts of hay fell at fifty fhillings or three pounds, at from about ſeven pounds ten ſhillings to nine pounds the acre. And it is found that the ſpring tare-crops are lighter, and moſt liable to be injured by a dry ſeaſon.

The produce in ſeed is likewiſe found to be conſiderable, being by ſome ſtated at from three to ſix ſacks; but in other inſtances forty buſhels or more have been obtained from the acre. It has been ſuggeſted, that this ſort of ſeed is greedily devoured by pigeons, and that it may probably be uſed for poultry with advantage and profit, as being a very ſtimulant ſort of food in the production of eggs.

In reſpect to the application of tare-crops, it has been well remarked by a late writer, that there can be little heſitation in pronouncing that of ſoiling them with horſes or other ſorts of live-ſtock on the farm, as the moſt advantageous and beneficial method of any which can be adopted for them.

It has, however, been adviſed by the author of the Agricultural Survey of the above diſtrict of Middleſex, that the farmer's ſtock ſhould be wholly ſupported on them, from the time they begin to blow till the bloſſoms begin to fall off, and the formation of pods to take place. And, on account of the riſk from wet, he adviſes that all the ſtock of a farm ſhould be ſoiled on them green, as it will have the good effect of taking the ſtock off the graſs land long enough to allow of its being mown for hay; and by this means the meadow-hay be much increaſed in quantity, and there will not be ſo much occaſion for paſture, the tares abundantly ſupplying its place. And that beſides, at the time the cattle return from green tares, the graſs land in the mean time having been mown, may be ready to receive them. The ſame able writer remarks, in addition, that as it would be waſteful in the extreme to turn live-ſtock into a field of tares, as their treading and lying down would do great miſchief to the crop, even by feeding it in ſmall patches hurdled off; the moſt adviſeable method would be to mow the tares of the firſt half acre, and to carry the produce into the ſtables, cow-houſes, and fold-yards, or on poor land, to be conſumed by ſtock; then to hurdle the growing tares from ſuch *cleared ground*, into which put the ſtock, and feed them all with the tares, given to them in racks, removing the hurdles and the racks forward daily to the edge of the growing tares; which will manure the land uniformly, and depoſit all the urine in the ſoil. But the writer of the Corrected Glouceſter Report on Agriculture, has ſtated another method of proceeding, where ſheep are the ſort of ſtock employed, which ſeems by no means ineligible, *viz.* to feed them through rack hurdles, which are made the ſame as the common five-railed ones, only leaving the middle rail out, and nailing upright pieces acroſs, at proper diſtances, to admit the ſheep to put their heads through. A ſwathe of vetches being mown in the direction you wiſh to plough the land, a ſufficient number of theſe hurdles, allowing one to five ſheep, are ſet up cloſe to it: at noon, the ſhepherd mows the ſwathe and throws it to the hurdles, and the ſame at night: next morning, a ſwathe being firſt mown, the hurdles are again ſet, thus moving them once in the twenty-four hours. By this trifling additional trouble, the vetches are, it is ſaid, eaten clean off, and the land equally benefited.

The writer of the Hertfordſhire Corrected Agricultural Report remarks, that in the heavy land diſtricts, he has found tares very generally cultivated for ſoiling the teams; a huſbandry, he thinks, that cannot be too much commended. And he contends farther, that it appears by the writings of Ellis, that this branch of agriculture was common in this county above ſixty years ago, before it was at all practiſed in many other counties, and he was glad to find it holds its place ſteadily in the management of the preſent period. It is noticed, that Mr. Leach, of the ſame diſtrict, manures for tares, and that they are mown early, and then three earths are given to the land, when he gets good turnips after them. And that they are univerſal about Rickmanſworth and Watford, many being fed off by ſheep.

And the ſame writer ſays, in his Agricultural Survey of Norfolk, that the culture of this plant has increaſed very conſiderably in that diſtrict: within his memory they are multiplied at leaſt tenfold. And that Mr. Overman there begins ſowing winter tares about Michaelmas, once more before Chriſtmas, and ſometimes twice or thrice more, with ſpring tares for a ſucceſſion. That after mowing, he does not plough the land, but runs ſheep over it till the wheat-ſowing. But that the cultivator who has made by far the greateſt exertions in this huſbandry that he ever met with, is Mr. Purdis, of Eggmore, who has 300 acres every year, feeding no more than is neceſſary to ſupply himſelf: they are fed by his ſheep; uſed in ſoiling his numerous horſes; and immenſe quantities made into hay.

It is ſuggeſted, as the remark of Mr. Blithe, that the ſowing tares for ſummer-feeding ſheep, is an abſolutely new improvement in the huſbandry of Weſt Norfolk, and that he thinks it a very great and important one.

And in both the counties of Glouceſter and Worceſter, it is the practice to ſow theſe crops as paſturage or feed for horſes, and eat or get them off early enough to allow of turnips being ſown the ſame ſeaſon. But, as in the wet ſeaſons, when the tare-crops are large, the ſtems are apt to become rotten upon the ground, and in this condition ſuch food often proves prejudicial to the horſes; in all ſuch caſes, it will be imprudent to cut or eat them any longer for the purpoſe of ſoiling in theſe ways.

It is noticed in the twenty-ſecond volume of the Annals of Agriculture, that in the county of Suſſex, theſe ſorts of crops are of ſuch uſe and importance, that not one-tenth of the ſtock could be maintained without them; horſes, cows, ſheep, and hogs, all feed upon them, the hogs are ſoiled upon them without any other food. This plant maintains more ſtock than any other plant whatſoever. Upon one acre, Mr. Davis, of this diſtrict, can maintain four horſes in much better condition than upon five acres of graſs. Upon eight acres he has kept twelve horſes and five cows for three months without any other food. No artificial food whatever is equal to this excellent plant in his opinion.

They here find this crop to be a hearty and moſt nouriſhing food for all ſorts of cattle. Cows give more butter when fed with this plant than with any other food whatſoever. And by having one crop of vetches ſucceeding another, Mr. Halſtead, in the ſame county, inſures a crop the whole ſummer of the beſt food that can be given to cattle; after this, he ſows turnips, and then wheat.

In many of the ſouthern counties, as Cornwall, Devon, Kent, and ſome others, the culture of this ſort of crop might be greatly extended with vaſt advantage, eſpecially if it were grown with the view of ſoiling different kinds of live-ſtock, to which purpoſe it is by far the beſt ſuited. Alſo, in many caſes, as a highly valuable early ſort of green ſpring feed for many kinds of young animals; the climates and ſoils being mild, and particularly favourable for their very early production and abundant growth, when ſown at the moſt proper ſeaſon.

It is remarked alſo, that they have on the South Downs an admirable practice in their courſe of crops, which cannot be too much commended, that of ſubſtituting a double crop of tares, inſtead of a fallow for wheat. Let the improving cultivator give his attention to this practice, for it is worth, in the opinion of the writer, a journey of five hundred miles.

They

They sow forward winter tares, which are fed off late in the spring with ewes and lambs: they then plough and sow summer tares and rape, two bushels and a half of tares, and half a gallon of rape; and this they feed off with their lambs in time to plough once for wheat. A variation is for mowing, that of soing tares only in succession, even so late as the end of June for soiling. See SOILING.

TARE *and Tret*, in *Commerce*, any defect, waste, or diminution in the weight, the quantity, or the quality of goods.

The seller is usually to account to the buyer for the *tare* and *tret*.

Tare is more particularly used for an abatement, or deduction in the price of a commodity, on account of the weight of chests, casks, bags, &c. in which goods are put up, and whose weight may be known separately from that of the goods: and which being subtracted from the gross weight, or that of the cask, &c. and goods together, gives the weight of the goods alone, or the nett or neat weight. But if the tare is not known separately, and an allowance made for it at so much *per* hundred weight, or hundred yards, &c. then the deduction of the tare is by the rule of three.

Before the tare is taken off, the allowance called the *draft* or draught is subtracted from the original or gross weight of goods.

Tare is distinguished by a variety of denominations; thus: *Real* tare, or *open* tare, is the actual weight of the package; *customary* tare is an established allowance for the weight of the package; *computed* tare is an estimated allowance agreed upon at the time; *average* tare is when a few packages only among several are weighed, their mean or average taken, and the rest tared accordingly; *super* tare is an additional allowance or second tare, when the commodity or package exceeds a certain weight.

When tare is deducted, the remainder is called the *nett* weight; but if tret be allowed, it is called the *suttle* weight.

Tret is a deduction of 4 lbs. from every 104 lbs. of the *suttle* weight.

There was another allowance that was formerly made for dust or sand, or for the waste or wear of the commodity on foreign articles paid by the pound avoirdupois; but this is now nearly discontinued by merchants, or rather allowed in the price. It is wholly abolished at the East Indian warehouses in London, and neither tret nor draft is allowed at the custom-house.

The allowance called *tret* is calculated in the same way with tare. *Ex.* 1.—At 7 lbs. tare, or tret, to 112 lbs. gross, what is the tare, and also the nett weight, when 746 lbs. gross was received? say, as 112 lbs. to 7 lbs. so is 746 lbs. to the tare sought, which subtracted from 746 lbs. the remainder is the nett weight.

Ex. 2.—At 5 lbs. tret to 112 lbs. gross, what gross weight must be received, when 84 lbs. nett was paid for: and how much is allowed? subtract 5 from 112, then say, as 107, the remainder to 112, so is 84 to the gross weight sought; the difference of which and 84 is the allowance. Or thus: as 107 to 5, so is 84 to the allowance sought, which, added to 84, gives the gross weight sought. Thus from the gross weight, nett weight, and allowance, or any two of these in one case given, with any one of them in another case, we find the other two in that other case.

There are sometimes two allowances deducted out of the same quantity; first tare, and then tret: after the tare is deducted, the remainder is called particularly *subtle* or *suttle* weight, out of which the tret is deducted, and the last remainder is called *nett* weight.

Ex. 3.—Tare being allowed at 4 to 112, and tret at 5 to 112, what is the nett weight in 87 lbs. gross? say, as 112 to 108 ($= 112 - 4$), so is 87 lbs. to the subtle; then as 112 to 107 ($= 112 - 5$), so is the subtle to the nett. And if you multiply 108, 107, and 87 continually, and also 112 by 112, and divide that product by this, the quotient is the nett weight sought. Malcolm's Ar. p. 564.

The tare is very different in different merchandizes: in some there is none at all allowed. It is a thing much more regarded in Holland than in England, or elsewhere: a modern author, M. Ricard, treating of the commerce of Amsterdam, observes, that the tares are one of the most considerable articles with which a merchant is to be acquainted, if he would trade with security.

Sometimes the tare is, as it were, regulated by custom; but generally, to avoid all dispute, the buyer and seller make a particular agreement about it.

For a comprehensive and accurate table of the custom-house and commercial allowances for various kinds of goods, we refer to the first volume of Dr. Kelly's "Cambist," our limits not allowing the insertion of it, though the liberality of the author would not object to our thus availing ourselves of his labours.

TAREEKAB, in *Geography*, a town of Candahar, on the Cameh; 23 miles E.S.E. of Cabul.

TAREF, a town of Arabia, in the province of Hedsjas; 25 miles N.E. of Medina.

TAREIBOIA, in *Zoology*, the name of a species of serpent found in America, and called also *cacaboia*; though, according to some authors, the tareiboia and cacaboia are two different species.

They are both of the amphibious kind, and live in lakes and waters, as well as on land; but they are not very poisonous. They are small snakes, and all over black; when offended they will bite, but the wound is curable. Authors have written differently of those serpents, some making the latter very different from the former, and of a yellow colour. Ray.

TAREINSKA, in *Geography*, a harbour of Kamtschatka, in Avatcha bay; 10 miles S. of St. Peter and St. Paul.

TAREIOU, a town of Brasil, in the government of St. Francisco; 160 miles S.W. of Fernambuco.

TAREIRA, in *Ichthyology*, the name of a fish caught in the American seas, and eaten, but of no fine flavour. It is of an oblong and thick body, gradually tapering toward the tail; its head resembles that of a snake, and is raised into two tubercles over the eyes; its eyes are yellow, with a black pupil; its nose pointed, and its mouth large and yellow within; it has extremely sharp teeth in both its jaws, and on its tongue; it has eight fins, the tail being accounted one, and this is forked; but this, as well as the rest, is of the consistence of a poppy-leaf, tender, thin, and soft, and sustained by soft rays; its scales are so nicely laid on one another, that it seems smooth to the touch; its belly is white, and its back and sides are variegated with longitudinal green and yellow lines. Marcgrave.

TAREIRI, in *Geography*, a river of Brasil, which runs into the Atlantic, S. lat. 6°. W. long. 34° 43′

TAREKA, in *Hindoo Mythology*, is the name of a sort of demon slain by Rama, in his warfare described in the Ramayana.

TAREM, in *Geography*, a city of Persia, in the province of Laristan, which is a meanly built place, situated in a

 plain

plain on the banks of a falt river. It confifts of a mud fort, furrounded on all fides by wretched huts, formed of the branches of a date-tree, which grows in great abundance on the plain. It is the refidence of many refpectable merchants, who trade to Mafcat, Gombroon, and Shirauz; and contains about 12,000 inhabitants; 30 miles N.N.E. of Lar, which is fituated in N. lat. 27° 30′. E. long. 52° 45′.

TAREMDSONG, or Tarengasong, a town of Thibet; 160 miles S.S.E. of Laffa. N. lat. 27° 40′. E. long. 92° 50′.

TARENT, a river of England, which runs into the Stour, in the county of Dorfet, 3 miles S.E. of Blandford.

Tarent, an ifland of the Perfian gulf, clofe to the fhore, and immediately oppofite to Ketif; although not fo large, is a finer ifland than Bahrein. It is about feven miles long, and about as much in breadth, well fupplied with good frefh water, and embellifhed with many delightful gardens, which produce fruits of various kinds in abundance.

TARENTAISE, *County of*, a province of Savoy, bounded north by the lordfhip of Faucigny, eaft by the duchy of Aofta, fouth by the county of Maurienne, and weft by the duchy of Savoy; erected into a bifhopric about the fifth century, and an archbifhopric in the eighth. The kings of Burgundy erected it into a county; and towards the end of the eleventh century, Humbert II., earl of Maurienne and Savoy, became mafter of it, and his defcendants held it afterwards. The foil is barren, and the afpect of the country, abounding with mountains and precipices, unpleafant, with little good land. The Ifere croffes it from eaft to weft. In its union with France, it formed part of the department of Mont Blanc.

TARENTO, a city of Naples, and province of Otranto, the fee of an archbifhop, fituated on a fmall peninfula, which projects into a bay of the Mediterranean, to which it gives name. *Tarentum* (which fee) was anciently the capital of a celebrated republic; but after undergoing many revolutions, it was deftroyed by the Saracens or Hungarians: foon afterwards it was rebuilt in a new fituation. After the total expulfion of the Greeks, duke Robert, the Norman, created his fon, Bohemund, prince of Tarento; but his iffue failing, it was beftowed on Henry, fon of king Roger, and afterwards on William, a baftard of that family. It was wrefted from him, on account of his illegitimacy, and conferred on Manfred of Swabia, who long bore the title of prince of Tarento. Its next transfer was made by Charles II. to his fon Philip, titular emperor of Conftantinople, by whofe daughter it was conveyed to the houfe of Baux. Upon the failure of this family, it was obtained by Raymond Orfini, a younger fon of the family of Nola. King Ladiflaus, by marrying the widow of Raymond, became mafter of Tarento. Queen Joan II. gave it to her hufband, the earl of La Marche; and he fold it to John Anthony Orfino Balzo, the right owner. When this prince died without iffue, Tarento efcheated to the crown. The inhabitants, neglecting the culture of the foil, directed their whole attention to fifhing. Their number is eftimated at 18,000. Its harbour, which was once excellent, is now fo fhallow as to admit only fifhing boats. It is defended by a fort. The bay of Tarento is remarkable for fprings of frefh water at the bottom, which, as it is faid, may be taken up in a calm from the furface; 60 miles W.N.W. of Otranto. N. lat. 40° 45′. E. long. 17° 10′.

TARENTUM, in *Ancient Geography*, a town of Italy, in Magna Græcia, upon a fmall promontory of the Meffapia. Tarentum was a very ancient city: fome have afcribed its origin to the Cretans, before the Trojan war. In the 21ft Olympiad, a powerful body of emigrants arrived under Phalanthus from Laconia, that it feemed to be refounded. Here they fettled upon an ariftocratical plan, enlarged the fortifications of the city, and transformed it into a near refemblance of Sparta. Places were called by new names; and as moft of the nobles had perifhed in a war with the Japyges, democracy was introduced. The favourable fituation of this city, when it was firft founded, contributed to its rapid profperity. Placed in the centre of three feas, it obtained the whole commerce of the Adriatic fea, of the Grecian or Ionian fea, and of that portion of the Mediterranean called the Tyrrhenian fea. The adjacent country was fertile in grain and fruit; the paftures were excellent; the flocks afforded a very fine wool. It is no wonder, then, that the city fhould become rich, and that riches fhould be fucceeded by luxury. Philofophy was not neglected at Tarentum; and that of Pythagoras gained the preference. The arts were alfo diligently cultivated. Strabo mentions the gymnafium of this city with high commendation, and the bronze coloffus of Jupiter, which was fcarcely inferior to that of Rhodes. Fabius Maximus found here abundance of pictures and ftatues, which ferved to adorn his triumph. With the wealth of Tarentum, its power alfo rofe above that of all the colonies of Magna Grecia: its land forces were eftimated at 32,000 foot and 3000 horfe, in conftant pay; and thirteen confiderable cities acknowledged its dominion. At fea, their fleets rode triumphant and unrivalled. The moft brilliant epoch of their hiftory was that of the government of Archytas, whofe profound learning as a philofopher, and fkill as a mechanic, was no impediment to his political talents and exertions. His virtues alfo commanded refpect. He frequently led the Tarentines to battle, and always returned after fuccefs. With Archytas, however, terminated the profperity of Tarentum. At length this city partook of the horrors of thofe wars which defolated the fouthern part of Italy. The inhabitants not only expofed themfelves to the Roman arms by fome outrages committed againft their ambaffadors, but in the year 541 of Rome, Annibal having taken poffeffion of Tarentum, the Romans fent againft them a body of troops under Fabius Maximus, who retook it, and gained poffeffion of its ample ftores of wealth. In the year 664 or 665, it was made municipal; and in procefs of time, it became a very pleafant city. Whilft Totila was ravaging Italy in the year of Chrift 546, the Greeks took poffeffion of Tarentum, but fuddenly abandoned it at the approach of a detachment of troops belonging to the king of the Goths; which event occurred in the year 548. In 552 the troops of Narfes retook it; but it was doomed to pafs under the dominion of Romwald I., duke of Beneventum, in the year 668. On the decline of the Lombard power, the Grecian emperors regained poffeffion of this country, and retained it till Robert Guifcard drove them for ever out of Italy. For its fubfequent hiftory, &c. fee Tarento.

TAREYEN, in *Geography*, a town on the weft coaft of the ifland of Celebes. N. lat. 1° 13′. E. long. 119° 12′.

TAREYRAS, a town of Brafil, in the government of Goyas; 75 miles E.N.E. of Villa Boa.

TAREZA, a river of Hungary, which runs into the Samos, 20 miles S.W. of Tokay.

TARF, a river of Tunis, which runs into the Mediterranean, 3 miles S. of Maharefs.

TARFE, a town of Egypt; 7 miles W. of Cairo.

TARFOKIRAT, a town of the kingdom of Fez, on the coaft of the Mediterranean; 22 miles W. of Melilla.

TARFOWA, a town of Africa, in Tunis, fuppofed to be be the ancient Taphrura or Taparura; 24 miles W. of Thainee.

TARFVALA, a town of Sweden, in the province of Tavaftland; 70 miles N.N.E. of Jamfio.

TARGA, a fea-port town of Fez, near which is an oyfter fifhery; 90 miles S.E. of Tangiers.

Targa. See Tirga.

TARGAR, a name given by fome of the chemical writers to oil of juniper.

TARGET, a *fhield;* thus called from the Latin, *tergum, back*, becaufe originally made of leather, wrought out of the back of an ox's hide.

Target is alfo the name of a mark for the artillery to fire at in their practice.

Target, in *Geography*, a town of France, in the department of the Allier; 2 miles S.E. of Montmarault.

TARGIONI, Tozzetti, Giovanni, in *Biography*, an eminent Italian phyfician, was born at Florence in 1712, and took his degree of M.D. at Pifa, where he had ftudied and acquired fingular reputation. Upon his return to Florence, he applied to the ftudy of botany under the celebrated Micheli, who, at his death, bequeathed to him his library, herbarium, and MSS., and alfo the fucceffion to his directorfhip of the botanical garden. He was likewife nominated profeffor of botany in the Florentine college by the grand duke; and admitted to the two academies of the Apatifti and Della Crufca. In conjunction with Cocchi, he engaged in making a catalogue of the library of Magliabecchi, which he had bequeathed to the public; and in recompence of his labour, the grand duke appointed him librarian. His various occupations, in connection with his practice, rendered it neceffary for him to refign the office of director of the botanical garden in 1749. The mind of Targioni, however, was fo active, that not content with his literary and profeffional employments at home, he made feveral fcientific excurfions, the refult of which he publifhed in his "Relazioni d'alcuni Viaggi fatti in diverfe parte della Tofcana per offervar le Produzioni naturali, e gli antichi Monumenti d'effe," Firenz. t. 1. 1751, 8vo. As a phyfician, he alfo publifhed feveral pieces, and among thefe were "Directions for the Recovery of drowned Perfons." He alfo promoted inoculation for the fmall-pox; and directed his attention to the treatment of epidemics, the draining of marfhes, the prevention of the inundations of the Arno, and the examination of vegetables to be fubftituted for bread in a time of fcarcity. Having taken leave of literary labours by a work on the progrefs of the phyfical fciences in Tufcany, comprehended in four volumes, he reftricted himfelf to medical practice from the year 1770 to 1780. At length, in January 1782, being in his 71ft year, his life terminated by a gradual decay. Haller. Gen. Biog.

TARGIONIA, in *Botany*, was fo named by Micheli, in honour of his friend and fellow-labourer in the natural hiftory of Italy and other parts of the world, Dr. Cyprian Targioni, of Florence, whofe valuable mufeum he highly celebrates. There have been feveral perfons of this name, diftinguifhed at Florence, in medicine and natural hiftory. John Targioni, who took the furname of Tozzetti for an eftate, was profeffor of botany there, and died in 1782, aged 70. He publifhed Travels in Tufcany, as well as feveral other works relating to natural fcience, and purchafed the mufeum and library of Micheli. (See that article.)—Mich. Nov. Gen. 3. t. 3. Linn. Gen. 565. Schreb. 764. Mart. Mill. Dict. v. 4. Sprengel in Stockholm Tranf. for 1802. 85. t. 4: alfo in Bullet. des Sciences, 27. t. 2. f. 2. Juff. 8. Lamarck Illuftr. t. 877.—Clafs and order, *Cryptogamia Hepaticæ*. Nat. Ord. *Algæ*, Linn. *Hepaticæ*, Juff.

Gen. Ch. *Cal.?* Perianth a continued membrane, finely reticulated, enveloping the piftil, at length burfting. *Stam.?* Anthers numerous, roundifh, feffile, fcattered over the infide of the perianth. *Pift.* Germen oval, nearly feffile, accompanied at the bafe by the rudiments of others, with abortive ftyles; ftyle terminal, awl-fhaped, tubular, deciduous; ftigma concave. *Peric.* Capfule feffile, nearly globofe, of two hemifpherical valves, burfting vertically, and one cell. *Seeds* very numerous, minute, roundifh, connected by five threads into a denfe globular mafs.

Eff. Ch. Capfule globofe, of two concave valves, and one cell. Seeds numerous, combined by fibres into a globe.

1. T. *hypophylla*. Dotted Targionia. Linn. Sp. Pl. 1603. Hudf. 519. Engl. Bot. t. 287. Dickf. Dr. Pl. 20. (T. minima et vulgaris; Mich. n. 1. Lichen petræus minimus, fructu orobi; Dill. Mufc. 532. t. 78. f. 9. L. alter acaulis ὑποφυλλοκαρπος; Column. Ecphr. part 1. 333. t. 331.)—Very common in heathy rather moift places, among moffes, on old walls and rocks, in moft parts of Italy. It is faid alfo to have been found in Devonfhire, and in Scotland. We have had living plants from a bank near Nayland in Suffolk, where the *Targionia* was difcovered by the Rev. Mr. Kirby. The *fronds* are oblong, inverfely heart-fhaped, three quarters of an inch in length, growing nearly horizontally, in denfe imbricated patches, attached by copious fine fibrous *roots;* their upper furface dark green, marked with a flight longitudinal furrow, and befprinkled with pale prominent points; the under fide black, becoming vifible when, by drought, the margins are curled in. The parts of the *flower* we have not feen. The *fruit* ftands at the back of the frond, a little below the end, and looks like the feed of a vetch, being nearly globular, of a very dark brown, almoft black; feparating when ripe into two hemifpherical valves, enclofing a globular mafs of black powdery *feeds*, connected by fibres. The habit of the plant is exactly like that of a Marchantia, (fee that article,) but the generic character differs effentially, by the fruit alone, from that genus, as well as from Jungermannia, of which latter Hedwig fufpected it to be a fpecies. We rely on the obfervations of Sprengel for the ftructure of the flower, though without any folid conviction that the *anthers* are what he defcribes. The female parts of fructification refemble thofe of true Musci, (fee that article,) but the *capfule* is totally different. This part is called *calyx* in the *Englifh Botany*, from a fuppofed analogy to *Sphærocarpus*, which we now believe to have little foundation. Whether there be any membrane extended from the bafe of the ftyle over the germen, like the *calyptra* of moffes, does not appear from Sprengel's defcription, but it is highly probable; though as he exprefsly fays the ftyle itfelf is deciduous, that circumftance would ftill afford a material diftinction.

TARGON, in *Geography*, a town of France, in the department of the Gironde; 6 miles N.E. of Cadillac.

TARGOWISKA, a town of Poland, in Volhynia; 9 miles S. of Lucko.

TARGUM, in the *Sacred Literature*, a name which the Jews give to their Chaldee gloffes and paraphrafes on the Scripture. See Paraphrase.

Thefe Chaldee paraphrafes, which were tranflations of the fcriptures of the Old Teftament, from the Hebrew text into the language of the Chaldæans, were called *Targums:* for the word *targum* fignifies in Chaldee an interpretation or verfion of one language into another, and may properly be applied to any fuch verfion or tranflation; but it is moft commonly by the Jews appropriated to thefe Chaldee paraphrafes by way of eminence.

As the Jews, during their long captivity in Babylon, had forgot their ancient language, the Hebrew; and now underſtood nothing but the language of their maſters, the Chaldeans; there was a neceſſity of explaining the prophets in that language; and to this neceſſity is owing the firſt beginning of the Chaldee paraphraſe.

To make the ſenſe of the text underſtood, each doctor made a paraphraſe of ſome part of it in the vulgar tongue; and as theſe ſeveral interpretations, in time, became very voluminous, certain rabbins undertook to collect them together; and this collection they called *The Targum.*

The Jewiſh doctors do not agree about the antiquity of the Targum; for the more modern Jews having blended their own comments with thoſe of the ancients, no certain age or era can be fixed for the whole work.

It is commonly believed, that R. Jonathan, who lived under the reign of Herod the Great, made the firſt Chaldee verſion of the prophets; and with this verſion mixed the interpretations borrowed from tradition. Onkelos, it is certain, tranſlated the Pentateuch almoſt word for word; and without any paraphraſe; and another verſion of the Pentateuch is aſcribed to Jonathan, but that without much certainty.

Dr. Prideaux thinks, that the verſion or Targum of Onkelos is the moſt ancient of all that are now extant: and the principal reaſon of his adopting this opinion is, that the ſtyle in which it is written approaches nearer to the ſtyle of that part of Daniel and Ezra, which is written in the Chaldee language, and which may be conſidered as a ſtandard of its purity, more than any other. This Targum has been held in higher eſteem among the Jews than all the other Targums, and being ſet to the ſame muſical notes with the Hebrew text, it is thereby made capable of being read in the ſame tone in their public aſſemblies. The next to this in the purity of its ſtyle, is the Targum of R. Jonathan Ben Uzziel on the prophets; that is, on Joſhua, Judges, the two books of Samuel, the two books of Kings, Iſaiah, Jeremiah, Ezekiel, and the twelve minor prophets. The Targum of Onkelos is a ſtrict verſion, rendering the Hebrew word for word; whereas Jonathan takes the liberty of a paraphraſt, by enlargements and additions to the text. The third Targum, or that on the law, aſcribed to Jonathan, is not his, becauſe the ſtyle of it is wholly different from that of his true Targum on the prophets, and ſeveral things are mentioned in it, which had no being, or at leaſt no name, till after Jonathan's time. The fourth Targum is on the law, written by an unknown author, and at an unknown period. It is called the *Jeruſalem* Targum, probably becauſe it was written in the Jeruſalem dialect, which was ſpoken by the Jews after their return from Babylon, and which contains a mixture of Hebrew words with the Chaldee. This Jeruſalem Targum is not a continued paraphraſe, as all the reſt are, but confined to ſelect paſſages, as the author ſeems to have thought the text moſt wanted an explication. In many places it is taken word for word from the Targum, ſaid to be Jonathan's on the law: and contains ſeveral things, which are delivered in the ſame words in the New Teſtament by Chriſt and his apoſtles. Dr. Prideaux accounts for this circumſtance, by ſuppoſing that theſe were ſayings and phraſeologies, which had obtained among the Jews in the time of our Saviour, and continued among them long after: and hence Chriſt and his apoſtles, and afterward the author of this Targum, derived them from the ſame ſource. The fifth Targum, which is that on the Megilloth, *i. e.* Ruth, Eſther, Eccleſiaſtes, Solomon's Song, and Jeremiah's Lamentations; the fixth, which is the ſecond Targum on Eſther; and the ſeventh, which is that on Job, the Pſalms, and the Proverbs, are all written in the moſt corrupt Chaldee of the Jeruſalem dialect. Of the two former, no author is named; but the author of the third is ſaid to be Joſeph the one-eyed, but who he was, or when he lived, we are not told: that on the Megilloth, which mentions the Miſchna and the Talmud with the explication, muſt have been written after the Babyloniſh Talmud, or the year of Chriſt 500. The eighth and laſt of theſe Targums, is that on the two books of Chronicles; publiſhed by Beckius at Augſburg in Germany, that on the firſt book in 1680, and that on the ſecond in 1683. On Ezra, Nehemiah, and Daniel, there is no targum.

That the Targum of Onkelos on the law, and that of Jonathan on the prophets, are as ancient as our Saviour's time, if not more ancient, is the general opinion of both Jews and Chriſtians. As to all the other Targums beſides theſe two, they are certainly of a much later date; the ſtyle of every one of them is more barbarous and impure than that of the Jeruſalem Talmud, and they muſt, therefore, have been written after the compoſure of that work, *i. e.* after the beginning of the fourth century after Chriſt; and if the Talmudic fables, with which they abound, were taken out of the Babyloniſh Talmud, this will bring their date ſtill lower, and prove them to have been written after that Talmud, or after the beginning of the ſixth century after Chriſt.

The Targums of Onkelos and Jonathan are in ſuch great eſteem among the Jews, that they hold them to be of the ſame authority with the original ſacred text, and for the ſupport of this opinion, they feign them to be derived from the ſame fountain. The Chaldee paraphraſe of Onkelos, they ſay, was delivered in the ſame manner with the real law, when God gave the written law unto Moſes at Mount Sinai; and when by his holy Spirit he dictated to the prophets the prophetical books, he delivered ſeverally to them upon each book the Targum of Jonathan at the ſame time. Theſe were delivered by faithful hands, the firſt from Moſes, and the other from the prophets, till they came down to Onkelos and Jonathan, who only put them into writing.

Agreeably to the high opinion that was entertained of them, they were read every Sabbath-day in their ſynagogues, in the ſame manner as the original ſacred word itſelf, of which they were verſions; and this uſe of them was continued to late times. Whether the Targums of Onkelos and Jonathan were received for this uſe ſo early as our Saviour's time is not certain; however, it ſeems that theſe, or ſome others, were uſed for the inſtruction of the people, and were read among them in private as well as in public. Agreeably to this purpoſe, they had ſome of their bibles written out in Hebrew and Chaldee together; that is, each verſe firſt in Hebrew, and then in Chaldee; and thus from verſe to verſe through the whole volume. In theſe bibles, the Targum of Onkelos was the Chaldee verſion for the law; and that of Jonathan for the prophets; and for the Hagiographa, the other Targums that were written on them. One of theſe bibles, thus written, Buxtorf tells us he had ſeen at Straſburg: and biſhop Walton acquaints us, that he had the peruſal of two others of the ſame ſort, one in the public library of the church of Weſtminſter, and the other in the private ſtudy of Mr. Thomas Gataker. The other Targums are all of a much later date than thoſe of Onkelos and Jonathan, and of far leſs authority: however, biſhop Walton has introduced moſt of them into his Polyglot. The Targums of Onkelos and Jonathan are of great uſe for the better underſtanding not only of the Old Teſtament, on which they are written, but alſo of the New. As to the Old Teftament, they ferve to vindicate the genuinenefs of the prefent Hebrew text, by proving it to be the fame that was in ufe when thefe Targums were made, contrary to the opinion of thofe who think the Jews corrupted it after our Saviour's time. They help to explain many words and phrafes in the Hebrew original, and they hand down to us many of the ancient cuftoms of the Jews. And fome of thefe, with the phrafeologies, idioms, and peculiar forms of fpeech, which we find in them, do in many inftances help as much for the better illuftration and better underftanding of the New Teftament as of the Old: the Jerufalem Chaldee dialect, in which they are written, being the vulgar language of the Jews in our Saviour's time. They alfo very much ferve the Chriftian caufe againft the Jews by interpreting many of the prophecies of the Meffiah in the Old Teftament, in the fame manner as the Chriftians do. Many inftances are produced to this purpofe by Dr. Prideaux in his Connect. of the Hift. of the Old and New Teft. vol. iv. p. 777, &c.

Thefe Targums are publifhed to the beft advantage in the fecond edition of the great Hebrew bible fet forth at Bafil by Buxtorf the father, anno 1610, for he has rectified the Chaldee text, and reformed the vowel pointings in it: the Targums having at firft been written without vowel points, which were afterwards added very erroneoufly by fome Jews.

TARHONA, in *Geography*, a town of Africa, in Tripoli; 25 miles S.W. of Lebida.

TARI, or TORN, a river of Africa, which runs through the kingdom of Popo into the fea.

TARI, in *Commerce*. See TARO.

TARICHIÆ, in *Ancient Geography*, iflands fituated on the coaft of Africa, in the Mediterranean fea, between Leptis and Thapfus, mentioned by Strabo.

TARIDEGO, in *Geography*, a town of Africa, on the river St. Domingo. N. lat. 12° 10′. W. long. 13° 56′.

TARIENTO, a town of Italy, in Friuli; 8 miles N. of Udina.

TARIER of Buffon, in *Ornithology*. See MOTACILLA *Rubetra*.

TARIERA, in *Ichthyology*, the name of a river-fifh caught in many parts of America.

It is an oblong fifh, with a ftraight back, and a belly fomewhat hanging down; its under jaw is longer than its upper, and its teeth are extremely fharp: among thefe are two longer than the reft in the middle of the under jaw, and four fuch in the upper; its fcales are large, its back brown, and its belly and fides whitifh. It is a well-tafted fifh, but full of bones. Marcgrave.

TARIF, or TARIFF, *Book of Rates;* a table or catalogue, drawn ufually in alphabetical order, containing the names of feveral kinds of merchandize, with the duties or cuftoms to be paid for the fame, as fettled by authority, and agreed on between the feveral princes and ftates, that hold commerce together.

TARIFFA, in *Geography*, a fea-port town of Spain, in the province of Seville, fituated on a bay to which it gives name, on the north fide of the Straits of Gibraltar, fortified with old walls and towers, with a caftle, in which the governor refides. By the Romans it was called "Julia Traducta," and "Julia Joza." The prefent name is from the Moors; 27 miles S.S.E. of Medina Sidonia. N. lat. 36° 3′. W. long. 5° 41′.

TARIFILON, in *Botany*, a name by which Avicenna, and fome other authors, have called the *trifolium bituminofum*, or ftinking trefoil.

TARIJA, in *Geography*, a jurifdiction of South America, in Peru, but placed under the viceroyalty of Buenos Ayres. This is reprefented a charming and fertile country, with a ferene fky and a fine temperature of air, producing wheat, maize, and all other things that are effential to the fupport of man; together with the tree, which produce, the herb of Paraguay, the cocoa, the vine, and flax, which is cultivated merely for the fake of its feed. In the abundance of paftures are fed a vaft number of cattle and fheep. The annual tranfports of black cattle alone are computed at little lefs then 10,000 head, which are valued at from eight to ten piaftres each. The hides tanned and prepared form fole-leather for the inhabitants of La Plata, Potofi, &c. The demands for Spanifh and colonial merchandife annually exceed 60,000 piaftres; the returns for which are made in productions of the province. St. Bernardo de Tarija is the chief town. Chicas and Tarija form one government.

TARIJA, a river of South America, which runs into the Vermejo, in the province of Tucuman.

TARIJA. See ST. *Bernardo de Tarija*.

TARIN, in *Ornithology*, a name given by the French, and from them by many others, to the citrinella; a bird common in Italy, and kept in cages for its beauty and fine notes. See FRINGILLA.

TARINGASONG, in *Geography*, a town of Thibet; 17 miles S.S.E. of Laffa. N. lat. 28° 6′. E. long. 93°.

TARINGTING, in *Ornithology*, a name given by the people of the Philippine iflands, to a fpecies of lapwing, which is common on the fea-fhores, and runs remarkably fwift.

TARINURAK, in *Geography*, a river of Ruffia, which runs into the Lena, N. lat. 61°. E. long. 124° 14′.

TARISKERI, a town of the ifland of Metelin, on the N. coaft; 12 miles E. of Cape Sigri.

TARITH, one of the many names given by chemifts to mercury.

TARITO, in *Geography*, a town of Thibet; 33 miles S.E. of Tchontori.

TARKA, a mountain of Tranfylvania; 28 miles N.N.E. of Udvarhely.

TARKI, a town of Hungary; 15 miles N.N.W. of Topoltzen.

TARKI, or *Tarku*, a town of Afia, in Dagheftan, capital of the diftrict of Schamgul, feated in N. lat. 42° 50′, and fuppofed to contain 10,000 inhabitants, ftands on the Cafpian fhore, in a narrow glen, through which run many ftreams of falt-water.

TARKIRA-HOUTCHIN, a poft of Chinefe Tartary, in the country of the Monguls. N. lat. 44° 34′. E. long. 113° 48′.

TARKO, a town of Hungary, 6 miles E.S.E. of Szeben.

TARKSHA, a name of the fabulous bird Garuda, on which, in the mythology of the Hindoos, their god Vifhnu rides. This vehicle, or vahan, in the Sanfcrit tongue, is reprefented as half man half eagle; and offers an argument for the identity of the Hindoo deity, and the Jupiter of the Greeks. Another name of this bird is *Superna;* which fee. See alfo VAHAN.

TARMA, in *Geography*, a jurifdiction of South America, in Peru, fituated to the north of Atun Xauxa, about 90 miles from Lima, to which diocefe it belongs, and is one of the moft extenfive in this part of Peru. The climate is temperate, and the foil fertile, except towards the mountains, where it is cold, and the land is chiefly applied to feeding of cattle; and many mines of filver are found. Tarma, the capital,

capital, is 85 miles E. of Lima. S. lat. 11°. W. long. 75° 50′.

TARMONBARRY Bridge, a village of the county of Roſcommon, Ireland, at which there is a bridge over the Shannon. The royal canal, if it ſhould ever be completed, is to join the Shannon near this place. It is 4 miles N.W. from Longford, and above 60 from Dublin.

TARMON-HILL, a mountain at the ſouthern extremity of the peninſula, called *The Mullet*, being a detached part of the county of Mayo, Ireland.

TARN, a river of France, which riſes in the mountains of Lozere, paſſes by Florac, Iſpanhac, St. Enimie, Compeyre, Milhau, St. Rome, Alby, L'Iſle, Rabaſtens, Villemur, Montauban, &c. and joins the Garonne, near Moiſſac, in the department of the Lot.

Tarn, a department of France, being one of the nine departments of the ſouthern region, and formerly a portion of Upper Languedoc, in N. lat. 43° 40′, bounded on the N. and N.E. by the department of the Aveiron, on the S.E. by that of Herault, on the S. by that of the Aude, and on the W. by the departments of the Upper Garonne and the Lot, and taking its name from the river Tarn, which traverſes it from E. to W. Its territorial extent is 6080 kiliometres, and its population comprehends 272,163 perſons. It is divided into 4 circles, 35 cantons, and 356 communes. The circles are Gaillac, including 59,501 inhabitants; Alby, 63,064; Caſtres, 106,918; and Lavaur, 42,680 inhabitants. Its contributions in the 11th year of the French era, amounted to 2,693,820 francs; and its expences to 252,749 fr. 18 cents. According to Haſſenfratz, its extent in French leagues is 30 in length, and 20 in breadth: it is divided into 5 circles and 48 cantons, and its population comprehends 289,148 ſouls. Its capital is Alby. This department is diverſified with hills and plains, and abounds in a variety of productions, *viz.* grain, flax, hemp, wine, fruits, and paſtures. It has conſiderable foreſts, with mines of iron, copper, lead, coal, quarries of marble, &c.

TARNA, a town of Sweden, in the lapmark of Umea: 145 miles N.W. of Umea.

TARNAC, a town of France, in the department of the Correze, on the Vienne; 25 miles N. of Tulle.

TARNAVAY, a town of Hindooſtan, in the county of Calicut; 20 miles N.E. of Paniany.

TARNISHING, a diminution of the natural luſtre of any thing, eſpecially of a metal.

Gold and ſilver, when tarniſhed, reſume their brightneſs, by ſetting them over the fire in certain leys. Copper, pewter, &c. that are tarniſhed, recover their luſtre with tripoli and potaſhes.

TARNOGROD, in *Geography*, a town of Poland, in the palatinate of Belcz; 52 miles W.S.W. of Belcz.

TARNOPOL, a town of Auſtrian Poland, in Galicia; 72 miles E. of Lemberg. N. lat. 49° 30′. E. long. 25° 40′.

TARNOW, a town of Auſtrian Poland, in Galicia; 52 miles S.W. of Sandomir. N. lat. 49° 56′. E. long. 20° 53′.

TARNOWITZ, a town of Sileſia, in the principality of Oppeln, near which is a ſilver mine; 6 miles N. of Ober Beuthen. N. lat. 50° 25′. E. long. 18° 47′.

TARO, a river which riſes in the ſouthern part of the duchy of Parma, and runs into the Po, 9 miles E. of Buſſeto. The country through which it paſſes is called *Val di Taro.*—Alſo, a late department of France, formed by the duchies of Placentia and Parma.

Taro, in *Commerce*, a money of account and copper coin of Naples, Sicily, and Malta. For the accounts at Malta, ſee Scudo. The banks at Naples keep their accounts in ducati, tari, and grani. A ducat contains 5 tari, 10 carlini, or 40 cinquini: a taro, or tarino, is worth 2 carlini, or 20 grani. Among the ſilver coins are tari, at 2 carlini. By the coinage of 1804, the piece of 12 carlini ſhould contain 350⅘ Engliſh grains of fine ſilver; ſo that it is worth 49*d.* ſterling; and the ducat of 10 carlini is worth 41*d.* ſterling nearly, or 1*l.* ſterling = 5 ducats 88 grani. The taro of Sicily is worth about 4*d.*, or more accurately, 1*l.* ſterling = 1 ounce 28 tari 15 grani.

TAROATAIHETOOMO, is the name of one of the two firſt or ſupreme deities at Otaheite: the other, who is ſuppoſed to have been a rock, is called *Tepapa.* Theſe produced a ſon called *Tane*, to whom their prayers are generally addreſſed, and who is ſuppoſed to intereſt himſelf in the affairs of mankind; and a daughter called *Tellowmatatayo*, the *Year*, from whom proceed the months and days. From the two firſt beings they ſuppoſe alſo to have ſprung an inferior race of deities called *Eatuas.* Hawkeſworth's Voy. vol. ii. p. 238.

TARODUNUM, in *Ancient Geography*, a town of Germany, near the Danube, and in the vicinity of Aræ Flaviæ.

TAROM, in *Geography*. See Tarum.

TARON, or Tiroan, a town of Perſia, in the province of Adirbeitzan; 120 miles S.E. of Tauris.

TARONA, in *Ancient Geography*, a town of the Tauric Cherſoneſus, S.E. of Taphra, and E. of Satarcha.

TAROONCHI, in *Geography*, a town of Hindooſtan, in Myſore; 15 miles S.S.W. of Chinna Balabaram.

TAROUC Yamdson, a lake of Thibet, about 53 miles in circumference. N. lat. 31° 52′. E. long. 84° 38′.

TAROUCA, a town of Portugal, in the province of Beira; 9 miles S. of Lamego.

TAROULA, a town on the eaſt coaſt of the iſland of Tidor. N. lat. 0° 42′. E. long. 127° 20′.

TAROURS, a town of Hindooſtan, in Berar; 30 miles N.N.E. of Neermul.

TAROUT, a town of Arabia, in the province of Hedsjas; 32 miles S.E. of El Catif.

TARP, a town of Sweden, in the province of Dalland; 12 miles N. of Uddevalla.

TARPANS, a kind of wild horſes in the Caucaſian deſert, E. of the river Yaik. They are of a middling ſize, roundiſh, ſhort, generally of a blueiſh-grey colour, with big heads, and ewe-necked. They are taken with a nooſe, and broken to the ſaddle by being coupled to a tame horſe.

TARPAULIN, or Tarpawling, is a piece of canvas, well pitched and tarred over, to cover the hatchways of a ſhip at ſea, in order to prevent the penetration of the rain or ſea-water, which may occaſionally ruſh over the decks.

The term is alſo uſed in deriſion for a perſon bred at ſea, and educated in the mariner's art. We alſo, of late, uſe it to expreſs a painted floor-cloth.

Tarpaulin *Cove*, in *Geography*, a bay on the S. of Maſſachuſetts, near Falmouth.

TARPEIAN, Tarpeius, in *Antiquity*, an epithet given to a rock in ancient Rome, of conſiderable height; whence, by the law of the Twelve Tables, thoſe guilty of certain crimes were precipitated. It was on this rock that the Capitol was built.

The Tarpeian rock might formerly be ſteep enough on one ſide to break a man's neck; but it could never have been of that ſurpriſing height mentioned by ſome writers, if any judgment can be formed from its appearance at preſent. See Burnet's Letters, p. 238, and Miſſon's N. Voyage, p. 103.

It took its name from a veſtal, called *Tarpeia*, who betrayed the Capitol, of which her father was governor, to the Sabines; on condition that they would give her all they bore

bore on their left arms, meaning their bracelets. But, inftead of bracelets, they threw their bucklers (which were likewife borne on their left arm) upon her head, and crufhed her to death.

Others afcribe the delivery of the Capitol to her father, Spurius Tarpeius; and add, that he was precipitated down this rock by Romulus's order, and that this henceforward became the punifhment of all criminals of the like kind.

Tarpeian *Games*, *Ludi Tarpeii*, were games inftituted by Romulus in honour of Jupiter Feretrius; and called alfo *Capitolini ludi*. See Capitoline.

TARPORLEY, in *Geography*, a fmall market-town in the hundred of Edifbury, and county palatine of Chefter, England, is fituated on the great road from London to Chefter, at the diftance of 172 miles N.W. from the former, and 11 miles E.S.E. from the latter. In ancient records, Tarporley is called a borough, and the houfes burgages: it had in former times a mayor, as appears by deeds of the years 1348 and 1396: it is now governed by a conftable. The market, which was originally on Tuefday, was granted in 1281 to Hugh de Tarporley, then lord of the manor: it had been many years difufed, but was reftored in 1705 by fir John Crew, who alfo procured a grant of three annual fairs, and built a market-houfe. The parifh of Tarporley, which includes the townfhips of Eaton, Rufhton, and Utkinton, contained in the year 1811, according to the population report, 365 houfes, and 1852 inhabitants. An annual fox-hunt, of great celebrity, is held at Tarporley, on the firft week in November, during which week are horfe-races, at a place called Crab-tree Green, on Delamere foreft.

About two miles fouthward of Tarporley rifes the great infulated rock of Beefton. It is compofed of fand-ftone, and is nearly perpendicular on one fide, which gives it a tremendous appearance, but the other fide gradually flopes to the level of the country. Its height is 366 feet. On the creft of this rock are the ftately ruins of the far-famed Beefton caftle, whofe almoft impregnable ftrength was once proverbial. This fortrefs was erected in 1220 by Ranulph de Blundeville, earl of Chefter. It confifted of an outer and inner area. The outer was defended by a ftrong wall, fortified with round towers, which ran acrofs the flope from one end of the precipice to the other. Some parts of this wall, and fix of the towers, are ftill extant. The area inclofed is nearly five acres. The caftle was defended, on one fide of the area, by a deep ditch cut out of the folid rock; on the other, by the abrupt precipice that overhangs the vale of Chefhire. The entrance is through a noble gateway, guarded on each fide by a great round tower, with walls of prodigious thicknefs. During the civil wars of the 17th century, this foreft was alternately befieged by the royal and parliamentary forces; and in 1646 was difmantled by order of the parliament.—Lyfons's Magna Britannia, vol. ii. part 2. Chefhire. Beauties of England and Wales, vol. ii. Chefhire, by J. Britton and E. W. Brayley.

TARPOU, a lake of Thibet, about 60 miles in circumference. N. lat. 30° 32′. W. long. 81° 54′.

TARQUINIUS PRISCUS, *Tarquin the Ancient*, in *Biography*, the fifth king of Rome, was the fon of an opulent merchant of Corinth, who, efcaping from tyranny at home, fettled at Tarquinii, in Etruria, where he married a female of rank, by whom he had two fons. One of them died, and the other, named Lucumo, was urged by his wife Tanaquil, a lady of rank and of ambition, to remove from Etruria to Rome; where he changed his prænomen Lucumo into Lucius, and his family name Damaratus into Tarquinius, borrowed from his native city. Here he ingratiated himfelf by his manners with Ancus Martius, the king, and alfo with the people; and by the liberal application of his wealth to public purpofes, particularly to the fupport of the wars in which Rome was engaged, as well as by his fkill and valour in the field, he gained a reputation which ferved to advance him to the rank of patrician and fenator. Ancus alfo appointed him to the confidential office of guardian to his two fons. Upon the death of Ancus, B. C. 616, the ambition of Tarquin prompted him to take meafures for fecuring the fucceffion to himfelf. The crown being elective, he contrived, by bribes and folicitations, to obtain the fuffrages of the people, who proclaimed him king; and in order to ftrengthen his intereft in the fenate, he introduced from plebeian families 200 new members into this body. In his wars with the Latins, he took feveral of their towns, and obliged the Sabines and Etrurians, whofe confederacy he defeated, to feek an alliance with Rome on humiliating terms. Tarquin, in honour of his fuccefs, was granted a triumph; and the fpoils of war were devoted to the erection of the Circus Maximus, for the exhibition of the Roman or great games. The Etrurians, having afterwards rebelled, obtained peace upon condition of their recognizing Tarquin as their fovereign. During an interval of peace, after a nine years' war, Tarquin employed himfelf in improving the city, by enclofing it with walls, and by conftructing thofe fewers, which were in fubfequent times the objects of admiration. On occafion of a new war with the Sabines, Tarquin, whofe army was deficient in cavalry, augmented the ftrength of each divifion; and having defeated the Sabines, they fubmitted, and furrendered all their fortreffes to the Romans. At this time Tarquin fulfilled his vow of erecting a temple to Jupiter, Juno, and Minerva, on the Tarpeian rock; and by this act he acquired the honour of founding the principal feat of the Roman worfhip. Having attained to his 80th year, the fons of Ancus took occafion to make an attempt for defeating his plan of continuing the crown in his own family by the marriage of his daughter to Servius Tullius, by confpiring againft his life. They fo far fucceeded as to procure the affaffination of the king. His queen Tanaquil, however, by keeping the event fecret, adopted meafures for fecuring the fucceffion of her fon-in-law: and the fons of Ancus, whofe plot had been detected, went into voluntary banifhment. Thus ended, in the year B. C. 570, the profperous and fplendid reign of Tarquin the elder, one of the moft illuftrious of the Roman kings, and equally diftinguifhed by his conduct in peace and in war. Univ. Hift.

Tarquinius Superbus, or *Tarquin the Proud*, fuppofed to have been a grandfon of the elder Tarquin, afcended the throne in the year B. C. 534. His government was arbitrary and tyrannical, and it was fupported by a band of foreign mercenaries, employed in the defence of himfelf and his party, who had contributed to advance him to the throne in contempt of the fuffrages of the people. Many of the principal fenators dreading the fate of thofe who were made the victims of his fufpicion and avarice, retired into a voluntary exile. The plebeians, at firft pleafed with the humiliation of the fenate, had fome reafon to complain of the yoke impofed upon themfelves. The laws that had been made in their favour were abrogated; fpies and informers watched their words and actions; and all public affemblies for bufinefs or amufement were prohibited. Tarquin, confcious of the odium of the Roman citizens, took meafures for ingratiating himfelf with the allies; and with this view, he erected a temple near the ruins of Alba, confecrated to Jupiter Latialis, at which the diets of the confederate cantons were annually to affemble; the Romans, as chief members of the confederation, prefiding at the facrifices and deliberations. This inftitution contributed to the ftrength of the Roman ftate, and the extenfion of its dominion throughout Italy. Having taken up arms againft the Volfcians and Sabines, he returned, after a fuccefsful war, to Rome, and twice triumphed; and he took occafion to finifh the great circus and the fewers, which his grandfather had begun. But a war again commenced with fome difcontented patricians, who had taken refuge at Gabii, a Latin city not far from Rome; and this war lafted feven years. At length Gabii was conquered by the treachery of Sextus, one of Tarquin's fons; and the inhabitants, whom he treated with lenity, were incorporated with the Romans. During the reign of this Tarquin, the Sibylline books were brought to Rome, as we have related under that article, and the Capitolian temple finifhed. Ardea, the capital of the Rutuli, was the next object of Tarquin's military enterprife; and this circumftance was the remote caufe of the rape of Lucretia by Sextus Tarquin, which at length occafioned the expulfion of the Tarquinian family from Rome, as well as the extinction of the kingly government. Brutus, availing himfelf of the paffions excited among the multitude by the tragic fate of Lucretia, and expofing the tyrannical government under which Rome groaned, obtained a public decree for the banifhment of Tarquin and his fons, and the army concurring in this refolution, the king was reduced to the neceffity, at the age of 76, B. C. 509, to abandon his capital, and take refuge at Cære, in Etruria. Many attempts were made for his reftoration, but all proved ineffectual. Tarquin retired into Campania, and died there, in the 90th year of his age, and 14th of his exile. Poffeffing talents fit for command, he was neverthelefs violent, cruel, and wholly unprincipled. Univ. Hift. Gen. Biog.

TARRA, in *Ancient Geography*, a town of Afia Minor, in Lydia.—Alfo, a town and mountain of Crete.

TARRABERRY, in *Geography*, a town of Bengal; 30 miles N. of Dinagepour.

TARRABOGA, a town of Bengal; 45 miles S. of Doefa.

TARRACE, TARRASS, *Terrace*, or *Terrafs*, a coarfe fort of plafter, or mortar, durable in the wet, and chiefly ufed to line bafins, cifterns, wells, and other refervoirs of water. See *Calcareous* CEMENT.

That which is called the Dutch terrafs, is made of a foft rock-ftone, found near Collen, upon the lower part of the Rhine; it is burnt like lime, and afterwards reduced to powder by means of mills: from thence it is brought to Holland in great quantities, where it has acquired the name of Dutch terrafs. It is of a greyifh colour when it is not mixt, which is very feldom the cafe: becaufe it is very dear, and the demand for it in aquatic works very great. It is faid that in fome parts of England there is found a foft ftone, refembling that of Dutch terrafs, and which might ferve as well in aquatic works.

An artificial terrafs, refembling the true, may be formed of two parts of lime, and one of plaifter of Paris, well beaten together, and ufed immediately. There is another fort of terrafs, ufed for coarfer ufes, which is fometimes called *Welfh* terrafs, formed of one part lime, and two parts of well-fifted coal-afhes, thoroughly mixt by being well beaten together. Handm. to the Arts, vol. ii. p. 32.

TARRACO, in *Ancient Geography*, a town of Hifpania Citerior, belonging to the Cofetani. This was an ancient town in the time of the Romans. Some Spanifh authors have attributed its foundation to Tubal. Others, with greater probability, afcribe it to the Phœnicians, who called it Tarcon, which the Romans changed into Tarraco. Having been deftroyed, it was re-eftablifhed by the two Scipios. At length it became the capital of that region, to which it gave the name of Hifpania Tarragonenfis. Auguftus vifited this city on occafion of his war againft the Cantabri; and it was here that the firft altar was erected to his honour. Galba, A.D. 68, was prefented by the Tarraconians with a crown of gold. It was in the year 121 or 122 that Adrian re-eftablifhed the temple built in this city in honour of Auguftus, under the reign of Tiberius. See TARRAGONA.

TARRAGON, in *Botany*, a name fometimes given to *fouthernwood;* which fee. See alfo ARTEMISIA.

TARRAGONA, in *Geography*, a town of Spain, in the province of Catalonia, fituated on a rifing ground on the coaft of the Mediterranean, at the mouth of the river Francoli, and one of the moft ancient cities in Spain, faid to have been founded by the Phœnicians. Under the Romans it was the capital of a province, called Tarragonenfis, and was fortified by Scipio as a defence againft the Carthaginians. In the year 467 it was taken by the Goths, and levelled with the ground. In 516, a council was held here, in which monks are firft mentioned; when it was ordained that the fabbath fhould commence on Saturday evening. It afterwards fell into the hands of the Moors, from whom it was recovered in the latter part of the 11th century, and rebuilt by the archbifhop of Toledo, who was by the pope abfolved of the oath he had taken of going to the holy war, on condition that he would lay out the fum defigned for that expedition in rebuilding Tarragona. In the war of the fucceffion, the Englifh obtained poffeffion of this city, and intended to keep and fortify it, by bringing the river Francoli quite round it; and for this purpofe threw up vaft outworks and redoubts, the ruins of which are yet vifible. On the poffeffion of Gibraltar, they gave up the defign. The environs at Campus Tarragonenfis they efteem one of the moft fertile fpots in Europe. Tarragona has but few remains of its ancient grandeur; infcriptions almoft deftroyed by time, fome coins, and a few ruins, give but an imperfect idea of what it formerly was. It is now depopulated, and of little importance. The harbour is dangerous, and not much frequented; there are a few baftions in bad repair, which were formerly built for its defence. Tarragona is, however, the fee of an archbifhop, the metropolis of Catalonia, and difputes with Toledo the primacy of Spain. The eftablifhment of the fee is faid to have been in the firft ages of the church: the fucceffion of archbifhops was interrupted by the Moors, and remained fufpended until the 11th century. The cathedral is worthy of attention for its vaft dimenfions, the elegance of its Gothic architecture, and a magnificent chapel, built with rich marble and jafper, in honour of St. Thecla, tutelar faint of the church; 98 miles E.S.E. of Saragoffa. N. lat. 41° 8'. E. long. 1° 33'.

TARRAGUNGE, a town of Bengal; 22 miles S.E. of Moorfhedabad.

TARRAPOUR, a town of Hindooftan, in Bengal; 17 miles S.W. of Boglipour.—Alfo, a town of Hindooftan, in Malwa, on the Nerbuddah; 12 miles S. of Mundu.

TARRAR, a circar of Hindooftan, in Allahabad, bounded on the north by Allahabad Proper, on the E. by Chunar, on the fouth-eaft by Boggilcund, and on the weft by Bundelcund; about 35 miles long, and 12 broad.

TARRASA, a town of Spain, in Catalonia; 13 miles N. of Barcelona.

TARRATZ POINT, a cape on the north coaft of St Vincent. N. lat. 13° 24'. W. long. 65° 15'.

TARREGA, a town of Spain, in Catalonia, on the Cervera;

Cervera; 5 miles W. of Cervera. N. lat. 41° 36′. E. long. 0° 19′.

TARRIE, in *Commerce*, a meafure at Algiers for corn and dry goods, holding fomewhat lefs than 2¼ pecks Englifh meafure; 16 tarries make a caffife.

TARROCK, in *Ornithology*, the name of a fea-fowl of the larus or gull-kind, and diftinguifhed by authors by the name of the *larus cinereus Bellonii;* and called by Linnæus the LARUS *tridactylus;* which fee.

It is of the fize of the common pigeon, and is not much unlike it in fhape, except that the head is larger and thicker. The bill is black, fhort, thick, and ftrong; the throat, neck, and under fide are white; near each ear, and under the throat, is a black fpot; on the hind part of the neck is a black crefcent, with the horns pointing to the throat.

Its great diftinction, however, from all the other birds of the gull-kind, is, that it has no hinder toe, but in lieu of it a fmall protuberance. It is very common on the coafts of Cornwall, and fome other of the Englifh fhores. Ray and Pennant.

TARRY-TOWN, in *Geography*, a town of New York, where major André, of the Britifh army, was apprehended as a fpy; 24 miles N. of New York.

TARSAH, a town of Hindooftan, in Berar; 18 miles E. of Nagpour.

TARSI, in the *Materia Medica*, a name by which fome authors have called the root of the *cyperus efculentus*, or fweet cyperus of the fhops, and by which it is, in fome places, ufually called by the druggifts. See AVELLANDA and HABHAZZIS.

TARSO, in the *Glafs Trade*, a fort of white ftone found in many rivers in Italy, and other places; and ufed inftead of fand for the fineft cryftal-glafs, being firft burnt, and calcined with the falt of the polverine into frit. Neri's Art of Glafs, p. 7.

Neri calls this ftone a kind of white marble; and adds a general rule, that all ftones that will ftrike fire with fteel, are fit to vitrify; and thofe that will not ftrike fire with fteel, will never vitrify.

The criteria or determinate characters of foffils were not at all fixed in this author's time, otherwife he had not called this ftone a kind of marble; fince his own general rule of trying ftones by fteel is, though liable to a few exceptions, a very good one; and, according to that, this tarfo could be of no affinity to marble; for marble will not ftrike fire with fteel, nor ever be converted into glafs.

The tarfo, therefore, of this and other authors, could be nothing of the marble kind; but is truly a cryftalline matter debafed by an admixture of white earth, and found in form of fmall pebbles, of a whitifh, yellowifh, or pale reddifh colour; and this is common in all the gravel-pits of England, and in the beds of fome of our rivers; and might be ufed with great advantage by our glafs-makers, if they knew it was fo eafily to be had.

On comparing thefe ftones of ours, with the cuogoli, or tarfo of the foreign glafs-makers, there is no difference diftinguifhable to the eye, nor will the niceft experiments by the fire, acid menftrua, &c. fhew the leaft diftinction between them. We are not to wonder, however, that the glafs-makers did not hitherto diftinguifh this to be the true cuogoli, or tarfo, fince the characters of foffils have been hitherto fo little afcertained, that the beft and lateft author on thefe fubjects, Dr. Woodward, fo far miftook the ftructure of this ftone, as to call it a fparry pebble. It is certain that fpar could never have any thing to do with glafs-making; but this ftone has no fpar in its compofition.

TARSUS, in *Ancient Geography*, a town and country of Afia, in Bithynia. Steph. Byz.

TARSUS, in *Geography*, a fea-port town of Afiatic Turkey, in the government of Marafch, faid to have been founded by Sardanapalus. It was at one time the capital of Cilicia, and traverfed by the river Cydnus. It is mentioned by Dionyfius Periegetes, Ptolemy, Mela, Pliny, and Strabo, the latter of whom fays, that it was very powerful and populous; that its inhabitants excelled in the ftudy of philofophy, and of all the fciences cultivated among the Greeks; indeed in this refpect they furpaffed Athens, Alexandria, and all other academies in the world. It is now inhabited by Turks, Greeks, and Armenians, and is the fee of a Jacobite bifhop and Neftorian archbifhop. It is large, and furrounded with a double wall. St. Paul called himfelf a native of Tarfus; and here the emperor Julian was buried. It has been faid that in the time of St. Paul, Tarfus was a Roman colony, and that the apoftle was a citizen of Rome by virtue of his nativity at Tarfus. (Acts, xxi. 37—39. ch. xxii. 3.) But Dr. Lardner has particularly examined this point, and alleged feveral arguments to prove, that Tarfus, though it was no mean city, as St. Luke fays, was not a municipium, or town of Roman citizens. (See *St.* PAUL.) Tarfus was taken by the Saracens in 640; 25 miles W. of Adana. N. lat. 37° 1′. E. long. 34° 37′.

TARSUS, in *Anatomy*, that part of the foot (confifting of about its pofterior half) to which the leg is articulated. Its front portion correfponds to the inftep in common language. Sea EXTREMITIES.

The fame name is applied to the portion of cartilage contained in each eyelid. See EYE.

TARTAGLIA, NICHOLAS, in *Biography*, a celebrated mathematician, was born at Brefcia about the beginning of the 16th century. Being left deftitute in his childhood by the death of his father, he was no lefs unfortunate at the fiege of Brefcia in 1512, in receiving feveral wounds, and particularly one which divided his lip, fo that he loft the power of diftinct articulation; and from this circumftance he got the name of Tartaglia. The defects of his early education were amply compenfated by his genius and diligence. Having refided ten years at Verona, he afterwards, *viz.* in 1534, became profeffor of the mathematics at Venice; and here, except during an interval of eighteen months at Brefcia, he remained till the time of his death, in 1557. His works are numerous. Befides tranflations of Archimedes and Euclid, he wrote many original treatifes in mathematics, one of the moft important of which, entitled "Quefiti e' inventione diverfi," was publifhed at Venice in 1546, and dedicated to Henry VIII. of England. It is comprehended in nine books, and contains anfwers to feveral queftions that were propofed to him at different times concerning mechanics, hydroftatics, &c.; and more particularly worthy of notice is the hiftory of the invention of the rules for folving cubic equations, which he communicated to Cardan, under an oath that he would keep the fecret. (See ALGEBRA and CARDAN.) Tartaglia's genius was no lefs confpicuoufly difplayed in other fciences than in algebra. He treats of artillery and gunnery, and alfo of the different methods of fortifying towns, befides various mechanical and algebraical queftions. He alfo propofes many queftions with regard to the motion of bodies, and the method of meafuring diftances, in his "Nuovia Scienzia" and "De' Numeri e Mefure." To Tartaglia we owe the firft difcovery of the beft angle, *i. e.* 45°, as it was then thought, for elevating a piece fo as to throw a ball or fhell to the greateft diftance. He alfo announced a method of raifing veffels that were

 funk,

ſunk, and other heavy bodies, from the bottom of the ſea, and the means by which a perſon may be enabled to remain a conſiderable time under water; and to him we owe a treatiſe on the ſigns which indicate changes in the atmoſphere. He has likewiſe furniſhed us with a large treatiſe on arithmetic, algebra, and geometry, publiſhed at Venice, in folio, in 1556. Tiraboſchi remarks, that all Tartaglia's works manifeſt great penetration and acuteneſs, and that they would claim higher commendation, if the author had paid more attention to his ſtyle, and if the editions were more correctly printed. But with all their imperfections and faults, and after all the improvements to which they have led the way, they were juſtly eſteemed at the time when they were written, and they have been uſeful to thoſe who have in more modern times purſued the ſame courſe of ſtudy and inveſtigation. Tiraboſchi. Montucla. Hutton.

Tartaglia is mentioned by Pietro della Valle among great Roman muſicians in 1640, and the compoſer of "Clearco," the firſt opera that was performed at a public theatre in Rome. For though ſeveral muſical dramas had been exhibited in the palaces of ambaſſadors and other great perſonages in that city, no theatre had been previouſly opened there for the public at large.

TARTAGLINI, LA ROSA, the daughter of Tibaldi, an excellent tenor ſinger in the ſervice of the emperor at Vienna. She was extremely celebrated for her beauty and agility of voice, and quitted the ſtage in 1768.

TARTALA, in *Geography*, a town of Hindooſtan, in Calicut; 21 miles E. of Paniany.

TARTAN, in *Sea Language*, a ſmall coaſting veſſel navigated in the Mediterranean ſea, and having only one maſt and a bowſprit, the principal ſail, which is extremely large, being extended by a lateen-yard.

When tartans put up a ſquare ſail, it is called *a ſail of fortune.*

TARTAR, TARTARUS, or *Tartarum*, in *Chemiſtry*, an acid concrete ſalt which riſes from wines, after complete fermentation, and ſticking to the top and ſides of the caſks, forms a cruſt, which hardens to the conſiſtence of a ſtone. It is in this ſtate a hard, brittle, brown-red maſs, interſperſed with imperfectly cryſtallized particles; and called *crude* or *rough* tartar, or *argol*, by way of diſtinction from that which is purified.

Its goodneſs rather depends on the number of repeated fermentations, which a ſucceſſion of new wines in the ſame caſks for ſeveral years makes, than on the ſoil or climate where the wine is produced.

The ſweet wines afford always leſs tartar than the ſharp ones, and it is alſo leſs valuable. The tartar of Rheniſh wine is better than that of any other; and in general thoſe wines which have the moſt acid in them, and which are the moſt coloured and ſtrongeſt-bodied, afford the greateſt quantity of tartar, and that in the largeſt cryſtals.

The taſte of tartar is vinous, and ſlightly acid. It is not entirely a product of fermentation, for it is contained in the "muſt," or grape juice, and aſſiſts in the proceſs of fermentation, and the production of alcohol. This ſalt has alſo been found native, under different combinations, in ſome other vegetable juices.

Beſides the uſual way in which tartar is produced, there is a very remarkable account in the Memoirs of the Academy of Sciences at Paris, an. 1737, of its having been found in a more than ordinary beautiful ſtate on a human ſkull: the diſcovery was owing to accident, and it was found that there had been lees of wine in the veſſel in which the ſkull had been laid ten days in ſoak.

The formation of the cryſtals of this tartar on the ſkull, while the ſides of the veſſel had none created on them, ſhews that the ſkull had a diſpoſition for receiving the cryſtals more than any other body; and their peculiar brightneſs proves, that it had ſome ſhare in their formation.

Tartar conſiſts of a large quantity of extractive matter, ſcarcely ſoluble in water, to which it owes its colour, and of a ſalt, quite white when pure, compoſed of acid of tartar united to a ſmall portion of potaſh, leſs than is required for the ſaturation of the acid, but which, in this proportion, forms a diſtinct cryſtallizable ſalt of conſiderable importance in ſeveral arts and manufactures.

Tartar is either *white*, or *red*, according to the colour of the wine from which it is produced. That brought from Germany is the beſt, as being taken out of thoſe monſtrous tuns, ſome of which hold a thouſand pipes of wine, ſo that the ſalt has time to come to its conſiſtence, which is one of the chief qualities to be regarded in tartar. That of Montpellier is the next in order; then that of Lyons, Paris, &c.

White tartar is preferred to red, and is really better, as containing leſs of the droſſy or earthy part; though both kinds, when purified, are exactly the ſame. The marks of good tartar of either kind are, its being thick, brittle, brilliant, and but little earthy.

Tartar, in its *crude* ſtate, is much uſed as a flux in the aſſaying of ores. As it contains both alkali and carbonaceous matter, it acts both in aſſiſting the fuſion of refractory ores, and in reducing metallic ſalts and oxyds. When heated *per ſe* to redneſs in cloſe veſſels, the extractive matter and the tartareous acid both become charred, and the reſult is a black alkaline carbonaceous maſs. In open veſſels the charcoal burns off totally, and at laſt nothing remains but pure white carbonate of potaſh. But tartar is for the moſt part refined, in order to obtain the pure ſalt; which is called *purified* tartar, *cream* of tartar, *cryſtals* of tartar; or more accurately, according to the modern nomenclature, *acidulous tartrite of potaſh*, or *ſupertartrite of potaſh*, and ſometimes with leſs preciſion, ſimply *tartar*. This ſalt is purified in large quantities at Venice, and in France near Montpellier, by two different proceſſes, which have been deſcribed by Deſmaret (Journ. Phyſ. tom. i. p. 67.) and by M. Fizes (Mem. de l'Acad. for 1725), and which we ſhall here extract from Aikin's dictionary. At Venice the method is as follows: "The crude tartar is firſt dried in an iron boiler, with a very gentle heat and frequent ſtirring, that the acid may not be burnt, and is then pounded in iron mortars. The ground tartar is then diſtributed into wooden tubs, and boiling water poured upon it, which diſſolves the ſalt, and leaves a ſediment, which is thrown away. The clear ſolution is left three days at reſt, during which time it depoſits browniſh cryſtals of tartar. The mother-liquor from this operation is reſerved, and is uſed hot in the ſubſequent proceſs in the firſt lixiviation of the tartar. The browniſh cryſtals of tartar are then put into a copper boiler, with the mother-liquor of former proceſſes, and ſlowly brought to boil, by which a ſaturated ſolution of a deep yellow wine-colour is produced. This is clarified in the following way: a workman ſtands by the ſide of the copper with a baſket of eggs, and a bucket full of finely ſifted wood-aſhes. He begins with breaking one of the eggs, and putting the white of it only into a bowl; he beats this up with ſome of the boiling liquor, and then pours the whole into the boiler: he then inſtantly throws in a ladleful of the wood-aſhes, and ſtirs up the liquor from the bottom. A briſk efferveſcence takes place, and the ſurface is covered with a red ſcum, which is carefully taken off with a perforated ſkimming-diſh, and put aside: a second portion of ashes is then added, and the effervescence and scum are renewed and treated as before. The whole of this operation is repeated fourteen or fifteen times, after which the liquor becomes quite clear and colourless. The fire is then withdrawn, and the liquor suffered to remain perfectly at rest for three days. On the fourth, a dirty white saline crust is removed from the surface, and two-thirds of the liquor laded out: the crystals on the sides are then collected by a ladle, and washed in the remaining liquor; they are thus obtained perfectly clean, and require no further preparation than drying on a wicker frame. The crystals from the bottom are still somewhat coloured, and are either sold as an inferior sort, or are refined again with fresh portions of the crude tartar. The liquor that remains in the boiler, after the deposition of the crystals, is a cold saturated solution of tartar, and is employed in the first lixiviation of the rough tartar."

The method used near Montpellier has been found so convenient and effectual, that it has continued without any material alteration for a century. It is as follows: "The apparatus required for this purpose is, 1st, a large copper boiler; 2d, a stone cistern, larger than the boiler; 3d, a number of glazed earthen pots (generally twenty-seven), which, together, hold somewhat more than the boiler; 4th, some strainers of coarse cloth stretched on wooden frames; 5th, four smaller copper boilers, which, together, hold as much as the larger boiler, and are used in the refining part of the process; and 6th, a mill to grind the tartar.

"The large copper is first filled with two-thirds of mother-liquor, remaining from the previous operations, and one-third of spring-water; a quantity of rough tartar is then thrown in, and, when the liquor is saturated and boiling, it is strained into the earthen pots. In about half an hour the liquor in these pots, though still very hot, begins to deposit crystals on the surface and sides of the pot; during which time, more liquor and tartar are thrown into the large copper, as at first.

"The liquor in the pots is then emptied into the stone cistern, leaving the crystallized crust of tartar behind; and when the second boiling is saturated, the pots are again filled as before, and the large copper again charged with the clear liquor from the cistern, and fresh tartar. By thus five times alternately preparing a hot saturated solution, and allowing it partially to deposit its tartar in the pots, the latter become lined to a considerable thickness with a crust of reddish-white tartar, much purer than at first, and which obviously consists of an irregular crystallized saline mass, and when washed with cold water, is fit for the second or proper refining process. For this purpose the four small boilers are filled with water, in which a small quantity of clay is diffused, which renders it milky, rejecting the stony and larger particles of earth. The half-purified tartar is then added in such proportion, that the water, when boiling, shall be sufficient to dissolve all the soluble part, and the ebullition is continued for a quarter of an hour; the fire is then withdrawn, and the liquor allowed to remain at rest till the next day. It is then found covered on the surface with a white hard saline crust, and a similar crust, but more distinctly crystallized, has concreted on the sides and bottom of the boiler. They are both very pure tartar, the crust on the surface, which is an amorphous mass, is called *cream of tartar*; and the other, *crystals of tartar;* but they are indiscriminately mixed.

"The crust is then broken down, and falls to the bottom; and the liquor, which is a clear pale red, is poured off gently into the stone cistern, till it begins to run white, owing to the clay at bottom, which latter portion passes into a separate vessel. The whole mass of solid tartar left in the boiler is then washed with cold water, till all the foulness (which is merely superficial) is got out, and the water comes away quite clear; after which the purified tartar is taken out, and dried on stoves or in the sun, and is perfectly pure and white. The ordinary rough tartar yields about three-fifths of its weight of the white pure salt. All the residuary liquors are employed in subsequent operations, in the way already mentioned."

Schaub says (Annal. de Chim. xlix. 61.), that tartar may be purified by simply boiling it with powdered recent charcoal, and thus very white crystals are obtained.

TARTAR, *Burnt*, a preparation used by glass-manufacturers, and consisting of large lumps of red tartar, burnt or calcined in earthen pans in an open fire, till they have done smoaking: it is of a blackish purple colour. Neri's Art of Glass.

TARTAR, *Cream of*, *Cremor Tartari.* See CREAM *of Tartar*, TARTAR, *supra*, *Super-tartrate of Potash*, under SALTS, and TARTRITES.

Cream of tartar has a sensibly acid taste; it reddens the blue colours of vegetables; it may be saturated by uniting with any of those substances, which are capable of forming with acids neutral salts; and it may be afterwards separated from those substances, and recover its former appearance.

In the arts, and in the materia medica, this is a very valuable salt. It is much used in dyeing, more especially in giving the scarlet and other modifications of the cochineal colours. It is also often combined with alum, as a mordant in fixing colours. (See DYEING.) As an article of the materia medica, cream of tartar, dissolved in water, forms an agreeable and cheap acidulous drink; and as a sweetener of the blood, some have taken it in whey or water-gruel, in the spring-time, to the quantity of half an ounce every morning, for three or four weeks. The solution in water, sweetened with sugar, is a pleasant beverage in febrile diseases, when its purgative quality is not likely to prove injurious. See the next article.

The difficult solubility of cream of tartar being an objection to its medical use, some experiments were made by Dr. Peter Jonas Berg, for rendering it more soluble by certain additions, without altering its medicinal qualities. Borax was found to answer best for this purpose. To four parts of cream of tartar one of borax was added. These were dissolved in a sufficient quantity of water, and the liquor strained: about a sixteenth part of impurities was left behind. The pure solution evaporated yielded an acid, and extremely soluble white salt. Lemery has also recommended borax. It has, however, been observed, that as borax contains an excess of alkali, the acid of the tartar would be neutralized, and a very different salt would be produced, *viz.* the *tartrite of potash and soda;* which see. Nova Act. Phys. Med. Acad. Cæs. Leop. Carol. Nat. Curios. tom. iv.

TARTAR, *Crystals of.* See TARTAR, *supra*, and TARTRITES.

These crystals are small and irregular, but generally run together into little masses of a white colour, semi-transparent, brittle, and easily reduced into powder. Crystals of tartar are in common use as a laxative and mild cathartic; they are also esteemed for their cooling and diuretic qualities, and have therefore been much employed in dropsies, and in other cases requiring an antiphlogistic treatment. Dr. Cullen says, that in large doses they act like a purgative, in exciting the action of the absorbents in every part of the system, and more powerfully than the operation of any entirely neutral salts. On this property is founded their utility in the case of dropsy. They occasion a considerable discharge of serous fluid into the bowels, which is thrown off in in the form of ſerous ſtools; the diſcharge by urine being alſo augmented. The water in the cavity of the abdomen is thus rapidly carried off; and the chances of a return of the diſeaſe are ſuppoſed to be fewer than when other diuretics are employed. It is remarked, that they do not readily paſs off by the kidnies, unleſs they are taken with a large quantity of water; and, therefore, when intended as a diuretic, they ought to be given in a liquid form, as Dr. Holme has directed. It has been ſuggeſted, that, in caſes complicated with hepatic obſtructions, the effects of this remedy are very uncertain. It may be advantageouſly united with ſquills; and, on account of the exhauſtion which it occaſions, the uſe of it ſhould be followed by preparations of iron, and other tonics. As a purgative and hydragogue, the doſe is from ʒiv to ʒvj, in the form of electuary; and for the latter purpoſe, this doſe muſt be repeated until the kidnies are affected; diluting freely during its uſe. Theſe ſalts enter ſeveral officinal compoſitions: ſuch as "carbonas potaſſiæ puriſſimus," Ed. Ph.; "ferrum tartarizatum," L. D.; "pulvis jalapæ compoſitus," E.; "pulvis ſcammonii compoſitus," E.; "pulvis ſennæ compoſitus," E.; "potaſſæ tartras," L.E.D.; "antimonium tartarizatum," L.E.D.; "ſoda tartarizata," L.E.D. Woodville. T. Thomſon.

Tartar, *Emetic.* See Antimony.

A conſiderable diverſity has occurred in the method of preparing this tartar, probably from want of conſidering, that the emetic quality of this preparation proceeds from the metallic earth being diſſolved by the acid of tartar, and forming with it a kind of ſoluble tartar, a true neutral ſalt, no leſs capable of a very exact ſolution than the vegetable ſalt, the ſalt of ſeignette, and all the other ſoluble tartars. By conſidering this ſaturation as a fixed point, there may be produced only one kind of emetic tartar, always equally ſtrong. See a detail of M. Geoffroy's experiments on this ſubject, in Mem. Acad. Par. for 1734. M. Beaumé directs it to be prepared by mixing together equal parts of cream of tartar, and of porphyriſed glaſs of antimony, or rather a larger quantity of the latter ingredient. This mixture is to be thrown gradually into boiling water; and the boiling muſt be continued gently, till there is no efferveſcence, and till the cream of tartar be entirely ſaturated. The liquor is to be filtrated; and when it is cooled, there will be formed in it fine cryſtals, in the form of pyramids with triangular baſes, which are a ſoluble tartar perfectly ſaturated with glaſs of antimony. Theſe are tranſparent while moiſt; but by expoſure to a dry air, they loſe a part of the water of their cryſtallization, and become opaque and white. Emetic tartar thus prepared, very well produces an emetic effect when taken from a grain to two and a half, or three, according to the conſtitution of the patient. The reſult of M. Beaumé's experiments on the manner and duration of boiling this preparation is, that veſſels of iron and copper ought to be avoided, and thoſe of ſilver or glaſs uſed, becauſe in theſe it may be boiled for any length of time, without being decompoſed; and that as the intention of the operation is to perfectly ſaturate the cream of tartar, the boiling muſt be continued till this ſaturation be effected, which requires a long time, when the glaſs of antimony is groſsly pounded, but a much ſhorter time when it is well porphyriſed. Macquer, in the Chemical Dictionary, obſerves, that we are not certain that the emetic tartar, prepared by ſaturating tartar with glaſs of antimony, has always an uniform and conſtant emetic power. And therefore he recommends the *powder of algaroth*, or mercury of life, which, however dangerous in itſelf, may be rendered ſafe, by waſhing it with a little fixed alkali, which will ſeparate all that marine acid that communicates to it a certain degree of cauſtic quality. The powder thus waſhed, he ſays, is altogether ſoluble by cream of tartar, and convertible into a ſoluble emetic tartar, perfectly neutral, by boiling it, and ſaturating it with cream of tartar, and treating it in the manner above directed, for the preparation of emetic tartar with glaſs of antimony. The powder of algaroth, thus prepared, is a calx of antimony conſtantly of the ſame degree of emetic ſtrength. The total evaporation of the fluid appears to be the beſt way of ſecuring uniformity of ſtrength to the medicine; and the ſolubility of the compound affords one of the beſt means for eſtimating its ſtrength, or the degree of its impregnation with the antimony.

Dr. Saunders relates, that an ounce of cold water, about the middle temperature of the air, diſſolved, of ſome of the common emetic tartars of the ſhop, not thirty-two grains, or one-fifteenth of its own weight; whereas of a well ſaturated ſort, which he had himſelf prepared by long boiling, the ſame quantity of water diſſolved fifty-two grains, or near one-ninth of its own weight.

The beſt way, probably, of obtaining a ſaturated and uniform preparation of this kind, would be to digeſt the common emetic tartar in eight times its weight, or leſs, of cold water, and evaporate the filtered yellow ſolution to dryneſs; or to continue the boiling of the glaſs of antimony and tartar for twelve hours, or longer, adding water occaſionally to keep the tartar always diſſolved, and at length to let the water waſte ſo far, as not to exceed eight times the quantity of the tartar employed, after which the liquor is to be ſuffered to cool, and then filtered and evaporated. The doſe of this preparation, as an emetic, is from two or three to ſix or eight grains. It may be given alſo as an alterative, or diaphoretic, in doſes of a quarter of a grain, or half a grain, or more, and added, in the quantity of a grain or two, as a ſtimulus to the milder vegetable cathartics. Lewis's Mat. Med. by Aikin.

Tartar, *Foliated*, is a preparation of tartar with diſtilled vinegar, which reduces it into white leaves. See *Acetas* Potassæ, and Terra *Foliata*.

Tartar *of Iron.* See Tartrite *of Potaſs and Iron.*

Tartar, *Oil of*, is the ſalt of tartar expoſed to the air for ſome days in an open veſſel, in a moiſt place, till it diſſolve into a fluid; though it is improperly called an oil, being no more than a diſſolved ſalt.

Oil of tartar *per deliquium* is held the beſt counter-poiſon to corroſive ſublimate.

Tartar, *Regenerated.* When cream of tartar has been made ſoluble by any alkaline ſubſtance whatever, it may be revived, or regenerated, into cream of tartar again; its acid in this ſtate has diſſolved the alkaline matter preſented to it, and that has been itſelf attenuated in ſuch a manner as to render it capable of inſinuating itſelf between the molecules or integrant parts of the conſtituent matter of the cream of tartar; on this only depends the ſolubility of this preparation: and to render the whole of its primitive nature again, there requires no more than the addition of a new acid, which ſhall free the tartar from this alkali; but this muſt neceſſarily be ſtronger than that naturally in the tartar. Thus ſpirit of nitre, or oil of vitriol, regenerate the ſoluble tartar in a moment, as being more powerful acids than that in the cream of tartar, and therefore taking from it all its alkali. The acid of diſtilled vinegar, which is not only a vegetable acid, but the ſame with that of tartar, is alſo able to regenerate the ſoluble tartars. It might ſeem wonderful that this ſhould be able to effect this change without any ſuperiority of force: but it is to be obſerved, that in the cream

cream of tartar the acid has a terreftrial and alkaline bafis, which is natural to it in that form; but in the ftate of foluble tartar it takes a new alkaline bafis, which is not natural to it: and when we view the procefs in this light, it does not appear wonderful, that an acid of its own kind fhould be able to take away from it this artificial alkaline bafis, though it was not able to take from it the natural one. Mem. Acad. Par. 1733.

This fecond or artificial bafis is different, according to the different alkalies which have been employed to render the tartar foluble, and confequently the fame acid may attach itfelf more to one than to another of thofe alkalies, or quit them the more or lefs eafily. There is one kind of foluble tartar, however, which is not to be regenerated at all; this is that which is made with borax.

Dr. Huxham fays, he has often experienced the good effects of regenerated tartar in the cure of obftructions of the bowels, and for fluggifh humours. See *Acetate of Potafh* under SALTS, and TERRA *Foliata*.

TARTAR, *Salt of*, is made of tartar wafhed, ground, purified, or cream of tartar, and calcined either *per fe* or with nitre, by a reverberatory fire; or it is made by pulverizing what remains in the retort after the diftillation of tartar, and calcining it as above by a reverberatory fire. On the one or the other of thefe preparations, they pour a great quantity of hot water, to make a ley of it; this they filtrate, and evaporate the liquor by a fand-heat, till the fixed falt be found at the bottom of the veffel. This is the pure alkali, or fixed falt of tartar. See CARBONATE *of Potafh* under SALTS, and SALT *of Tartar*.

TARTAR, *Soluble*, (fee *Tartrate of Potafh* under SALTS, and TARTRITE *of Potafh*,) may be made by the following procefs: Take of an alkaline fixed falt, a pound; of water, a gallon; and having diffolved the falt in this water boiling, throw cryftals of tartar in powder as long as any fermentation is raifed, which ufually ceafes before thrice the weight of the alkali is thrown in. Then ftrain the liquor through paper, and after due evaporation fet it by for the falt to cryftallize, or elfe evaporate the liquor wholly away, that the falt may be left dry.

This falt, by the action of the alkali on the acid of tartar, being freed from thofe grofs terreftrious parts, with which the cryftals of tartar, how pure foever, remain ftill charged, diffolves readily, and keeps fufpended in cold water.

The feveral alkaline falts, that of tartar itfelf, the common pot-afhes, borax, &c. all make a very good foluble tartar; and not only thefe, but the common terreftrial alkalies, whether of the mineral kingdom, as chalk or lime; or of the vegetable, as the afhes of plants after elixiviation; or of the animal, as oyfter-fhells calcined or not calcined, and hartfhorn: all thefe give a better or worfe foluble tartar; but of thefe, none fucceeds fo well as the oyfter-fhell, after it has been calcined; the foluble tartar, prepared with this, cofts alfo greatly lefs than when prepared with falt of tartar.

In wood-afhes there is always a part, which when mixed with water fwims, and is fufpended in it a long time, and at length fubfides into a kind of foft and impalpable matter; and another part, which fubfides readily to the bottom, and feels rough and harfh. It is the firft of thefe fubftances alone, which being mixed with cream of tartar, renders it foluble: the other part will not mix with the cream of tartar, or produce any fuch effect, unlefs reduced to the nature of the firft, by repeated and violent calcinations, and then only a part becomes fo altered, the whole never is fo. It appears that the firft portion has been wholly divefted of its acid by the fire, and thence is become fufceptible of the impreffion of the weakeft acid, fuch as is that of the cream of tartar, but in the fecond, or coarfer part, the acid it naturally contained remains fixed and concentrated, fo that it is not fufceptible of any impreffion from the weak acid of the cream of tartar. Mem. Acad. Par. 1733.

The different kinds of foluble tartar have alfo their different degrees of folubility, or different readinefs to run into a liquor *per deliquium*. The moft eafily foluble of all are thofe made with chalk, with lime, and with wood-afhes; and that which is moft difficultly fo, is the kind made with borax; it will at length run however, and is truly foluble tartar.

For the chemical and medical properties of this falt, fee *Tartrate of Potafh* under SALTS, and TARTRITE *of Potafh*.

TARTAR, *Vitriolated*, which fome call *magiftery of tartar*, is a neutral falt, compofed of a vitriolic acid, faturated with the fixed alkali of tartar, or with any other pure vegetable fixed alkali.

Vitriolated tartar may be decompofed by nitrous acid in the following manner, according to M. Baumé. Equal parts of both are put into a matrafs, and heated till the falt be diffolved. From the liquor when cold, true cryftals of nitre may be obtained. And according to M. Margraaf, vitriolated tartar may, in the fame method of treatment, be decompofed by marine acid.

This falt is not of any ufe in the arts, and little ufed in chemiftry. It is chiefly employed in medicine. Like the other neutral falts, with bafes of fixed alkali, it is aperitive in fmall dofes, as a grofs, or $59\frac{1}{2}$ grs., and it is laxative, when taken from 6 to 12 grofs. See *Sulphate of Potafh* under SALTS.

The chemifts have fometimes boafted of great virtues, in what they call the magiftery of this falt; this is the earth precipitated in the making of it. It is the opinion of fome ingenious authors, that all fixed falts are produced by a blending together of the acid and alkaline falts, which the plants they are obtained from originally contained, with fome earth. The making of this preparation of tartar and vitriol, gives great ftrength to this opinion by means of this magiftery; which fhews, that an earth neceffary to the cementing a mixture of an acid and an alkali into a neutral falt, may exift even in one of the principles themfelves, though unfeen by us; and that, as in the prefent inftance, in fo large a quantity, as not only to be fufficient for the combining the two volatile fubftances into a fixed one, but even to leave a remainder of it, that was not neceffary.

While the acid of vitriol is poured upon the diffolved falt of tartar, or its oil *per deliquium*, for the making of this falt, during the great effervefcence between the acid and the alkali, there is a precipitation made of an earth, for the feparation of all which great care is to be had to the degree of faturation of the alkali with the acid. This earth afterwards may be fevered by filtration. This earth is precipitated, not out of the fpirit of vitriol, but out of the falt of tartar; and this experiment fhews, that this fixed falt did originally contain that earth, which, according to the fyftem of the formation of fixed falts out of volatile ones, originally refiding in plants, muft neceffarily be mixed with them, and which, not being able to mix with the acid, is feparated and thrown off in the conflict, in which the acid mixes itfelf with the reft.

This earth is what is pompoufly called the *magiftery of vitriolated tartar*; but it is very wrong to give that name to an earth which has none of the properties of that or any other falt; and they greatly deceive themfelves and their patients, who prefcribe it inftead of the falt itfelf. Its faline tafte, probably, has induced them to think that it poffeffed great virtues; but this is not innate but adventi-

tious,

tious, and the effect only of the fluid in which it was precipitated: it cannot but have some of the salts of that fluid hanging about it, when first made; but these may, by repeated washings, be carried wholly off, and the magistery will then remain a pure simple earth, and shew itself to be no other than that earth, which may be properly called the earth of all fixed salts; and which, though necessary to give the salt of tartar its form as a lixivial salt, yet being not necessary to it in its new form of a neutral salt, is deposited in the making it into that form. It yet remains to be proved by more numerous experiments, that the fixed salts of plants owe that form only to a fixing earth, combining their two original volatile principles into a fixed mass; for if this be truly the case, there then needs no more to the volatilizing them again, but the divesting them of this earth. Phil. Trans. N° 90.

TARTAREOUS or TARTARIC *Acid*, was first separated from cream of tartar, and obtained in a solid crystalline form, by a method which was discovered by Scheele, and which, with little variation, is as follows: it very much resembles the mode used by the same ingenious chemist in obtaining the citric acid: Having analysed cream of tartar (see Swedish Transactions, part iii. for 1770.), he found that this is not a pure acid, but a compound salt, containing the fixed vegetable alkali, united with a superabundance of the tartareous acid, and therefore, that it differs from soluble tartar only in the proportion of acid which it contains. For obtaining this acid, he dissolved any given quantity of the cream of tartar in boiling water, and whilst boiling, added gradually some clean powdered chalk. Upon this a copious effervescence will arise, and the addition of chalk must be continued till this ceases, when the mixture may be set by to cool. It then contains a white dense sediment, which consists of the lime of the chalk, united with the excess only of the acid of the cream of tartar; and the supernatant liquor is, therefore, a solution of the cream of tartar deprived of its excess of acid, or neutral *tartrite of potash*, or *soluble tartar*, as it is also called, and which may be obtained crystallized by subsequent evaporation. Wash the precipitated tartrite of lime repeatedly with cold water, then put it into a glass vessel, and add to it a diluted sulphuric acid, composed of as much concentrated acid, as is equal to the weight of chalk employed in saturating the cream of tartar, mixed with four or five times its weight of water.

The sulphuric acid having a stronger affinity for the lime than the tartareous acid has, totally decomposes the tartrite of lime, during a digestion of two or three days (or in a shorter time if assisted by a gentle heat,) and the white sediment, though it does not alter its appearance, is changed to sulphate of lime, whilst the supernatant liquor contains naked acid of tartar. Then pour off the clear liquor, wash the sulphate of lime to extract all the adhering acid, and add the washings to the former liquor, and evaporate the whole, (at first with a boiling heat, and as it concentrates, with a much gentler warmth,) till it is of a thick syrupy consistence, and then set it by for some hours, that all the selenite, which it may hold in solution, may be deposited. Then again dilute the mixture with cold water sufficient to redissolve every thing but the selenite, and slowly evaporate the solution to a syrupy consistence, and after some hours it will deposit the pure tartareous acid in crystals, which are generally pretty large irregular hexahedrons. Cream of tartar decomposed in this way by chalk (and therefore only partially) will yield about a third of its weight of the crystallized acid. This quantity however must not be taken as the proportion of the acid in cream of tartar, for much of the weight of the crystallized acid is water of crystallization, whereas the cream of tartar contains very little water.

In the above detailed method of obtaining tartareous acid, chalk, or carbonate of lime, is used to decompose the cream of tartar, which it does merely by engaging the excess of acid, and leaving the remainder of the salt in the state of tartrite of potash. But if quick-lime be substituted to the chalk, the whole of the cream of tartar is decomposed, a much larger quantity of tartrite of lime, and consequently of tartareous acid, is obtained, and the supernatant liquor is a solution of caustic potash. It has been found however by Vauquelin, that the potash retains a small quantity of tartrite of lime in solution, so that when the alkaline liquor is evaporated nearly to dryness it gelatinizes by cooling, owing to the separation of this calcareous salt. It may be decomposed by carbonate of potash or soda, which produces carbonate of lime and tartrite of the alkali employed: or the tartareous acid may be destroyed by calcination, and the lime, carbonated in the process, will remain.

Calculating from the observed proportions of acid in the tartar, and of chalk required in the first-mentioned process, and of pure lime in chalk, we may estimate that all the acid in 100 parts of cream of tartar (which Thenard reckons at 57 *per cent.*) will require full 42 parts of pure lime for its saturation, and somewhat more lime should perhaps be added to ensure the complete decomposition of the tartar. The lime should be previously slaked and mixed with sufficient water to bring it to the consistence of paste.

Lowitz has proposed another method, which is perhaps preferable in every respect, except that it is somewhat more expensive, and that no caustic alkali is obtained. It consists first in decomposing the cream of tartar by chalk in the usual way, added as long as any effervescence takes place; and then pouring into the filtered supernatant liquor muriate of lime, as long as any precipitate falls down. By this means the tartrite of potash in liquor is totally decomposed, muriate of potash remains in solution, and the precipitated tartrite of lime is added to that produced by the chalk; and both are afterwards decomposed by sulphuric acid in the usual way. The same chemist also advises to add to the solution of tartareous acid in the last part of the process a quantity of *charcoal* powder, (the depurating power of which has been mentioned under CARBON.) This, however, is certainly not essential to the obtaining a perfectly fine colourless crystallized acid, and, we believe, is seldom, if ever, used.

The tartareous acid has a strong acid taste, and is soluble in five or six parts of water, and in a much less quantity of boiling water. The crystals are permanent in the air.

When heated *per se* in a retort with a receiver, this acid melts, boils up, and exhales a sour pungent vapour, which condenses in the receiver into a red acid empyreumatic liquor, equal to about a quarter of the weight of the tartareous acid.

This liquor has a pungent, acid, and empyreumatic taste, strongly reddens litmus, and effervesces with the alkaline carbonates. It is called the Pyrotartareous acid, which has not been much examined. The other products from the distillation of tartareous acid, are a large quantity of carburetted hydrogen and carbonic acid gas, and a soft spongy coal is left in the retort, which, heated in the open air, burns with scarcely any residue.

The tartareous acid, besides being found native in some vegetable juices, and in the deposit from wine during and after fermentation, is also produced by the action of nitric acid on alcohol. A further digestion of tartareous with nitric acid converts the former into oxalic acid, and a still further

further digeftion changes the whole of the vegetable acid into vinegar. Thefe curious experiments, which were at firft noticed by Scheele, have been fully examined by Hermbftaedt, and other chemifts.

Tartareous acid is compofed, according to Fourcroy and Vauquelin, of 70.5 of oxygen, 19 of carbon, and 10.5 of hydrogen, and differs from the oxalic acid in containing more carbon and lefs oxygen. The order of affinity of this acid for the feveral bafes is, according to Thenard, lime, barytes, ftrontian, potafh, foda, ammonia, magnefia, and alumine. Aikin's Dict.

For the combinations of the tartareous acid with the feveral bafes, we refer to the article TARTRATES or TARTRITES.

TARTARIAN OAT, in *Agriculture*. See OAT.

TARTARIZATUS CHALYBS. See IRON, in the *Materia Medica*, and TARTRITE *of Potafs and Iron*.

TARTARIZING, a term ufed by fome writers for the act of refining or purifying, by means of falt of tartar.

TARTARO, in *Geography*, a river of Italy, which rifes in the Veronefe, and running eafterly, traverfes the Polefe de Rovigo, paffes by Adria, and foon after feparates into two branches, one of which runs into the Adige, and the other into the Po.

TARTARON, a fort of fine cloth or filk, mentioned in the ftat. 4 Hen. VIII. c. 6. Blount, Cowel.

TARTARUGA, in *Zoology*, a name by which the Portuguefe in America call a fpecies of tortoife, known among authors by its Brazilian name *jurucua*.

TARTARUM TARTARISATUM, *tartarifed tartar*, in *Chemiftry*, the name of a preparation of tartar; the manner of doing which is given by Boerhaave, and is as follows: Reduce fome of the pureft white tartar to powder, and boil this powder in ten times its weight of water in a large copper veffel, till it appears perfectly diffolved: let it after this continue boiling till the liquor becomes tolerably tranfparent, and of an acid tafte; then drop into it from on high oil of tartar *per deliquium*, the liquor being ftill kept boiling: upon the falling in of each drop there arifes a great ebullition, occafioned by the meeting of the acid and alkali. Large bubbles appear on this, and in thefe the chemifts have imagined they found the figures of clufters of grapes.

The operation is to be patiently continued till there is no more effervefcence made by the falling in of the drops of the oil. The acidity of the tartar will be then fo perfectly faturated with its own alkali, that it will appear neither acid nor alkaline, but a third falt; great caution however muft be ufed in obferving the true point of faturation; otherwife the falt will be when finifhed either a little acid, or a little alkaline, as the one or the other exceeds. The liquor is to be then ftrained feveral times through a flannel, till perfectly clear: it is of a deep brownifh colour, and brackifh faline tafte, but has no fcent. If this be evaporated to a pellicle, and fet to cryftallize, it forms a falt which is a tartar, eafily foluble in water, even when cold; and very properly to be called foluble tartar. Boerhaave Chem. part ii. p. 161.

TARTARUS, in *Ancient Mythology*, is one of the general divifions of the fubterraneous world, or the place of torments. The origin of the fable of Tartarus is traced in Hefiod's account of the war of Jupiter againft his father Saturn and the Titans, who, after he had gained a victory over them, was driven from Olympus, and condemned to the bottom of Tartarus, in the extremities of the earth. Typhon alfo, threatening to deprive Jupiter of his empire, was plunged into the fame abyfs. The abbé Banier has given the following explication of this fable. The Greeks, he fays, regarded the places fituated to the eaft of them as higher than thofe that lay weftward; and hence they took the former for heaven, and the latter for hell. According to this notion, they placed their hell either in Spain, the refidence of Pluto, or in Italy, and laftly in Epirus, or rather in Thefprotia, all which countries were fituated to the weft of Greece. Now as the Titans, in the feveral confpiracies they formed, were obliged to enter into Italy and Spain, the poets fabled that they were precipitated into the gulf of Tartarus; but as their notion of Tartarus was taken from Tarteffus, a river of Spain, on the banks of which Pluto refided, it is no wonder that the Titans, having been defeated near that river, were fabuloufly faid to be plunged headlong into the Tartarian gulf.

The other two divifions of Ades, according to Virgil, are Erebus and Elyfium. The prince or judge who prefides over Tartarus, is Rhadamanthus. The miferable inhabitants of this horrid region are of two forts, *viz.* the fouls of fuch as are tormented, and the infernal deities, called the Furies, who attend there either to inflict or aggravate their torments.

Virgil diftinguifhed thofe that are tormented in Tartarus, into two general claffes; the firft, of fuch as have been ungrateful or impious towards the gods; and the fecond, of fuch as have been mifchievous and hurtful among men: thofe of the latter, more particularly, who hated their brethren, ufed their parents ill, or cheated their dependents; who made no ufe of their riches; who committed inceft, or difturbed the marriage union of others; thofe who were rebellious fubjects, or knavifh fervants; who were defpifers of juftice, and betrayers of their country; and who made and unmade laws, not for the good of the public, but only to get money for themfelves. All thefe, and the defpifers of the gods, of whom the rebel giants occupied the chief clafs, Virgil places in Tartarus, and in that vaft abyfs, which was the moft terrible part of this infernal region. The great road that paffes through Erebus, is reprefented as divided into two; of which the right-hand road leads to Elyfium, or the place of the bleft; and the left-hand road to Tartarus, or the place of the tormented. Virgil Æn. vi. v. 540—549. 566—580. 607—624. Spence's Polymetis, p. 259, &c.

TARTARS, or TATARS, in *Geography*, a comprehenfive denomination, including all tribes beyond Perfia and India, as far as the Eaftern ocean, however differing from each other in regard to their origin, language, manners, cuftoms, and religion. It is now known, however, that the Tartars compofe a diftinct nation, which originally belonged to the grand Turkifh ftock. The name, it is faid, may originate either from a Turkifh horde, which bore this denomination; and accordingly it is alleged, that the Yakutes have among their deities, a Tatar, who probably enjoys that honour as the patriarch of the nation; or from the Chinefe, who call all their neighbours, without diftinction, Tata or Ta-dfe, in proof of which derivation it is intimated, that the Perfians and Arabians know nothing of the Tartars under that appellation. It was firft brought into general ufe in Europe after Baaty's incurfion into Hungary, under king Frederic II. Whatever be the origin of the name, it feems to be clear, that the Tartars are of Turkifh origin, and that their proper name was Turk or Turkman, and not Tatar. In this opinion, the learned men of their own nation concur: to which circumftance it may be added, that the Tartarian language is merely the old Turkifh; and the modern Ottoman Turks fpeak the Tartarian tongue only in another dialect. And the Tartars pretend to derive their defcent from

from Turk, the oldeſt ſon of Japhet: and although from the time in which Jenghis Khan ſubdued all Tartary and a great part of Aſia, and made irruptions even into Europe, they have been known by the name of Tartars, to which that of Monguls or Moguls, of whom he was properly the prince, appeared inferior; nevertheleſs the Tartars preſerve among themſelves the name of Turks. See MONGOLES.

The firſt known mother-country of the Turks or Tartars lies ſomewhere in the countries on the eaſtern and northern ſides of the Caſpian, where their deſcendants are ſtill ſituated. In ancient times they were ſpread from the Oxus or Gihon into the Mongoley and the Orenburg territory; that is, in regions where they had conſtantly ambitious and domineering nations for their neighbours and enemies: on the E. the Chineſe; on the S.W. the Perſians, Macedonians, Romans, Partho-Perſians, and Arabians; and towards the N.E. the Mongoles. Here they ſerved from time immemorial as a mound againſt the incurſions of the nations which could penetrate from the E. to the W., or contrariwiſe, till at length the Mongoles, like a ruſhing ſtream that has burſt its banks, ſwept away all oppoſition.

The Tartars, ſays baron de Tott, in his "Memoirs," (vol. i.) have the beſt title to the higheſt antiquity. To this purpoſe he obſerves, that the flat high land of Tartary, which extends to the north, and the chain of the mountains of Caucaſus and Thibet, continued almoſt as far as the peninſula of Corea, (if we may judge by the courſe of the water, which, from the centre of Aſia, ſpreads to the S. and to the N. of that part of the globe,) preſent the higheſt portion of land which ſeparates the Indian ſeas from thoſe of Kamtſchatka. This obſervation, it is alleged, ſeems to prove, that the country at preſent occupied by the Tartars, muſt have been the firſt land diſcovered in Aſia, the firſt inhabited, the firſt ſource of population, and the origin of thoſe emigrations, which, conſtantly repelled by the Chineſe wall, and the defiles of Thibet and Caucaſus, have paſſed from the north of Aſia into Europe. (See HUNS.) However, the annals of the Tartars are involved in conſiderable uncertainty before the time of Jenghis Khan, who was elected grand cham (khan) by the chams of the different tribes, and was only choſen to be the king of kings, becauſe he was the moſt powerful among them. It is well known, that Jenghis Khan conceived and executed projects of uſurpation, by which he formed the moſt extenſive empire known in hiſtory.

The Tartars began to acquire ſome importance in hiſtory, after the time of their ſubjugation by the Mongoles; but from the moment that their hiſtory excites attention, it ceaſes to be the hiſtory of a peculiar nation. Diſtributed under the banners and commanders of the Mongoles, theſe enjoy with poſterity the glory of their conqueſts, while the Tartars are conſtrained to lend their name to the devaſtations with which both nations every where marked the bloody progreſs of their armies. (See MONGOLES.) Subjugated in their conquered countries, and even forced from a great part of their old habitations, ſome few of the Tartar hordes (few in reference to the whole Tartarian tribes,) have preſerved their independence: *i. e.* thoſe who inhabit the ſouth-weſtern part of the former Great Tartary, towards the Perſian, Indian, and Soongarian borders. Here we find the great Kirghiſian horde, the Bukharians, the Khivans or Khivinſes, the Karakalpahs, Truchmenes, Taſchkantians, Turkeſtans, Arabians, and ſome other races, which ſtill form diſtinct ſtates, and retain a kind of national liberty; but they exiſt in ſo feeble a ſtate, that they are obliged to ſeek protection ſometimes from one power, and ſometimes from another. The whole remnant of this nation, once ſo great, ſubſiſts under foreign ſovereignty. Many hordes belong, either as ſubjects or as dependent wards of the Ruſſian empire; others are, in like manner, appanages to the Ottoman Turks, or ſubject to the Great Mogul, to China, and to Perſia.

Mr. Strahlenburg, a Swediſh officer, who reſided ſome years in Siberia, places them in ſix claſſes: the firſt, containing ſeven different nations, all in the dominions of Ruſſia, *viz.* the Mordvines, who dwell in the government of Nizegorod; the Tſcheremiſſes, or Czeremiſſes, in the government of Kazan; the Permians, in the government of Perm; the Votiaks, in the government of Viatka; the Vogouls, who dwell on both ſides of the mountains, which formed a ſeparation between Ruſſia and Siberia; the Oſtiaks, who dwell on the coaſts of the river Oby; and the Barabintzi, who inhabit the country between Tara and Tomſk. The ſecond claſs of people, called Tartars, includes the Budziaks, which dwell on the coaſts of the Black ſea; the Crim Tartars, who inhabit the province of Taurida; the Kuban Tartars, on the borders of the Kuban river; and the Tartars of Dagheſtan; the Nogais, or Tartars of Aſtrachan, of Kazan, and Upha; the Baſchkirs and the Tartars about the towns of Tiumen, Tara, Tobolſk, and Tomſk; the Uſbeck Tartars, the Turcomans, the Kurguis, the Karakalpas, the Sayantzi, who dwell near the head of the Yeniſſey; the Kirghiſes, who occupy the mountains ſouth of lake Baikal; the Burats; the Arintzi, who alſo inhabit near the ſame mountain; and the Yaktai, more to the north, on the ſides of the Lena. The third claſs includes the Samoiedes, on the coaſt of the Frozen ſea, from Archangel to the Lena. The fourth claſs includes the Kalmucks and Monguls, who were formerly but one people. The fifth claſs includes the Mantcheux and the Tunguſes. The ſixth claſs contains the ſavage nations on the north-eaſt coaſt of Aſia, as the Tſchutki, &c. with the inhabitants of Kamtſchatka, and the Kurile iſlands. Of theſe, the firſt, third, and ſixth claſs are ſubject to Ruſſia, except that a ſmall part of the ſecond is independent. The fourth is partly independent, and partly ſubject to China. The fifth claſs is wholly ſubject to China.

Abulgaſi, in his account of the Turkiſh ſtems, mentions among them the Tartarian as one of the moſt ancient and famous, and derives its origin from a khan of the name of Tatar. This ſtem, which in proceſs of time increaſed to 70,000 families, was at firſt governed by its own commander, and afterwards divided into various branches, diſperſed into ſeveral and very diſtant regions, by which diſperſion their power was weakened. The moſt conſiderable branch ſettled on the borders of Kitay (China), and fell under the ſovereignty of that empire, againſt which it frequently rebelled, and thereby gave occaſion to ruinous wars. At the time of Jenghis Khan, ſome Tartars dwelt on the Oxus or Amur, who were tributary to the emperor of Kin, reigning in Kitay.

The Tartars who belong to the Ruſſian empire inhabit the northern coaſts of the Euxine and the Caſpian, the north ſide of the mountains of Caucaſus, the extenſive ſteppes from the river Ural to the Soongarey, the ſouthern Ural, in Siberia the ſouthern frontier mountains and ſteppes from the Tobol quite over the Yeniſſey, and the deſerts in the middle region of the Lena; and ſome few Tartar colonies are diſperſed among the Ruſſian habitations, particularly in the governments of Upha, Kazan, and Tobolſk. Frequent memorials are found in various regions of their ancient grandeur, magnificence, and culture, ſome of which are demonſtrably of 1000 years' antiquity. The branches of this nation which belong to Ruſſia are the proper Tartars, or the defcendants of thofe two great ftates, which the fucceffors of Jenghis erected on the Volga and in Siberia (fee KAPTSCHAK, and the fequel of the article); the Nogayans, the Mefchtfcheryaks, the Bafchkirs, the Kirghifes, the Bucharians, the Yakutes, the Teleutes, and in part the tribes of Caucafus. The Kaptfchak Tartars are reduced to a fmall refidue, intermixed among the Bafchkirs and Kirghifes. The Kazan Tartars are alfo a feeble remnant of what they formerly were, and are difperfed in the governments of Kazan, Simbirfk, Riefen, Viatka, Perm, and Upha. The Aftrachan Tartars are for the moft part Nogayans: they are diftinguifhed into town, village, and tent Tartars. The firft dwell in Aftrachan, the fecond in fix villages near Aftrachan, and the third wander about the Cafpian. In 1772, thofe of the two former claffes were only 1200, and of the tent Tartars fcarcely 2000 kettles, or families. For the ftate of the Krim Tartars, fee CRIMEA. The ftems of the Siberian Tartars, who are numerous, are the Turalinzes, one of the firft colonies that became permanent in Siberia, when the Tartars fubjugated the country in the 13th century; the Tobolfkian Tartars, who dwell on the river Tobol; the Tomfkian Tartars, who inhabit both fides of the river Tom, above and below the city of Tomfk; the Krafnoyarfkian and Kufnetzkian Tartars; the Tartars of the Oby; the Tfchulymfkian Tartars, inhabiting the territory along the river Tfchulym; the Barabinzes, between the Oby and Irtifh; the Katfchinzes, on the left fhore of the Yeniffey; the Kiftim and Tulibert Tartars, on the left bank of the Tom; the Biriuffes; the Abintzes; the Sayane Tartars; the Beltirs, the Verchotomfkian Tartars, and fome other infignificant ftems. For the other branches of the Tartars who inhabit Ruffia, we refer to the feveral articles, NOGAYANS, &c. &c.

The Tartars who are Mahometans bordering on Ruffia, but independent of that crown, take every opportunity of robbing their neighbours: the Kalmucks and Monguls are very different in their behaviour, living quietly on the produce of their foil, without doing injury to others. The Tartars of Afiatic Ruffia are likewife reprefented as a quiet, inoffenfive people, living chiefly by the chafe and fifhing. See the following articles. See alfo MANDSHURS, MONGOLES, TUNGUSES, &c.

TARTARY, or TATARY, a vague name, as it relates to Afiatic Ruffia, which cannot be ufed with precifion as defcriptive of any particular country: inftead of it might therefore be fubftituted names derived from the feats of the chief nations, as Tungufia or Mandfhuria in the eaft, Mongolia in the centre, and Tataria in the weft. In a general fenfe, however, whilft the name remains, it may include three diftinct countries, *viz.* Chinefe Tartary, Independent Tartary, and Ruffian Tartary.

TARTARY, *Chinefe*, according to the abbé Grofier's defcription, is bounded on the north by Siberia, on the eaft by the gulf of Kamtfchatka and the Eaftern fea, on the fouth by China, and on the weft by the country of the Kalmucks, who are eftablifhed between the Cafpian fea and Kafhgar. The different tribes which at prefent inhabit it, were formerly comprehended under the general name of Mongul or Mogul Tartars, a warlike and formidable nation, who, on the one hand, conquered Hindooftan, under the famous Jenghis Khan, and on the other, fubdued China. It was in the 13th century that the Monguls took poffeffion of the latter empire; but after having reigned there for 100 years, they were expelled by the Chinefe, in the year 1368. The fugitives took different routes; fome went towards the Eaftern fea, and eftablifhed themfelves between China and the river Saghalien; the reft returned weftward to their former country, where, intermixing with the Monguls that remained, they foon refumed their ancient manner of living; thofe who fettled towards the eaft, having found the country almoft a defert, and without inhabitants, retained the fame cuftoms which they had brought from China: hence thefe two Mongul nations differ at prefent in language, government, religion, and cuftoms. Thofe of the eaft retain their ancient name of Mongul, or Mogul Tartars; the reft are known by the name of Mantchew, or Eaftern Tartars. Chinefe Tartary is therefore divided into two parts, the Eaftern and Weftern. Eaftern Chinefe Tartary extends, north and fouth, from the 41ft to the 55th degree of north latitude; and eaft and weft, from about the 120th degree of longitude, as far as the Eaftern fea. It is bounded on the north by Siberia, on the fouth by the gulf of Leao-tong and Corea, on the eaft by the Eaftern fea, and on the weft by the country of the Monguls. The Tartars who retired hither, after their expulfion from China, in the year 1368, immediately began to build cities, towns, and villages, and to cultivate the earth, after the manner of the Chinefe, among whom they had lived: hence the greater part of them have remained fixed, and are much more civilized than the reft of the Mongul nation. They were at firft governed by particular khans, each independent of the other; but fince that of Ningouta (who was the moft powerful among them) took poffeffion of China, about the middle of the 17th century; the emperor, who is ftill one of his defcendants, has reduced under his dominion all the other khans of this part of Tartary: this prince governs it immediately by himfelf, and fends thither governors and officers, as into all the other provinces of the empire. The country of the Mantchew Tartars is divided into three grand departments: *Chen-yang*, *Kirin*, and *Tcitcicar;* which fee refpectively.

Ningouta, already mentioned, which is confidered as the cradle of the prefent imperial family, is furrounded by a wooden wall, confifting of ftakes, touching each other and twenty feet high, and alfo another palifado without this, a league in circumference, and having four gates, correfponding to the four cardinal points. The Mantchew Tartar, who refides in it as lieutenant-general, extends his jurifdiction over the adjacent country, and all the villages of Yupi-tafe, and fome other petty nations that inhabit the banks of the rivers Oufouri and Saghalien, and along the fea-coaft. The Tartars of Yupi-tafe are peaceful in their difpofition, but ftupid and clownifh, without letters, and without any religious worfhip. They fow neither wheat nor rice, nor any thing elfe except tobacco, which they cultivate in fome of the fields furrounding their villages. They are fupplied with fifh from the river Oufouri, and this is their only food: nor have they any clothes befides thofe which they make of their fkins, dreffed, dyed of three or four colours, and artfully fewn together with a thread cut from an exceedingly fine fkin. The women fufpend from the bottoms of their long cloaks pieces of money and little bells; and the treffes of their hair, which hang over their fhoulders, are loaded with fmall mirrors, rings, and other toys. Of one part of their fifh, which they employ the fummer in taking with harpoons and fmall nets, they make oil for their lamps; another fupplies them with food; and a third part is referved for winter, when the ice prevents them from fifhing. Beyond the Yupi-tafe Tartars are the Ketcheng-tafe Tartars, who inhabit both banks of the river *Saghalien-oula* (which fee), and extend as far as the Eaftern fea. Thefe Tartars are lefs clownifh than the preceding, and employ much of their time in hunting fables.

The Mantchews, difperfed throughout Eaftern Chinefe Tartary, have neither temples nor idols; they adore (as they exprefs it) only the "emperor of heaven," to whom they offer

offer facrifices : but fince they have entered China, fome of them worfhip the god " Fo," and other idols reverenced in the empire. When they became mafters of China, they pretended to a celeftial extraction, and placed a god at the head of their race. Since the Tartars have had poffeffion of the throne of China (fee CHINA), their language has become familiar at the court of Pe-king. This language they are very careful in preferving, and it is faid that it may be much more eafily acquired than that of China. Although the Tartars have only one kind of characters, they write them in four different ways, which they write with a pencil, or a kind of pen, formed of the bamboo reed, and which they can read with equal eafe when reverfed.

TARTARY, *Weftern Chinefe*, is called alfo the country of the Mongoles, or Moguls ; for an account of which, fee the article MONGOLES. See alfo KALKAS, KALMUCKS, and KOKONOR. We fhall here add that the country of the Ortous, who inhabit N. of the great wall, and W. of the Moguls properly fo called, is 110 leagues in extent from E. to W., and 70 from N. to S. Thefe people are divided into fix ftandards, which comprehend 166 companies, each compofed of 150 heads of families. The Ortous are of a free difpofition, very lively, and never fubject to melancholy, and may be juftly called the " French of Tartary."

Wild animals of various kinds are innumerable in the plains and forefts of Tartary. The country abounds with game, and all the animals that are hunted in Europe, with large flocks of yellow goats, wild mules, wild camels, and horfes ; an animal refembling the elk, a fpecies of lynx, whofe fkin is highly valued, tygers of prodigious fize and agility, whofe fkins are ufed for ornament ; a fpecies of leopard, and ftags. Some of their rivers wafh down gold mixed with their fands ; and they are acquainted with the method of applying it to ufe, and of forming it into vafes and fmall ftatues, of which they often make offerings to their idols. It appears that the ufe of gold is very ancient among them.

The vulgar name of Tartary, or Tatary, fays Mr. Pinkerton, was originally extended over the vaft regions lying between Thibet, China, and the Arctic ocean ; and from the Black fea in the weft to the utmoft bounds of north-eaftern difcovery in Afia. But as geographical knowledge has improved, the northern part has acquired the name of Siberia, while the fouthern is diftinguifhed by the appellation of Weftern and Eaftern Tartary. But in this part, which might more properly be named Central Afia, the Tartars, properly fo denominated, are few, the moft numerous tribes being Monguls in the weft and Mandfhurs in the eaft. See MONGOLES and MANDSHURS.

The wide and interefting portion of Afia, formerly known by the appellation of Eaftern and Weftern Tartary, but now properly ftyled Central Afia, and comprehending the Middle Mongolia and the Eaftern Mandfhuria, which has repeatedly fent forth its fwarms to deluge the arts and civilization of Europe, fays the geographer above cited, extends from E. long. 72° to 145°, a fpace of not lefs than 73° of longitude, which, at the medial latitude of 45°, will yield about 3100 geographical miles. The breadth from the northern frontier of Thibet to the Ruffian confines, is about 18°, or 1080 geographical miles. The limit between Ruffia and Chinefe Tartary is partly an ideal line, and partly the river Argoon, which joined with the Onon, conftitute the great river Amur. From the treaty publifhed by Du Halde it appears, that the river Kerbatchi, the neareft to the river Chorna or Ourouon, and which difcharges itfelf into the great river Saghalien-oula, was the Chinefe definition of the boundary between the two empires, to which was added the long chain of mountains above the fource of the river Kerbatchi and the river Argoon. The eaftern boundary is the fea, while the fouthern extends along the great Chinefe wall, and the northern limits of Thibet. The weftern boundary is fupplied by the celebrated mountains of Belur-Tag, or the Cloudy Mountains, which divide the Chinefe empire from Balk, and the greater Bucharia ; while the range on the W. of the lake Palkati feparates the Kalmucks, fubject to China, from the Kirgufes of Independent Tartary.

The original population of Central Afia appears to have been indigenous. The weft was partly held by the ancient Scythæ, feemingly a Gothic race, who were fubdued or expelled by the Tatars, or Huns, from the eaft, preffed on the other fide by the Monguls, beyond whom were the Mantchews, who, in the 17th century, conquered China. Pinkerton's Geography, vol. ii. See MONGOLES and MANDSHURS.

TARTARY, *Independent*, an extenfive, celebrated, and interefting region, confidered as diftinct from Mongolia and Mandfhuria, or as thefe countries have been lefs properly called, Chinefe Tartary, and independent of the great neighbouring powers, China, Ruffia, and Perfia : this country was probably the feat of the moft ancient Perfian kingdom, the poffeffion of the Greek monarchs of Bactriana, and after many revolutions, diftinguifhed by the wide empire of Jenghis or Zingis, and Timur. Its extent may be meafured from the Cafpian fea to the mountains of Belur, a fpace of about 870 Britifh miles. From the mountains of Gaur in the S., to the Ruffian boundaries in the N. of the defert of Iffim, it may be near 1500 Britifh miles, of which a great part is defert. The chief divifions are the wide fteppes, or barren plains in the N., held by three hordes of Kirgufes or Kirghifes, the Great, Middle, and Leffer, befides fome fmall Tataric tribes near the fea of Aral. This portion was anciently called Turkeftan, and its capital was Taraz. (See both thefe articles.) Southwards of the mountains of Argun, the land begins to become fertile along the river Sirr or Jaxartes, called alfo the river of Shufh from the chief territory, and alfo on the banks of its tributary ftreams. Ilak and Shufh, the moft northern provinces on the Sihon, are followed by Fergana, and a diftrict called Ozrufhna, round a town of the fame name. Divided from thefe provinces by deferts and mountains is the kingdom of Kharifm, or Kharafm, which fee. South of the range of the Ak Tam is the fertile region of Sogd, or Sogdiana, with its capital Samarcand. On the S., the provinces of Balk, Kilan, Tokareftan, and Gaur, terminate the bounds of Independent Tartary, here feparated by defarts on the W. from the Perfian province of Chorafan or Khoraffan. See thefe articles refpectively. See alfo BELUR-TAG, BUCHARIA, IMAUS, KIRGHISES, MASSAGETÆ, SCYTHIA, and UZBECKS.

TARTARY, *Crim*. See CRIMEA.

TARTARY, *Ruffian*. See RUSSIA and TARTARS.

TARTARY, *Little*, a name that has been given by fome writers to the country containing the peninfula of the Crimea, the Kuban, a part of Circaffia, and all the lands which feparate the empire of Ruffia from the Black fea. This circuit, continued from Moldavia almoft to Taganrog, between the 44th and 46th degrees of latitude, is from 30 to 40 leagues wide, and nearly 200 long. From E. to W. it includes Yetitchehoolai, Dgamboylafk, Yedefan, and Beffarabia. The latter province, at prefent called Boodjak, is inhabited by Tartars, who, as well as thofe of the peninfula, have fixed habitations in their villages ; but the inhabitants of the three other provinces have only felt-tents, which they carry wherever they pleafe. Thofe people, called Noguais, and fuppofed to be Nomades, are fettled, however, in the vallies that traverfe their plains from N. to S.,

 and

and their tents, ranged in a ſingle line, form thus a kind of villages of 30 and 35 leagues in length, which diſtinguiſh the different hordes. Tott's Memoirs, vol. i. See CRIMEA and RUSSIA.

TARTAS, a town of France, in the department of the Landes, and chief place of a canton, in the diſtrict of Saint-Séver, divided into two parts, the firſt containing 1556, and its canton 6154 inhabitants, and 8 communes; and the ſecond part containing 1656, and its canton 7952 inhabitants, and 12 communes: its whole territorial extent being 540 kiliometres; 15 miles W.S.W. of Mont-de-Marſan. N. lat. 43° 50′. W. long. 0° 44′.—Alſo, a river of Ruſſia, which runs into the Om, near Tartaſkoi.

TARTASKOI, a town of Ruſſia, in the government of Tobolſk, at the union of the Om and the Tartas; 40 miles W.S.W. of Kainſk.

TARTESSUS, in *Ancient Geography*, a town of Spain, in the part called Bœtica, ſituated between the two arms by which the river Bœtis diſcharged itſelf into the ſea. One of theſe arms has diſappeared, and the other ſtill ſubſiſts and paſſes into the ſea at San Lucan de Barrameda. Some geographers have ſuggeſted that Gades was the ancient Tarteſſus. Strabo intimates that anciently the river Bœtis was called Tarteſſus, and that the town of this name was afterwards called Cartheia. M. d'Anville gives the name of Tarteſſus to the iſland formed by the two branches of the Bœtis at its mouth.—Alſo, a mountain of Spain, in Bœtica.

TARTESSUS, *Iſle of*, was ſituated near Gades, and is ſuppoſed to have been the Tarſhiſh of the Phœnicians, to whom it was known about 1000 years B. C.

TARTI LAPIS, a ſtone mentioned by Ludovicus Dulcis, and ſome other authors, and ſaid to be very beautiful, having all the colours of the tail of a peacock, and to have many medicinal virtues. It was probably ſome ſpecies of agate; but the ſhort account given of it will not enable us to gueſs what particular kind.

TARTINI, GIUSEPPE, of Padua, in *Biography*, the greateſt performer on the violin and compoſer for that inſtrument of the laſt century. We ſhall here only conſider him as a practical muſician, though he has diſtinguiſhed himſelf as a theoriſt in a way ſuperior to all other contemporary profeſſors. See SYSTEM, and STILLINGFLEET.

This admirable muſician and worthy man was born at Pirano, in Iſtria, in 1692. His father, having been a great benefactor to the cathedral church at Parenzo, had been ennobled in reward for his piety. Giuſeppe was intended for the law, but mixing muſic with his other ſtudies during the courſe of his education, it ſoon grew too powerful for the reſt, and tyrannized over the whole circle of ſiſter ſciences. This is not ſo ſurpriſing as another ſtrong propenſity, which during his youth occupied his attention very much, which was *fencing*, an art that was not likely to become neceſſary to the ſafety or honour of a man of ſo pious and pacific a diſpoſition, in a civil employment; and yet he is ſaid to have equalled in this art even the maſter from whom he received inſtructions. In 1710 he was ſent to the univerſity of Padua to purſue his ſtudies as a civilian; but before he was twenty, having married without the conſent of his parents, they wholly abandoned him, and obliged him to wander about in ſearch of an aſylum; which, after many hardſhips, he found in a convent at Aſſiſi, where he was received by a monk his relation, who, commiſerating his misfortunes, let him remain there till ſomething better could be done for him. Here he practiſed the violin, to keep off melancholy reflections; but being diſcovered on a great feſtival in the orcheſtra of the church of the convent by the accident of a remarkable high wind, which forcing open the doors of the church, blew aſide the curtain of the orcheſtra, and expoſed all the performers to the ſight of the congregation; when, being recognized by a Paduan acquaintance, differences were accommodated, and he ſettled with his wife at Venice for ſome time. This lady, indeed, was of the Xantippe kind, and being himſelf very Socratic in wiſdom, virtue, and patience, her reign was unmoleſted by any domeſtic war, or oppoſition to her ſupremacy.

While he was at Venice, the celebrated Veracini arrived in that city, whoſe performance awakened an extraordinary emulation in Tartini, who, though he had been thought to have a powerful hand, had never heard a great player before, or conceived it poſſible for the bow to have ſuch varied powers of energy and expreſſion. He, therefore, quitted Venice the next day, and went to Ancona, in order to ſtudy the uſe of the bow in more tranquillity, and with more convenience than at Venice, as he had a place aſſigned him in the opera orcheſtra of that city.

This happened in the year 1714, the year in which he diſcovered the phenomenon of the third ſound. It was at Ancona, and in the carnival of the ſame year, that he heard and perceived the extraordinary effects of a piece of ſimple recitative, which he mentions in his "Trattato di Muſica." (See RECITATIVE.) It was likewiſe during his reſidence at Ancona, that, by diligent ſtudy and practice, he acquired ſufficient abilities and reputation to be invited, in 1721, to the place of firſt violin, and maſter of the band in the celebrated church of St. Anthony of Padua.

By this time his fame was ſo extended, that he had repeated invitations from Paris and London to viſit thoſe capitals; but by a ſingular devotion and attachment to his patron ſaint, to whom he conſecrated himſelf and his inſtrument, he declined entering into any other ſervice.

Before the year 1728, he had made many excellent ſcholars, and formed a ſchool, or method of practice, for the ſtudents on the violin, that was celebrated all over Europe, and which increaſed in fame to the end of his life.

The author of the compendium of his life informs us that his firſt book of ſolos was engraved at Amſterdam, 1734; the ſecond at Rome, 1745; and that he produced above two hundred of theſe compoſitions, which were handed about in manuſcript by the curious; but does not ſeem to know that nine or ten books of Tartini's ſolos were printed at Paris, of which we are in poſſeſſion of opera third, ſixth, ſeventh, and ninth, beſides the two books printed in England, amounting to upwards of fifty ſolos, excluſive of manuſcripts.

Of his concertos, which likewiſe amount to two hundred, this author gives a very unſatisfactory account; he ſays, that a ſurreptitious copy of two ſets having firſt appeared in Holland, he would never own them. The firſt ſix ſeem to have been compoſed in his firſt manner before he changed his ſtyle. But Walther tells us, in 1732, that eighteen of his concertos for five inſtruments, principal violin, two ripieno violins, tenor, and violoncello, were publiſhed at Amſterdam. But Le Cene, the publiſher, confeſſed, that he collected them from different people who had obtained copies from the author, and there ſeems not the leaſt doubt of their being genuine.

Though Tartini's compoſitions always afforded us great pleaſure, and were never obliterated from our memory; yet as they are now as much laid aſide as thoſe of Baſſani or Locatelli, we thought it right to give them a reviſion before we ventured our ſentiments concerning their merit.

Tartini, on a recent examination of his works, ſeems, to our conception and feelings, to have had a larger portion of genius and knowledge of compoſition as a mere inſtrumental compoſer,

composer, than any other author who flourished during the first fifty or sixty years of the last century. Though he made Corelli his model in the purity of his harmony, and simplicity of his modulation, he greatly surpassed that composer in the fertility and originality of his invention; not only in the subjects of his melodies, but in the truly cantabile manner of treating them. Many of his adagios want nothing but words to be excellent pathetic opera songs. His allegros are sometimes difficult; but the passages fairly belong to the instrument for which they were composed, and were suggested by his consummate knowledge of the finger-board, and powers of the bow. He certainly repeats his passages, and adheres to his original *motivo*, or theme, too much, for the favourite desultory style of the present times; but it must be allowed that by his delicate selection and arrangement of notes, his passages are always good; play them quick, or play them slow, they never seem unmeaning or fortuitous.

Indeed, as a harmonist, he was perhaps more truly scientific than any other composer of his time, in the clearness, character, and precision of his bases; which were never casual, or the effect of habit or auricular prejudice and expectation, but learned, judicious, and certain. Yet, with all our partiality for his style, talents, and abilities, as well as veneration for his principles and character, we must, in justice to others, own, that though the adagio and solo playing in general of his scholars were exquisitely polished and expressive, yet it seems as if that energy, fire, and freedom of bow, which modern symphonists and orchestra-playing require, were wanting. Perhaps the refinement of a Nardini and force of a Viotti are incompatible.

Since the time of Tartini, the productions of Boccherini, Haydn, Vanhal, Mozart, Pleyel, and others, have occasioned such a revolution in violin-music and playing, by the fertility and boldness of their invention, that compositions which were then generally thought full of spirit and fire, appear now totally tame and insipid.

This admirable musician and worthy man died the 26th of February, 1770, to the great regret of the inhabitants of the city of Padua, where he had resided nearly fifty years, and where he was not only regarded as its chief and most attractive ornament, but philosopher, saint, and sage. He had no children.

M. de Lalande says, he had from his own mouth the following singular anecdote, which shews to what degree his imagination was inflamed by the genius of composition. "He dreamed one night, in 1713, that he had made a compact with the devil, who promised to be at his service on all occasions; and during this vision every thing succeeded according to his mind; his wishes were prevented, and his desires always surpassed by the assistance of his new servant. In short, he imagined he gave the devil his violin, in order to discover what kind of a musician he was; when, to his great astonishment, he heard him play a solo so singularly beautiful, and executed with such superior taste and precision, that it surpassed all he had ever heard or conceived in his life. So great was his surprise, and so exquisite his delight upon this occasion, that it deprived him of the power of breathing. He awoke with the violence of this sensation, and instantly seized his fiddle, in hopes of expressing what he had just heard, but in vain; he, however, then composed a piece, which is perhaps the best of all his works, (he called it the Devil's Sonata,) but it was so inferior to what his sleep had produced, that he declared he should have broken his instrument and abandoned music for ever, if he could have subsisted by any other means."

He was one of the few composers of his time, who constantly drew from his own source; his melody was full of fire and fancy, and his harmony, though learned, yet simple and pure; and as a performer, his slow movements evince his taste and expression, and his lively ones his great hand. He was the first who knew and taught the power of the bow; and his knowledge of the finger-board is proved by a thousand beautiful passages, to which that alone could give birth. His scholar, Nardini, who played to us many of his best solos, as we thought, very well, with respect to correctness and expression, assured us that his dear and honoured master, as he constantly called him, was as much superior to himself in the performance of the same solos, both in the pathetic and brilliant parts, as he was to any one of his scholars.

Of his theoretical writings, we have had occasion to speak frequently and freely in former articles, particularly in our analysis of his SYSTEM, and Stillingfleet's Commentary. See STILLINGFLEET.

His practical works or compositions, always for his own instrument, the violin, consist of twelve solos on Corelli's model, six with double stops and fugues, with six of a lighter kind, in single stops, op. 1ª, six solos, op. 2ª, published by Walsh, about the year 1746, in a more free and original style. The first of this set, in E♯, which was Brown's "Cheval de Battaille," appeared more than ten years at every concert at which he performed a solo in London. Two sets of concertos, in a very florid and difficult style, collected in MS. by travellers, and published in Holland by Le Cene and Witvogel without the author's permission, he called in, and cancelled the plates. However, we procured a copy from Holland, that was printed after the plates were scratched. We scored several of them, and found more beautiful passages, more difficulties and knowledge of the finger-board, than in any other violin solo concertos which we had ever seen. Many sets of beautiful solos were printed at Paris of his composition, which are wholly unknown in England. More than 200 of his violin concertos and solos were dispersed over the continent in MS.; many of his unedited solos we procured from his favourite disciple Nardini, at Florence, after his decease. If the concertos which he composed for his own performance in the church of St. Antonio de Padua could be procured, they would probably be in a grave and ecclesiastical style, peculiarly suitable to the place and piety of the author.

TARTON RAIRE, in *Botany*, a name used by some authors for the heath-spurge, or that species of the thymelæa which is called *sannamunda* in the catalogues of the Materia Medica.

TARTOOR, in *Geography*, a town of Hindoostan, in the circar of Cicacole; 9 miles S. of Visianagram.

TARTRATES, or TARTRITES, in *Chemistry*, salts formed by the combination of any base with the tartareous acid. These salts are numerous; as with some the acid forms two salts, differing in the proportions of the acid and base, and also as it is liable to form triple salts in which two bases are united with their respective portion of acid into one uniform compound. All the soluble alkaline and earthy tartrites, the latter being less soluble than the former, are decomposed by the salts of lead, and the acid of all is destroyed by calcination, leaving the base in the state of carbonate.

TARTRATE, *Super*, *of Potash*, is a combination of potash and tartareous acid in excess (whence its name), and to which it is owing that it has an acid taste, and that it reddens blue vegetable colours. This is the *cream of tartar*, or *tartarum acidulum*, the nature and manufacture of which have been described under the article TARTAR. (See also *Super-tartrate of potash* under SALTS.) This salt is not soluble without great difficulty, requiring about 30 parts of boiling water,

water, and at leaſt 120, or as others ſay 60 parts of cold water; and hence a hot ſaturated ſolution begins to depoſit cryſtals almoſt immediately after it begins to cool. So great is the affinity between the tartareous acid and that proportion of potaſh which conſtitutes the ſuper-tartrate, that the acid of tartar will, partially or wholly, decompoſe all the neutral ſalts of potaſh, even the ſulphate. Nevertheleſs, the affinity between the ſuper-tartrate and the additional quantity of potaſh neceſſary for the complete ſaturation of this acid is much weaker than that of moſt other acids for potaſh; and hence ariſes a great number of decompoſitions, when tartareous acid, potaſh, and any other acid are mixed in different ways. The property, which the tartareous acid poſſeſſes, of decompoſing the neutral ſalts with the baſis of potaſh, is very uſeful in analyſis, as it ſerves to diſtinguiſh them at once from the correſponding ſalts of ſoda and ammonia, which are not decompoſable in the ſame manner. By ſaturating the exceſs of acid in cream of tartar with the ſeveral baſes (potaſh excepted) various triple ſalts are produced. Although ſome inconvenience attends the uſe of borax in adding the ſolution of *Cream of* TARTAR in water (ſee that article); yet ſimple boracic acid has the power of rendering ſoluble four times its weight of cream of tartar in only five or ſix parts of hot water, and, as it is ſuggeſted, without decompoſing the tartar, ſince the affinity of the boracic acid for the ſeveral baſes is remarkably weak.

If a ſolution of cream of tartar in water is expoſed to the air for a length of time, it gradually becomes turbid, a number of mucous flocculi are depoſited, and in the courſe of ſome months it ceaſes to be acidulous, after which it becomes ſenſibly alkaline to the taſte and to chemical teſts, and it is finally converted into a weak ſolution of carbonate of potaſh, the tartareous acid totally diſappearing, and carbonic acid taking its place. Fire operates a more rapid deſtruction of the tartareous acid, for if cream of tartar is calcined in an open fire with a red heat, it firſt ſoftens, blackens, becomes of a paſty conſiſtence, the acid burns off with flame and ſmoke, and finally a white carbonate of potaſh is left. The alkali procured in this way is very pure, and is often obtained for the laboratory by moiſtening crude tartar or cream of tartar to the conſiſtence of ſtiff paſte, wrapping up ſmall parcels of it in brown paper, and arranging them in a grate or furnace of any kind with charcoal, and kindling it. After the charcoal has burnt out, the tartar is converted into lumps of carbonate of potaſh, which ſtill cohere, and may be readily picked out of the aſhes of the charcoal. A very pure carbonate of potaſh may alſo be made by deflagrating in a red-hot crucible equal parts of nitre and cream of tartar.

This ſalt is compoſed, according to Thenard, of 57 *per cent.* of tartareous acid, and 33 of potaſh, the remaining 10 parts being chiefly water of cryſtallization. Of theſe 57 parts of acid, 20 are in exceſs, ſo that the compoſition of the ſalt may be ſtated, in a different manner, to be 70 *per cent.* of tartrite of potaſh, and 20 of tartareous acid.

Cream of tartar is decompoſed by lime and barytes, and probably by ſtrontian, and cauſtic potaſh is left in the ſolution.

TARTRITE *of Potaſh.* See *Soluble* TARTAR, and *Tartrate of Potaſh* under SALTS. This ſalt, conſiſting of tartareous acid and potaſh in mutual ſaturation, is moſt conveniently prepared by adding cream of tartar to a hot ſolution of carbonate of potaſh. During the efferveſcence, the addition of cream of tartar ſhould be continued; when this ceaſes, the ſolution ſhould be boiled down till a pellicle appears on the ſurface, and then left to cryſtallize by cooling. The tartrite of potaſh then ſeparates, generally in the form of parallelopipeds, with dihedral ſummits. When the ſalt is prepared in a large way for medicinal purpoſes, the evaporation is continued nearly to dryneſs, with frequent ſtirring, by which the ſalt is obtained in a ſhapeleſs granular maſs. This ſalt is partially decompoſed by the ſtronger acids. Tartareous acid dropped into a moderately ſtrong ſolution of tartrite of potaſh cauſes an immediate depoſit of cream of tartar. For other particulars, ſee the articles above cited.

TARTRITE *of Potaſh and Soda*, a triple cryſtallizable ſalt, prepared by throwing into boiling water about a fifth of its weight of cream of tartar, and adding gradually a quantity of carbonate of ſoda, whilſt any efferveſcence is excited; then evaporating the whole to the conſiſtence of ſyrup. As it cools, the triple ſalt will be obtained in large beautiful tranſparent cryſtals, generally of the form of eight-ſided priſms, and often divided longitudinally through the axis. This ſalt, which is perfectly neutral, diſſolves in about five parts of water, and ſomewhat effloreſces by being expoſed to the air. Barytes and lime totally decompoſe it, and the ſupernatant liquor contains a mixture of potaſh and ſoda. According to Vauquelin, it is compoſed of about 54 *per cent.* of tartrite of potaſh and 46 of tartrite of ſoda. It is decompoſed by the ſtronger acids, and yields cream of tartar. See RUPELLENSIS *Sal*, and SODA.

TARTRITE *of Potaſh and Ammonia*, a triple ſalt prepared, in the ſame general manner as the preceding, by ſaturating cream of tartar with carbonate of ammonia, evaporating and cooling. Expoſed to the air it effloreſces, loſes its ammonia, and returns to the ſtate of ſimple cream of tartar.

TARTRITE *of Potaſh and Lime*, *Barytes*, &c. Between tartrite of potaſh and lime there exiſts a certain affinity, which tends to the formation of a triple ſalt, though lime will completely decompoſe any alkaline tartrite. Thus though ſimple tartrite of lime is inſoluble in cold water, no precipitate is produced by the affuſion of a ſmall quantity of lime-water into a cold ſolution of tartrite of potaſh, which muſt therefore be owing to the tartrite of lime, then formed, being rendered ſoluble by the remaining tartrite or rather ſubtartrite of potaſh. Even when cream of tartar is as completely as poſſible decompoſed by lime in ſubſtance, in the proceſs of obtaining the acid, the cauſtic alkaline liquor, ſupernatant over the precipitated tartrite of lime, ſtill holds a ſmall quantity of the latter in ſolution, as has been remarked by Vauquelin, which may be conſidered as a triple ſalt of tartareous acid, lime, and potaſh, the latter being in very large exceſs.

The ſame applies to barytes and ſtrontian, the ſolutions of which do not immediately give a precipitate with tartrite of potaſh; and even if tartrite of barytes or of ſtrontian recently formed and ſtill wet be put into a ſolution of tartrite of potaſh, it is ſoon diſſolved; though the mere quantity of liquid preſent would be entirely unable to effect a ſolution. There is therefore ſuch a ſtrong affinity between tartrite of potaſh and theſe earthy tartrites, as may perhaps entitle us to conſider theſe compound ſolutions as triple ſalts, though they have not been obtained in a cryſtallized form like the triple tartrite of potaſh and ſoda.

Alumine unites with ſtill greater eaſe with tartrite of potaſh: for when this earth, recently precipitated from alum by a cauſtic or carbonated alkali, and ſtill wet, is transferred to a ſolution of tartrite of potaſh, it readily diſſolves therein, and forms an uncryſtallizable compound, which is not rendered turbid by any addition of potaſh or its carbonate. The Rochelle ſalt has the ſame habitude with alumine as the ſimple tartrite of potaſh, which therefore forms a quadruple compound of tartareous acid, potaſh, ſoda and alumine. See ALUMINE.

Tartrite *of Soda*, a ſalt produced in ſmall needled cryſtals from a due evaporation of tartareous acid ſaturated with ſoda. This ſalt, formerly confounded with the Rochelle ſalt, or *ſal Rupellenſis*, is not very ſoluble in water; however, when tartrite of potaſh is added to this ſalt, each in ſaturated ſolution, large cryſtals of the triple tartrite, or Rochelle ſalt, are immediately depoſited.

A *ſuper-tartrite of ſoda* is formed by partially ſaturating tartareous acid with ſoda, and alſo by adding a ſtrong acid to the ſaturated tartrite, which, being leſs ſoluble than the ſaturated compound, precipitates. It is obſerved, however, that tartareous acid will not form (viſibly) an acidulous tartrite, when added to the ſulphate and other ſalts of ſoda, as it will do with the ſalts of potaſh.

Tartrite *of Ammonia*, a ſalt formed by ſaturating the tartareous acid with ammonia or its carbonate. This ſalt cryſtallizes readily, and is decompoſed by the fixed alkalies and alkaline earths.

A *ſuper-tartrite of ammonia* is formed in a ſimilar manner to the ſuper-tartrite of ſoda, and with the ſame exception of the acid not viſibly decompoſing the other ammoniacal ſalts. See Ammonia, and *Tartrate of Ammonia* under Salts.

Tartrites, *Earthy*. See *Earthy* Salts. See alſo *Tartrate of Lime* under Lime.

The *tartrite of lime* is produced in a white precipitate, by adding tartareous acid to any ſoluble ſalt of lime, or lime to a ſoluble tartareous ſalt. Although this ſalt is inſoluble in mere water in a common temperature, it diſſolves readily in an exceſs of its own, or of any other acid that does not decompoſe it, ſuch as the acetous or muriatic. It is alſo rendered ſoluble in water by the addition of potaſh. When it is heated ſtrongly in an open fire the whole acid is conſumed, and carbonate of lime remains.

Tartrites *of Barytes and Strontiam*, are formed in the ſame manner as tartrite of lime; but they are not ſo inſoluble in water as this ſalt; and the tartrite of ſtrontian will even cryſtallize from its hot-ſaturated ſolution by cooling. With *magneſia* and *alumine* this acid forms very ſoluble compounds, which do not cryſtallize by evaporation, but dry up into a gummy maſs. Aikin's Dict.

TARTSCHIN, in *Geography*, a town of the duchy of Warſaw; 20 miles S.W. of Warſaw.

TARTURA, a town of Paleſtine, near the coaſt; 10 miles S. of Acre.

TARVA, a diſtrict of Arabia, on the banks of the Julfa.

TARUD, a town of Arabia, in the province of Hedſjas; 10 miles from El Catif.

Tarud *Eſherif*, a town of Egypt, on the left bank of the Nile; 6 miles S. of Melaui.

TARUDA, in *Ancient Geography*, a town of Africa, in Mauritania Cæſarienſis, near Ægea. Ptol.

TARUDANT, or Tarodant, in *Geography*, a town of Africa, and capital of the province, formerly kingdom, of Suſe, ſituated at the extremity of Morocco. The town is ancient and extenſive, and is ſaid to contain 25,000 inhabitants. It has a noble palace, to which belong gardens abounding with the moſt delicious fruits. Its population has lately decreaſed; and it is now famous only for ſaltpetre of a ſuperior quality, for the manufacture of leather and ſaddles, and for dyeing. The town is watered by the river Suſe, which paſſes through it; and it is reported that ſhips formerly took in their cargoes at this place. It has ſuſtained ſeveral ſieges, and in the laſt, the inhabitants were reduced to the neceſſity of eating rats and burning their doors for fuel; 110 miles S.S.W. of Morocco. N. lat. 30° 29′. W. long. 8° 35′.

TARVES, a village in the diſtrict of Ellon, and ſhire of Aberdeen, Scotland, is ſituated on the banks of the river Ythan; 15 miles N. from Aberdeen, and 139 miles N. by E. from Edinburgh. The pariſh is about nine miles in length and ſix in breadth. The general appearance is flat, interſperſed with ſome ſmall hills; the ſoil is in ſome parts deep, and in others ſhallow; but moſtly fertile. About a hundred acres are covered with thriving plantations. A general poſt-office is eſtabliſhed here; and two fairs are holden annually. The public roads are in good repair. The pariſh church is ancient and ruinous. Here is a reſpectable parochial ſchool, of which the ſalary is 300 marks, with ſchool-fees and perquiſites, and a rood of land. In the population return of the year 1811, Tarves was ſtated to contain 454 houſes, occupied by 1804 perſons.—Carliſle's Topographical Dictionary of Scotland, vol. ii. Gazetteer of Scotland, 8vo.

TARVIDUM, Taruedum, or *Orcas*, in *Ancient Geography*, a promontory on the ſouthern coaſt of the iſle of Albion, near the mouth of the river Nabaus.

TARVIN, or Tarven, in *Geography*, a townſhip and pariſh in the hundred of Ediſbury, and county palatine of Cheſter, England, is ſituated on the London road, five miles N. by E. from Cheſter. It had for ſome time a weekly market, procured by ſir John Savage, in the reign of queen Elizabeth; but this has been long diſcontinued. An annual fair was alſo held here till within the laſt thirty years, but was then aboliſhed. Tarvin was one of the parliamentary garriſons during the civil wars: in Auguſt 1644, it was a ſhort time in the poſſeſſion of the royaliſts; but in the following month it was retaken for the parliament, and fortified with ſtrong works. This and Nantwich were the only garriſons in Cheſhire not abandoned on the reported approach of the king, in May 1645; and the parliament retained it till the end of the war. A grammar-ſchool was founded here in the year 1600. John Thomaſen, a celebrated penman, was maſter of this ſchool thirty-ſix years in the early part of the laſt century. On the outſide of the pariſh church is an inſcription to his memory, ſtating that he "highly excelled in all the varieties of writing, and wonderfully ſo in the Greek character. Specimens of his ingenuity are treaſured up in the cabinets of the curious and in the public libraries throughout the kingdom." The townſhip of Tarvin was ſtated in the population return of the year 1811, to contain 180 houſes, occupied by 921 perſons. The pariſh is very extenſive, and includes 11 townſhips, containing in the whole 2877 inhabitants, the number of houſes being 525.—Lyſons' Magna Britannia, vol. ii. part 2, Cheſhire. Beauties of England and Wales, vol. ii. Cheſhire, by J. Britton and E. W. Brayley.

TARVISIUM, or Tarviso, in *Ancient Geography*, a town of Italy, towards the N.W. of Venetia.

TARUM, in *Botany*, a name given by Pliny to the *agallochum ſylveſtre*, a ſpecies of aromatic plants.

TARURAW, in *Geography*, a town of the ſtate of Georgia; 14 miles N. of Tugeloo.

TARUS, or Taro, in *Ancient Geography*, a river of Gallia Ciſpadana, which ran towards the N.E., and E. of Trebia.

TARUSA, in *Geography*, a town of Ruſſia, in the government of Kaluga, on the Oka. N. lat. 54° 52′. E. long. 36° 34′.

TARUSATES, in *Ancient Geography*, a people of Gallia Aquitanica, mentioned by Cæſar in the 3d book of his Commentaries, who were compelled to ſubmit by Craſſus, Cæſar's lieutenant. Their city was named Vicus Julii and alſo Aturas.

TARUSCO, a town of Gallia Narbonnenfis, near Glenum.

TARUSCONIENSES, a people of Gallia Narbonnenfis, mentioned by Pliny, who occupied part of the territory of Tarafcon on the Rhone.

TARWAS, in *Geography*, a town of Bengal; 28 miles E. of Nattore.

TASAGORA, in *Ancient Geography*, a town of Africa, in Mauritania Cæfarienfis, on the route from Cula to Rufucurum. Anton. Itin.

TASAPAN, in *Geography*, a fmall ifland in the Eaft Indian fea, near Junkfeilou. N. lat. 8° 20'. E. long. 98° 14'.

TASCA, Luigi, in *Biography*, an opera finger with a powerful bafe, or rather baritono voice, who arrived in England in 1782, was a good mufician, and not only a ufeful performer at the opera, but at the oratorio, and in the performances at Weftminfter Abbey in commemoration of Handel. His voice, however, wanted mellownefs and flexibility: for like an oaken plant, though ftrong, it was ftiff.

TASCHENMUL, in *Ornithology*, a name given by authors to the *anas clypeata*, a fpecies of duck, remarkable for the breadth of the end of its beak, and called in Englifh the *fhoveller*. See *Broad-beaked* Duck.

TASCHIEN, in *Geography*, a river of Bavaria, which runs into the Regen, 2 miles W. of Cham.

TASCHOW, a town of Bohemia, in the circle of Leitmeritz; 5 miles N. of Leitmeritz.

TASCIO, or Tascia, in *Coinage*, is a term, which either wholly or in part, appears on many ancient Britifh coins, and which has puzzled our antiquaries, who have formed feveral different opinions concerning it. Mr. Camden, Mr. Baxter, Dr. Pettingal, and others, have thought that this word is derived from *Tafk* or *Tafcu*, fignifying in the original language of Britain any land-burthen or tribute impofed by the Tag, or prince, and that all the money which had Tafcia or any of its abbreviations upon it, had been coined for no other purpofe but to pay the tribute which had been impofed on the Britons by Julius Cæfar, and the portaria or duties upon merchandize, which had been exacted by Auguftus and his fucceffors. Againft this opinion, however, others have urged ftrong objections. The derivation of Tafcio from Tag, a prince, by the intervention of Tafcu, a burthen or tafk, it has been faid, is far from being clear. Money coined for the fole purpofe of paying tribute, is a thing, fay the objectors, unknown in the hiftory of mankind; nor is it probable that Cunobeline, who was a free and independent prince, the friend but not the fubject of the Roman emperors, would have admitted a word of fuch ignominious import as Tafcio is in this fenfe of it, upon his coins.

A modern author (fee Wife Differt. in Numm. Bodl. Catal, p. 227.), diffatisfied with the above interpretation of the word Tafcio, has propofed another. He fuppofes that Tafcio is an abbreviation of fome nation or people to whom this money belonged, and of which Cunobeline was king; and finding in Pliny (lib. iii. c. 4.) a people of Gallia Narbonnenfis, called "Tafcodunitari Conorienfes," in the MSS. "Tafcoduni Taruconienfes," he conjectures, that Cunobelin Tafcio may mean Cunobelin Tafcodunorum. But this meaning is far-fetched, and depends upon improbable conjecture.

Another modern writer (fee Pegge's Eff. on Cunobeline's Coins, p. 55.) has conjectured, that Tafcio was the name of Cunobeline's mint-mafter, who ftruck all thefe coins. Although this opinion is more probable than the former, it is neverthelefs ftrange, that this word, if it was a proper name, fhould have been fpelled by the perfon to whom it belonged in fo many different ways, as Tafcio, Tafcia, and Tafcie.

TASCO, in *Geography*, a town of Mexico, in the province of Mechoacan; 90 miles S.E. of Mechoacan. N. lat. 19° 5'. W. long. 101° 36'.

TASCONI, in *Ancient Geography*, a people of Gallia Narbonnenfis, mentioned by Pliny, who occupied part of the diocefe of Montauban. Their city bore the fame name, and was fituated N. of Tolofe..

TASGOM, in *Geography*, a town of Hindooftan, in Vifiapour; 10 miles N. of Merritch.

TASHAM Dagh, a mountain of Afiatic Turkey, between Amafreh and Samfoun.

TASHKUND, Taschkund, or *Al Shafh*, a town of Turkeftan, on the Sir. This town has been often deftroyed and rebuilt; 210 miles N. of Samarcand. N. lat. 42° 40'. E. long. 64° 48'.

TASHKUPRI, a town of Natolia; 14 miles S.E. of Caftamena.

TASIEVA, a river of Ruffia, which runs into the Tchiuma, about 20 miles N.W. of Tafievfkoi.

TASIEVSKOI, a town of Ruffia, in the government of Tobolfk, on the Tafieva; 820 miles E. of Tobolfk. N. lat. 57°. E. long. 94° 14'.

TASIO, a river of Sweden, which joins the Angermann at Liden.

TASIS, τασις, in *Rhetoric*, is ufed for the continuation of a period longer than the breath can bear. Voff. Rhet. lib. iv. p. 66.

TAS-KUJE, in *Geography*, a town of Perfia, in the province of Lariftan; 84 miles N.E. of Lar.

TASLUI, a town of Moldavia; 20 miles S. of Niemecz.—Alfo, a river of Moldavia, which runs into the Siret, near Adzud.

TASMAN's Head, a cape on the coaft of Van Diemen's Land. N. lat. 43° 33'. E. long. 147° 28'.

TASMANIA. See *Van* Diemen's *Land*.

TASOPIUM, in *Ancient Geography*, a town of India, on this fide of the Ganges, near Caricardama, affigned by Ptolemy to the Sabaræ.

TAS-POULSASON, in *Geography*, a town of Chinefe Tartary, in the country of Hami. N. lat. 40° 22'. E. long. 95° 54'.

TASPOUR, a town of Hindooftan, in Bahar; 27 miles E. of Hajypour. N. lat. 25° 52'. E. long. 85° 51.

TASSA Point, a cape on the coaft of Guinea. N. lat. 8°. W. long. 12° 10'.

TASSA-CORTA, or Tassa-Croda, a town on the W. coaft of Palma, one of the Canary iflands, which is an inconfiderable loading-place for veffels. N. lat. 28° 37'. W. long. 17° 58'.

TASSASUDON, Tassisudon, or *Taffey-Seddein*, a town of Afia, and capital of the Bootan country, fituated in a valley, computed to be about three miles in length, and one in breadth, lying N. and S., through which runs the river Tchintchieu. This valley is in a high ftate of cultivation, bearing various kinds of grain, and diverfified by clufters of houfes. The caftle, or palace of Taffifudon, ftands near the centre of the valley, and is a building of ftone, of a quadrangular form; the walls are upwards of 30 feet high, floped a little from the foundation to the top; above the middle fpace is a row of projecting balconies, to each of which are curtains made of black hair; which are always drawn at night: the walls are pierced below with fmall windows, for the admiffion of air rather than light; and there are two entrances to the palace: the one facing the fouth by a flight of wooden ſteps, edged with plates of iron, and the other, which is the grand entrance on the eaſt front, aſcended by a flight of ſtone ſteps. Even with theſe is a ſpacious gateway, with two maſſy doors, fortified with knobs of iron, and ſecured when ſhut by a large bar of timber that ſlides within the maſonry. Within is the central ſquare building, which may be denominated the citadel, and which is the reſidence of the ſupreme Lama. It contains alſo the chief of their idols, Mahomoonie, amidſt a multitude of others of inferior note. To the right and the left are avenues that lead to ſpacious ſquares, paved with flat ſtones, and to the apartments of the Lama. The citadel is ſeven ſtories high, each from fifteen to eighteen feet, and covered with a roof of low pitch, compoſed of fir timber; from the centre ariſes a ſquare piece of maſonry, ſupporting a canopy of copper, richly gilt, which is ſuppoſed to be directly over the great idol, Mahomoonie. The raja lives upon the fourth floor from the ground; above that are two other ſtories; and the ſeventh ladder reaches to the temple of Mahomoonie. The eaſt, weſt, and ſouth angles of the building correſpond with each other, and have apartments on the ground floor appropriated for depoſiting all kinds of ſtores. A covered gallery runs all round them, beneath which are ſubterraneous places ſerving for kitchens. A range of good rooms, with boarded floors, on the firſt ſtory, accommodates all the officers of ſtate attendant on the raja, and thoſe towards the ſquare are ſkirted by a varande, ſupported by a row of handſome pillars, whoſe capitals are ornamented with carved work and gilding, and their ſides painted with vermilion. Over this ſtory is a ſort of terrace of cement, with rooms more roughly finiſhed for the inferior officers, called Zeenkerbs. For further particulars we refer to Turner's Embaſſy, in which is an engraving of the palace, and of the reſidence of Lama Glaſſetoo in its vicinity. The road from Bengal to Taſſaſudon lies chiefly over the ſummits of ſtupendous mountains, or along the borders of craggy precipices: and between this city and Peridroog is a chain of mountains ſtill higher than the other. Theſe are viſible from the plains of Bengal, at the diſtance of 150 miles, and are commonly covered with ſnow. They are a continuation of the mountains Emodus and Paropamiſus of the ancients; 206 miles S.W. of Laſſa. N. lat. 27° 48′. E. long. 89° 12′.

TASSEL, a ſort of pendent ornament, at the corners of a cuſhion, or the like thing.—Alſo, a ſmall ribband of ſilk ſewed to a book, to be put between the leaves.

TASSELS, in a *Building*, thoſe pieces of board that lie under the ends of the mantle-trees.

TASSEL, or *Tiercelet*, is alſo uſed in *Falconry* for a male hawk.

TASSELS are alſo a kind of hard burrs uſed by cloth-workers in dreſſing of cloth; they are the heads of the manured teaſel.

TASSES, or TASSETS, in *Ancient Armoury*, appendages to the corſelet, conſiſting of ſkirts of iron that covered the thighs, and that were faſtened to the cuiraſs with hooks.

TASSI, AGOSTINO, in *Biography*, the cognomen of an artiſt whoſe real name was Buonamici. He was born at Perugia in 1566, and ſtudied at Rome under Paul Brill, and received ſome aſſiſtance in the ſchool of the Carracci. His looſe and irregular conduct procured a ſeat for him on the bench of a galley at Leghorn; and there, though under confinement and diſgrace, he occupied his leiſure in painting views of the objects with which he was ſurrounded; and when he obtained his liberty, ſuch ſubjects became the favourite occupation of his pencil. His ſea-ports, calms, and ſtorms, were faithful tranſcripts of nature, and touched with great ſpirit and efficacy. His views of architectural ſubjects thrown into perſpective, which are in the pontifical palace of Monte Cavallo, and in that of the Lancellotti family, are admirable in their kind. His greateſt honour, however, is having been the inſtructor of Claude de Lorraine. He died in 1642, aged 76.

TASSING, in *Geography*. See TAASINGE.

TASSO, BERNARDO, in *Biography*, an eminent poet, born at Bergamo of an ancient and noble family in the year 1493, became an early proficient in the Greek and Latin claſſics. His uncle, the biſhop of Recanati, who was his inſtructor and patron, and ſupplied the place of a parent when he loſt his father, having been aſſaſſinated by robbers in 1520, Bernardo was under a neceſſity of quitting his native city, and in 1525 became ſecretary to count Guido Rangoni, general of the papal army. Having been for a ſhort time occupied in a ſimilar ſituation under the ducheſs of Ferrara, he afterwards purſued his ſtudies at Padua and Venice. In 1531 he publiſhed at Venice a volume of poems, which induced Ferrante Sanſeverino, prince of Salerno, to invite him to his court. Having accepted this invitation, he recommended himſelf to the prince, and obtained annual ſtipends, amounting to 900 ducats. He accompanied his patron in ſeveral expeditions, and accompanying him to Naples, he there married Porzia de' Roſſi, a lady of noble family. At Sorrento, whither he removed, he for ſome time led a tranquil and ſtudious life; until his patron, in 1547, incurred the diſpleaſure of the imperial court by concurring in preſenting a petition againſt the eſtabliſhment of the inquiſition at Naples. On this occaſion the prince joined the French party, ſo that he was declared a rebel, and his property was confiſcated. Influenced by reſpect for his patron, Bernardo accompanied him to France, where at firſt he obtained encouragement, but being in proceſs of time deprived of all ſupport, and having loſt his wife, he requeſted the prince's permiſſion to leave him; and complying with an invitation to the court of Guidubaldo II., duke of Urbino, a diſtinguiſhed patron of literary perſons, he was liberally compenſated for his paſt ſufferings, and made a member of the celebrated Venetian academy. In 1563 he became ſecretary at the court of Mantua, and in the ſervice of this court he died in 1569, being then governor of Oſtiglia. The duke of Mantua cauſed his remains to be honourably interred in that city, and a marble monument to be erected over his tomb, bearing the ſimple inſcription, "Oſſa Bernardi Taſſi." Of his poems, belonging to the claſs of "Romaneſque," there were two; *viz.* "Amadigi," conſiſting of 100 cantos, and "Il Floridante," left unfiniſhed, but corrected and publiſhed by his ſon Torquato, at Bologna, in 1587. His other works are five books of "Rime," with various kinds of poems, ſuch as eclogues, elegies, hymns, odes, &c. He was alſo the author of "A Diſcourſe concerning Poetry," and "Letters," of which an edition has been given in three volumes.

TASSO, TORQUATO, pre-eminent as an Italian poet, was the ſon of Bernardo and Porzia de Roſſi, born at Sorrento March 11, 1544, and ſent at the age of five years to the Jeſuits' ſchool at Naples. Here his proficiency was ſo rapid, that in two years he recited, publicly, verſes and orations of his own compoſition. At Bergamo, whither the circumſtances of his family conſtrained him to remove, he proſecuted the ſtudy of Latin and Greek with ſuch ſucceſs, that at the age of twelve years, he was admitted into the univerſity of Padua. Here his proficiency in various branches of literature was ſo ſignal, that in his ſeventeenth year he was honoured with degrees in the four branches of canon and civil law, theology, and philoſophy. For law he had no prediléction; but all the powers and affections of his mind were devoted to poetry. Thus diftinguifhed, he was invited by the celebrated Cefi to Bologna, in the fchools and academies of which city his talents were eminently difplayed. During his refidence in Bologna, he was charged with having written fome defamatory verfes, and deprived of his books; and though he avowed his innocence, he thought proper to withdraw from the city to a place called Caftlevetro, where he was protected by the count Rangoni. Some time after this event he fettled at Padua, and acquired diftinction among the academicians denominated " Eterei." At the age of eighteen years he had publifhed at Venice his poem of the Romanefque clafs, entitled " Il Rinaldo," which he dedicated to cardinal Luigi d'Efte, in confequence of which he was invited, in 1566, to the court of Ferrara, where he was liberally accommodated, and where, it is faid, he profecuted the execution of his plan of the " Gerufalemme Liberata;" fix cantos of which were compofed in the 17th year of his life. In 1571 he accompanied the cardinal d'Efte into France, where he was honourably received by Charles IX. and his court, and alfo by all the learned men of Paris. In the following year he returned to Italy, and caufed to be reprefented his dramatic paftoral of " Aminta." Several cantos of his " Gerufalemme" were at this time difperfed in MS. throughout Italy, and in 1579 the fourth canto was printed in a collection of poems at Genoa. In the following year, fragments of 16 cantos were publifhed at Venice, and we may naturally imagine that this mode of introducing to public notice a work on which he had beftowed much attention and labour, excited his difpleafure. In 1581 three editions were printed, and of thefe, the third at Ferrara has been confidered as that which firft exhibited this celebrated work in its genuine form. It has occafioned fome degree of furprife, that Taffo himfelf did not guard againft thefe incorrect publications, by committing his work to the prefs in a more perfect ftate. His negligence in this refpect has been attributed to fome mental malady under which he laboured. Of the caufe of this malady different accounts have been given. Tirabofchi has narrated a variety of circumftances, which operating on a mind like that of Taffo, might have contributed to produce, or at leaft to aggravate the mental diforder under which he laboured. His narration is recited in the General Biography; but within our limits we cannot do it full juftice. His firft provocation feems to have been excited by a courtier, who divulged the fecret of his amours, in the prefence-chamber of Alfonfo, duke of Ferrara, and whom he publicly infulted, fo that he was under a neceffity of defending himfelf with his fword againft the aggreffor and his three brothers. The brothers were banifhed, and Taffo was confined to his apartment. Difturbed in his mind, and dreading worfe confequences, he made his efcape, wandered to Turin, Rome and Sorrento, and at length obtained permiffion to return to Ferrara. Sufpecting fome hoftile defign, he withdrew to the court of Urbino, and again returned to Ferrara. Here his diforder was fo manifeft, that Alfonfo ordered him to be fhut up in a hofpital appropriated to lunatics. The evidence of his diforder is faid by fome to have been an indecorous liberty which he took in faluting the princefs Leonora, the duke's fifter; but others have thought this circumftance very improbable, and indeed it is hardly neceffary to make an attempt for juftifying the duke's conduct in the confinement of Taffo, after he had given fo many incontestible proofs of mental derangement. At length, however, Taffo was reftored to entire liberty. But his difpofition to wander ftill continued; and it is lamentable to reflect, that, as one of his biograpers obferves, " the admired author of ' Jerufalem delivered,' the favourite of princes and the boaft of Italy, fhould have harboured in his mind fomething which defeated every plan to render his circumftances profperous." His laft retreat was with cardinal Cinzio Aldobrandini, at Rome, who obtained for him a penfion from pope Clement VIII., and had intended, as a compenfation for his fufferings, to procure for him the honour of a folemn poetical coronation in the Capitol; but the ceremony was delayed on account of the cardinal's illnefs, and Taffo manifefted fymptoms of approaching diffolution. As foon as he was apprized of his danger, he was removed to the convent of St. Onofrio, where, deriving every poffible confolation from the kindnefs of the cardinal, and exhibiting every evidence of fincere piety, he clofed his days in April 1595, at the age of 51. His remains were honourably interred, and after fome time a monument was erected to his memory by cardinal Bonifacio Bevilacque, in the church of St. Onofrio. Taffo, " in perfon, was tall, active, and well-proportioned, naturally of a firm temperament, and fit for all bodily exercifes. He was fparing of words, fedate and grave in manner, and in converfation difplayed little of the fire that animates his works. He was kind and affectionate in all his focial relations, and conducted himfelf with great propriety in company."

His works are very numerous. Thofe in profe confift of a great number of treatifes, dialogues, and letters, on moral, literary, and familiar topics. In poetry, his " Gerufalemme Liberata" is pre-eminent. " Its fubject is fingularly happy, its characters well-drawn and fupported, its fictions ftrongly imagined, its ftyle dignified, and its verfification harmonious." His " Gerufalemme Conquifata," publifhed in 1593, was a kind of recompofition of the former work, but lefs fatisfactory to its readers. His " Aminta" has been already mentioned; his " Rime" confifted of occafional and mifcellaneous pieces; his " Sella Giornata," or Works of the Seven Days, pieces on facred topics, bear the impreffion of the gloomy ftate of his mind. Tirabofchi. Gen. Biog.

Tasso, in *Geography*, a fmall ifland on the W. coaft of Africa, at the mouth of the river Sierra Leona.

Tasso, or *Thafo*, an ifland of the Grecian Archipelago, fituated in the gulf of Contefa, towards the W. extremity of Macedonia, and two leagues from the continent. The channel which feparates that ifland from the main land is alfo divided by a fterile inlet called " Little Taffo," and in Greek " Taffo-poulo," the veftige of an ancient continuity of lands, at prefent feparated. A fpacious road, where the ground is good for holding, lies between the two iflands. Taffo is the moft northern of the iflands of the Archipelago, and its high mountains, covered with forefts, are feen at a diftance. This ifland was formerly one of the moft famous for its rich gold mines. Herodotus fpeaks of them, and they were under the direction of Thucydides. Thefe mines led the Greeks to denominate it Chryfe, fignifying gold or gilt; its riches had become proverbial, and the expreffion was a " Thafos of wealth." Its natural treafures alfo were opals, amethyfts, and other precious ftones; but though thefe are loft, Taffo ftill furnifhes the beautiful marble, that forms the greater part of the mountains, which was anciently held in fuch eftimation by the Romans; the whitenefs of which vies with fnow, and the finenefs of its grain with that of Parian marble. The inhabitants of Paros are faid to have peopled the ifland of Taffo, and to have there built the town of Thafos, which was its capital, and the veftiges of which are ftill to be feen. The ifland is near 30 leagues in circumference; it produces abundance of corn, oil, wax, &c.; but the fertility, extolled by the ancients, is turned to no account for want of encouragement and culture.

ture. Its wines, famous even in the time of the Lower empire, as Chryfoftom exclaimed againft the exceffes to which they gave rife at Conftantinople, have no longer the excellent qualities which caufed them to fetch a high price. Its population has experienced the fame fate as the productions of its foil; it is confiderably diminifhed. Taffo, however, has ftill remaining a kind of wealth very important to a maritime and trading nation; this is capital wood for fhip-building. N. lat. 40° 34′. E. long. 24° 46′.

TASSONI, Alessandro, in *Biography*, an Italian poet and man of letters, was born of an ancient and noble family, at Modena, in the year 1565. Notwithftanding various difadvantages in early life, fuch as the lofs of his parents, a feeble difeafed frame, and the perfecution of enemies, he fuccefsfully cultivated Greek and Latin literature, poetry, and eloquence. At the age of twenty he fought further improvement in the univerfity of Bologna, and here, as well as at Ferrara, he directed his particular attention to jurifprudence. Being under a neceffity of feeking employment, he went to Rome, where, being known by his writings, he was admitted into the fervice of cardinal Colonne, as fecretary, and accompanied him to Spain in the year 1600. Being afterwards domefticated with cardinal Cefi, he became a member of the academies degli Umorifti and de' Lincei, and was held in high eftimation among the literati of Rome. A fpecimen of his "Penfieri diverfi" (Thoughts on various Subjects) was publifhed in 1608, under the title of "Quefiti," and the whole in 1612. His "Confiderations on Petrarch" were firft printed in 1609, and were intended to reftrain the prevalent idolatry of this author. In 1613 he entered into the fervice of Charles Emanuel, duke of Savoy, in which fituation he was regarded as an enemy to the Spanifh monarchy; and he was confidered as the author of "Philippics" againft the Spaniards, and of a book entitled "Effequie della Monarchia di Spagna." In 1623 he quitted the family of Savoy; and about this time he finifhed "A Compendium of the Annals of Baronius." In 1626 he was taken into the fervice of cardinal Lodovifio, nephew of Gregory XV.; and upon his death, in 1632, he was invited to the court of Francis I., duke of Modena, who gave him a penfion and fome honorary titles. Of this fituation death deprived him in 1635, at the age of 70. One of his biographers fays of him, that "he had a prepoffeffing countenance, with a cheerful expreffion, was open in converfation, a good fpeaker, ferious or pleafant, according to the occafion, of a lively imagination, and found judgment." The work by which the memory of Taffoni is chiefly preferved is his mock heroic poem "La Secchia Repita." Tirabofchi. Gen. Biog.

This penetrating and learned writer, in the tenth book of his "Penfieri diverfi," treats of mufic, ancient and modern, but not with his ufual acumen or feverity. He only retails the old ftories of its miraculous powers among the ancients, and tries to match them by wonders pretended to be performed by its inferior perfections in modern times, without any remarks or reflections which difcover a knowledge of the art, or doubts of the authenticity of thefe relations.

After fpeaking of extraordinary dilettante compofers of mufic in modern times, he fays, "among thefe we may enumerate James I., king of Scotland, who not only compofed facred mufic, but invented a new fpecies of plaintive melody, different from all others; in which he has been imitated by the prince of Venofa, who, in our times, has embellifhed mufic with many admirable inventions."

This paffage has given birth to two capital miftakes, into which the readers and writers of mufical hiftory have been led, particularly in Scotland. In the firft place, it infinuates that James I. was the inventor of the national melodies of that country; and fecondly, that thefe melodies had been imitated in Italy by the prince of Venofa, a voluminous and celebrated dilettante compofer of madrigals in the fixteenth century.

Unluckily for the favourers of thefe opinions, the Scots' national melodies can be proved of much higher antiquity, not only than David Rizzio, but the time of James I. See Rizzio, James I. *of Scotland*, and Ossian.

And the prince of Venofa, who was not the great mufician he was reported to be by learned men who were ignorant of mufic, has not in all his works, which we have carefully examined, a fingle paffage of melody which reminds us of the national tunes of Scotland; the melodies of which refemble thofe of no other country with which we are acquainted, except thofe of China. See Venosa, and Chinese *Mufic*.

Another Aleffandro Taffoni of Modena, born in 1488, made a compilation of the different annals of that city, publifhed in Muratori's Collection of Italian hiftorians.

TASSOW, in *Geography*, a town of Moravia, in the circle of Iglau; 30 miles S.E. of Iglau.

TASSU, a town of Perfia, in the province of Adirbeitzan; 60 miles W. of Tauris.

TASTATURA, Ital., the whole range or fet of keys, in an organ, harpfichord, virginal, fpinet, clavichord, or piano-forte. The term is naturally formed from *tafto*, *a touch*, or *key*. The Italians, we believe, call the fingerboard of the lute, guitar, viols, and all ftringed inftruments with a neck that is fretted, the *taftatura*.

TASTE, Savour, a fenfation excited in the foul by means of the organ of tafte, *viz.* the papillæ of the tongue, &c.

Dr. Grew, in a lecture on the diverfity of taftes, before the Royal Society, diftinguifhes them into *fimple* and *compound*. By *fimple* taftes he underftands fuch as are fimple modes of tafte, although mingled with others in the fame thing: thus, the tafte of a pippin is aci-dulcis; of rhubarb, amar-aftringent, and therefore compounded, in both; but yet in the pippin the acid is one fimple tafte, and the fweet another, as diftinct as the bitter and aftringent are in the rhubarb.

Two faults, he obferves, have here been committed: the firft, a defective enumeration of fimple taftes; the fecond, a reckoning of them indiftinctly among fuch as are compounded.

Simple taftes, of which we ufually only reckon fix or feven forts, are at leaft fixteen: 1. *Bitter*, as in wormwood; whofe contrary is, 2. *Sweet*, as in fugar. 3. *Sour*, as in vinegar; whofe contrary is, 4. *Salt*. 5. *Hot*, as in cloves; to which is oppofed, 6. *Cold*, as in fal prunellæ; for we may as properly fay a cold tafte as an hot one, fince there are fome bodies which do manifeftly imprefs the fenfe of cold upon the tongue, though not to the touch. 7. *Aromatic*; to which is contrary, 8. *Naufeous*, or malignant. 9. *Soft*, which are either vapid, as in water, ftarch, whites of eggs, &c. or unctuous, as in oils, fat, &c. 10. *Hard*, of which he reckons four kinds. 11. *Penetrant*, which worketh itfelf into the tongue without any pungency; as is found in the root and leaves of the wild cucumber. 12. *Stupefacient*, as in the root of black hellebore, which, being chewed, and for fome time retained upon the tongue, affects that organ with a numbnefs, or paralytic ftupor. 13. *Aftringent*, as in galls. And, 14. *Pungent*, as in fpirit of fal armoniac; which two laft taftes he makes contrary to the unctuous, as penetrant and ftupefacient are contrary to the vapid one.

The

The *compound* taftes are very numerous; but we have words to exprefs but fix of them: 1. *Auftere*, which is aftringent and bitter, as in the green and foft ftones of grapes. 2. *Acerb*, properly fo called, which is aftringent and acid, as in the juice of unripe grapes. 3. *Acrid*, which is pungent and hot. 4. *Muriatic*, which is falt and pungent, as in common falt. *Lixivious*, which is faltnefs joined with fome pungency and heat. 6. *Nitrous*, which is faltnefs joined with pungency and cold.

Tafte conftitutes one of the moft obvious characters of bodies, and much is to be judged from it of the nature of many things. Dr. Abercromby, in a treatife partly written on this fubject, has carried his obfervations fo far, as to lay down a fet of rules for the judging of any plant, or other body, without knowing what it is, merely from its tafte, in regard to its virtues in medicine.

In order to judge of what he exprefsly means by the names of the feveral taftes, it is proper to add the lift of them, with fome of the things to which they are applied.

Plants, fruits, &c. are either four as the common forrel, harfh as the medlar, auftere or rough as the quince, fweet as the frefh juice of ripe grapes, fat and oily as the fefamum, bitter as gentian or the wild cucumber, falt as common fea-falt, tart as garlic, or, laftly, infipid as the gourd, or of fome mixed taftes, made of two or more of thefe.

The harfh or acerb things are cold, repelling, and binding, hardly concocted, and they may all be known upon the tongue by their contracting or drying it. The auftere or rough things differ from thefe only in degree, as being fomewhat milder in tafte, and weaker in virtues.

The four or acid things are always cooling; but this never to excefs, by reafon of their penetrating parts: this tafte is known by a biting on the tongue, but without any heat. Sweet things are all nutritive; and taking the word in its proper fenfe, they only have this quality. Their fweetnefs arifes from their neither being too hot nor too cold upon the tongue.

Fat things are moderately hot, and, on this account they all, in fome degree, moiften and relax; but they alfo obftruct: they are known from the fweet things by filling, and, as it were, anointing the tongue, without giving that fenfe of pleafure that the others do.

Salt things are aftringent and deterfive; the one quality they have from their earthy part, the other from their watery.

Bitter things may be very beneficial to the ftomach; but, in improper cafes, they may alfo do hurt. The pungent bitters, fuch as the elaterium, or wild cucumber, are all hurtful, unlefs rendered fafe by other means.

Tart things are hot, and often bad for the head, but good in heavy and phlegmatic conftitutions: they are known by their heat in the mouth.

Laftly: infipid things in general have no peculiar quality, but are cold and watery; they are generally hurtful to the ftomach, unlefs mixed with hotter and fpicy things. Abercromb. Nov. Medic. Clavis.

It is obferved by fir John Floyer, that the tafte is fo good a judge for us, that all the chemical principles in plants may be difcovered by it, before their diftillation. All watery plants fhew their phlegm, as well to the tafte as by diftilling; and in all dry woods, the tafte difcovers the earth they contain, as well as a chemical analyfis; by the mucilaginous and gummy tafte, and by the manifeft oilinefs in fome plants, we diftinguifh their abounding in oil as well as by the retort. The fmell alfo helps us greatly in an extemporary judging of plants, and we are able to declare upon the fpot, that all the aromatic plants, and all the fetid ones, contain a large quantity of a volatile oil and falt. By the acrimony and pungency, we are well affured that there is a volatile falt in plants; and by the burning tafte of others, we find that there is a corrofive falt in them. By a crude rough acidity, we diftinguifh the tartar or effential falt of plants to be in large quantity; but if the acidity be of a vinous fmell, we obferve that it is of a middle ftate of digeftion, and may be called a vinous tartar, and diftinguifhed from the firft; but if the tartar have a pungent fmell, then it is evidently a volatile tartar, or an acid acrid tartar.

The fweet taftes are more numerous in plants, and more varied among themfelves than any other kind. Thefe, in general, fhew their oil by thin flimy fmoothnefs, and their tartar is evident in their extracts, as is very plain in the common liquorice-juice.

The grafs-fweets, as the common dogs-grafs, and the like, have much effential falt, and a moderate portion of oil; and the rufh, reed, horfe-tail, and cats-tail, are all fweet and rough; fome of thefe have more oil, and others more acid; and the moft crude among them have more oil than tartar. The corn-fweets, as barley, rye, wheat, oats, millet, and rice, have much oil and effential falt, and a little volatile; fo bread, prepared of any of thefe, yields, on analyfis, oil and effential and volatile falt.

It is to be obferved here, that fermentation and fire feverally produce a volatile falt, where it was not before, by fubtilizing and volatilizing the effential falt; and the flimy mealinefs in corn fupplies the oil. The goats-beard and fcorzonera-kind have the fame principles as the graffes, much oil and effential falt. The fub-acrid fweets, as rampions, campanulas, trachelia, and the like, contain much oil and effential falt; but the acrimony in thefe plants fhews that they have alfo a volatile falt, and that in no fmall quantity; though Lemery, and the other chemical writers, have not obferved this.

The ferns, polypodies, and all that clafs of plants, contain much oil and effential falt; but the chemifts in general have omitted to mention an acrid principle in all thefe, which befpeaks a volatile falt; and fragrancy is obferved in fome of the harts-tongues, which befpeaks a volatile falt alfo, and volatile oil, though hitherto unobferved.

All the leguminous flimy fweets have more oil than tartar; but all of them have a large quantity of both. Beans, peas, and lentils, have alfo a volatile falt, as has alfo that ftrange fruit, eaten in Ruffia, and fome other places, and called *lenticula aquatica* by fome; but by the botanical writers, *tribulus aquaticus;* the other name belonging to the common duck-weed. The aromatic legumens, fuch as melilot, have an exalted oil, and volatile falt. The honey-fuckle is faid by Lemery, and the other chemifts, only to have an effential falt and oil; but as there is a highly aromatic flavour, and great acrimony, there muft be alfo a volatile falt.

Thefe are fome few inftances, out of a vaft number recited by the author, for the reft of which we refer to the paper itfelf in N° 280 of the Tranfactions. Philof. Tranf. N° 299, p. 1160. See Tasting.

Taste is alfo ufed, in a figurative fenfe, for the judgment and difcernment of the mind.

We talk, and we hear every day of tafte, of good tafte, and of bad tafte, and yet without well underftanding what we mean by the word: in effect, a good tafte feems to be little elfe but right reafon, which we otherwife exprefs by the word judgment.

To have a tafte, is to give things their real value, to be touched with the good, to be fhocked with the ill; not to be dazzled with falfe appearances; but, in fpite of all colours,

lours, and of every thing that might deceive or amuse, to judge soundly.

Taste and judgment then should be the same thing; and yet it is easy to discern a difference: the judgment forms its opinions from reflection; the reason, on this occasion, takes a kind of circuit to arrive at its end; it supposes principles, it draws consequences, and it judges; but not without a thorough knowledge of the case: so that after it has pronounced, it is ready to render a reason of its decrees. Taste observes none of these formalities; before it has time to consult, it has taken its resolution: as soon as ever an object is presented to it, the impression is made, and the sentiment formed; and we ask no more of it. As the ear is wounded with an harsh sound, as the smell is soothed with an agreeable odour, before ever the reason has meddled with those objects, to judge of them; so the taste is struck at once, and prevents all reflection.

Reflections may come afterwards to confirm this taste, and discover the secret reasonings of its conduct; but it was not in its power to wait for them. Frequently, it happens not to know them at all; and what pains soever we use, we cannot discover what it was that determined it to think as it did.

This conduct is very different from that which the judgment observes in its decisions; unless we choose to say, that good taste is, as it were, a first motion, or a kind of instinct of right reason, which hurries us on with rapidity, and conducts us more securely than all the reasonings we could use. It is a first glance of thought, which discovers to us the nature and relation of things, as it were, by intuition.

In effect, taste and judgment are one and the same thing, one and the same disposition and habitude of the soul, which we call by different names, according to the different manners in which it acts: when it acts by sensation, by the first impression of objects, we call it taste; and when by reasoning, after having examined the thing by all the rules of art, &c. we call it judgment: so that one may say, taste is the judgment of nature, and judgment is the taste of reason.

Good taste, as defined by Madem. Scudery and Madem. Dacier, in an express treatise "Of the Corruption of Taste," is an harmony between the mind and reason; and a person has more or less of this taste, as that harmony is more or less just.

One might, perhaps, improve on this hint, and say, that good taste is nothing else but a certain ratio or relation between the mind, and the objects presented to it. Right reason cannot but be moved and affected with things conformably to it, and wounded by those contrary: there is, then, a kind of sympathy, which unites them as soon as ever they meet; and at their union, their good understandings discover each other.—Make a fine discourse; use only the richest and noblest expressions; if they contain an unhappy thought, or an incoherent reasoning, that thought, this reasoning, will immediately be felt by a person of taste: and the antipathy will shew itself by a movement of aversion, as sudden, as lively, and as natural, as that which nature inspires us withal for toads or spiders.

The term *taste*, used generally, is equivocal, and is used in at least three distinct acceptations. It sometimes means that peculiar mode of sensation, which resides in the tongue and palate; sometimes, the power of discrimination in the fine arts, or the feeling associated with it; sometimes, in a sense derived from the latter, it means liking or opinion in general.

It has been a subject of much controversy, whether taste, in the second sense, as we use the term in this article, be a distinct faculty, or merely a mode of judgment. The fact seems to be, says an anonymous writer, that pleasurable emotions are excited by certain objects or conceptions, and that, when we embody our feelings in words, we use expressions of comparison, and reference to a standard, as in other propositions. Feeling and judgment therefore concur; but to which the word *taste* should be peculiarly applied, it is not easy to determine. The primary sense of the word, and of its equivalents in modern languages, seems to imply the former, as the word *criticism* manifestly refers to the latter meaning.

Dr. Gerard, in his ingenious and elaborate "Essay on Taste," observes, that a fine taste is neither wholly the gift of nature, nor wholly the effect of art. It derives its origin from certain powers natural to the human mind, but these must be assisted by culture, in order to attain their full perfection. Taste, according to this writer, consists chiefly in the improvement of those principles, which are commonly called the powers of imagination, and are considered by modern philosophers as internal or reflex senses, supplying us with finer and more delicate perceptions, than any which can be properly referred to our external organs. The simple principles of taste are the senses of novelty, of sublimity, of beauty, of imitation, of harmony, of ridicule, and of virtue. Any one of the internal senses, existing in vigour and perfection, forms a particular branch of taste, and enables a man to judge in some one subject of art or genius; but all of them must at once be vigorous, in order to constitute taste in its just extent. Taste will also derive considerable assistance from another principle, distinct from all the internal senses; and this is such a sensibility of heart or delicacy of passion, as fits a man for being easily moved, and for readily catching, as by infection, any passion that a work is fitted to excite, to which we might add the influence of casual associations on taste. Moreover, the most complete union of the internal senses is not of itself sufficient to form good taste, even though they be attended with the greatest delicacy of passion. They must be aided with judgment, the faculty which distinguishes things different, separates truth from falsehood, and compares together objects and their qualities.—Good sense is an indispensible ingredient in true taste, which always implies a quick and accurate perception of things as they really are; and, as the poet observes,

"Is, though no science, fairly worth the seven."

Taste, like every other human excellence, is progressive and improveable: and goodness of taste lies in its maturity and perfection; consisting, as Dr. Gerard says, in certain excellencies of our original powers of judgment and imagination combined. These may be reduced to four, *viz.* sensibility, refinement, correctness, and the proportion or comparative adjustment of its separate principles. All these must be in a considerable degree united, in order to form true taste. And this excellence of taste supposes not only culture, but culture judiciously applied. Want of taste unavoidably springs from negligence; false taste from injudicious cultivation. Sensibility of taste, we are told, depends very much on the original construction of the mind, and is less improveable by use than any other of the qualities of good taste. Refinement or elegance of taste is chiefly owing to the acquisition of knowledge, and the improvement of judgment. Refinement of taste exists only, where to an original delicacy of imagination, and natural acuteness of judgment, is superadded a long and intimate acquaintance with the best performances of every kind. And as sensibility of taste disposes us to be strongly affected with whatever beauties or faults we perceive; and refinement of taste

makes

makes us capable of discovering both, even when they are not obvious; so correctness of taste prevents our being imposed upon by false appearances, and either approving shining faults, or condemning chaste virtues, and enables us to assign to every quality its due proportion of merit or demerit: thus distinguishing the various kinds, and measuring the different degrees of excellence and faultiness. The last finishing and complete improvement of taste, result from the due proportion of its several principles, and the regular adjustment of all its sentiments, according to their genuine value, so that none of them may engross our minds, and render us insensible to the rest. This due proportion of the principles of taste pre-supposes the correctness of each, and includes, besides, an enlargement and comprehension of mind. Dr. Gerard has also considered, how far taste depends on the imagination, evinced the connection of taste with genius, and the influence of taste on criticism, illustrated the objects and the pleasures of taste, and traced the effects of taste on the character and passions.

> " Ingenuas didicisse fideliter artes,
> Emollit mores, nec sinit esse feros."

Nothing is so improving, says Hume on the subject of delicacy of taste, to the temper, as the study of the beauties either of poetry, eloquence, music, or painting. They give a certain elegance of sentiment to which the rest of mankind are utter strangers. The emotions which they excite are soft and tender. They draw off the mind from the hurry of business and interest; cherish reflection; dispose to tranquillity; and produce an agreeable melancholy, which, of all dispositions of the mind, is the best suited to love and friendship. Besides, a delicacy of taste is favourable to love and friendship, by confining our choice to few people, and making us indifferent to the company and conversation of the greater part of mankind.

Taste, says Gerard, may be conceived as employing itself about nature, art, and science. With regard to nature, which is the common subject of the other two, taste and reason are employed in conjunction: as reason investigates the laws of nature, taste alone discovers its beauties. In art, taste is the ultimate judge, and reason but its minister. Scarcely any art is so mean, or so entirely mechanical, as not to afford subjects of taste. But the finer arts, which imitate the excellencies of nature, supply it with more proper materials; and thence derive their merit. Music, painting, statuary, architecture, poetry, and eloquence, (to which may be added gardening, including the art of improving grounds, and the stage,) constitute its peculiar and domestic territory, in which its authority is absolutely supreme. In science, reason is supreme, but may sometimes reap advantage from using taste as an auxiliary which serves to judge, not only of the manner in which science is communicated, but also of the subject-matter itself.

To this essay of Dr. Gerard are annexed three dissertations on the same subject; one by Voltaire; another by M. D'Alembert, read before the French academy in 1757, and intended to shew the great advantages of philosophy in its application to matters of taste, and to justify it from the accusations that have been brought against it by ignorance and envy; and the third is a fragment of Montesquieu.

We observe, that the arts above enumerated, are distinguished from those that are merely mechanical, as well as from the speculative sciences, by this circumstance; that their main end is neither utility, in the common sense of the word, nor instruction; but to minister to the pleasures of the imagination, by means of words, or of sensible images, or of both of these combined. But their most eminent characteristic, perhaps, which runs through all of them, is, that many of their principles, though in one sense founded upon nature, since their only object is to delight the imagination of men, are not derived from ordinary nature; but require a good deal of attention, and the formation of habits, before they can be relished or understood. When we say, that these eight arts are the proper objects of taste, we do not intimate that their principles are altogether in common; or that he who is thoroughly acquainted, *e. g.* with the theory of painting, will be necessarily a good judge of poetry or architecture; since all of them have many rules originally arbitrary, the accurate knowledge of which has become indispensible to the man of taste; and which, in many cases, suggest pleasures to the imagination, not inferior to those which appear more directly natural. Nevertheless, a man who has applied the accuracy of discrimination, delicacy of feeling, and habitual reference to an original standard, in which the exercise of taste consists, to any one of those arts, can hardly fail, by sufficient attention and experience, to become a judge of all the rest. This observation, however, is liable to some exceptions, particularly in reference to music, which no one whose ear is naturally imperfect, will ever be able to understand. After all it must be allowed by those who maintain the necessity of admitting principles and a standard of taste, that a prodigious difference will be found to remain in the sentiments of mankind, with regard to matters of taste; and this diversity of sentiment in judging concerning the productions of art, may be ascribed to three causes; *viz.* want of feeling, or inability to enjoy, in any great degree, the pleasures of the imagination, as in the instance to which we have above alluded; want of knowledge, because, as the principles of the fine arts are founded partly on general nature, and partly on arbitrary rules, no just judgment can be formed of their general nature without much attention and experience; and the arbitrary rules pertaining to all the arts are numerous and complicated, and easily confounded by unskilful judges; and further, hastiness or precipitance of decision, by which men are often misled. Having already remarked, that the laws of taste are partly natural, and partly arbitrary, we here suggest, that under the former fall, in poetry and eloquence, whatever suggests associations generally delightful and interesting, or awakens sympathies, which the constitution of mankind leads them to feel; in painting, truth of imitation, and forcibleness of expression; in music, gratification of the ear and power over the affections. Under the latter may be reckoned, what is called, style in writing, and the observance of those rules with which critics are conversant, in the other arts. Besides, independently of principles of approbation and disapprobation which exist in the objects of taste, all men are more or less influenced by circumstances peculiar to themselves; and to this class belongs a variety of accidental associations.

A late excellent writer has defined taste to be the power of receiving pleasure from the beauties of nature and of art. Though taste, says this writer, be ultimately founded on a certain natural and instinctive sensibility to beauty, yet reason assists taste in many of its operations, and serves to enlarge its power. In this sense, it is a faculty common in some degree to all men. Quinctilian, however, (Instit. lib. vi. c. 3.) seems to include taste under what he calls *judicium.* The characters of taste, when brought to its most perfect state, are all reducible to two, delicacy, which principally respects the perfection of that natural sensibility on which taste is founded; and correctness, which chiefly respects the improvement that faculty receives through its connection with the

the underftanding: the former of thefe qualities is more the gift of nature; the latter more the product of culture and art. Among the ancient critics, Longinus poffeffed moft delicacy; Ariftotle moft correctnefs. Among the moderns, Mr. Addifon is a high example of delicate tafte; and dean Swift, if he had written on the fubject of criticifm, would perhaps have afforded the example of a correct one. In determining the ftandard of tafte, thofe who fay that nature is this ftandard, lay down a principle very true and juft, as far as it can be applied: neverthelefs, conformity to nature is an expreffion very often ufed, without any diftinct or determinate meaning: in a more clear and precife fenfe, nothing can be confidered as the ftandard of tafte, but the tafte, as far as it can be known, of human nature. That which men concur the moft in admiring, muft be held to be beautiful. His tafte muft be efteemed juft and true, which coincides with the general fentiments of men. In this ftandard we muft reft. To the fenfe of mankind the ultimate appeal muft ever lie, in all works of tafte. But this fenfe is founded on thofe principles of reafon and found judgment, which are applicable to matters of tafte: and yet the ultimate conclufions to which our reafonings lead, refer at laft to fenfe and perception. Accordingly it is obferved, that the difference between the authors who found the ftandard of tafte upon the common feelings of human nature, afcertained by general approbation, and thofe who found it upon eftablifhed principles, which can be afcertained by reafon, is more an apparent than a real difference. For they who lay the greateft ftrefs on fentiment and feeling, make no fcruple of applying argument and reafon to matters of tafte; they appeal to eftablifhed principles, and plainly fhew that the general approbation to which they ultimately recur, is an approbation refulting from difcuffion as well as from fentiment. And they, on the other hand, who, in order to vindicate tafte from any fufpicion of being arbitrary, maintain that it is afcertainable by the ftandard of reafon, admit, neverthelefs, that what pleafes univerfally, muft on that account be held to be truly beautiful: and that no rules or conclufions concerning objects of tafte, can have any juft authority, if they be found to contradict the general fentiments of men.

However, it is not pretended, that there is any ftandard of tafte, to which, in every particular inftance, we can refort for clear and immediate determination. But it is fufficient to conclude, that tafte is far from being an arbitrary principle, which is fubject to the fancy of every individual, and which admits of no criterion for determining whether it be falfe or true. Its foundation is the fame in all human minds. It is built upon fentiments and perceptions, which belong to our nature; and which, in general, operate with the fame uniformity as our other intellectual principles. When they are perverted by ignorance or prejudice, they are capable of being rectified by reafon. Their found and natural ftate is ultimately determined by comparing them with the general tafte of mankind.

The ingenious writer to whom we are indebted for the preceding obfervations, has diftinguifhed between tafte and genius. See GENIUS.

Mr. Alifon has treated the fubject of this article with fo much ingenuity and elegance, in his "Effay on the Nature and Principles of Tafte," that it would be almoft fufficient, without further enlargement, to refer to his excellent performance.

According to this much approved writer, the perception of the qualities that are denominated *beautiful* and *fublime* in the works of nature and art, is attended with an emotion of pleafure, very diftinguifhable from every other pleafure of our nature, and to which is appropriated the name of the "emotion of tafte." Accordingly, the diftinction of the objects of tafte into the *fublime* and *beautiful*, has produced a fimilar divifion of this emotion into the "emotion of fublimity" and the "emotion of beauty." The qualities that produce thefe emotions occur amid every variety of *external fcenery*, and among many diverfities of difpofition and affection in the mind of man. The moft pleafing arts of human invention are altogether directed to their purfuit, and even the neceffary arts are exalted into dignity by the genius that can unite beauty with ufe.

Our author, in his profecution of this fubject, firft inveftigates the nature of thofe qualities that produce the emotions of tafte, and then the nature of the faculty by which thefe emotions are received. He obferves, that the theories which have been formed in relation to this fubject have uniformly taken for granted the *fimplicity* of this emotion, and have referred it to fome *one* principle or law of the human mind; and have therefore concluded, that the difcovery of that *one* principle was the effential key by which all the pleafures of tafte were to be refolved. Thefe theories are arranged, in confequence of the affumption of this fundamental principle, into two claffes of fuppofition: *one*, which reduces the "emotion of tafte" directly into an original law of our nature, which fuppofes a fenfe, or fenfes, by which the qualities of beauty and fublimity are perceived and felt, as their appropriate objects; and hence concludes, that the genuine object of the arts of tafte is to difcover and to imitate thofe qualities in every fubject, which the prefcription of nature has thus made effentially either beautiful or fublime. To this firft clafs of hypothefes belong almoft all the theories of mufic, architecture, and fculpture, the theory of Mr. Hogarth, of the abbé Winkelman, and, perhaps, in its laft refort, alfo the theory of fir Jofhua Reynolds; and of all thofe who attend more to the caufes of thefe emotions, than to their nature. The *fecond* clafs of hypothefes refifts the idea of any new or peculiar fenfe, diftinct from the common principles of our nature; which fuppofes fome *one* known and acknowledged principle or affection of mind to be the foundation of all the emotions we receive from the objects of tafte; and, therefore, refolves all the various phenomena into fome more general law of our intellectual or moral conftitution. Of this kind are the hypothefes of M. Diderot, who attributes all our emotions of this kind to the perception of relation; of Mr. Hume, who refolves them into our fenfe of utility; of the venerable St. Auftin, who, with nobler views, one thoufand years ago, refolved them into the pleafure which belongs to the perception of order and defign, &c. This hypothefis has been adopted by rational and philofophic minds: by thofe who have been led by their habits to attend more to the nature of the emotions they felt than to the caufes which produced them. Mr. Alifon, purfuing an analyfis of the effect which is produced upon the mind, when the emotions of beauty or fublimity are felt, concludes that it is very different from the determination of a "fenfe;" that it is not a fimple but a complex emotion; that it involves, in all cafes, the production of fome fimple emotion, or the exercife of fome moral affection, and the confequent excitement of a peculiar exercife of the imagination; that thefe concomitant effects are diftinguifhable, and very often diftinguifhed in our experience; and that the *peculiar* pleafure of the beautiful and fublime is only felt when thefe two effects are conjoined, and the complex emotion produced.

Our author having inveftigated the caufes which produce this effect, or, in other words, the fources of the beautiful and fublime in nature and art, and having fhewn that there is no no fingle emotion into which thefe varied effects can be refolved; but, on the contrary, that every fimple emotion, and therefore every object capable of producing any fimple emotion, *may be* the foundation of the complex emotion of beauty or fublimity; and that this complex emotion is never produced, unlefs, befides the excitement of fome fimple emotion, the imagination alfo is excited, and the exercife of the two faculties combined in the general effect;—proceeds to fhew what is that "law of mind," according to which, in actual life, this exercife of imagination is excited, and what are the means by which, in the different fine arts, the artift is able to awaken this important exercife of imagination, and to exalt objects of fimple and common pleafure into objects of beauty and fimplicity. In the laft place, he inveftigates the nature of that faculty by which the emotions defcribed by him are perceived and felt. This he fhews has no refemblance to a fenfe; wherever it is employed, two diftinct and independent powers of mind are engaged, fo that it is not to be confidered as a feparate and peculiar faculty, but to be finally refolved into fome general principles of our conftitution. Thefe fpeculations further lead to the important enquiry, whether there is any ftandard by which our fentiments on thefe fubjects may be determined; to an explanation of the means by which tafte may be corrected or improved; and to an illuftration of the purpofes which this peculiar conftitution of our nature ferves; in the increafe of human happinefs, and the exaltation of human character. Our limits will not allow any further abftract or abridgment of this valuable work; and we muft refer thofe readers who wifh to purfue difquifitions of this kind to the work itfelf, in 2 vols. edit. 4, 1815.

We cannot forbear citing fome pertinent remarks, that are prefented to our notice by a living writer of diftinguifhed celebrity, profeffor Dugald Stewart. Tafte, fays this author, is not a fimple and original faculty, but a power gradually formed by experience and obfervation. It implies, as its ground-work, a certain degree of natural fenfibility; but it implies alfo the exercife of the judgment, and is the flow refult of an attentive examination and comparifon of the agreeable and difagreeable effects produced on the mind by external objects. In tracing the progrefs of tafte from rudenefs to refinement, we find an analogy to the progrefs of phyfical knowledge from the fuperftitions of a favage tribe to the inveftigation of the laws of nature, founded on the fuppofition, that, as in the material world there are general facts beyond which philofophy is unable to proceed, fo, in the conftitution of man, there is an inexplicable adaptation of the mind to the objects with which his faculties are converfant, in confequence of which, thefe objects are fitted to produce agreeable or difagreeable emotions. In both cafes, reafoning may be employed with propriety to refer particular phenomena to general principles; but in both cafes, we muft at laft arrive at principles of which no account can be given, but that fuch is the will of our Maker. In matters of tafte it fhould be confidered, that the tendency to cafual affociation is much ftronger than it commonly is, with refpect to phyfical events; and when fuch affociations are formed, they are not fo likely to be corrected by mere experience, unaffifted by ftudy. Hence fome have erroneoufly fuppofed, that affociation is fufficient to account for the origin of the notions we form concerning matters of tafte; and that there is no fuch thing as a ftandard of tafte founded on the principles of the human conftitution. Whenever, fays our author, affociation produces a change in our judgments on matters of tafte, it does fo by co-operating with fome natural principle of the mind, and implies the exiftence of certain original fources of pleafure and uneafinefs. The circumftances which pleafe, in the objects of tafte, are of two kinds: 1ft. Thofe which are fitted to pleafe by nature, or by affociations, which all mankind are led to form by their common condition; and, 2dly. Thofe which pleafe in confequence of affociations arifing from local and accidental circumftances. Hence we derive two kinds of tafte; the one enabling us to judge of thofe beauties which have a foundation in the human conftitution; the other, of fuch objects as owe their principal recommendation to the influence of fafhion. Thefe two kinds of tafte are not always, indeed rarely, united in the fame perfon. The perfection of the one depends upon the degree in which we are able to free the mind from the influence of cafual affociations: that of the other, on the contrary, depends on a facility of affociation, which enables us to fall in, at once, with all the turns of the fafhion, and (as Shakfpeare expreffes it) "to catch the tune of the times." For the author's application of his principles and remarks to the fubject of language, which affords numberlefs inftances to exemplify the influence which the affociation of ideas has on our judgments in matters of tafte, we muft refer to his own valuable work. See Dr. Blair's Lectures on Rhetoric, and Belles Lettres, vol. i. lect. ii. and iii. See alfo Hume's Effay of the ftandard of tafte, in his Effays, &c. vol. i. eff. xxiii. p. 253, edit. 1764. Stewart's Elements of the Philofophy of the Human Mind, part ii. ch. v. § 2. Knight's Analyt. Enq. into the Principles of Tafte, 8vo. 1805. Alifon on Tafte, 2 vols. 8vo. 1815. Edin. Rev. N° XIV.

Taste, in *Mufic*, is often confounded with *graces*, or change of paffages; but a movement compofed in good tafte, is often injured by what are called graces. We rather fuppofe tafte to depend on feeling and expreffion, than in flourifhes, or, as the Italians call them, *riffioramenti*; in forrow, pathos; in joy, brilliancy and fire. Yet when changes and embellifhments are neceffary, good tafte is likewife requifite in their choice and application. The compofer difcovers his tafte by his melodies, as much as the performer by expreffing his thoughts.

Tafte, fays Rouffeau, is of all Nature's gifts the moft eafily felt, and the moft difficult to explain; it would not be what it is, if it could be defined: for it judges of objects beyond the reach of judgment, and ferves, in a manner, as a magnifying glafs to reafon.

There are fome melodies more agreeable than others, though equally well phrafed and modulated; there are combinations in harmony of great effect, and others that excite no attention, all equally regular as to compofition; there is in the texture of the parts, an exquifite art of arranging and fetting off one paffage by another, which depends on fomething more fubtle than the laws of contraft.

Genius creates, but tafte felects. Genius is often lavifh and redundant, and in want of a fevere critic to prevent him from the abufe of his riches. Many great things may be achieved without tafte; but it is tafte that renders them interefting. It is tafte which enables a vocal compofer to feize and exprefs the ideas of the poet; it is tafte which guides the performer to the true expreffion of the compofer's ideas; it is tafte which furnifhes both with whatever can embellifh and enrich the fubject; and it is tafte which enables the hearer to feel all thefe perfections. Tafte is, however, not mere fenfibility. A cold heart may have much tafte; and a man tranfported with things truly fpirited and impaffioned, is little touched by grace and elegance. It feems as if tafte attached itfelf to minute refinements, and fenfibility to grand and fublime effects.

Taste *in finging and playing; Gout du Chant*, Fr. According to Rouffeau, there was, in his time, in France, a perfon person distinct from the music-master, to teach the necessary *agrémens* or graces thought necessary to cover, in some degree, the insipidity of French melody. Most of the young students in music used therefore to have two masters, one for music and one for taste, called *Maitre de Gout-de-chant*.

Gout-de-chant likewise consisted in imitating or *taking-off* the voice and manner of a particular singer; which is always done by exaggeration. The face of a man with a mole or wart upon it, is of great use to a portrait painter in fixing a likeness: so a singer, with a little tendency to nasality, to coarseness, to singing through the throat, or of quivering upon one note in attempting to shake, which the Italians have well denominated *tosse di capra*, a goat's cough, are easily taken off.

TASTINA, in *Ancient Geography*, a town of Asia, in the Greater Armenia, between Surta and Cozala. Ptol.

TASTING, the sense by which we distinguish savours; or the perception which the soul has of external objects, by means of the organs of taste.

Authors differ much as to the organ of tasting. Bauhin, Bartholin, Vestingius, &c. place it in the laxer fleshy parts of the tongue; Dr. Wharton, in the glands at the root of the tongue; Laurentius, in the thin tunic covering the tongue; others in the palate, &c. But the great Malpighi, and after him all the latest writers, place it in the papillæ chiefly lying about the tip and sides of the tongue. See Tongue.

These papillæ arise from the corpus nervosum, which covers the muscular flesh of the tongue; whence, passing through the corpus reticulare, they stand up under the external membrane of the tongue, erect, and covered with vaginæ, or sheaths of the said membrane, to defend them from objects too violent. These vaginæ are porous, and stick out so far, that when the aliment is squeezed, they enter with the same to receive the object, or the matter of taste.

These papillæ Boerhaave conjectures to arise from the ninth pair of nerves; and these, he asserts, are the only organ of taste: the others, whether of the tongue, palate, or jaws, &c. he observes, contribute nothing to them; though probably those of the cheeks next the dentes molares may.

The *object* of tasting, is any thing, either in animals, vegetables, or minerals, from which salt or oils may be extracted.

Tasting, then, is performed by the objects being attenuated and mixed with saliva, warmed in the mouth, and applied to the tongue; where, insinuating into the pores of the membranous vaginæ of the nervous papillæ, and penetrating to the surface of the papillæ themselves, it affects and moves them: by which means a motion is communicated along the capillaments of the nerve to the common sensory, and an idea excited in the mind, of salt, acid, sweet, bitter, hot, aromatic, austere, or the like; according to the figure of the particles that strike the papillæ, or the disposition of the papillæ to receive the impulse.

The taste, considered in a medical view, may be diminished by crusts, filth, mucus, aphthæ, pellicles, warts, &c. covering the tongue: it may be depraved by a fault of the saliva, which, being discharged into the mouth, gives the same sensation as if the food which the person takes had really a bad taste; or it may be entirely destroyed by injuries done to the nerves of the tongue and palate. Few things prove more hurtful, either to the sense of tasting or smelling, than obstinate colds, especially those which affect the head. When the taste is diminished by filth, mucus, &c. the tongue ought to be scraped, and frequently washed with a mixture of water, vinegar, and honey, or some other detergent. When the saliva is vitiated, which seldom happens, unless in fevers or other diseases, the curing of the disorder is the cure of this symptom. To relieve it, however, in the mean time, the following things may be of use: if there be a bitter taste, it may be taken away by vomits, purges, and other things, which evacuate bile: what is called a nidorous taste, arising from putrid humours, is corrected by the juice of citrons, oranges, and other acids: a salt taste is cured by plentiful dilution with watery liquors: an acid taste is destroyed by absorbents, and alkaline salts, as powder of oyster-shells, salt of wormwood, &c. When the sensibility of the nerves, which supply the organs of taste, is diminished, the chewing of horse-radish, or other stimulating substances, will help to recover it.

TASTNESS, in *Geography*, a cape on the N. of the island of Sanday. N. lat. 59° 10′. W. long. 2° 20′.

TASTO, in *Italian Music*, the touch or part of any instrument, whereon, or by means of which its notes are made to sound, be it on the neck, as lutes, viols, &c. which are called fixed and immoveable; or the front of organs, spinets, or harpsichords, where the keys are disposed to raise the jacks, called moveable touches; and is properly no more than the finger-board of each.

Tasto *Solo*. These two Italian words, written over or under a base to solos that are figured, generally at a pause, or preceding a close, imply that the accompanier on a keyed-instrument ought to play no chords with the right hand; but only to strike the base note with the left hand, which is implied by the word *tasto solo*, a single key; or at most to double that sound with the right hand in the octave: as it is hardly possible to divine or figure the harmony of an *ad libitum* or cadence, either written or played extempore, which the composer or the performer is allowed to write or play on these occasions. Solos are now no longer in fashion; but the violin solos of the early part of the last century, by Corelli, Geminiani, Somis, and Tartini, have all closes of this kind, to which the base is confined to a single note, or *tasto solo*.

TATA, or Dotis, in *Geography*, a town of Hungary, built in the midst of water and swamps, with a castle; 20 miles W. of Gran.

Tata *Youba*, in *Botany*, a name used by some for the tree which yields what the dyers call the fustic, or yellow wood used in dyeing.

TATACUL, in *Geography*, a town of Hindoostan, in Mysore; 11 miles N. of Vencatighery.

TATALISGA, a town of Africa, in Galam, on the Senegal; 60 miles W. of Galam.

TATAPARY, a town of Hindoostan, in the province of Tinevelly; 15 miles N.E. of Palamcotta.

TATAPATNAM, a town of Hindoostan, in Baramaul; 22 miles S.S.E. of Darempoury.

TATAR Bassarddscihi, a town of European Turkey, in Romania, on the Mariza; 16 miles N.N.W. of Filippopoli.

Tatar *Bunar*, a town of European Turkey, in Bessarabia; 32 miles S.W. of Akerman.

TATARSKOI, a fort of Russia, in the government of Kolivan, on the E. side of the Irtisch. N. lat. 53° 44′. E. long. 85° 34′.

TATENAGUR, a town of Hindoostan, in the Carnatic; 6 miles S.W. of Devicotta.

TATENAY, the chief town of the island *Gilolo;* which see.

TATH, in *Old Laws*, a privilege which some lords of manors enjoyed, of having their tenants' sheep folded at night

night on their demefne lands, for the improvement of the ground.

TATH, in *Agriculture*, a term applied by ftock-farmers, in fome fituations, to all fuch graffes as are particularly rank and luxuriant, and which have a tendency to induce the rot in fheep.

They commonly diftinguifh two kinds of it; namely, the *water-tath*, which arifes and proceeds from an excefs of moifture; and the *nolt-tath*, which is the produce of dung. The latter, it is faid, is darker coloured than the former; but that their foftnefs, luxuriancy, and tendency to produce the rot in the animals, are nearly the fame. The water-tath is noticed to be the produce of either lands naturally too moift, of wet feafons, of accidental or artificial floodings of them, or of fome other fuch caufes. Nothing is fo apt, it is fuppofed, to produce the rot in thefe animals, as the grafs which grows in low marfhy grounds, in what is called *awald* lands, and that around the heads of fprings, efpecially on the north fide of hills, infomuch fo, indeed, that fuch paftures were formerly confidered as naturally rotten, and of courfe rejected by all intelligent fheep-farmers.

In fhort, wherever a very foft and tender tath fuddenly rufhes up in fheep-pafture lands, there is always much danger of its effects; and as dung greatly promotes the growth of very rank tath, the pernicious confequences of fuch nolt-tath are to be remedied, by not allowing horfes or neat cattle to pafture among the fheep.

TATHAA, in *Geography*, a river of Africa, which runs into the Indian fea, S. lat. 28° 20′.

TATHILBA, in *Ancient Geography*, a town of India, on this fide of the Ganges, which belonged to the Bidamæi. Ptolemy.

TATIAMBETTY, in *Geography*, a town of Hindooftan, in Myfore; 5 miles N. of Wombinellore.

TATIAN, in *Biography*, a native of Affyria, from which circumftance he is fometimes called "the Affyrian," and an ecclefiaftical writer, who, according to Cave, flourifhed about the year 172. He was originally a heathen, and by profeffion a fophift, and teacher of rhetoric. His reading appears to have been extenfive, and he is allowed to have been well acquainted with Grecian literature and philofophy. After his converfion to Chriftianity, he became a difciple of Juftin Martyr, to whom he was attached, and of whom he fpeaks with great refpect. He accompanied this father to Rome, and travelled through different countries with a view to his improvement. But fome time after Juftin's death, which happened about the year 165, he adopted a number of abfurd opinions. Accordingly he is charged, and probably not without reafon, with being the founder of the fect of the Encratites; he condemned the ufe of wine, and denied the lawfulnefs of marriage, the reality of Chrift's fufferings, and the falvation of Adam. He alfo embraced the Æons of Valentinus, and afferted with Marcion, that there are two gods. Eufebius dates his herefy about the twelfth year of the emperor Marcus Antoninus, or the year 172. But however erroneous were his principles in the latter part of his life, his works afford us fatisfactoy evidence of the antiquity and high efteem of the gofpels in his time. After propagating his doctrines for fome time at Rome, he opened a fchool in Mefopotamia, about the year 172: and he is faid to have preached at Antioch, and in fome other places. The place and time of his death are not known. He appears to have written a confiderable number of books, one of which, ftill extant in Greek, and entitled "Oratio ad Græcos," or Oration againft the Gentiles, was either an apology for Chriftianity, or an attack on Heathenifm. This was firft printed at Zurich in 1546, with the Latin verfion of Conrad Gefner. It is annexed to the edition of Juftin Martyr's works, and thofe of other fathers: but the beft edition is that of Worth, Greek and Latin, Oxon. 1700, 8vo. His defign in this work, which difplays great learning, was to prove that the Greeks were not the inventors of any of the fciences, but that they were indebted for their acquaintance with them to thofe whom neverthelefs they denominated Barbarians. This work, according to Brucker, every where breathes the fpirit of the Oriental philofophy, the leading tenets of which he details; and he feems to have adopted feveral of the opinions of Plato, and of the Alexandrian Platonifts, concerning the creation of the world by the Logos, and its animation by a fubordinate fpirit; concerning the exiftence of demons in material vehicles, who occupy the aerial regions, and that of æons, who refide above the ftars. He alfo held with Plato the imperfection of matter as the caufe of evil, and thence he inferred the meritoriounfefs of rifing above corporeal appetites and paffions. Another work of Tatian, cited by St. Clement, was entitled "Perfection according to the Saviour," in which he argued againft marriage. Eufebius cites another work compofed by Tatian, which was a "Book of difficult queftions, for the explication of feveral obfcure places of Scripture." We have alfo in Latin a work afcribed to Tatian, called "Harmony" or "Dia-Teffaron" of the Four. But fome approved writers have doubted whether we have one copy of Tatian's Harmony now extant. Dr. Lardner has inveftigated this fubject with his ufual judgment and impartiality: and he inclines to the opinion, that we are in poffeffion of this work: and he thinks that the commentaries written upon it by Ephrem, the Syrian, afford reafon for concluding that it was not fo contemptible or fo heretical as fome have thought. This Harmony is fhorter than that attributed to Ammonius, and contains a compendious hiftory of our Lord and Saviour Jefus Chrift, taken out of the four Gofpels. It confifts of four parts; the firft is a kind of introduction, containing the hiftory of our Lord's nativity, and the former part of his life; the other three parts are the three years of our Lord's miniftry. Brucker by Enfield. Lardner's Works, vol. ii.

TATIANITES, TATIANITÆ, in *Ecclefiaftical Hiftory*, a fect of ancient heretics; thus called from Tatian, a difciple of Juftin Martyr.

This Tatian, who has the character of one of the moft learned men of all antiquity, was perfectly orthodox during the life of his mafter. He was, like him, a Samaritan, by nation, not by religion, as Epiphanius feems to infinuate. They both belonged to the Greek colonies which were fpread throughout the country of the Samaritans.

Juftin being dead, Tatian is faid by fome to have inclined to many of the errors of the Valentinians; but Mofheim fays, that his doctrine approached nearer to that of the oriental philofophy concerning the two principles. He adds, that it appears from the teftimony of credible writers, that Tatian looked upon matter as the foundation of all evil, and therefore recommended, in a particular manner, the mortification of the body; that he diftinguifhed the creator of the world from the Supreme Being: denied the reality of Chrift's body; and corrupted the Chriftian religion with feveral other tenets of the oriental philofophy. (See the preceding article.) He had a great number of followers, who were, after him, called *Tatianifts*; but were neverthelefs more frequently diftinguifhed from other fects, by names relative to the aufterity of their manners. For as they rejected, with a fort of horror, all the comforts and conveniencies of life, and abftained from wine with fuch a rigorous obftinacy, as to ufe nothing but water, even at the celebration of the Lord's fupper; as they macerated their bodies by continual fafting, and lived a fevere life of celibacy and abstinence; so they were called Encratitæ, or temperate; Hydroparastatæ, or drinkers of water; and Apotactitæ, or renouncers. Mosh. Eccl. Hist. vol. i.

TATIANSKAIA, in *Geography*, a fort of Russia, in the government of Saratov, on the Volga; 12 miles S.E. of Tzaritzin.

TATIEN, a town of Chinese Tartary; 55 miles N.E. of Tam-san.

TATILLUM, in *Ancient Geography*, a town of Africa, in Mauritania Cæsariensis, on the route from Carthage to Cæsarea, between Aræ and Ausa. Anton. Itin.

TATISCHEVA, in *Geography*, a fortress of Russia, in the government of Upha, on the Ural; 28 miles W. of Orenburg.

TATISM KOH, a mountain of Persia, in the province of Irak; 12 miles N. of Com.

TATIUS, ACHILLES, in *Biography*, a Greek writer of Alexandria, is supposed to have lived in the latter part of the third century. He is known to us as the author of a work on the Sphere, of which there remains a fragment, being an introduction to a commentary on the Phenomena of Aratus. A copy of this from a MS. in the Florentine library, by Peter Victorius, was printed. It was afterwards translated into Latin by Petau, under the title of "Isagoga in Phænomena Arati." We learn from Suidas, that Tatius also wrote "Erotics," in which he includes "the Loves of Leucippe and Clitophon." This work is preserved, and affords one of the examples of Greek romance. The Latin version of it was made by Annibal Cruceius, and published at Basil in 1554. The latest edition of this piece is that of Bodem, Greek and Latin, Lipf. 1776, 8vo. It is elegantly written, but of a licentious cast; and hence it has been inferred that the author was a heathen, when he composed it; but Suidas affirms, that he afterwards became a Christian, and attained to episcopacy.

TATNALL, in *Geography*, a county of the state of Georgia.

TATOBIT, a town of Bohemia, in the circle of Boleslau; 5 miles E. of Turnau.

TA-TOU-CHE, a town on the W. coast of the island of Formosa. N. lat. 24° 8′. E. long. 119° 58′.

TA-TSIN, a river of China, which runs into the sea, N. lat. 37° 46′. E. long. 118° 19′.

TATTA, supposed to be at or near the ancient *Pattala*, a town of Asia, which, before the building of Hydrabad, was considered as the chief city of Scind, was founded, according to the tradition of the natives, in the 906th year of the Hegira, and stands on a rising ground, four miles W. of the Indus. It has still a population of 18,000 souls, and is about four miles and a half in circumference. Its wall, constructed for its defence, is now in ruins. The houses of the higher rank are built of bricks, but those of the lower class of wood, plastered with mud. The remains of the mosques, and other handsome edifices of this city, are evidences of its former prosperity; and although on the decline, it enjoys a considerable trade. Its trade is much diminished, on account of the bad government of Scind or Sindy, and the hostile or rapacious disposition of the Seiks, the present possessors of the countries of Moultan and Lahore. The country in the vicinity is a fine rich soil, being watered by canals drawn from the river. Agriculture, however, is much neglected, and the inhabitants of Tatta indicate extreme poverty and wretchedness. To the north of the city is a range of hills, extending several miles in a northerly direction; and to the south is also a range of Table land, reaching almost to the banks of the Indus. Boats trading to Tatta come no farther than Begemah, a village at the distance of about five miles. The river at this place is about a mile in breadth, and four fathoms in depth in the deepest parts. N. lat. 24° 44′. E. long. 68° 17′, as stated in Kinneir's account of Persia; but according to major Rennell, N. lat. 24° 50′. E. long. 67° 37′.

TATTAH, a town of Africa, on the frontiers of Drah and Morocco, in the route from Morocco and Suse to Tombuctoo; 170 miles S.S.E. from Morocco. N. lat. 28° 25′. W. long. 6° 15′. Tattah and its territory contain 10,000 inhabitants. Jackson's Morocco.

TATTAHAR, a town of Bengal; 13 miles N. of Toree.

TATTAMUNGALUM, a town of Hindoostan, in Calicut; 5 miles S. of Palicaudery.

TATTAR. See YOOL.

TATTARAN, a small island in the Sooloo Archipelago. N. lat. 6° 10′. E. long. 121° 58′.

TATTERSHALL, a small market-town in the wapentake of Gartree, Lindsey division of the county of Lincoln, England, is situated on the river Bain, near its junction with the Witham, 9 miles S.S.W. from Horncastle, and 130 miles N. from London. The manor was granted by William the Conqueror to Eudo, one of his Norman followers, whose descendants assumed the name of Tattershall, from this place. Robert Fitz-Eudo obtained a grant from king John, for the inhabitants of the town to hold a weekly market: and another of the family, in the time of Edward III., received the royal licence to erect a castle within his manor of Tattershall. But the present fortress was built by sir Ralph, afterwards lord Cromwell, treasurer of the Exchequer to Henry VI. The castle and manor were granted by Henry VII. to Margaret, countess of Richmond, and entailed on the duke of Richmond; who dying without issue, they were granted by Henry VIII. to the duke of Suffolk; and in the next reign passed to Edward, lord Clinton, afterwards earl of Lincoln. By marriage with an heiress of the Clintons, they are now in the possession of lord Fortescue. The castle stands on a level moor, and is surrounded by two great fosses, the outer one formed of earth, and the inner faced with brick, ten feet deep. It was originally intended as a place of defence, and was progressively raised to great height and extent. In the civil wars it was, however, dilapidated. Till very lately the principal gateway was remaining: the part at present left standing, is a square tower of brick, flanked by four octangular embattled turrets, which are crowned with spires covered with lead. It was divided into four stories. The main walls were carried to the top of the fourth story, where a capacious machicolation surrounded the tower, on which there is a parapet wall of great thickness. This was to protect the persons employed at the machicolations. The tower is constructed upon ponderous groined arches, which support the ground-floor. Near the outer moat stands the parish church, a beautiful and spacious edifice, built in form of a cross. Few churches, perhaps, have suffered more dilapidations than this. It consisted of a nave, having five large arches on a side, and eight clerestory windows, placed in pairs; on each side is a transept, and a magnificent choir. The windows of the latter were glazed with stained glass, which was removed, by a late earl of Exeter, to the chapel of Burleigh, on condition that he replaced it with plain glass, which could have been done for the sum of forty pounds; but this being neglected, the inside has suffered greatly from the weather; although the walls, roof, and pavement remain almost entire. The ruined screen and stalls of wood, richly carved, are almost rotten: behind it is a stone screen, in the arches of which are painted figures. The body of the church and transepts had their windows richly adorned with the legendary histories hiftories of Romifh faints. Before the altar lay two rich brafs figures of Ralph, lord Cromwell, who died in 1455, and of Margaret his wife, who died in 1453. This nobleman, in the feventeenth year of Henry VI., obtained a licence to make the church of Tatterfhall collegiate, for a mafter or warden, fix priefts, fix fecular clerks, and fix chorifters. He alfo founded, near the church-yard, an hofpital or almshoufe, for thirteen poor men and women. At the diffolution, the collegiate revenues were granted to Charles, duke of Suffolk. The hofpital ftill remains, with a fmall endowment. The population report of the year 1811, ftated that Tatterfhall contained 506 inhabitants, occupying 105 houfes. The market is held on Tuefdays, and there are three fairs annually.—Beauties of England and Wales, vol. ix., Lincolnfhire, by J. Britton, F.S.A. Hiftory, &c. of Tatterfhall, with plates, 8vo. 1801.

TATTICOMBA, a town of Hindooftan, in Myfore; 4 miles N. of Dindigul.

TATTO, Ital. from *Tactus*, Lat. in *Mufic*, implies a meafure, or bar, the period when the hand or foot is beaten down in marking the time. See TACTUS, and BATTUTA.

TAT-TOO, *q. d. Tap-to*, a beat of a drum, at night, to advertife the foldiers to retreat, or repair to their quarters in a garrifon, or to their tents in a camp. See RETREAT.

TATTOOING, in *Modern Hiftory*, a name given at Otaheite, and other iflands of the South fea, to the operation of ftaining the body. For this purpofe they prick the fkin, fo as juft not to fetch blood, with a fmall inftrument, fomewhat in the form of a hoe, or blade of a faw: that part which anfwers to the blade is made of a bone or fhell fcraped very thin, and from a quarter of an inch to an inch and a half wide: the edge is cut into fharp teeth or points, from the number of three to twenty, according to its fize. When this is to be ufed, they dip the teeth into a mixture of a kind of lamp-lack, formed of the fmoke that rifes from an oily nut which they burn inftead of candles, and water, or charcoal-duft diluted with water; the teeth, thus prepared, are placed upon the fkin, and the handle to which they are faftened, being ftruck by quick fmart blows, with a ftick fitted for the purpofe, they pierce it, and at the fame time carry into the puncture the black compofition, which leaves an indelible ftain. This operation is performed upon the youth of both fexes, when they are about twelve or fourteen years of age, in feveral parts of the body, and in various figures, according to the fancy of the parent, or perhaps the rank of the party. The women are generally marked with this ftain in the form of a Z, in every joint of their fingers and toes, and frequently on the outfide of their feet: the men are alfo marked with the fame figure; and both men and women have fquares, circles, crefcents, and ill-defigned reprefentations of men, birds, or dogs, and various other unintelligible devices, impreffed upon their legs and arms. But the part on which thefe ornaments are lavifhed with the greateft profufion is the breech; this, in both fexes, is covered with a deep black; above which, arches are drawn over one another, as high as the fhort ribs. Thefe are often a quarter of an inch broad, and the edges are indented. Thefe arches are exhibited, both by the men and the women, with fingular oftentation. The face in general is left unmarked. Some old men had the greateft part of their bodies covered with large patches of black, deeply indented at the edges, like a rude imitation of flame. It is only at New Zealand, and in the Sandwich iflands, that they tattoo the face. There is alfo this difference between the two laft, that, in the former, it is done in elegant fpiral volutes, and in the latter, in ftraight lines, croffing each other at right angles. The hands and arms of the women are very neatly marked, and they have among them a fingular cuftom, the meaning of which could not be learned, that of tattooing the tip of the tongues of the females. This cuftom of tattooing, it is apprehended, is frequently defigned as a fign of mourning on the death of a chief, or any other calamitous event. Perfons of the loweft clafs are often tattooed with a mark, that diftinguifhes them as the property of the feveral chiefs to whom they belong. Hawkefworth's Voyages, vol. ii. p. 189. Marchand's Voyage, vol. i. p. 99. Cook's Third Voyage, vol. iii. p. 155.

TATTUBT, anciently TADUTTI, in *Geography*, a town of Algiers, formerly a confiderable city, now almoft completely in ruins: fome beautiful granite pillars were dug up fome years ago, and placed in a mofque at Conftantina; 25 miles S. of Conftantina.

TATU, in *Ancient Geography*, an ifland fituated in the Nile, in the vicinity of the town of Meroe. Pliny.

TATU, in *Zoology*, the Brafilian name for the armadillo, or fhell-hedge-hog, or *dafypus* of Linnæus. See DASYPUS.

TATU-*Apara*, the name of a creature of the armadillo kind, being the three-banded or *tricinctus dafypus* of Linnæus. See DASYPUS.

This animal burrows under ground, keeps its hole in the day, and rambles out at night: when it would fleep, or when it is afraid of being taken up, it contracts its cruft into a round figure; and hiding its whole body within, it might fooner be taken for a fea-fhell than a land-animal. It is hunted with little dogs, feeds on potatoes, &c. drinks much, grows very fat, and is reckoned delicious eating when young, but when old, has a mufky difagreeable tafte; breeds every month, and brings four at a time. Ray and Pennant.

TATU-*Muftelinus*, the *Weafel-headed Armadillo*, the name of a fmall animal of the armadillo kind. This is the *dafypus unicinctus* of Linnæus, and banded armadillo of Pennant: it has a very flender head, fmall erect ears, the cruft on the fhoulders and rump confifting of fquare pieces; eighteen bands on the fides; five toes on each foot; length from nofe to tail about fifteen inches; the tail five and a half. It inhabits South America. Ray, Pennant, and Grew's Muf. Reg. Soc. p. 19.

TATU-*Paba* of Brafil, is the fix-banded dafypus of Linnæus, having the cruft of the head, fhoulders, and rump, formed of angular pieces, and between the bands, and alfo on the neck and belly, a few fcattered hairs; the tail thick at the bafe, tapering to a point, and not fo long as the body, and five toes on each foot. It inhabits Brafil and Guiana. Pennant.

TATU-*Porcinus*, the name of the pig-headed armadillo, or nine-banded dafypus of Linnæus, with long ears, cruft on the head, fhoulders, and rump, marked with hexangular figures; the nine bands on the fides diftinguifhed by tranfverfe cuneiform marks; breaft and belly covered with long hairs; four toes on the fore-feet, and five on the hind; the tail taper, and a little longer than the body; and length of the whole animal three feet. This animal inhabits South America: and one, that was brought into England a few years ago from the Mofquito fhore, was fed with raw beef and milk, but refufed our grains and fruit. Pennant.

TATUETE, the name of a fpecies of tatu, or armadillo, being the nine-banded dafypus of Linnæus, though Buffon and Pennant afcribe to it only eight bands; it has upright ears, two inches long; fmall black eyes; four toes on the fore-feet, and five on the hinder ones; the length from nofe to tail about ten inches, the tail nine: it is of an iron colour on the back, and whitifh at the fides; its belly alfo is whitifh and naked, except for a few hairs. It inhabits Brafil.

The

The flesh of this is accounted more delicious than that of any other creature of this kind, though they may all be eaten. Ray and Pennant.

TATULA, in *Botany*, a name used by Clusius, and some other authors, for the stramonium, or thorn-apple.

TATZO, in *Geography*, a town of Hungary; 40 miles E. of Munkacz.

TAU, in our *Ancient Customs*, signifies a cross.

"Tradendo dicto comiti Thau eboreum." So Mr. Selden, in his notes upon Eadmerus, p. 159. "Ego Eadgisa prædicti regis ava hoc opus egregium crucis Taumate consolidavi." See Mon. tom. iii. p. 121.

Tau, in *Entomology*, a species of beetle. See Scarabæus.—Also, a species of *Phalena bombyx*.—Also, a species of *Musca*.

Tau, or *Taw*, in *Heraldry*, an ordinary, in figure of a T, supposed to represent St. Andrew's cross, or a cross potence, the top part cut off.

It is thus called from the name of the Greek T, *tau*.

Tau, in *Ichthyology*, a species of *Gadus;* which see.

TAUA, in *Ancient Geography*, a town of Egypt, and the metropolis of the nome Phthemphthus. Ptol. and Steph. Byz.—Also, a town of Asia, between Namaris and Augara. Ptol.—Also, a gulf of the isle of Albion, on the south-eastern coast. This estuary is the firth of Tay.

Taua, in *Geography*, a town of Egypt; 12 miles S. of Denutar.

TAVACCARÆ, in the *Materia Medica*, the name by which many authors call the *coccus Maldiviæ*, or Maldive nut.

TAUAG, in *Geography*, a town of Persia, in Farsistan; 39 miles S.E. of Bender-Rigk.

TAVAI, an island in the Indian sea, near the coast of Siam, about 20 miles long and 3 broad. N. lat. 13°. E. long. 97° 52'.

Tavai, a town of Asia, in Lower Siam; 148 miles S. of Martaban. N. lat. 14° 10'. E. long. 98° 12'.

Tavai *Point*, the extreme point of a tract of land on the coast of Lower Siam. N. lat. 13° 40'. E. long. 98°.

Tavai or *Tovy Poenammoo*, the southernmost of the two islands into which New Zealand is divided by Cook's strait, which is for the most part mountainous and apparently barren, and in this respect of a less favourable aspect than the other island, or *Eaheinomauwe;* which see. The straits, which are about four or five leagues broad, were discovered by Capt. Cook at the close of the year 1769. The islands are situated between the latitudes of 34° and 48° S., and between the longitudes of 181° and 194° W. Tavai-Poenammoo is said to be 500 miles long from S.W. to N.E., and from 55 to 140 broad. See *New* Zealand.

TAVANAGUROY, a town of Hindoostan, in Mysore; 13 miles W. of Colar.

TAVARADO, a town of Portugal, in the province of Beira; 7 miles W.S.W. of Montemor o Velho.

TAVARES, a town of Portugal, in the province of Beira; 13 miles E. of Viseu.

TAVASTLAND, a province of Sweden, bounded on the N. by East Bothnia, on the E. by Savolax or the government of Kuopio, and the Russian government of Viborg, on the S. by Nyland, and on the W. by the government of Abo, or Finland Proper; about 150 miles in length from N. to S., and from 35 to 100 in breadth from E. to W. The country is very fertile, and consists of fine plains, watered by a great number of rivers and lakes, which abound in fish. It is diversified with arable and meadow lands; so that with respect to these natural advantages, it may not only be looked upon as the best part of Finland, but is indeed scarcely surpassed in those particulars by any province in Sweden. It is likewise stored with cattle, fish, and all sorts of game. But notwithstanding this country is so fertile, it is far from being well cultivated; and, consequently, the peasants are generally very poor. Sometimes, indeed, the corn is much damaged by keen and unexpected frosty nights. The northern part of Tavastland is more mountainous and woody than the southern. In the morasses and uncultivated sandy wilds, a ferruginous earth is dug up, from which the Eisensand ertz, or iron sandy ore, as it is called, is prepared. The inhabitants subsist by agriculture, grazing, and breeding of cattle, and some of them are employed in the fisheries. They also traffic in corn, peas, beans, flax, hemp, dried fish, cattle, leather, tallow, butter, lime, the bark of trees, &c.

TAVASTHUS, or Kroneborg, a town of Sweden, and principal place in the province of Tavastland, built in the year 1650, on a pleasant spot, by count Pehr Brahe, and endowed with considerable privileges. In 1713, this town was taken by the Russians; and in the last war between them and the Swedes, it was laid in ashes. The castle, which, exclusive of the town, is properly called "Tavasthehus," or "Tavasteborg," is well fortified, and serves for an arsenal and royal magazine; 80 miles N.N.E. of Abo. N. lat. 61° 1'. E. long. 24° 15'.

TAVAVIS, or Thaouaouis, a town of Asia, in Grand Bucharia; 15 miles N.E. of Bucharia.

TAUBATE', a town of Brasil; 130 miles W. of Rio Janeiro.

TAUBE, Frederick William *Von*, LL.D., in *Biography*, was the son of Dr. Taube, physician to queen Caroline, consort of George II., and born in London in the year 1728. After the queen's death, the father settled at Zelle, where he died in 1742; and in the following year his son was entered at the university of Gottingen. Here he assiduously applied to the study of jurisprudence; and before he left the university, being in his 19th year, he published a dissertation "De Differentiis Juris civilis a jure Naturæ," intended to prove that the principles of the Roman, Canon, and German law were contrary to the law of nature, and inconsistent with the rights of man. When he quitted the university, in the year 1747, he travelled into foreign countries, and particularly through some parts of Africa and America. On his return he practised the law at Gottingen, but finding, in consequence of some displeasure which he had excited by the freedom with which he censured the tediousness of law-suits, that he had no prospect of advancement, he removed to Vienna in 1756, where he obtained some preferment in the army. Soon after an engagement in which he was wounded during the seven years' war, he abandoned Lutheranism, and embraced the tenets of the church of Rome, hoping thus to rise in the Imperial service. Having given proof of his talents and fidelity in an honourable office, which he occupied, and being acquainted with the English language, he was appointed secretary to the Imperial ambassador at the court of London, and repaired hither in October, 1763. Here he married a niece of the celebrated Dean Tucker, with whom he lived in habits of intimacy and friendship. In 1766 he returned to Vienna, and was appointed secretary to the council of trade, which was an office of great fatigue, on account of the journies which it obliged him to take to distant places. When this college was dissolved, in 1776, he retired to Brussels. Having fulfilled another confidential commission with which he was entrusted, he returned from Belgrade to Vienna in 1777, and was ennobled by the emperor, and appointed a member of the government of Lower Austria. His health being

being much impaired, required an attention which it did not fuit his inclination or occupation to give it: his diforder, which was an inflammation of the lungs, increafed, and terminated his life in June, 1778, in the 50th year of his age. He was juftly honoured for his integrity, his zeal to ferve his friends, and his liberality. His literary labours evince the extent of his learning and refearches. His principal works are the tract already mentioned; "Thoughts on the prefent State of our Colonies in America, on their Behaviour to the Mother-Country, and on the true Intereft of the Nation in regard of the Colonies," London, 1766; "Hiftorical and Political Sketch of the prefent State of the Englifh Manufactures, Trade, Navigation, and Colonies, &c." 1774, 8vo.; "Hiftory of the Englifh Trade, &c. from the earlieft Periods till the Year 1776, with an authentic Account of the true Caufes of the prefent War with North America," 1776, 8vo.; "J. J. Schetzen's Elements of Geography, improved and enlarged," 1786, 8vo.; "Hiftorical and Geographical Defcription of the Kingdom of Sclavonia and Duchy of Syrmia, &c. in three parts," 1777, 1778; "An Account of various New Difcoveries, made in 1776 and 1777, in Sclavonia, &c. &c." Leipfic, 1777, 4to. He contributed alfo, between the years 1773 and 1778, to Bufching's periodical publications. He alfo communicated to the Royal Society of London "A fhort Account of a particular Kind of Torpedo found in the River Danube, with feveral Experiments on that Fifh," publifhed in the Phil. Tranf. for 1775. Gen. Biog.

Taube, in *Geography*, a river of Weftphalia, which runs into the Aland, near Seehaufen.

TAUBER, a river of Germany, which rifes about eight miles S. of Rotenburg, in Franconia, and runs into the Maine at Wertheim.

Tauber *See*, a lake of Bavaria; 6 miles W. of Berchtefgaden.

TAUCAEL, or Tuchel, a town of Pruffian Pomerelia. This town was taken and burned, in the year 1320, by the Teutonic knights, and afterwards rebuilt; 44 miles S.S.W. of Dantzic.

TAUCHA, a town of Saxony, in the circle of Leipfic. This town was built in the year 1221, by Albert, archbifhop of Magdeburg, afterwards rebuilt, and in the year 1431 deftroyed by the Bohemians and Huffites, when moft of the inhabitants removed to Leipfic; 6 miles N.E. of Leipfic. N. lat. 51° 22′. E. long. 12° 30′.

TAUCHIRÆ, in *Ancient Geography*, a town of Africa, in Libya, belonging to the territory of Barcé, according to Herodotus, afterwards called Arfinoe. M. D'Anville fuppofes that it is the prefent Teukéra.

TAVDA, in *Geography*, a river of Ruffia, which rifes in Pelim lake, and runs into the Tobol, 40 miles S. of Tobolfk.

TAUDECONDA, a town of Hindooftan, in Golconda; 25 miles S.W. of Warangole.—Alfo, a town of Hindooftan, in Dindigul; 7 miles N. of Dindigul.

TAUDENNY, or Tudenny, a Moorifh and Negro town or village, on the borders of the Defart in Africa; at which place are large ponds or beds of falt, which both the Moors and Negroes purchafe, as well as dates and fig-trees of a large fize. The falt-beds are about 5 or 6 feet deep, and from 20 to 30 yards in circumference. The falt comes up in red lumps mixed with earth, and part of it is red; 270 miles N.N.W. of Tombuctoo. N. lat. 21° 15′. W. long. 1° 25′.

TAUDOON, a town of Hindooftan, in Lahore; 34 miles S.S.E. of Nagercote.

TAVE, a river of France, which runs into the Rhone, about 6 miles below Loudon.

Tave, or *Taff*, a river of Wales, which runs into the fea, near Llaugharn.—Alfo, a river, which rifes in two ftreams in the fouthern part of Brecknockfhire, and runs into the Severn below Cardiff.

TAVERA, a town of Corfica, 18 miles N.N.E. of Ajazzo.

Tavera *di Orta*, a town of Naples, in Capitanata; 14 miles S.S.W. of Afcoli.

TAVERNA, a town of Naples, in Calabria Ultra, formerly the fee of a bifhop, transferred to Catanzaro; 15 miles N. of Squillace.

TAVERNER, John, in *Biography*, an eminent mufician, who flourifhed in the early part of the 16th century. He is often mentioned by Morley among our early contrapuntifts, and by Anthony Wood, as having begun his career by being organift of Bofton, in Lincolnfhire. At the eftablifhment of Cardinal college, now Chrift-church, Oxford, by cardinal Wolfey, he was appointed organift there; but narrowly efcaped martyrdom for herefy, having held frequent converfations with fome Lutherans on the abufes of religion. They were all imprifoned in a deep cave under the college, ufed for the keeping of falt-fifh, of which the ftench occafioned the death of fome of them, and fome were burnt in Smithfield.

Taverner had not gone fuch lengths as many of the fraternity; the fufpicions againft him were founded merely on his having hidden fome heretical books under the boards of the fchool where he taught, for which reafon, and on account of his profeffional eminence, the cardinal excufed him, faying "he was but a mufician," and fo he efcaped.

A fet of books containing maffes and motets to Latin words, fome of which were compofed in the time of Henry VII., and all before the Reformation, is preferved in the mufic-fchool at Oxford. Thefe volumes contain compofitions by John Taverner, Dr. Fayrfax, Avery Burton, John Marbec, William Kafar, Hugh Afhton, John Norman, John Sheppard, and Dr. Tye. The pieces by the three or four laft are entered in a more modern hand, with different characters, and paler ink. The chief parts of the compofitions are tranfcribed in a large, diftinct, and fine hand and character; but bars not having been yet introduced, and being all *ad longam*, *alla breve*, or in *tempo di Capella*, the ligatures, prolations, and moods, render thefe books extremely difficult to read, or tranfcribe in fcore. However, by dint of meditation and perfeverance, we arranged the parts under each other, of feveral movements by all thefe founders of our church mufic, particularly John Taverner, Dr. Fayrfax, and Dr. Tye; having fcored an entire mafs by each of them: as they are the moft ancient and eminent of thefe old mafters, in whofe compofitions the ftyle is grave, and harmony, in general, unexceptionable, if tried by fuch rules as were eftablifhed during their time; but with refpect to invention, air, and accent, the two firft are totally deficient.

The compofitions, however, of thefe early Englifh mafters, have an appearance of national originality, free from all imitation of the choral productions of the continent. Few of the arts of canon, inverfion, augmentation, or diminution, were as yet practifed by them: fhort points of imitation are fometimes difcoverable, but they feem more the effects of chance than defign: and to characterife the chief of thefe compofers in the order they have been named; Taverner and Fayrfax have but little defign and no melody in their compofitions; and it feems as if they fhould not have

have been ranked, as they are by Morley, with thofe of a much higher clafs, at a later period.

We can venture to give a character of Taverner, from an actual furvey of his principal works which have been preferved, and which we have taken the pains to fcore. This author is in general very fond of flow notes, fo that all his pieces which we have feen, are *ad longam*, or, at quickeft, *alla breve*. Long notes in vocal mufic, unlefs they are to difplay a very fine voice, have little meaning, and are wholly deftructive of poetry and accent; but our old compofers have no fcruples of that kind; and being as great enemies to *fhort* fyllables, as to *fhort notes*, exercifed the lungs of a finger as frequently upon one as the other.

As the firft effays at harmony were made in extemporary difcant, upon a plain-fong, fo in written counterpoint, it was long a favourite and ufeful exercife, to build the feveral parts of a movement upon fome favourite chant, making it the ground-work of the compofition. And this cuftom anfwered feveral purpofes: it excited ingenuity in the conftruction of the parts; it regulated and reftrained the modulation within the ecclefiaftical limits; and as the plain-fong had been long ufed in the church, by the priefts and people, it was ftill eafy for the mufical members of the congregation, to join the chorus in finging this fimple and effential part, while the chorifters and choirmen by profeffion, performed the new and more difficult melodies, which had been fuperadded to it by the compofer. The firft reformers, or at leaft their followers, who were perhaps no great muficians, wifhed to banifh every fpecies of art from the church; and either retaining fmall portions of ancient chants, or making melodies, in the fame plain and fimple ftyle, for their hymns and pfalms, threw afide all figurative harmony and florid counterpoint; and fung in notes of equal duration, and generally in mere unifon, thofe tunes which are ftill retained by the Calvinifts, and in moft of the reformed churches of Chriftendom. At the latter end of the fifteenth, and during the whole of the fixteenth century, as fome chant or tune was the foundation upon which the harmony of almoft every movement of a mafs or motet was built, the additional parts were the fuperior, medius, countertenor, tenor, to which was given the plain-fong in fquare black notes, of equal lengths to femibreves in alla breve time, and baffes. The clofe or final movement of one of thefe maffes is inferted in Burney's General Hiftory of Mufic, vol. ii. p. 557.

TAVERNES, in *Geography*, a town of France, and chief place of a canton, in the department of the Var, and diftrict of Brignolles. The place contains 1536, and the canton 4529 inhabitants, on a territory of 280 kiliometres, and 9 communes; 3 miles N. of Barjols.

TAVERNIER, John Baptist, in *Biography*, a diftinguifhed traveller, was the fon of a native of Antwerp, and born at Paris in the year 1605. The frequent infpection of the maps and charts fold by his father, infpired him with a paffion for travelling; fo that at the age of twenty-two he had made tours through France, England, the Low Countries, Germany, Switzerland, Poland, Hungary, and Italy. In his bufinefs as a jeweller he was eminently fkilful; and he employed 40 years in fix journies in Turkey, Perfia, and the Eaft Indies, by all the practicable routes. Having acquired great wealth, on his return from his fixth journey in 1668, he determined as a Proteftant to live under a free government; and, with this view, purchafed the barony of Aubonne, near the lake of Geneva. But having fuffered very confiderable lofs of property by the mifconduct of a nephew, he fold his barony in 1687, and commenced a feventh journey, which terminated his life at Mofcow in 1689, at the age of 84. Deftitute of talents for writing, he employed Sam. Chappuzeau of Geneva to arrange his memoirs, which is faid to have been no eafy tafk. The fruit of this labour was given to the public in two volumes, defcribing his fix journies, in 1679; and another was added in 1681, by La Chapelle, containing an account of Japan and Tonquin, with a hiftory of the colony of the Dutch in the Eaft Indies. Thefe memoirs of Tavernier, notwithftanding reflections on his veracity, and charges of plagiarifm, have been often cited as authority by later writers. Gibbon reprefents him as "the jeweller who faw fo much and fo well." Bayle. Moreri. Gen. Biog.

Tavernier *Key*, in *Geography*, a fmall ifland on the north coaft of Cuba, near Tortuga.

TAVERNY, a town of France, in the department of the Seine and Oife; 6 miles E. of Pontoife.

TAVETCH, a community which, with that of Difentis, forms one of the high jurifdictions of the Grey League in Switzerland. Thefe two communities occupy the weftern extremity of the valley of Sopra Selva, ftretching as far as the confines of Uri. Tavetch is a pleafant valley, lying at the foot of the Alps, which feparate the Grifons from the canton of Uri. The villages are numerous, confifting of fcattered cottages chiefly conftructed of wood. This valley produces pafture, hemp, and flax, and a fmall quantity of rye and barley. The trees are chiefly firs and pines, and their number gradually diminifhes towards the extremity of the vale.

TAVETSCHE, a town of the country of the Grifons; 13 miles from Ilantz, the capital.—Alfo, a mountain of the fame country; 5 miles S.W. of Ilantz.

TAUFFERS, a town of the county of Tyrol; 6 miles S.S.W. of Glurentz.

TAUGHT, or Tau't, *Tight*, in the *Sea Language*, denotes the ftate of being extended or ftretched out. Thus they fay, *fet taught* the fhrouds, the ftays, or any other ropes, when they are too flack and loofe.

TAVI, in *Geography*, a town of Sicily, in the valley of Noto; 7 miles N.E. of Caftro Giovanni.

TAVIANO, a town of Naples, in the province of Otranto; 11 miles W.N.W. of Alefano.

TAUJEPOUR, a town of Bengal; 60 miles S.S.W. of Calcutta. N. lat. 21° 52′. E. long. 87° 45′.—Alfo, a town of Bengal; 32 miles E. of Purneah. N. lat. 25° 48′. E. long. 88° 11′.—Alfo, a town of Hindooftan, in Bahar; 15 miles N. of Chuprah. N. lat. 26° 2′. E. long. 84° 50′.

TAVIGNANO, a river of Corfica, which runs into the fea, 15 miles S. of Cervione.

TAUILA, a town of Arabia, in the province of Yemen; 24 miles W. of Tana.

TAUILE, a town of Egypt, on the Nile; 2 miles N. of Manfora.

TAVIRA, or Tavila, a fea-port town of Portugal, in the province of Algarve, furrounded with walls, and defended by a caftle; the harbour is protected by two forts. It contains two churches, an hofpital, five convents, and about 5000 inhabitants; 111 miles S.S.E. of Lifbon. N. lat. 37° 7′. W. long. 7° 35′.

TAVISTOCK, an ancient borough and market-town, in a hundred of the fame name, in the county of Devon, England, is fituated on the banks of the river Tavy, 34 miles W.S.W. from Exeter, and 206 miles in the fame bearing from London. Its origin and growth feem to have arifen from the foundation and eftablifhment of a magnificent abbey in the tenth century, by Ordgar, earl of Devon, and his

his son Ordulph. Within thirty years after its foundation, this abbey was burnt by the Danes, but was soon afterwards rebuilt, and became more flourishing than before. By a charter granted by Henry I., it appears that he bestowed "the jurisdiction, and the whole hundred of Tavistock," upon the abbey, together with the privilege of a weekly market, and a three-days' fair. This charter is recited and confirmed by one granted 21 Edw. III. The riches of the abbey progressively increased; and Richard Barham, the thirty-fifth abbot, obtained from Henry VIII. the privilege of sitting in the house of peers, or, in other words, was mitred. His patent was dated January 23d, 1513; but the honour continued only till the year 1539, when John Peryn, the thirty-sixth abbot, surrendered the abbey to the crown, and had a pension of 100*l. per annum*. The possessions of the abbey, with the borough and town of Tavistock, were given by the king to John, lord Russel, whose descendant, the present duke of Bedford, is now proprietor. Various fragments of the abbey still remain, but are, for the most part, incorporated with other buildings. The abbey church is described by Leland as 126 yards in length; the cloisters as extensive; and the chapter-house as a most magnificent structure: but all these have long since been completely demolished. Several buildings, that seem to have belonged to the abbey, are now used for warehouses; and adjoining to the principal inn is a large, handsome, arched gateway, ornamented with lofty pinnacles, apparently of the time of Henry VI. The town of Tavistock is large and populous; but the streets are narrow, and indifferently paved; and many of the houses have an appearance of age. The river is here crossed by two bridges, and after storms of rain, by flowing over various ledges and masses of rock, presents a very tumultuous spectacle. The church is a spacious edifice, consisting of four aisles, a chancel, and a tower at the west end, raised on arches. Within the church are preserved some human bones of a gigantic size, which were found in a stone coffin, dug out of the ruins of the abbey, and are said by tradition to be those of Ordulph, whom William of Malmsbury represents of such immense stature, that he could stride over rivers ten feet wide! Tavistock is a borough by prescription, and has sent two members to parliament from the 23d year of Edward I. The right of election is in the freeholders resident in the borough. The town is one of the stannaries of Devonshire, but does not appear to have been incorporated. It is governed by a portreve, who is elected annually at the court of the lord of the manor. The population of the parish, according to the return of the year 1811, amounted to 4723; the number of houses to 514. Many of the inhabitants are employed in the manufacture of serges for the East India Company. Five fairs are held annually, and a weekly market on Saturdays. An institution for the study of Saxon literature existed in Tavistock at a very early period, and lectures were read in that language in a building purposely appropriated, and called the Saxon school. These lectures were discontinued about the time of the reformation. Several of the abbots were learned men; and the encouragement they gave to literature is evident, by the establishment of a printing-press in the abbey within a few years of the time when the art was brought into England. Among the books that issued from this press was Walton's translation of "Boethius de Consolatione," "emprented in the exempte Monastery of Tavestoke in Denshyre, by me Dan Thomas Rychard, monke of the said Monastery," 1525, 4to.; and the "Confirmation of the Tynners Charter," 26th of Henry VIII., 16 leaves, 4to. Bishop Gibson also mentions a Saxon Grammar as having been printed here about the commencement of the civil wars; but this assertion is supposed by other antiquaries to be unfounded.

Among the more eminent natives of Tavistock was sir Francis Drake, one of the most distinguished seamen that Britain ever produced, and the first Englishman that circumnavigated the globe.

Morwell-house, about three miles from Tavistock, was the hunting-seat of the abbots of Tavistock; and from its situation near Morvel-down, and the woods on the banks of the Tamar, was well adapted for this purpose. Its form is quadrangular, with a large arched gateway in front, ornamented in a similar manner to those of the abbey. The vaulted ceiling of this entrance has several coats of arms sculptured in moor-stone. At a little distance is Morwell-rock, which rises almost perpendicularly to an immense height from the bed of the Tamar.

About four miles north of Tavistock is Bren-Tor, a vast mass of craggy rock, which shoots up from the road between Tavistock and Lydford, and becomes a very conspicuous sea-mark to mariners in the British Channel, though more than 20 miles distant. The summit is frequently enveloped in clouds, but in fair weather commands an extensive prospect, and the ships in Plymouth harbour may be distinctly seen from its summit. Near the top is the parish church of the little village of Brent, which, like most of the churches in similar situations, is dedicated to St. Michael. On Dartmoor, about three miles east of Tavistock, are several masses of rock, and also the remains of Druidical circles and avenues.—Beauties of England and Wales, vol. iv. Devonshire, by J. Britton and E. W. Brayley.

TAVIUM, or TAVIA, in *Ancient Geography*, a town of Asia, in Galatia, and capital of the Trocmi, according to Ptolemy, Strabo, and Pliny.

TAULACUM, in *Natural History*, a name given by the people of the East Indies to a species of orpiment, which is very common with them.

It is of a dirty yellow colour, and is composed partly of an irregular mass, partly of fine flakes, like scales of fishes. These are of the best colour. The whole mass, on being exposed to the fire, burns, and emits copious fumes; but it does not melt readily. After it has been several times calcined, the Indians give it internally in intermittent fevers, with safety and success. Woodw. Catal. Foss. vol. i. p. 24.

TAULE', in *Geography*, a town of France, in the department of the Finisterre; 3 miles N.W. of Morlaix.

TAULE, a town of Hindoostan, in Mysore; 47 miles E. of Seringapatam.

TAULIGNAN, a town of France, in the department of the Drôme; 12 miles S.E. of Montelimart.

TAUMACO, a town of Greece, in the province of Thessaly; 18 miles N.W. of Zeiton.

TAUMAGO, an island in the Pacific ocean, discovered by Quiros, in 1606; about 24 or 25 miles in circumference. The island abounded with bananas, cocoa-trees, and palms: it produces also sugar-canes, and many kinds of nutritious roots. The fleet here obtained, without difficulty, refreshments, water, and wood, of which it stood in great need. The Spaniards lived on good terms with the natives, who were eager to procure them all the assistance that their island afforded; nor was peace infringed till the very moment of their departure. Thinking that it would be of service in the remainder of their voyage, to have some Indians on board, who might act as guides or interpreters, the Spaniards seized four whom they carried on board by force. Their chief was soon informed of it, and came to demand them in the most earnest manner; but they were refused, and

and war was inſtantly declared. A fleet of canoes came out to attack the Spaniſh ſhips, which their fire-arms quickly diſperſed, and would totally have deſtroyed, had not theſe brave iſlanders, with all their courage, been ſenſible of their inferiority. S. lat. 10°. E. long. 169° 25′.

TAUME, a river of England, which riſes in the county of York, and runs into the Merſey, in Lancaſhire, oppoſite Stockport.

TAUNA, a town of Egypt, on the Bahir Joſeph, or Canal of Joſeph, which forms a communication between the Nile and the Birket el Kerum; 5 miles S.W. of Aſhmunein.

TAUNDA, a town of Hindooſtan, in Oude; 50 miles S.E. of Fyzabad. N. lat. 26° 32′. E. long. 82° 53′.

TAUNNA, a town of Hindooſtan, in Oude; 30 miles W. of Lucknow.

TAUNT, a ſea-term, ſignifying high or tall. When the maſts of a ſhip are too tall for her, the ſailors ſay, ſhe is *taunt-maſted*.

TAUNTON, in *Geography*, a conſiderable market-town and borough, in the hundred of Taunton-Dean, county of Somerſet, England, is ſituated on the high road between Bath and Exeter, 52 miles S.W. from the former city, 32 miles N.E. from the latter, and 144 W. by S. from London. It was anciently called Thonodunum, or the Town of the Tone, by which river it is watered. Taunton is unqueſtionably a place of remote antiquity: from the diſcovery of coins and other relics, there is reaſon to ſuppoſe it was not unknown to the Romans; but it is certain it was of great note in the time of the Saxons. For Ina, a Weſt-Saxon monarch, built a caſtle here for his reſidence in the year 700, which was deſtroyed in 722 by his queen Ethelburga, who prevailed on him to reſign the crown, and retire to a monaſtery. A new caſtle, on the ſcite of the former, was erected by William Giffard, biſhop of Wincheſter in the time of Henry I. By various documents of the biſhops of that ſee, dated Taunton caſtle, it ſeems to have been a place of their frequent reſidence. In 1495 the whole building was repaired, and an embattled gateway built by biſhop Thomas Langton. Though the building has been much modernized, this gateway ſtill remains. Conſiderable improvements were made in 1577, by biſhop Robert Horn, who likewiſe built the great hall as it now ſtands, in which the aſſizes, county ſeſſions, and biſhop's courts are held: it is 119 feet in length, 30 in width, and 20 in height. The other apartments are applied to various public uſes. The whole caſtle occupied a front of 195 feet, with a circular tower at each end, of which only one is now remaining. Taunton had a diſtinguiſhed ſhare in the various civil commotions of this kingdom: in the conteſts of the Saxon kings; in the civil wars between the houſes of York and Lancaſter; and in the inſurrection in favour of Perkin Warbeck, in Henry VII.'s reign. In the civil wars of Charles I., it became an object of vigorous ſtruggle between the royal and parliamentary forces which ſhould poſſeſs its fortreſs, it being conſidered as the key to the weſt of England. It was alſo deeply involved in the rebellion of the duke of Monmouth, who here aſſumed the title of king, and was publicly proclaimed.

The town of Taunton, in point of ſize, buildings, and reſpectability of inhabitants, may vie with moſt cities. It contains two pariſhes, extends nearly a mile from eaſt to weſt, and conſiſts of four principal ſtreets, which are well built, and of commodious width. Though ancient and populous, it was not incorporated till the reign of Charles I., 1627. It did not long enjoy this privilege; for Charles II., on his reſtoration, out of reſentment for the town's adherence to the parliament againſt his father, deprived it of its charter. It continued disfranchiſed 17 years, when the king granted it a new charter. The corporation conſiſts of a mayor, recorder, a juſtice of the peace, two aldermen, ten capital, and ten inferior burgeſſes. The juſtice is always the laſt mayor, who, with the two aldermen, are annually elected out of the capital burgeſſes; and the vacancies occaſioned by this election are filled up from the inferior members of the corporation. The officers are a town-clerk, two ſerjeants at mace, a bell-man, and a beadle. There are acting under the mayor, and ſworn in by him, two conſtables and ſix tything-men or petty conſtables, who, with two portreves and two bailiffs, are annually choſen by a jury, and are, properly ſpeaking, the officers of the biſhop of Wincheſter, in whoſe court they are elected. The mayor's officers cannot arreſt within the borough; and there being no priſon, except a kind of town-bridewell called the Nook, debtors are ſent to the county gaol at Ilcheſter. Though the town has for ages been flouriſhing, and of great importance in the county, yet the corporation has neither land, houſes, nor joint ſtock in money; their charter excluding them from ſuch poſſeſſions.

Taunton is an ancient borough by preſcription, and has returned two members to parliament from the year 1294, 23 Edward I. The right of election is veſted in a deſcription of people called pot-wablers, or pot-wabloners. Theſe are all ſuch inhabitants as reſide within the borough, and boil their own pots, provided they are not paupers, and have not received relief from the fund of any charity within a year. The number of voters is eſtimated at about 500. The bounds of the borough, to which the right of election is limited, are ſmall in proportion to the town, comprehending only a part of the pariſh of St. Mary Magdalen. The principal article of trade in Taunton is the woollen manufacture, which has flouriſhed to a great extent almoſt ever ſince its introduction into England by the famous John Kempe, the firſt manufactory being eſtabliſhed ſo early as the year 1336. Upwards of one thouſand looms are ſaid to have been employed at one time; but the trade is now greatly reduced, and the population decreaſed: houſes in the ſuburbs have fallen to ruin, and have been deſtroyed. A large ſilk manufactory was eſtabliſhed in the year 1780. Two large markets are held on Wedneſday and Saturday, and here are two annual fairs. By the population report of the year 1811, Taunton was ſtated to contain 1371 houſes, and 6997 inhabitants.

The edifices for religious worſhip in this town are two pariſh churches, and five diſſenting meeting-houſes. The church of St. Mary Magdalen is a ſpacious beautiful ſtructure, with a lofty and ſtrong tower of excellent workmanſhip, of the florid ſtyle, having four ſtately pinnacles thirty-two feet high, making the whole height 153 feet. This tower has thirteen handſome windows, with a variety of curious prominent ornaments, that give the whole an air of magnificence, united to a delicate elegance, not to be equalled in the county, nor perhaps in the kingdom. It was probably erected by Henry VII., who, when he came to the crown, rebuilt many of the churches in Somerſetſhire, as a reward of the attachment of the county to the Lancaſtrian party. The inſide of the church is anſwerable to the exterior, and makes a grand appearance. Its curious roof is ſupported by twenty-four pillars, in four rows, dividing it into five aiſles and a chancel. There are forty-four windows, ſome of which have painted glaſs. The other church, St. James's, though every way inferior to the former, is a ſtrong, plain, ancient ſtructure, ſuppoſed to have been built in the 13th century. The meeting-houſes are St. Paul's, and the new meeting,

ing, for Proteſtant diſſenters; one for Baptiſts, one for Quakers, and one for Weſleyan Methodiſts. The buildings for charitable purpoſes are, a free grammar-ſchool, founded by Richard Fox, biſhop of Wincheſter, about the year 1500; two large and well endowed alms-houſes, founded in the 17th century, by Mr. Robert Graye and Mr. Richard Huiſh; two other alms-houſes, on a ſmaller ſcale; two work-houſes; and an hoſpital, the moſt capital of its kind in the county: it is a ſquare ſtructure, 90 feet on a ſide; contrived to admit through every part a free circulation of freſh air; and forming on the whole a commodious receptacle for the diſeaſed. The firſt corner-ſtone was laid by lord North in 1772, and the building was completed in 1774. In the centre of the town is a ſpacious building, erected in 1772, under the ſanction of an act of parliament; the lower part is the market-houſe, over which is the town-hall, where the borough ſeſſions are held.

On the eaſt part of the town was a priory for Black canons, founded in 1127, by biſhop Giffard: at the diſſolution, it was granted to Matthew Colehurſt. A leper-houſe was alſo founded about the year 1280, by Thomas Lambritz; and a houſe of White or Carmelite friars, in 1322, by Walter de Meryet. Both theſe houſes are ſuppoſed to have been private property previous to the diſſolution. —Collinſon's Hiſtory of Somerſetſhire, vol. iii. Toulmin's Hiſtory of the Town of Taunton; 4to. 1791. Maton's Obſervations on the Weſtern Counties of England, vol. ii. 8vo. 1797.

Taunton, a river of Maſſachuſetts, which runs into the ſea at Rhode iſland, N. lat. 41° 24′. W. long. 71° 10′.—Alſo, a town of Maſſachuſetts; 29 miles S. of Boſton. N. lat. 41° 48′. W. long. 71° 2′.—Alſo, a river of America, in the province of Maine, which runs into the ſea near New Briſtol.

TAUNTON-DEAN, a valley of England, extending about thirty miles in length, in the county of Somerſet, of fertility and produce equal to almoſt any in the kingdom. It takes its name from Taunton, the principal town.

TAVOLADOTO, a ſmall iſland near the eaſt coaſt of Sardinia. N. lat. 40° 54′. E. long. 9° 5′.

TAVOLARA, a ſmall iſland near the eaſt coaſt of Sardinia. N. lat. 40° 52′. E. long. 10° 5′.

TAVORA, a river of Portugal, which runs into the Duero, 5 miles N.E. of Lamego.—Alſo, a town of Portugal, in the province of Beira; 6 miles E. of Lamego.

TAVOYVOVEL, a ſmall iſland near the eaſt coaſt of Lewis. N. lat. 58° 6′. W. long. 6° 29′.

TAURAGUR, a town of Hindooſtan, in Lahore; 24 miles W.N.W. of Nogarcot.

TAURASI, a town of Naples, in Principato Ultra; 12 miles S.E. of Benevento.

TAURASIA, in *Ancient Geography*, a town of Italy, in Gallia Tranſpadana.

TAURAT, in *Geography*, a town of the iſland of Cuba; 38 miles N.N.E. of St. Jago.

TAUREA, among the Romans, a puniſhment inflicted by whipping with ſcourges made of bulls' hides.

TAUREAU, in *Geography*, an iſland on the French coaſt, with a fort to defend the harbour of Morlaix.

TAUREE, a town of Bengal; 35 miles S.S.E. of Ghidore.

TAURESIUM, in *Ancient Geography*, a town of European Dardania, on the other ſide of the territory of Duras; the birth-place of Juſtinian, who founded here a magnificent town, called after his own name.

TAURI *liberi libertas*.—In ſome ancient charters, *taurus liber* ſignifies a common bull kept for all tenants within ſuch a manor, or liberty.—"Cum libertate faldiæ, liberi tauri, et liberi apri, &c." See *Free* Bull.

Tauri, in *Ancient Geography*, a people of Sarmatia, in the vicinity of Scythia. According to Herodotus, theſe people had a cuſtom of ſacrificing to Iphigenia, the daughter of Agamemnon, the ſtrangers whom chance threw on their coaſts, and alſo the Greeks who fell into their hands.

TAURIA, Ταυρεια, in *Antiquity*, a feſtival in honour of Neptune. Pot. Archæol. tom. i. p. 432.

Tauria, in *Ancient Geography*, an iſland of the Mediterranean ſea, between New Carthage and Cæſarea of Mauritania. Anton. Itin.

TAURIANA, a town of Italy, in Brutium.

TAURICA Chersonesus. See Chersonesus *Taurica* and Crimea.

TAURIDA, Tauricheskaia, or *province of Tauris*, in *Geography*, a province of Ruſſia, being part of the government of Catherinenſlaf or Ecaterrinenſlaf or Ekaterinoſlav, bounded on the N. by the rivers Dnieper and the Konſkija, on the W. and S. by the Black ſea, and on the E. by the ſea of Azoph. This fertile peninſula, which is the great mart of commerce in the Black ſea, was colonized for the purpoſes of trade by the Greeks, Romans, Genoeſe, occupied by the Turks under Mahomet II., and governed by the khan of the Tartars, a vaſſal to the Porte. On the peace of Kninardi, in 1774, it was declared an independent ſovereignty, taken poſſeſſion of by Catharine II. on the abdication of the khan Salim Gerai, in 1783, and confirmed to Ruſſia by the Porte in the ſame year by the treaty of Conſtantinople. The empreſs revived ſeveral of the ancient Greek names. M. Pallas has exhibited an animated and delightful picture of this province in his account of a journey made in 1794, for which we refer to Tooke's Ruſſia, vol. i. For a farther account of it, ſee Crimea. See alſo Russia.

Taurida, *Mountains of*, are extended and lofty, forming the ſouthern ſide of the province, and the ſhore of the Euxine ſea. The range extends from Theodoſia in a ſtraight line weſtwards, quite up to Balbeck. At Karaſobaſar two towering pinnacles ſhoot up, and at Akmelchat a very elevated one, called Aktau. The ſmaller mountains ſtand diſtinct and ſcattered. It is very probable that this range is partly a continuation of the Caucaſian, and partly of the Carpathian mountains; and that theſe two principal chains are connected by it: which alſo ſeems apparent from the nature and qualities of the mountains oppoſite to thoſe of Taurida, which extend beyond the Danube, through Bulgaria, and are called Pulkanian. The greater part of theſe mountains of Taurida conſiſts of chalk-maſſes with petrifactions, and many beds of ſand and marle, and chalk-hills with flints. Hence it is preſumed that they are not to be claſſed with the original, but only with the alluvial or depoſited mountains. A part of them is thought to owe its origin even to the ſubterranean fires. Whether this be the caſe or not, it is ſaid that lead, copper, and iron ores are found in them, as well as jaſper, agate, and mountain cryſtal. They are very rich in lime-ſtone, marble, ſlate, ſand-ſtone, coals, naphtha, and common ſalt. The iſle of Taman conſiſts merely of beds of ſand and marle, without lime-ſtone. The height of the Taurida mountains is moderate; and they are in a great degree deſtitute of foreſts. The trees that grow upon them are thoſe of the richeſt foliage, ſuch as oak, beech, cheſnut, &c. But what they want in wood is made up very amply by the rich and beautiful herbs of the vallies. The rivers that take their riſe from theſe mountains are the Alma, Katſha, Kabarda, Salgyr, Karuſſu, and many leſſer ſtreams, that form pleaſing natural caſcades.

TAURILIA, among the Romans, games in honour of the infernal gods. They were otherwife called *ludi taurii.*

TAURINIA, in *Ancient Geography*, a town of European Sarmatia, in the peninfula called "Curfus Achillis." Steph. Byz.

TAURIS, in *Geography*. See TABREEZ.

TAURISCI, in *Ancient Geography*, a Celtic people, who were eftablifhed along the Danube. They were feparated from the Scordifci by a mountain called by Pliny Mons Claudius.

TAURO, a town of European Sarmatia, in the peninfula of "Curfus Achillis." Suidas.

TAUROBOLIUM, or TAUROBOLION, among the *Ancients*, facrifices of bulls, which were offered to Cybele, the mother of the gods, to render thanks to the goddefs of the earth, for her teaching men the art to tame thofe animals, and fit them for labour.

The Taurobolium was a kind of facrifice of expiation and purification; of which no trace occurs before the reign of Antonine, and which feems to have terminated under Honorius and Theodofius the younger. It was principally employed in the confecration of the priefts of Cybele.

TAVRO-CASTRO, in *Geography*, a town of Greece, in Livadia; 20 miles N.N.E. of Athens.

TAUROCINIUM, in *Ancient Geography*, a river of Italy, in Magna Græcia; and the people who lived upon its banks in the vicinity of the town of Rhegium, were called Taurocini.

TAUROCOLLA, *Bull-Glue*, a fort of glue much ufed among the ancients in works that required ftrength, being accounted far ftronger than any other kind. It was made by boiling down the ears and genital parts of a bull in water.

TAUROENTUM, in *Ancient Geography*, a colony founded by the ancient Marfeilloife on the fea-fhore, to the right of the entrance into the bay of Ciotat.

TAUROGEN, in *Geography*, a town of Samogitia; 30 miles S.W. of Rofienne.

TAUROMENIUM, in *Ancient Geography*, a town of Sicily. See TAORMINA.

TAUROPOLIA, in *Antiquity*, feafts celebrated in honour of Diana and Apollo, in the Icarian ifles, *viz.* thofe of the Archipelago and of the Ægean fea.

TAUROPOLIAN, in *Ancient Geography*, the name of a temple fituated in the ifle of Samos; dedicated to Artemis, or Diana.—Alfo, a temple dedicated to Diana, in the ifle of Icaria. Strabo.

TAUROPOLIS, a town of Afia Minor, in Caria.

TAURUS, in *Aftronomy*, the *Bull*, one of the twelve figns of the zodiac, and the fecond in order.

The ftars in the conftellation Taurus, in Ptolemy's catalogue are 44; in Tycho's catalogue, 43; in Hevelius's catalogue, 51; in the Britannic catalogue, 141. See CONSTELLATION.

TAURUS, in *Ancient Geography*, a name given by the ancients to a chain of mountains, which commenced in Afia Minor, occupied the northern part of Cilicia, and proceeded to join, towards the north of Syria, mount Amanus; but afterwards the name has comprehended the mountains which reach from the Taurus of the ancients to the fouth of the Cafpian fea.—Alfo, the name of a promontory on the eaftern coaft of Sicily. Ptolemy.—Alfo, a mountain of Scythia. It is a branch of mount Taurus that extends to the environs of the Palus Mæotides and the Cafpian fea. Jornandes.—Alfo, a mountain of Germany, and a mountain of Æthiopia.—Alfo, a place of Paleftine, at the entrance of the town of Jericho.—Alfo, a river of Greece, in the Peloponnefus.—Alfo, a river of Afia, in the vicinity of Pamphylia.—Alfo, the name of one of the three canals by which the town of Alexandria, in Egypt, communicates with the fea.—Alfo, a place of Sicily, 60 ftadia from the town of Syracufe.—Alfo, a marfh of Gallia Narbonnenfis.

TAURUS, in *Geography*, was a general name given by the ancients to any thing of a gigantic nature, and hence it has been applied to a celebrated range of mountains, which is faid to extend from the Grecian Archipelago to the extremities of Afia. By Strabo it is thought to originate in Caria and Pamphylia; and by fome modern geographers, on the coaft of Cilicia, not far from Scanderoon. However this be, it interfects Afia Minor from E. to W., and advancing in a N.E. direction, intercepts the courfe of the Euphrates, and fpreads itfelf over the kingdom of Armenia, where it unites with mount Caucafus. It then detaches a variety of branches into Perfia, of which the moft confpicuous is that named Mont Zagros by the ancients. This long and lofty range formerly divided Media from Affyria, and now forms the boundary of the Perfian and Turkifh empires. It runs parallel with the river Tigris and Perfian gulf, and almoft difappearing in the vicinity of Gombroon, feems once more to rife in the northern diftricts of Kerman, and following an eafterly courfe through the centre of Meckraun and Balouchiftan, is entirely loft in the deferts of Sinde.

TAURUS, in fome *Ancient Cuftoms*, fignifies a hufband.

Leg. H. I. cap. 7. "Videtur autem matris ejus, cujufcunque taurus alluferit."

TAURUS, in *Entomology*, a fpecies of *Scarabæus*.—Alfo, a fpecies of *Cicada*, found in Coromandel.—Alfo, a fpecies of *Cimex*.

TAURUS, in *Ornithology*, a name given by the ancients to the bittern or butter-bump, from its imitating the roaring of a bull in its noife.

TAURUS, in *Zoology*. See BOS and BULL.

TAURUS *Æthiopicus*, the *Æthiopian Bull*, an animal defcribed in a very remarkable manner by Pliny; but fo contrary to the courfe of nature, that we may very juftly rank it among the other extraordinary animals, fuch as the mantichora and the vermis cæruleus, of fixty or feventy feet in length.

TAUSA, in *Geography*, a town of Saxony, in the circle of Neuftadt; 2 miles N. of Ziegenbruck.

TAUSCHELIN, a town of Bohemia, in the circle of Schlan; 10 miles W.N.W. of Schlan.

TAUSCHIN, a town of Bohemia, in the circle of Kaurzim; 7 miles S.E. of Kofteletz.

TAUSEN, JOHN, in *Biography*, called the "Danifh Luther," becaufe he was one of the firft promoters of the reformation in Denmark, was born of parents who were peafants in the ifle of Fyen, in the year 1499. Having finifhed his courfe of education, he became a monk in the convent of the order of St. John of Jerufalem, at Antoorfkow, and here he ingratiated himfelf fo much with the prior, that he obtained a penfion for travelling into foreign countries, on condition that he fhould avoid Wittenberg, which was at that time the focus of herefy. In his progrefs he vifited Louvain and Cologne, where he had an opportunity of perufing fome of the works of Luther, with which he was fo captivated, that he could not refift the inclination of proceeding to Wittenberg, notwithftanding the prior's interdict. In this place he purfued his ftudies under the inftruction of Melancthon with fuch fuccefs, that he was appointed to give public lectures on theology in the univerfity of Copenhagen. In his convent, to which he was foon recalled, he frequently preached; and at length, *viz.* in 1524, publicly avowed himfelf a difciple of Luther. The confequence

quence was his expulſion from the convent at Antoorſkow, and his retirement to another at Wiborg. As he here propagated his doctrine, he was impriſoned by the prior; but by this act of ſeverity he was emboldened to proceed, and preached to the populace from a window. Being liberated in 1526, he was in the ſame year appointed chaplain to the king, and permitted to preach openly at Wiborg. He ſoon acquired a number of followers, who went to church armed, in order to protect him from the violence of the Papiſts. In 1529 he was invited to officiate in the church of St. Nicholas, at Copenhagen; and in the following year he attended, as director, at a conference which took place in that city between the Lutherans and the Roman Catholics. On the death of Frederic I. he was baniſhed from Zealand, but being after a few days invited to return, he was appointed clergyman and lecturer in theology at Roſchkild. In 1542 he was advanced to the epiſcopal chair of Ribe, and died in the year 1561. Tauſen, beſides an improved Daniſh tranſlation of the Pſalms, printed in 1544, and at Copenhagen in 1557, was the author of ſeveral works, conſiſting of Daniſh hymns, and treatiſes on the doctrine of Luther. A full account of his meritorious ſervices may be found in Profeſſor Munter's Hiſtory of the Reformation in Denmark, &c. Gen. Biog.

TAUSS, or Domazlitz, in *Geography*, a town of Bohemia, in the circle of Pilſen; 26 miles S.S.W. of Pilſen. N. lat. 49° 25′. E. long. 12° 52′.

TAUSTE, a town of Spain, in Aragon; 25 miles N.W. of Saragoſſa.

TAUTENBURG, a town and citadel of Saxony, in Thuringia; 3 miles S. of Camburg.

TAUTICA, in *Ancient Geography*, a town of Aſia, in Media.

TAUTOLOGICAL Echoes, are ſuch echoes as repeat the ſame ſound or ſyllable many times. See Echo.

TAUTOLOGY, in *Grammar*, a needleſs repetition of the ſame ſenſe in different words; or, a repreſentation of any thing as the cauſe, condition, or conſequence of itſelf. Of the firſt kind is that of Virgil:

> " ——Si fata virum ſervant, ſi veſcitur aura
> Ætherea, neque adhuc crudelibus occubat umbris."

Such alſo is this of Addiſon:

> " The dawn is overcaſt:—the morning lours;
> And heavily in clouds brings on the day." Cato.

Here the ſame thought is repeated thrice in different words.

It is alſo conſidered as of the nature of tautology, to lengthen a ſentence by coupling words altogether or nearly ſynonimous, whether they be ſubſtantives or adjectives, verbs or adverbs. This is a very common fault, and to be found even in our beſt writers. It ſhould ever be remembered, as an invariable maxim, that words which add nothing to the ſenſe or to the clearneſs, muſt diminiſh the force of the expreſſion. There are two occaſions, however, on which ſynonimous words may be properly uſed. One is, when an obſcurer term, which we cannot avoid employing, on account of ſome connection with what either precedes or follows, needs to be explained by one that is clearer: the other is, when the language of the paſſions is exhibited. Paſſion dwells on its object; the impaſſioned ſpeaker always attempts to riſe in expreſſion; but when that is impracticable, he recurs to repetition and ſynonymy, and thus produces in a degree the ſame effect. An adjective and its ſubſtantive will ſometimes include a tautology. Moreover, in ſome ſingle words, there is ſo much the appearance of tautology, that they ought, in proſe at leaſt, to be avoided; ſuch are worſer for worſe, leſſer for leſs, chiefeſt for chief, extremeſt for extreme; Moſt Higheſt, as in the liturgy, for Moſt High. Campbell's Philoſophy of Rhetoric, vol. ii.

TAUVES, in *Geography*, a town of France, in the department of the Puy de Dôme; 15 miles W. of Beſſe.

TAUVO, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 64° 50′. E. long. 24° 31′.

TAVY, a river of England, which riſes in Devonſhire, paſſes by Taviſtock, &c. and joins the Tamar, two miles below Saltaſh.

TAUZIM. See Teusing.

TAW, a river of England, which riſes about three miles S.E. from Oakhampton, and runs into the Briſtol channel below Appledore, forming a large bay at its mouth, called Barnſtaple bay.

Taw, a town of Pruſſia; 23 miles W.S.W. of Tilſit.

TAWALLY, one of the Molucca iſlands, 25 miles long from north to ſouth, and from 5 to 9 broad. S. lat. 0° 21′. E. long. 127° 14′.

TAWANDEE Creek, a river of Pennſylvania, which runs into the E. branch of the Suſquehanna, N. lat. 41° 45′. W. long. 76° 30′.

TAWARRAN, a town on the N.W. coaſt of the iſland of Borneo. N. lat. 6° 9′. E. long. 116° 15′.

TAWAS, Indians in the Ohio, on the river Miami of the Lake.

TAWEE-TAWEE, an iſland in the Sooloo Archipelago, 30 miles long, and from 3 to 10 broad. N. lat. 5° 15′. E. long. 120°.

TAWING, Skinning, the art or manner of preparing or dreſſing ſkins in white, to fit them for uſe in divers manufactures, particularly for gloves, &c.

All kinds of ſkins may be tawed; but it is chiefly thoſe of ſheep, lambs, kids, and goats, that are uſed to be dreſſed this way, as being thoſe fitteſt for gloves.

Method of tawing or dreſſing Skins in White.—The wool or hair being well got off the ſkins by means of lime, &c. (as deſcribed under the article Shammy,) they are laid in a large vat of wood or ſtone, ſet in the ground, full of water, in which quick-lime has been ſlaked; in this they continue a month or ſix weeks, as the weather is more or leſs hot, or as the ſkins are required to be more or leſs ſoft and pliant.

While in the vat, the water and lime are changed twice, and they are taken out and put in again every day. When taken out for the laſt time, they are laid all night to ſoak in a running water, to get out the greateſt part of the lime; and in the morning they are laid ſix together on the wooden leg, to get off the fleſh by ſcraping them ſtoutly, one after another, on the fleſh-ſide with a cutting two-handed inſtrument, called a knife; and while this is in hand, they cut off the legs, and other ſuperfluous parts about the extremes.

This done, they are laid in a vat or pit with a little water; where, being well fulled with wooden peſtles for a quarter of an hour, the vat is filled up with water, and the ſkins are rinſed in it. They are next thrown on a clean pavement to drain; which done, they are caſt into a freſh pit of water, where being well rinſed they are taken out, and laid on the wooden leg ſix at once, with the hair-ſide outermoſt, over which they rub a kind of whetſtone very briſkly, to ſoften and fit them to receive four or five more preparations given them on the leg, both on the fleſh-ſide and the hair-ſide, with the knife, after the manner above-mentioned.

They are then put into a pit with water and wheat-bran, and ſtirred about in it with wooden poles, till the bran is perceived

perceived to ſtick to them, and then are left. After this, as they riſe of themſelves to the top of the water by a kind of fermentation, they are plunged down again to the bottom, and, at the ſame time, fire is ſet to the liquor, which takes as eaſily as if it were brandy, but goes out the moment the ſkins are all covered.

This operation is repeated as often as the ſkins riſe above water; and when they riſe no more, they are taken out, laid on the wooden leg, the fleſh-ſide outermoſt, and the knife is paſſed over it to ſcrape off the bran. The bran thus cleared, the ſkins are laid in a large baſket, where they are loaded with huge ſtones to promote their draining; and when ſufficiently drained their feeding is given them, which is performed after the following manner: For 100 large ſheep-ſkins, and for ſmaller in proportion, they take eight pounds of alum and three of ſea-ſalt, melt the whole with water in a veſſel over the fire, pouring the ſolution out, while yet lukewarm, into a kind of trough, in which are 20 pounds of the fineſt wheat-flour, with eight dozen yolks of eggs; of all this together is formed a kind of paſte, a little thicker than children's pap, which, when done, is put into another veſſel, to be uſed in manner following.

A quantity of hot water being poured into the trough in which the paſte was prepared, two ſpoonfuls of the paſte are mixed with it; in order to which they uſe a wooden ſpoon, which contains juſt what is required for a dozen ſkins; and when the whole is well diluted, two dozen of the ſkins are plunged into it, care being taken by the way, that the water be not too hot, which would ſpoil both the paſte and hurt the ſkins. Having ſtaid ſome time in the trough, they are taken out one after another with the hand, and ſtretched out; this is repeated twice; when they have all had their paſte, they are put into tubs, where they are fulled afreſh with wooden peſtles.

Then they are put into a vat, where they remain five or ſix days or more, and are at laſt taken out in fair weather, and hung out to dry on cords or racks; the quicker they dry the better, for if they be too long in drying, the ſalt and alum within them are apt to make them riſe in a grain, which is an eſſential fault in this kind of dreſſing.

When the ſkins are dry, they are put up into bundles, and juſt dipt in fair water; from which being taken out and drained, they are thrown into an empty tub, and, after ſome time, are taken out, and well trampled under foot.

They are then drawn over a flat iron inſtrument, the top of which is round, like a battledore, and the bottom fixed into a wooden block, to ſtretch and open them: when opened, they are hung in the air upon cords to dry; and when dry they are opened a ſecond time, repaſſing them over the ſame inſtrument.

Laſtly, they are laid on a table, pulled out and laid ſmooth, and are thus in a condition for ſale and uſe.

After the ſame manner are dreſſed horſes', cows', calves' ſkins, &c. for the ſadlers, harneſs-makers, &c., as alſo dogs', wolves', bears' ſkins, &c. excepting that in theſe the uſe of paſte is omitted, ſalt and alum-water being ſufficient. See Tanning.

By ſtat. 9 Ann. c. 11. and 10 Ann. c. 26. the following duties are impoſed on hides or ſkins tawed or dreſſed in Great Britain. For horſe-hides dreſſed in alum and ſalt, or meal, or otherwiſe tawed, 1*s.* 6*d.* a hide; hides of ſteers, cows, and all other (except horſe-hides) dreſſed in alum and ſalt or meal, or otherwiſe tawed, 3*s.* a hide; calve-ſkins and kips, dreſſed in alum and ſalt or meal, or otherwiſe tawed, $1\frac{1}{2}$*d.* a pound; ſkins ſo dreſſed or tawed with the hair on, 3*s.* a dozen, and without hair, 1*s.* a dozen; dog-ſkins ſo dreſſed or tawed, 1*s.* a dozen; buck and doe-ſkins (except what paid the duty on importation) dreſſed in alum and ſalt or meal, or otherwiſe tawed, 6*d.* a pound; kid-ſkins ſo dreſſed or tawed, except as before, 1*s.* a dozen; goat-ſkins ſo dreſſed or tawed, 2*s.* a dozen; beaver-ſkins ſo tawed, 2*s.* a dozen; ſheep-ſkins and lamb-ſkins ſo dreſſed or tawed, $1\frac{1}{2}$*d.* a pound; and all other tawed ſkins, not before charged, 30*l.* for every 100*l.* value. All theſe duties are to be paid by the tawers or makers.

For hides and ſkins dreſſed in oil, 6*d.* a pound; deer, goat, and beaver-ſkins dreſſed in oil, 6*d.* a pound; calve-ſkins dreſſed in oil, 8*d.* a pound; ſheep and lamb-ſkins dreſſed in oil, 3*d.* a pound; all ſkins dreſſed in oil, not before charged, 15*l.* in the 100*l.* according to the real value; all which are to be paid by the oil leather-dreſſers.

For other regulations, ſee Leather and Tanner.

TAWIXIWI, in *Geography*, a town of America, on the Miami. N. lat. 40° 35′. W. long. 84° 4′.

TAWY, in *Geography*, a river of South Wales, which riſes in Brecknockſhire, and runs into the ſea at Swanſea.

TAX, formed from τάξις, *order*, denotes a certain aid, ſubſidy, or ſupply, granted by the commons of Great Britain in parliament aſſembled, conſtituting the king's extraordinary revenue; and paid yearly towards the expences of the government. See Money-*Bills*, Parliament, and Supply.

Anciently, the tax ſeems to have been impoſed by the king at his pleaſure; but Edward I. bound himſelf, and his ſucceſſors, from that time forward, not to levy it, but by conſent of the realm.

To this purpoſe the celebrated Mr. Locke, in his "Eſſay on Government," (ch. xi. § 140.) lays down the following propoſition as fundamental. "'Tis true, government cannot be ſupported without great charge; and 'tis fit every one who enjoys his ſhare of protection, ſhould pay out of his eſtate his proportion for the maintenance of it. But ſtill it muſt be with his own conſent, *i. e.* the conſent of the majority, giving it either by themſelves, or their repreſentatives choſen by them: for if any one ſhall claim a power to lay and levy taxes on the people by his own authority, and without ſuch conſent of the people, he thereby invades the fundamental law of property, and ſubverts the end of government. For what property have I in that, which another may by right take when he pleaſes to himſelf?"

Dr. Adam Smith, the ingenious author of "An Enquiry into the Nature and Cauſes of the Wealth of Nations," to whoſe work we have had occaſion to refer, lays down (vol. ii. p. 2.) the four following maxims with regard to taxes in general. "1. The ſubjects of every ſtate ought to contribute towards the ſupport of the government, as nearly as poſſible, in proportion to their reſpective abilities, that is, in proportion to the revenue which they reſpectively enjoy under the protection of the ſtate. 2. The tax, which each individual is bound to pay, ought to be certain, and not arbitrary. The time of payment, the manner of payment, the quantity to be paid, ought all to be clear and plain to the contributor, and to every other perſon. When it is otherwiſe, every perſon ſubject to the tax is put more or leſs in the power of the tax-gatherer, who can either aggravate the tax upon any obnoxious contributor, or extort, by the licence of ſuch aggravation, ſome preſent or perquiſite to himſelf. 3. Every tax ought to be levied at the time, or in the manner, in which it is moſt likely to be convenient for the contributor to pay it. 4. Every tax ought to be ſo contrived, as both to take out and to keep out of the pockets of the people as little as possible, over and above what it brings into the public treasury of the state." This maxim may be counteracted by requiring for the levying of the tax a great number of officers, whose salaries may consume the greater part of the produce of the tax, and whose perquisites may impose another tax upon the people;—by obstructing their industry, and discouraging them from applying to certain branches of business, which might give maintenance and employment to great multitudes;—by the forfeitures and other penalties which those unfortunate individuals incur, who attempt unsuccessfully to evade the tax, which may ruin them, and thus put an end to the benefit the community might have received from the employment of their capitals; the penalties of smuggling being so ordered as to rise in proportion to the temptation; and by subjecting the people to the frequent visits and the odious examination of the tax-gatherers, which occasion much trouble, vexation, and oppression.

As the private revenue of individuals arises ultimately from the three different sources of rent, profit, and wages, every tax must finally be paid from one or other of these three different sorts of revenue, or from all of them indifferently. The first kind of taxes comprehends those upon the rent of land. (See LAND-TAX.) Taxes upon the produce of the land are in reality taxes upon the rent. (See TITHES.) Taxes upon the rent of houses include that which may be called the Building rent, and that which is commonly called the Ground rent; and so far as these fall upon the inhabitants, they must be drawn from the same source as the rent itself, and must be paid from their revenue, whether derived from the wages of labour, the profits of stock, or the rent of land; and it is in every respect of the same nature as a tax upon any other sort of consumable commodities. Houses not inhabited ought to pay no tax; houses inhabited by the proprietor ought to be rated, not according to the expence which they might have cost in building, but according to the rent which an equitable arbitration might judge them likely to bring, if leased to a tenant. Ground rents are still a more proper subject of taxation than the rent of houses, or even the rent of land. The principal objection to all taxes upon houses and windows is their inequality, and therefore they are directly contrary to the first of Dr. Smith's maxims above stated. Their natural tendency is to lower rents.

Taxes upon profit, or upon the revenue arising from stock, comprehend the tax upon stock, such as is imposed by the land-tax in England, by which it was intended that the stock should be taxed in the same proportion as the land, and taxes upon the profit of particular employments. Taxes upon the wages of labour must finally fall upon the consumer. Besides the taxes already enumerated, there are others, such as capitation taxes, and taxes upon consumable commodities, which must be paid indifferently from whatever revenue the contributors may possess; from the rent of their land, from the profits of their stock, or from the wages of their labour. The impossibility of taxing the people, in proportion to their revenue, by any capitation, seems to have given occasion to the invention of taxes upon consumable commodities; and these are either necessaries or luxuries. A tax upon the necessaries of life operates exactly in the same manner as a direct tax upon the wages of labour, and will fall, if the labourer be employed by a manufacturer, on the consumer; or if he be employed by a farmer, it will fall upon the rent of the landlord. But it is otherwise with respect to taxes upon luxuries. The rise in the price of the taxed commodities, will not necessarily occasion any rise in the wages of labour. Any rise in the average price of necessaries, unless it is compensated by a proportionable rise in the wages of labour, must necessarily diminish more or less the ability of the poor to bring up numerous families, and consequently to supply the demand for useful labour; whatever may be the state of that demand, whether increasing, stationary, or declining; or such as requires an increasing, stationary, or declining population.

Taxes upon luxuries have no tendency to raise the price of any other commodities except that of the commodities taxed. Taxes upon necessaries, by raising the wages of labour, necessarily tend to raise the price of all manufactures, and consequently to diminish the extent of their sale and consumption. Taxes upon luxuries are finally paid by the consumers of the commodities taxed, without any retribution. They fall indifferently upon every species of revenue, the wages of labour, the profits of stock, and the rent of land. Taxes upon necessaries, so far as they affect the labouring poor, are finally paid, partly by landlords in the diminished rent of their lands, and partly by rich consumers, whether landlords or others, in the advanced price of manufactured goods; and always with a considerable over-charge.

In Great Britain, the principal taxes upon the necessaries of life are those upon salt, leather, soap, and candles. Heavy taxes upon these commodities must somewhat increase the expence of the sober and industrious poor, and must, consequently, more or less raise the wages of their labour. Such taxes, notwithstanding their immediate effect, afford a considerable revenue to government, and accordingly they are continued and multiplied.

Consumable commodities, whether necessaries or luxuries, may be taxed in two different ways. The consumer may either pay an annual sum on account of his using or consuming goods of a certain kind; or the goods may be taxed while they remain in the hands of the dealer, and before they are delivered to the consumer. The consumable goods which last a considerable time before they are consumed altogether, are most properly taxed in the one way. Those of which the consumption is either immediate or more speedy, in the other.

Of the latter kind is the greater part of the duties of excise and customs. Those of excise are imposed chiefly upon goods of home produce destined for home consumption; and they are imposed only upon a few sorts of goods of the most general use. The duties of customs are much more ancient than those of excise. (See CUSTOMS and EXCISE.) It is observed that high taxes, sometimes by diminishing the consumption of the taxed commodities, and sometimes by encouraging smuggling, frequently afford a smaller revenue to government than what might be drawn from more moderate taxes.

When the diminution of revenue is the effect of the diminution of consumption, there can be but one remedy, and that is the lowering of the tax.

When the diminution of the revenue is the effect of the encouragement given to smuggling, it may perhaps be remedied in two ways; either by diminishing the temptation to smuggle, or by increasing the difficulty of smuggling. The temptation to smuggle can be diminished only by the lowering of the tax; and the difficulty of smuggling can be increased only by establishing that system of administration which is most proper for preventing it.

The duties upon foreign luxuries imported for home consumption, though they sometimes fall upon the poor, fall principally upon people of middling or more than middling fortune. Such are, for example, the duties upon foreign wines, upon coffee, chocolate, tea, sugar, &c.

The

The duties upon the cheaper luxuries of home produce destined for home consumption, fall pretty equally upon people of all ranks in proportion to their respective expence. The poor pay the duties upon malt, hops, beer, and ale, upon their own consumption: the rich, upon both their own consumption and that of their servants.

The whole consumption of the inferior ranks of people, or of those below the middling rank, it must be observed, is in every country much greater, not only in quantity, but in value, than that of the middling and of those above the middling rank. The whole expence of the inferior is much greater than that of the superior ranks. Although the expence of people of inferior ranks, taking them individually, is very small, yet the whole mass of it, taking them collectively, amounts always to by much the largest portion of the whole expence of the society; what remains, of the annual produce of the land and labour of the country for the consumption of the superior ranks, being always much less, not only in quantity but in value. The taxes upon expence, therefore, which fall chiefly upon that of the superior ranks of people, upon the smaller portion of the annual produce, are likely to be much less productive than either those which fall indifferently upon the expence of all ranks, or even those which fall chiefly upon that of the inferior ranks; than either those which fall indifferently upon the whole annual produce, or those which fall chiefly upon the larger portion of it.

The best taxes, says Mr. Hume, (vol. i. Ess. 8.) are such as are levied upon consumptions, especially those of luxury; because such taxes are least felt by the people. They seem, in some measure, voluntary: since a man may chuse how far he will use the commodity which is taxed. They are paid gradually and insensibly; they naturally produce sobriety and frugality, if judiciously imposed; and being compounded with the natural price of the commodity, they are scarcely perceived by the consumers. Their only disadvantage is, that they are expensive in levying. Taxes upon possessions are levied without expence; but they have every other disadvantage. Most states, however, are obliged to have recourse to them, in order to supply the deficiencies of the other. When a tax is laid upon commodities which are consumed by the common people, the necessary consequence may seem to be, either that the poor must retrench something from their way of living, or raise their wages, so as to make the burden of the tax fall upon the rich; but there is a third consequence, which often follows upon taxes, namely, that the poor increase their industry, perform more work, and live as well as before, without demanding more for their labour. Where taxes are moderate, are laid on gradually, and do not affect the necessaries of life, this consequence naturally follows; and it is certain, that such difficulties often serve to excite the industry of a people, and render them more opulent and laborious than others, who enjoy the greatest advantages. The most pernicious of all taxes are the arbitrary: they are commonly converted, by their management, into punishments on industry; and, also, by their unavoidable inequality, are more grievous than the real burden which they impose. Poll-taxes are commonly arbitrary. A duty upon commodities checks itself; and a prince will find, that an increase of the impost is no increase of his revenue.

After all the proper subjects of taxation have been exhausted, if the exigencies of the state still continue to require new taxes, they must be imposed upon improper ones. It has been well observed, "that oppressive taxation is a monster, which, after devouring every other thing, devours itself at last."

The taxes which are raised on the British subject are either annual or perpetual. The usual annual taxes are those upon land and malt.

The first of these is the land-tax, for an account of which see LAND-*tax*.

See also HIDAGE, SCUTAGE, TALLIAGE, TENTH, FIFTEENTH, and SUBSIDY.

The other annual tax is the malt-tax, which is a sum raised every year by parliament ever since 1697. See MALT.

The perpetual taxes are the customs, which are a tax immediately paid by the merchant, although ultimately by the consumer (see CUSTOMS); the excise-duty, which is an inland imposition, paid sometimes upon the consumption of the commodity, or frequently upon the retail sale, which is the last stage before the consumption (see EXCISE); the duty upon *salt*: that for the carriage of letters or *post*; the *stamp-duties*; the duty upon houses and *windows*; the duty arising from licences to hackney-*coaches* and chairs in London, and the parts adjacent; and the duty upon offices and pensions. See LAND-*tax*, &c. &c.

The assessed taxes comprehend those on windows, houses, servants, carriages, horses and mules, dogs, horse-dealers, hair-powder, armorial bearings, and game licences. For those on windows, see the following schedule.

Schedule (A.) 48 G. III. c. 55.

Number of windows according to which the duties shall be charged	Duties. £	s.	d.
Not more than 6 windows or lights (except in such houses which shall be worth the rent of 5*l.* by the year, and shall be charged to the duty mentioned in Schedule (B.), according to the rent thereof)	0	6	6
Not more than 6 windows or lights, if of the value before-mentioned, and charged to the said duty accordingly	0	8	0
7 windows or lights	1	0	0
8 do.	1	13	0
9 do.	2	2	0
10 do.	2	16	0
11 do.	3	12	6
12 do.	4	9	6
13 do.	5	6	6
14 do.	6	3	6
15 do.	7	0	0
16 do.	7	17	0
17 do.	8	14	0

130 - 139 do.	72	6	0
140 - 149 do.	76	16	0
150 - 159 do.	81	5	6
160 - 169 do.	85	15	6
170 - 179 do.	90	5	0
180 and upwards do.	93	2	6
And for every fuch dwelling-houfe which fhall contain more than 180 windows or lights, for every window or light exceeding the number of 180	0	3	0

See WINDOWS.

Schedule (B.) 48 Geo. III. c. 55. Duties on inhabited dwelling-houfes.

For every fuch inhabited houfe with the houfehold and other offices, yards, and gardens, therewith occupied and charged, as are or fhall be worth the rent herein-after mentioned by the year, there fhall be charged the yearly fums following; *viz.*

	Value in the Pound. £	s.	d.
5*l.* and under 20*l.* rent, by the year	0	1	6
20*l.* and under 40*l.* rent, by the year	0	2	3
40*l.* rent by the year, and upwards	0	2	10

The duties payable by 48 Geo. III. c. 55. annually for male fervants are as below.

Schedule (C.) N° 1.

Number of Servants.	Amount of Duty for each Servant. £	s.	d.
For 1 fuch fervant	2	4	0
2 - do.	2	16	0
3 - do.	3	7	0
4 - do.	3	18	0
5 - do.	4	9	0
6 - do.	4	14	0
7 - do.	4	16	0
8 - do.	5	3	0
9 - do.	5	12	0
10 - do.	6	3	0
11 - do. and upwards	7	1	0
For every fuch fervant retained or employed by any male perfons, never having been married, over and above the before-mentioned duties, the further fum of	1	14	0

Schedule (C.) N° 2. Duties payable annually for male fervants retained or employed in the feveral capacities herein mentioned.

	£	s.	d.
For every gardener or perfon employed to work in any garden under any perfon chargeable to the duties mentioned in Schedule (C.), N° 1; and for every gardener employed in any garden wherein the conftant labour of one perfon fhall not be neceffary, the fum of	0	6	0

To be paid by each perfon in whofe garden fuch perfon fhall be employed.

Exemptions from the Duties as fet forth in Schedule (C.) N° 1. and 2.

Any perfon employed by the day or week to work as a day labourer, at the ufual rate of wages for day labourers in agriculture, in any garden belonging to a dwelling-houfe, being a farm-houfe, and exempted as fuch from the duties mentioned in Schedule (B.), or in any garden belonging to a dwelling-houfe not chargeable to the duties mentioned in the faid fchedule, fuch garden not requiring the conftant labour of one fuch labourer.

Schedule (C.) N° 3. Duties payable annually for every male perfon or fervant retained or employed in the feveral capacities herein mentioned.

	£	s.	d.
For every male perfon employed by any merchant or trader as a traveller or rider, the duties following; *viz.*			
Where one fuch traveller or rider and no more fhall be fo employed, the fum of	2	8	0
And where more than one fuch traveller or rider fhall be fo employed, for each the fum of	3	10	0
For every male perfon employed by any perfon in trade, or exercifing any profeffion whatever, as a clerk or book-keeper, or office-keeper, except apprentices, where no premium, or a premium lefs in value than the fum of 20*l.* has been paid or contracted for with fuch apprentice, the duties following; *viz.*			
Where one fuch clerk, book-keeper, or office-keeper, and no more fhall be fo employed, the fum of	1	4	0
And where more than one fuch clerk, book-keeper, or office-keeper fhall be fo employed, for each the fum of	2	8	0
For every male perfon employed by any perfon in trade as a fhopman, for the purpofe of expofing to fale or felling goods, wares, or merchandife, in fuch fhop or warehoufe, whether by wholefale or retail; and every male perfon employed as a warehoufeman, porter, or cellarman, in fuch fhop or warehoufe, except apprentices as aforefaid, the fum of	1	4	0

The faid duties to be paid by the employer or employers of fuch perfons, and to extend to every body politic or corporate, whether aggregate or fole, and to every fociety, fraternity, or partnerfhip, although not corporate; and to every manufacture or concern (except hufbandry) whereby the employer fhall feek a profit.

	£	s.	d.
For every male ſervant employed as a waiter (except occaſional waiters, over and above the ordinary number uſually kept) in any taverns, coffee-houſes, inns, ale-houſes, or other licenſed houſes, or in eating or victualling houſes, or in hotels or lodging-houſes, being eating or victualling houſes, the ſum of -	2	5	0
For every male ſervant retained by any ſtable-keeper to take care of any horſe, mare, or gelding, of any other perſon or perſons, kept for the purpoſe of racing or running for any plate, prize, ſum of money, or other thing, or any horſe, mare, or gelding, in training for any of the ſaid purpoſes, whereby ſuch ſtable-keeper ſhall gain a livelihood or profit, the ſum of - - - - - - - -	1	4	0
For every male ſervant *bonâ fide* retained for the purpoſes of huſbandry, manufacture, or trade, by which the maſter or miſtreſs ſhall gain a livelihood or profit, and at any time employed in any domeſtic employment in any of the capacities in Schedule (C.), N° 1, and not chargeable to the duties in the ſaid ſchedule, the ſum of - - - - - - -	0	6	0
For every male ſervant *bonâ fide* retained for the purpoſes of huſbandry, or any manufacture or trade, by which the maſter or miſtreſs ſhall gain a livelihood or profit, and at any time employed in the capacity of a groom, ſtable-boy, or helper in the ſtables, where the maſter or miſtreſs ſhall be chargeable for one horſe, and no more, to the duty on horſes kept for the purpoſes of riding, or drawing a taxed cart, or to the duty on ſuch taxed cart, and not on any other carriage chargeable with duty by this act, the ſum of - - -	0	6	0

The ſaid laſt-mentioned duties to be paid by the employer, or maſter or miſtreſs of ſuch perſons or ſervants.

Schedule (C.) N° 4. Duties payable on ſervants let to hire.

	£	s.	d.
For every coachman, groom, poſtilion, or helper, kept for the purpoſe of being let to hire for any period of time leſs than one year, and in ſuch manner that the ſtamp-office duty payable by law on horſes let to hire ſhall not be payable on every ſuch letting by any poſt-maſter, inn-keeper, or other perſon, duly licenſed to let poſt-horſes by the commiſſioners for managing the duties on ſtamped vellum, parchment, and paper, or by any coach-maker or maker of ſuch carriages, or other perſon, the annual ſum of - - - -	2	4	0

The ſaid duty to be paid by the perſon or perſons letting the ſame to hire.

Theſe ſeveral duties are ſubject to certain exemptions. The proviſions of 43 Geo. III. c. 161. relating to the aſſeſſments of ſervants, are as follow. Perſons liable to theſe duties are to return liſts of their ſervants, and are chargeable accordingly from the year commencing from the days ſtated in their returns; and they are ſubject to the powers of ſurcharge. Perſons beginning or ceaſing to keep ſervants are to give notice in writing to the aſſeſſor of the diſtrict in which they reſide.

Schedule (D.) N° 1. Duties payable on all carriages of any of the deſcriptions mentioned herein.

Number of Carriages.	Amount of Duty for each Carriage. £	s.	d.
For carriages with four wheels:			
For 1 ſuch carriage, the annual ſum of -	11	5	0
2 - do. - - - - - -	12	7	0
3 - do. - - - - - -	13	10	0
4 - do. - - - - - -	14	0	0
5 - do. - - - - - -	14	12	0
6 - do. - - - - - -	15	3	0
7 - do. - - - - - -	15	14	0
8 - do. - - - - - -	16	5	0
9 - do. and upwards - - -	16	16	0
And for every additional body ſucceſſively uſed on the ſame carriage or number of wheels, the further ſum of - - - - - -	5	12	0

Schedule (D.) N° 2.

	£	s.	d.
For carriages with leſs than four wheels:			
For every ſuch carriage (except taxed carts, conſtructed, kept, and uſed, under the regulations of this act) drawn by one horſe, mare, or gelding, and no more - - - - -	5	18	0
And for every ſuch carriage, drawn by two or more horſes, mares, or geldings - - -	8	5	0
And for every additional body of the deſcription herein-after mentioned, ſucceſſively uſed on the ſame carriage or number of wheels, the further ſum of - - - - -	2	16	0

Schedule (D.) N° 3.

	£	s.	d.
For carriages hired for any period of time leſs than one year, or kept to be let to hire, or to carry paſſengers:			
For every ſuch carriage kept for the purpoſe of being let to hire, with horſes to be uſed therewith, for any period of time not exceeding twenty-eight days, ſo that the ſtamp-office duty, payable by law on horſes let to hire ſhall be duly paid and ſatisfied on every ſuch letting by any poſt-maſter, inn-keeper, or other perſon duly licenſed to let poſt-horſes, by the commiſſioners for managing the duties on ſtamped vellum, parchment, and paper, and whereon the name or names and place of abode of the perſon or perſons ſo licenſed ſhall be marked or painted, according to the directions of the act in that caſe made and provided; if ſuch carriage ſhall have four wheels, the ſum of - - - -	9	9	0
And if ſuch carriage ſhall have leſs than four wheels, the reſpective ſums mentioned in Schedule (D.) N° 2, according to the number of horſes uſed therewith, as therein mentioned.			
And for every coach, diligence, caravan, or chaiſe with four wheels or more, or other carriage with four wheels or more, by whatever name the ſame ſhall be called or known, which ſhall be kept and employed as a public ſtage-coach or carriage for the purpoſe of conveying paſſengers for hire to and from different places, and which ſhall be duly entered as ſuch with the ſaid commiſſioners of ſtamp duties, the like ſum of - - - - -	9	9	0

All which laſt-mentioned duties ſhall reſpectively be paid by the perſon or perſons keeping the ſame, for the purpoſes aforeſaid. £ s. d.

For every carriage kept for the purpoſe of being let to hire for any period of time leſs than one year, and in ſuch manner that the ſaid ſtamp-office duty ſhall not by law be payable on ſuch letting by any perſon ſo licenſed as aforeſaid, or by any coach-maker or maker of ſuch carriages, or other perſon, if ſuch carriage ſhall have four wheels, the annual ſum of - - - - - - 11 5 0

The ſaid laſt-mentioned duty to be paid by the perſon or perſons keeping the ſame for the purpoſes aforeſaid.

Provided, if a due return thereof ſhall not be made by the hirer or hirers according to the directions of the acts herein mentioned, the progreſſive duty, as ſet forth in Schedule (D.) N° 1, ſhall be chargeable in reſpect of every ſuch carriage on the perſon or perſons hiring the ſame, and making ſuch default as aforeſaid, ſubject to the proviſions contained in the ſaid acts concerning the ſame.

And if ſuch carriage ſhall have leſs than four wheels, the reſpective ſums mentioned in Schedule (D.) N° 2, according to the number of horſes to be uſed therewith, to be paid by the perſon or perſons keeping the ſame for the purpoſe aforeſaid, ſubject to the proviſions herein-after contained concerning the ſame. See Coach and *Taxed* Cart.

By 50 Geo. III. c. 104. certain new duties are impoſed.

A Schedule of the Duties payable on Carriages called Taxed Carts.

N° I.

For every carriage called a taxed cart, built and conſtructed according to the regulations of the ſaid act, in every reſpect the original price of which ſhall not have exceeded, or the value whereof ſhall not at any time exceed the ſum of 15*l.* ſterling, and which ſhall not at any time be uſed with a covered or ſtuffed ſeat, or with a covered foot-board or apron thereto fixed or not fixed, there ſhall be charged the annual ſum of - - - £1 6 6 (£ s. d.)

N° II.

For every ſuch carriage called a taxed cart, built and conſtructed with a ſpring or ſprings of any materials whatever, (except of iron, ſteel, or any other metallic ſubſtance, or any compoſition of iron, ſteel, or other metallic ſubſtance, either wholly or in part,) the original price of which carriage ſhall not have exceeded, or the value whereof ſhall not at any time exceed the ſum of 20*l.* ſterling, or which ſhall be uſed with a ſtuffed ſeat or cuſhion, or with a covered foot-board or apron thereto fixed or not fixed, there ſhall be charged the annual ſum of - - - - - - 2 10 0

A Schedule of the Duties payable on Carriages with leſs than Four Wheels.

N° III.

For every carriage with leſs than four wheels chargeable by the ſaid act of the forty-eighth of his preſent majeſty's reign with the duty of 5*l.* 18*s.* if drawn by one horſe, mare, or gelding, and no more, there ſhall be charged the like amount of duty for every ſuch carriage drawn by one horſe, mare, gelding or mule, and no more, *viz.* the annual ſum of - - 5 18 0 (£ s. d.)

For every ſuch carriage chargeable by the ſaid act with the duty of 8*l.* 5*s.* if drawn by two or more horſes, mares, or geldings, there ſhall be charged the like amount of duty for every ſuch carriage drawn by more than one horſe, mare, gelding or mule, *viz.* the annual ſum of 8 5 0

And for any additional body ſucceſſively uſed on the ſame carriage or number of wheels chargeable by the ſaid act with the further duty of 2*l.* 16*s.* there ſhall be charged the like amount of further duty, for every additional body ſucceſſively uſed on the ſame carriage or number of wheels, if drawn in the manner herein mentioned, *viz.* the further annual ſum of - 2 16 0

Schedule (E.) N° 1. Duties payable for all horſes, mares and geldings, kept and uſed for the purpoſe of riding, or of drawing any carriage chargeable with duty by Schedule (D.)

Number thereof.	Amount of Duty for each Horſe, Mare, or Gelding. £	s.	d.
For 1 ſuch horſe, mare, or gelding - -	2	13	6
2 ſuch horſes, mares, or geldings - -	4	9	6
3 - do. - - -	4	18	6
4 - do. - - -	5	2	0
5 - do. - - -	5	3	0
6 - do. - - -	5	7	6
7 - do. - - -	5	10	0
8 - do. - - -	5	10	0
9 - do. - - -	5	12	0
10 - do. - - -	5	17	6
11 - do. - - -	5	17	6
12 - do. - - -	5	17	6
13 - do. - - -	5	18	0
14 - do. - - -	5	18	0
15 - do. - - -	5	18	0
16 - do. - - -	5	18	0
17 - do. - - -	5	18	6
18 - do. - - -	5	19	6
19 - do. - - -	6	0	0
20 and upwards - - - - -	6	1	0

Rules.—The ſaid duties to be payable annually for every horſe, mare, or gelding, uſed on any occaſion for the purpoſe of riding, or of drawing any carriage for which any duty is payable by this act, or hired by the year, or any longer period, and to be paid by the perſon or perſons uſing the ſame. Theſe duties are ſubject to certain exemptions in favour of huſbandry, under certain circumſtances.

Schedule (E.) N° 2. Duties payable on horſes let to hire.

For every horſe, mare, or gelding, let to hire for the purpoſe of riding, or of drawing any ſuch carriage as aforeſaid, for any period of time leſs than one year, in any manner ſo that the ſtamp-office duty payable by law on horſes let to hire ſhall not be payable, the ſum of - 2 13 6 (£ s. d.)

To

To be charged annually on the perſon or perſons letting the ſame; provided, if a due return thereof ſhall not be made by the hirer or hirers, according to this act, the progreſſive duty, as ſet forth in Schedule (E.) N° 1, ſhall be chargeable in reſpect of every ſuch horſe, mare, or gelding, on the perſon or perſons hiring the ſame, and making ſuch default as aforeſaid, ſubject to the proviſions of this act.

Schedule (E.) N° 3. Duties payable on horſes kept for the purpoſe of racing or running for any plate, prize, or ſum of money, or other thing, or kept in training for any of the ſaid purpoſes.

For every horſe, mare, or gelding, *bonâ fide* kept for the purpoſe of racing or running for any plate, prize, or ſum of money, or other thing, or kept in training for any of the ſaid purpoſes, whether in the ſtables of the proprietor or proprietors, or of any other perſon or perſons, the ſum of - - - - - - £ 2 s. 13 d. 6

The ſaid duty to be charged annually on the perſon or perſons having the cuſtody, charge, or management of ſuch horſes, mares, or geldings.

Schedule (F.) N° 1. Duties payable for all horſes, mares, and geldings, not charged with any duty according to the Schedule (E.) N° 1, 2, 3, and alſo on mules.

For every horſe, &c. not chargeable with any duty according to the Schedule (E.) N° 1, 2, and 3, as aforeſaid, and for every mule, except in the caſes herein-after mentioned, wherein other duties are made payable, the ſum of £ 0 s. 14 d. 0

Schedule (F.) N° 2. Duties payable on huſbandry-horſes, in the caſes herein-after mentioned.

Any perſon occupying a farm at rack-rent, the rent of which ſhall be leſs than 20*l.* a-year, and making a livelihood ſolely thereby, or occupying any eſtate on any other tenure than as tenant at rack-rent ſolely, or ſuch other eſtate, together with the farm at rack-rent, the value of which in the whole ſhall be leſs than equivalent to a farm at the rack-rent of 20*l.* a-year (reckoning the value of every eſtate occupied by the owner thereof, or on any tenure other than as tenant at rack-rent, as equivalent to double the amount of the like farm at rack-rent), and making a livelihood ſolely by ſuch his own eſtate, or by ſuch eſtate and farm jointly, or principally thereby, and likewiſe a profit by any trade or employment, and keeping not more than two horſes, mares, geldings, or mules, *bonâ fide* for the purpoſe of ſuch occupation, ſhall be charged for each of ſuch two horſes, mares, geldings, or mules, the ſum of - - - - - - - £ 0 s. 2 d. 10

Any perſon occupying a farm at rack-rent in Wales or Scotland, the rent of which ſhall be leſs than 10*l.* ſterling a-year, and making a livelihood principally thereby, or occupying any eſtate on any other tenure than as tenant at rack-rent, or ſuch other eſtate, together with a farm at rack-rent, the value of which in the whole ſhall be leſs than equivalent to a farm at the rack-rent of 10*l.* ſterling a-year (reckoning the value of every eſtate occupied by the owner thereof, or on any tenure other than as tenant at rack-rent, as equivalent to double the amount of the like farm, at rack-rent), and making a livelihood principally thereby, and likewiſe a profit by any trade or employment, and keeping not more than two horſes, mares, geldings, or mules, *bonâ fide* for the purpoſes of ſuch occupation, and of ſuch trade or employment jointly, or either of them ſeparately, ſhall be charged for each of ſuch two horſes, mares, geldings, or mules, the ſum of - - - - - - - £ 0 s. 2 d. 10

Rules for charging the duties, as ſet forth in Schedule (F.) N° 1 *and* 2.

The ſaid duties to be charged annually, and paid by the perſon or perſons keeping or uſing ſuch horſes, mares, geldings, or mules, and to be payable for every horſe, mare or gelding, and mule, which ſhall not be chargeable nor have been charged with any duty payable in that year, according to the preceding ſchedule marked (E.) by virtue of the rules or exemptions therein contained, except as herein-after is mentioned.

Exemptions from the duties in Schedule (E.) N° 1 *and* 2.

Any perſon whatever, for any horſe, mare, or gelding, not being by due admeaſurement of the height of thirteen hands, of four inches to each hand, or which ſhall not at any time whatever have been uſed for any purpoſe of labour or otherwiſe. See HORSE and HORSE-*Dealer*.

Schedule (G.) N° 1. Duties payable on dogs.

For every greyhound, hound, pointer, ſetting-dog, ſpaniel, lurcher, or terrier, the annual ſum of - - - - - - - - £ 0 s. 11 d. 6

For every dog, of whatever deſcription or denomination the ſame may be, where any perſon ſhall keep two or more dogs, either for his or her own uſe, or the uſe of any other perſon or perſons, the annual ſum of - - - - £ 0 s. 11 d. 6

For every dog not being a greyhound, hound, pointer, ſetting-dog, ſpaniel, lurcher, or terrier, kept by any perſon having one ſuch dog, and no more, whether the ſame be kept for his or her own uſe, or the uſe of any other perſon or perſons, the annual ſum of - - - £ 0 s. 7 d. 0

The ſaid duties to be paid by the perſons reſpectively keeping ſuch dogs.

Exemptions from the duties in Schedule (G.)

Caſe 1.—Any dog belonging to his majeſty, or any of the royal family.

Caſe 2.—Any perſon who, on account of poverty, ſhall be diſcharged from the aſſeſſment made in reſpect of his or her dwelling-houſe, in purſuance of the regulations of any of the acts herein-mentioned, and having one dog, and no more, the ſame not being a greyhound, hound, pointer, ſetting-dog, ſpaniel, lurcher, or terrier.

Caſe 3.—Any perſon, in reſpect of a dog or whelp, which at the time of returning the liſts of dogs as by this act is required, ſhall not actually be of the age of ſix calendar months.

Caſe 4.

Caſe 4.—Any perſon in reſpect of the whole number of hounds by him or her kept in Great Britain, who ſhall compound for the ſame, in any year within thirty days after the 5th day of April in ſuch year, in purſuance of notice given to the collector or collectors of the ſaid duty for any pariſh or place, where ſuch perſon ſhall be liable to be aſſeſſed, of his or her intention ſo to do, and on payment of the full ſum of 34*l.* ſterling to ſuch collector or collectors, for which a receipt ſhall be given within the period before-mentioned.

Schedule (H.) Duties payable by horſe-dealers.

	£	s.	d.
Every perſon who ſhall uſe or exerciſe the trade and buſineſs of a horſe-dealer within the cities of London and Weſtminſter, and the liberties of the ſame reſpectively, the pariſhes of St. Mary-le-Bone and St. Pancras, in the county of Middleſex, the weekly bills of mortality, or the borough of Southwark, in the county of Surrey, the annual duty of - - - -	22	10	0
Every perſon who ſhall uſe or exerciſe the trade and buſineſs of a horſe-dealer in any other part of Great Britain, the annual duty of - -	11	5	0

Schedule (I.) Duties payable by perſons in reſpect of hair-powder uſed or worn by them.

	£	s.	d.
By every perſon who ſhall have uſed or worn any hair-powder within the period limited by any of the acts herein mentioned, the annual ſum of - - - - - - - -	1	3	0

Schedule (K.) Duties payable by perſons in reſpect of any armorial bearing or enſign, uſed or worn by them, by whatever name the ſame ſhall be called; *viz.*

	£	s.	d.
By every ſuch perſon chargeable with any duty made payable by this act, for any coach or other carriage, the annual ſum of - -	2	8	0
By every ſuch perſon not chargeable for any ſuch coach or other carriage, but who ſhall be chargeable to any of the duties on inhabited houſes, or to the duties on houſes, windows, or lights, made payable by this act, the annual ſum of - - - - - - - -	1	4	0
By every ſuch perſon not chargeable for any ſuch coach or other carriage, nor being chargeable to the ſaid duties on inhabited houſes, or to the duty on houſes, windows, or lights, the annual ſum of - - - - -	0	12	0

Schedule (L.) Duties payable in reſpect of killing game.

	£	s.	d.
Upon every perſon who ſhall uſe any dog, gun, net, or other engine, for the purpoſe of taking or killing any game whatever, or any woodcock, ſnipe, quail or landrail, or any conies, in any part of Great Britain:			
If ſuch perſon ſhall be a ſervant to any perſon duly charged in reſpect of ſuch ſervant to the duties granted on ſervants by this act, and ſhall uſe any dog, gun, net, or other engine, for any of the purpoſes before-mentioned, upon any manor or royalty in England, Wales, or Berwick-upon-Tweed, or upon any lands in Scotland, by virtue of any deputation or appointment, duly regiſtered or entered as game-keeper thereto, there ſhall be charged the annual ſum of - - -	1	1	0
And if ſuch perſon as laſt aforeſaid ſhall not be a ſervant, for whom the ſaid duties on ſervants ſhall be charged, there ſhall be charged the annual ſum of - - - - -	3	3	0
Upon every other perſon who ſhall uſe any dog, gun, net, or other engine for any of the purpoſes before-mentioned, there ſhall be charged the annual ſum of - - - - - -	3	3	0

By the 46 Geo. III. c. 84. every perſon having more than two children born in lawful wedlock, and *bonâ fide* maintained at the expence of ſuch perſon, ſhall for every ſuch child above two be allowed at the rate of 4 *per cent.* on the amount of all the aſſeſſments on ſuch perſon by virtue of the 43 Geo. III. c. 161. 45 Geo. III. c. 13. 46 Geo. III. c. 78. in caſe the total amount of all the aſſeſſments ſhall be under 40*l.* in any one year, which allowance ſhall be made annually out of the duties ſo charged, at any time in the year of aſſeſſment, on delivery of a declaration in writing, containing the whole number of ſuch children, and their reſpective names and places of reſidence, and which of them are of the family, or reſide elſewhere.

By ſ. 2. this proviſion ſhall extend to children by a former marriage, either of the huſband or wife.

The ſtatute 43 Geo. III. c. 99. reciting that it is expedient that certain of the proviſions contained in any acts relating to the duties on windows or lights, on inhabited houſes, ſervants, carriages, horſes, mules, and dogs, and other duties lately transferred to the commiſſioners for the affairs of taxes, ſhould be conſolidated and amended: enacts that all the ſaid duties under the management of ſuch commiſſioners (except the land-tax) ſhall, from and after April 5, 1804, be aſſeſſed, raiſed, levied, and paid under the regulations thereof.

And as new duties may hereafter be placed under their management, to be aſſeſſed in like manner, it is declared that this act ſhall, with reſpect to ſuch duties, take effect after the time fixed by the act or acts granting them for the commencement of the ſame. See the proviſions of this act detailed in Burn's Juſtice, ubi ſupra.

The property-tax being now extinct, we are happily relieved from giving any account of it.

For the qualifications and powers of commiſſioners, the appointment of aſſeſſors and collectors, the mode of making aſſeſſments, ſurcharges, appeals, &c. &c. we refer to Burn's Juſtice, art. *Taxes*.

For the duty on poſt-horſes, &c. ſee Post-*Horſe*.

The revenue ariſing from the ſeveral taxes, which is annually paid to the creditors of the public, or carried to the ſinking fund, is firſt depoſited in the royal exchequer, and thence iſſued out to the reſpective offices of payment: for the manner in which it is applied, ſee Fund and National *Debt*. See alſo Revenue.

The people of France were ſtrangers to tailles or taxes till the time of St. Louis, when they were firſt impoſed in form of ſubſidies neceſſary for the ſupport of the war in the Holy Land. See Croisade.

They were then extraordinary levies, and were raiſed by capitation; but they were afterwards made perpetual under Charles VII. and Philip the Fair, who, to raiſe money without diſturbing the people, called the people, as a third eſtate, into the general councils of the realm.

Tax alſo denotes the tribute which tenants were occaſionally to pay their lord.

Moſt lords had a right of taxing on four occaſions: *viz.* when the lord was taken priſoner in a juſt war; when he made

made his eldest son a knight; when he married his eldest daughter to a gentleman; and when he made the voyage of the Holy Land.

Naude shews the extravagant rise of this kind of taxes: those, he observes, which under Charles VI. only amounted to the sum of 40,000 livres, were increased under Charles VII. to the sum of 1,800,000; under Louis XI. to 4,740,000; under Charles VIII. to 6,000,000; and under Louis XII. to 7,640,000 livres.

Taxes were distinguished into *free*, which were those due, in the four cases, by freemen, or those who held free lands; and *servile* and *base*, which were those due from persons of base condition.

They were also distinguished into *real* and *personal*. The personal were imposed on the head of the servant or man in mainmort, and so followed him wherever he went.

TAXA, in *Geography*, one of the small Western islands, near the south-east coast of Ilay. N. lat. 55° 43′. W. long. 6° 3′.

TAXAMALCA, a town of Mexico; 60 miles S. of Mexico.

TAXAMARCA, a town of Mexico, in the province of Mechoacan; 40 miles E. of Mechoacan.

TAXANTHEMA, in *Botany*, so named by Necker, from ταξις, *a row*, and ανθημα, *inflorescence*, because some of the plants on which this supposed genus is founded differ from other species of *Statice*, in having their flowers disposed in a regular series, or row, and not in a round head; witness *S. Limonium* and its allies. These species indeed constitute Tournefort's genus of *Limonium*, but he associates with them others with dispersed flowers. (See STATICE and LIMONIUM.) Mr. Brown, Prodr. Nov. Holl. v. 1. 426, adopts Necker's genus and name, citing Tournefort's *Limonium* as a synonym. The latter name was probably judged too near *Limonia* to be retained. We presume to think the genus of *Statice* is in itself so natural, and so well distinguished from every other, that if a practical example were desired, to warn us against founding generic distinctions upon inflorescence alone, no better could be selected. See CYME and GENUS.

TAXERS, two officers yearly chosen in Cambridge, to see the true gauge of all weights and measures observed.

The name took beginning from taxing and rating the rents of houses, which was anciently the duty of their office.

TAX-GUTIUM, in *Ancient Geography*, a town of Rhætia, towards the source of the Rhine, near Brigantium. Ptol.

TAXIANA, an island situated in the Persian gulf, on the coast of Susiana, west of the isle of Tabiana. Ptol.

TAXILA, a large town of India, on this side of the Ganges. Ptol. and Strabo.

TAXIMIRA, a town of Phœnicia. Strabo.

TAXIPA, in *Geography*, a town of Mexico, in the province of Guasteca; 30 miles N.N.W. of Panuco.

TAXIS, ταξις, in the *Ancient Architecture*, signifies the same with ordonnance in the new, and is described by Vitruvius to be that which gives every part of a building its just dimensions with regard to its use.

TAXIS, from τασσω, *to put in order*, in *Surgery*, the operation of reducing a hernia with the hand. See a particular account of it in the article HERNIA.

TAXITLAN, in *Geography*, a town of Mexico, in the province of Guasteca; 38 miles S. of St. Yago de los Valles.

TAXUS, in *Botany*, the ancient Latin name of the Yew-tree, used by Pliny. The word is supposed by some to be derived from τοξον, *a bow*, *arrow*, or *dart*, because missile weapons were poisoned with its berries. We are confident that this precise explanation is erroneous, because, whatever may be the noxious qualities of any other part of the plant, the berries are simply mucilaginous and saccharine, eatable with impunity, as we have often experienced. The ancient use of this wood for bows, perhaps also for arrows or darts, might more truly account for the above etymology, did not Dioscorides expressly tell us ταξος was Latin. — Linn. Gen. 532. Schreb. 706. Willd. Sp. Pl. v. 4. 856. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1086. Prodr. Fl. Græc. Sibth. v. 2. 265. Ait. Hort. Kew. v. 5. 415. Pursh 647. Juss. 412. Lamarck Illustr. t. 829. Gærtn. t. 91. — Class and order, *Dioecia Monadelphia*. Nat. Ord. *Coniferæ*, Linn. Juss.

Gen. Ch. Male, *Cal.* none, except the scales of the bud, resembling a perianth of four leaves. *Cor.* none. *Stam.* Filaments numerous, united below into a column, longer than the bud; anthers depressed, blunt, with eight notches, at the edge, splitting all round at the base, and after shedding their pollen becoming flat and peltate, remarkable for their eight marginal segments.

Female, *Cal.* inferior, of one leaf, close, undivided, entire. *Cor.* none. *Pist.* Germen superior, ovate, acute; style none; stigma obtuse. *Peric.* none, except a spurious incomplete berry, formed of the calyx elongated into a globose juicy coloured sheath, open at the top, at length shrivelling and drying away. *Seed* one, ovate-oblong, projecting with its summit beyond the berry.

Ess. Ch. Male, Calyx none. Corolla none. Stamens numerous. Anthers peltate, with eight segments.

Female, Calyx cup-shaped, entire. Style none. Seed one, partly enveloped in the pulpy calyx.

Obs. Linnæus properly mentions that the berry of this genus cannot, strictly speaking, be denominated a pericarp. "It is a remarkable species of berry, like which nothing else is to be seen, except perhaps in *Gaultheria*." If the analogy here cited be just, the part in question is a real calyx, not more extraordinary in its change than that of *Blitum*, or of *Morus*, and we have always ventured to term it such, trusting to the analogies of *Juniperus* and *Ephedra* for our support.

1. T. *baccata*. Common Yew. Linn. Sp. Pl. 1472. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 746. (Taxus; Ger. Em. 1370. Matth. Valgr. v. 2. 444. Camer. Epit. 840.)—Leaves linear, two-ranked, crowded, nearly flat. Male flowers globose.—Native of mountainous woods, particularly in the clefts of high calcareous rocks, in various parts of Europe, from Norway to Greece, flowering in March or April. Dioscorides indeed, who calls this tree σμιλαξ, speaks of it as an exotic, the ταξος of the Romans; but Mr. Hawkins noticed it wild on the rocks of mount Cyllene in Laconia. Thunberg says it is common in Japan. The *trunk* is straight, of slow growth, with a smooth deciduous bark, and very hard, tough, close-grained wood. *Branches* spreading horizontally in two directions. *Leaves* numerous, scattered, crowded, spreading in two rows, nearly sessile, linear, entire, slightly revolute, obtuse with a small point, smooth, of a dark shining green, permanent, about an inch long. *Flowers* axillary, solitary, nearly sessile, enveloped with imbricated *bracteas*; the male ones numerous, sometimes two or three together, cream-coloured, half the size of a pea, globose, abounding with pollen; females drooping, their green entire *calyx* just visible beyond the *bracteas*. This afterwards assumes the appearance of a bright scarlet *berry*, the size of a currant, open at the top, where the *seed* appears. The *leaves* are very poisonous, and if accidentally eaten by domestic cattle, prove fatal. The ancients

ancients report that it is dangerous to fleep under this tree. It was formerly much planted in church-yards; and many Yews, perhaps "the tenants of a thoufand years," ftill remain in the northern and Welfh village cemeteries. This was the favourite tree for clipping into any fantaftic fhape, on which art our old gardeners fo much valued themfelves; but the art and the material are now nearly alike difcarded; and the garden is freed from one of the greateft afylums for vermin, the trim yew hedge.

2. T. *canadenfis*. North American Yew. Willd. n. 2. Purfh n. 1. (T. baccata β, minor; Michaux Boreal.-Amer. v. 2. 245.)—Leaves linear, two-ranked, crowded, revolute. Male flowers globofe, always folitary.—In fhady rocky places in North America, flowering in March and April. In Canada. *Michaux*. Covering a great part of the rocky banks of the Antietum, in Maryland. Under the fhade of other trees, it does not rife above two or three feet. *Purfh*. Michaux defcribes this fpecies as of humbler growth than the former, fpreading, and with fmaller *flowers* and *fruit*. Willdenow fays it is fmaller and narrower in all its parts, nor does it alter by culture, and yet a fpecific diftinction is hardly to be detected. The *leaves*, however, are narrower, fmaller, and revolute at the margin. Male *flowers* always folitary in the bofoms of the leaves.

3. T. *elongata*. Long-leaved African Yew. Ait. ed. 1. v. 3. 415. ed. 2. n. 3. Willd. n. 3. Thunb. Prodr. 117.—Leaves fcattered, linear-lanceolate. Branches fomewhat whorled. Male flowers cylindrical, with fpirally imbricated, very numerous, anthers.—Native of the Cape of Good Hope. Sent to Kew in 1774, and kept in feveral curious greenhoufes in England as well as on the continent, flowering in July. Wild fpecimens, anfwering to Thunberg's character of the whorled *branches*, but without a name, are preferved in the Linnæan herbarium. In thefe the *leaves* are fcattered, on fhort broad ftalks, flat, coriaceous, fomewhat glaucous, occafionally falcate, from one to two inches long. *Male flowers* axillary, folitary, cylindrical, obtufe, about half an inch in length, their fcale-like *anthers* imbricated, exactly like thofe of a Fir. The garden plant has *leaves* half as long again, not glaucous, fometimes oppofite on the young branches.

4. T. *montana*. Mountain Peruvian Yew. Willd. n. 4.—"Leaves two-ranked, linear, with a callous point; their upper edge rounded at the bafe; lower contracted."—Gathered by Humboldt and Bonpland on the mountains of Peru. Akin to *T. baccata*, but differing in the above character of the *foliage*. The fame travellers noticed, in Mexico, what Willdenow judged to be a mere variety of this fpecies, with *leaves* half as long again.

5. T. *nucifera*. Acorn-bearing Yew. Linn. Sp. Pl. 1472. Willd. n. 5. Ait. n. 3. Thunb. Jap. 275. Kæmpf. Am. Exot. 814. t. 815.—Leaves two-ranked, diftant, lanceolate, pointed, but half the length of the fruit.—Frequent, according to Kæmpfer, in the northern provinces of Japan, flowering in fpring, and ripening fruit late in autumn. Thunberg obferved it here and there near Nagafaki, and in the ifland of Nipon. Mr. Aiton fays it was cultivated in the greenhoufe of Capt. Thomas Cornwall, in 1764. We have never examined this fpecies. Kæmpfer defcribes it as a lofty *tree*, with many oppofite fcaly *branches*; the wood light. *Leaves* hardly an inch long, one-third of an inch afunder, nearly feffile, tipped with a fhort point; dark fhining green above; glaucous beneath. Female *flowers* axillary, folitary, difperfed, fomewhat quadrangular, their thick flefhy fcales becoming a fort of permanent cup at the bafe of the *feed*, or *nut*, which is coated, oval, pointed, above an inch long. The oil of the kernel is efteemed for culinary purpofes. The kernel itfelf is too aftringent to be eaten in general.

6. T. *macrophylla*. Long-leaved Japan Yew. Thunb. Jap. 276. Willd. n. 6. Ait. n. 4. Banks Ic. Kæmpf. t. 24. (*Sin*, vulgò Máki, feu *Fon Máki*, id eft *Maki* legitima; Kæmpf. Am. Exot. 780.)—Leaves fcattered, lanceolate, pointlefs, fpreading every way. Fruit ftalked.—Common in Japan, flowering in June. *Thunberg*. Mr. William Kerr brought it from China to Kew in 1804. A greenhoufe plant, flowering in July and Auguft. *Aiton*. Kæmpfer defcribes this as a large and ftout *tree*, whofe wood is valued for cabinet work, being not liable to the attacks of infects, or other caufes of decay. The *leaves* are a finger's length, fpreading equally in all directions; paler beneath. Male *flowers* cylindrical. *Fruit* axillary, ftalked, with a pair of awl-fhaped revolute fcales at the top of the ftalk. The *feed* is oval, the fize of a pea, and feems by Kæmpfer's figure to be elevated on a partial ftalk above the flefhy *calyx*. Thunberg, however, fpeaks of the "ovate fmooth green *berry*, turning black in drying, filled by an ovate white *feed*." Perhaps this may be a coated nut, as in *T. nucifera*.

7. T. *fpinulofa*. Spinous-leaved Yew.—Leaves partly oppofite or whorled, lanceolate, fpinous-pointed, fpreading every way. Fruit ftalked.—For a fpecimen of this, faid to have been brought by governor Philip from Port Jackfon, New South Wales, we are indebted to A. B. Lambert, efq. It very much refembles Kæmpfer's plate of the laft, in general habit, but the *leaves* are hardly an inch and quarter long, and have each a fpinous point. The ftalks of the *fruit* are axillary, each crowned with a pair of lanceolate, revolute, permanent fcales. *Fruit* oval, elevated on a ftalk, which is equal in length to the *calyx*, compofed of feveral flefhy fcales, that envelopes it. The fize and whole appearance of this *fruit* and its accompaniments are fo precifely like Kæmpfer's figure of the laft, which indeed they help us to underftand, that thefe two plants muft be of the fame genus, and are more truly perhaps akin to *T. nucifera*, than to *T. baccata*. On this fubject we may expect information hereafter from Mr. Brown; if at leaft our prefent plant be really a native of New South Wales.

8. T. *latifolia*. Broad-leaved Cape Yew. Thunb. Prodr. 117. Willd. n. 7.—"Leaves folitary, lanceolate, pointed, fmooth."—Found by Thunberg at the Cape of Good Hope.

9. T. *falcata*. Sickle-leaved Cape Yew. Thunb. Prodr. 117. Willd. n. 8.—"Leaves folitary, lanceolate, falcate, fmooth."—From the fame country. One of our wild fpecimens of *T. elongata* anfwers to this definition.

10. T. *tomentofa*. Downy Cape Yew. Thunb. Prodr. 117. Willd. n. 9.—"Leaves oppofite, lanceolate, downy beneath."—Gathered at the Cape by Thunberg, whofe fpecific characters of thefe fpecies, except of the laft, are not fufficient to diftinguifh them from the reft. We have feen no fpecimens.

11. T. *verticillata*. Whorled Japan Yew. Thunb. Jap. 276. Willd. n. 10. (*Kcu fin*, item *Sen baku*, vulgò *Inu Máki*, id eft *Máki* fpuria; Kæmpf. Am. Exot. 780.)—Leaves whorled, linear, falcate.—Native of Japan. A *tree* with denfe branches, gradually fhorter upward, fo as to affume a conical figure, like a Cyprefs, three fathoms high. *Fruit* oblong, in two divifions; the lower part refembling moufe-dung; the upper a grain of pepper, in which is loofely enclofed a flefhy, foft, fweetifh kernel. Such is Kæmpfer's defcription, by which it is eafy to perceive the clofe refemblance of this fruit to our *T. macrophylla* and *fpinulofa*. A fpecimen from Thunberg, without fructification, in the Linnæan herbarium, anfwers well to his own defcription,

tion, having round, ſmooth, greyiſh *branches*. Whorls from one to two inches aſunder, each of about eight ſeſſile, linear, falcate, entire, ſmooth, ſingle-ribbed *leaves*, a finger's length, or more; two lines broad; obtuſe, or ſlightly emarginate, at the end; of a dark ſhining green above; paler beneath.

TAXUS, in *Gardening*, furniſhes a plant of the hardy evergreen kind, of which the ſpecies moſtly cultivated is the common yew-tree (T. baccata.) This is a tree which has ſeveral varieties, as thoſe with very ſhort leaves, with broad ſhining leaves, and with ſtriped or variegated leaves.

Method of Culture.—In this tree, the increaſe may be effected in ſeveral ways, as by ſeeds, and ſometimes by layers and cuttings. In the firſt mode, after having procured a quantity of the yew berries, and diveſted them of the pulp or mucilage, they ſhould be ſown in beds of light earth, either in ſhallow drills, or ſcattered over the ſurface in the autumn or ſpring ſeaſon; but the former is the beſt method, as the plants riſe in the following ſpring; and be covered near an inch deep with light mould, out of the alleys, &c. They require no further care, only to keep the beds clean from weeds before and after the plants come up, and to give occaſional waterings in dry weather, in ſpring and ſummer, to forward and ſtrengthen the plants in their growth. They ſhould have two years' growth in the ſeed-bed; then in the autumn or ſpring be planted out upon four-feet-wide beds, in nurſery rows, a foot aſunder, to remain two, three, or four years, when ſome may be planted out finally for hedges, where required; others in the nurſery quarters, in rows, two or three feet aſunder, to be trained in a ſuitable manner for the purpoſes they are intended.

And after growing in the nurſery till they obtain from half a yard to four or five feet ſtature, they may be finally planted out in autumn or ſpring, for their intended purpoſes; when they will riſe from the ground with a large ſpread of roots. They ſhould be planted in their places as ſoon after removal as poſſible, giving each plant a good watering at the time.

In the future culture, thoſe trained in hedges, &c. muſt be clipped or cut in annually, once or twice in the ſummer; and thoſe in the ſhrubberies and rural plantations have the lower branches pruned up occaſionally to a ſingle ſtem; but the head ſhould generally be permitted to ſpread agreeably to its natural mode of growth, except juſt reducing any conſiderable rambling branch, &c.

But the ſtriped or variegated yews, and other varieties, ſhould be increaſed by layers, ſlips or cuttings, as they are rarely permanent by ſeeds. The layers ſhould be made from the young ſhoots of not more than a year or two old, being laid down in ſpring, ſummer, or early in autumn, when many of them will take root, and in one or two years be fit for planting off into nurſery rows.

And the ſlips and cuttings ſhould be made by cutting or ſlipping off a quantity of the one-year's ſhoots, diveſting them of the lower leaves, and planting them in a ſhady border thick together, in ſmall trenches, in the early ſpring or autumn, giving water at planting, and afterwards occaſionally in dry hot weather. They will be well rooted in two years, and be fit for being planted out into wide nurſery rows, or in any other ſimilar manner.

All theſe plants may be employed as ornamental evergreens, and as foreſt-trees; and they were formerly much uſed in hedges and trained figures: they have a good effect in ſhrubberies among others of the evergreen tribe, being permitted to aſſume their natural growth, in common with other trees and ſhrubs; and alſo when planted as detached ſtandards, in extenſive diſtant opens of graſs-ground, in parks, and the ſides of hills, &c.; likewiſe when introduced as foreſt-trees in timber plantations of the evergreen kind. See PLANTATION.

The different ſorts of hedges and figure-works which were formerly in ſo high repute in gardens and pleaſure-grounds, are now almoſt wholly in diſuſe, theſe being at preſent laid out in a more open and rural manner, ſo as to have a greater imitation of nature, and a more full diſplay of their ſeveral quarters and parts, as the lawn, walks, and other places, together with the various plants belonging to them.

Single yews are now even hardly ever admitted in modern deſigns by way of ornament, but theſe trees, in their natural growths, are deſirable for introducing into large plantations of the durative kind, for the ſake of increaſing the variety; and though ſome perſons reject them in conſequence of their poiſonous nature, and gloomy mournful aſpect, others admire them for ſuch ſolemn appearances, and think they afford a remarkably fine contraſt with the other more lively evergreens. There can be no doubt that the leaves, eſpecially when withered, or dried a little, are of a poiſonous quality; beſides, the tree has had the title of the *deadly yew* given to it by ſome, and been looked upon as an emblem of mortality, and on that account planted in church-yards, to remind people of their latter end. That accidents have frequently ariſen to cattle, of both the horſe and cow kind, from eating the green leaves and tender ſhoots, but more particularly when in the above ſtates, is certain. Therefore, as the cuttings or clippings of this ſort are often liable to be eaten with greedineſs by ſome cattle, particularly cows, even when they have lain in the ſun for a day or two, and are become half dried, it is proper and neceſſary that they ſhould be either carefully deſtroyed by fire, or put quite out of the way of all ſorts of animals, and not, as is too frequently the practice, be careleſsly thrown over the walls or hedges, into the roads, lanes, or on the rubbiſh heaps, where cattle frequent.

The beſt ſizes of yew plants are probably from two or three, to five or ſix feet in height; but thoſe of ſeven or eight may be removed with balls of earth about their roots, and be uſed for particular purpoſes and occaſions. Watering at the time of planting them is conſtantly requiſite.

TAXUS, in *Zoology*, the URSUS *Mæles*, or common *Badger*; which ſee.—Alſo, a name given by Kæmpfer to the hyæna of the ancients. See CANIS *Hyæna*, and HYÆNA.

TAY, in *Geography*, is a river in Perthſhire, Scotland, conſidered as the greateſt of the Scottiſh rivers, has its ſource in the weſtern extremity of the county, in the diſtrict of Breadalbane, on the frontiers of Lorn, in Argyleſhire; but has not the appellation of Tay till it iſſues from the lake of that name. At its ſource it bears the name of Fillan; and deſcending in a circuitous courſe of eight or nine miles through a valley, to which it gives the name of Strathfillan, it falls into Loch Dochart. This lake, about three miles in length, has an ancient caſtle upon an iſland, overhung by a huge promontory; the whole embowered with wood, ſo as to have a moſt romantic appearance. Iſſuing from Loch Dochart, the river retains that name, and gives the appellation of Glen-Dochart to the vale through which it runs. At the eaſtern extremity of this valley, the water is again detained in its courſe; and being augmented by the river Lochay, the united ſtreams form one of the moſt beautiful of the Scottiſh lakes, called Loch Tay. Iſſuing hence, the river aſſumes the name of the lake, which name it retains till it mingles with the waters of the ocean. The valley through which it paſſes may be conſidered as the paradiſe of the Highlands. On Loch Tay, and the river for ſome fome miles below it, the banks are richly cultivated, or covered with beautiful plantations, the whole overlooked and fheltered by mountains towering to the clouds; among which rifes the lofty Benlawers, the third mountain in point of height in the ifland. Here, near the village of Kenmore, is the magnificent feat of the earl of Breadalbane, called Taymouth; and in this valley, although the parifhes are twenty, thirty, or forty miles in extent, feveral parifh-churches are fituated in a tract of a few miles; a circumftance which demonftrates the difcernment of the clergy in ancient times in felecting their place of refidence. After leaving the lake about two miles, the Tay acquires a great increafe from the waters of the Lyon; at Logierat it receives the united ftreams of the Garry and the Tummel, and becomes a river of uncommon fize and beauty. Near Dunkeld it is increafed by the waters of the Bran, and receiving in its courfe the Ifla, with its tributary ftreams from the eaft, and the Almond from the weft, proceeds by Perth between the hills of Kinnoul and Moncrieff, till it meets the Earn, after which it proceeds eaftward, forming the eftuary or Frith of Tay; which expands to the breadth of three miles, but contracts to two miles as it approaches Dundee, about eight miles below which, it pours its waters into the German ocean. The hills of Kinnoul and Moncrieff afford extenfive profpects; that from the latter is denominated by Pennant the "Glory of Scotland." The Tay is navigable as far as Newburgh, in Fife, for veffels of 500 tons; and veffels of confiderable fize can go up as far as Perth. The Frith of Tay is not fo commodious as that of the Forth; but from the Buttonnefs or Barray fands to Perth (an extent of nearly forty miles), the whole may be confidered as a harbour; having the county of Fife on one fide, and thofe of Angus and Perth on the other. There are fewer great falls of water on the Tay than in moft other rivers which rife in a highland diftrict; but it poffeffes feveral cafcades of confiderable height, particularly at the Linn of Campfie, near its junction with the Ifla, where the water is precipitated over a huge bafaltic dike into a pool of great depth.—Beauties of Scotland, vol. iv. Perthfhire, 1806. Gazetteer of Scotland, 1806.

Tay, *Loch*, a lake in Perthfhire, Scotland, extends about fifteen miles in length from the village of Killin, its weftern extremity, to its eaftern termination at the village of Kenmore; its breadth is only from one to two miles. Its depth varies in different parts, from fifteen to a hundred fathoms. The banks on both fides are fertile, and finely diverfified by the windings of the coafts and the varied appearances of the mountains. On a fmall promontory near the eaftern extremity, are the church and village of Kenmore, near which, on a fmall ifland covered with trees, ftand the ruins of a priory, which was dependent on the religious eftablifhment of Scone. It was founded, in 1122, by king Alexander I., who depofited there the remains of his queen Sybilla, the natural daughter of Henry I. of England. On the death of Alexander the priory was more liberally endowed, that the monks might perform maffes for the repofe of his foul, as well as for that of his queen. The loch abounds with falmon, pike, perch, eels, charr and trout. The falmon are peculiarly excellent; the fifhery for which commences in December, and ends on the 26th of Auguft. The earl of Breadalbane has the exclufive right of fifhing there at all feafons. This privilege was originally granted for the purpofe of fupplying fifh for the monks of the priory, and at the diffolution was, with the ifland, claimed by this noble family. The waters of this lake have at times fuffered violent and unaccountable agitation. An ample account of one of thefe phenomena, which occurred on Sunday, September 12, 1780, is publifhed in the firft volume of the Tranfactions of the Royal Society of Edinburgh. It was written by Mr. Fleming, late minifter of Kenmore. He ftates, that "about nine o'clock in the morning the water was obferved to retire about five yards within the ordinary boundary, and in four or five minutes to flow out again. In this manner it ebbed and flowed fucceffively three or four times within the fpace of a quarter of an hour, when all at once the water rufhed from the eaft and weft in oppofite currents, and rofe in the form of a great wave to the height of five feet above the ordinary level, leaving the bottom of the bay dry to the diftance of between ninety and an hundred yards from its natural boundary. When the oppofite currents met, they made a clafhing noife and foamed; and the ftronger impulfe being from the eaft, the wave, after rifing to its greateft height, rolled weftward, but flowly diminifhing as it went, for the fpace of five minutes, when it wholly difappeared. As the wave fubfided, the water flew back with fome force, and exceeded its original boundary four or five yards; then it ebbed again about ten yards, and again returned, and continued to ebb and flow in this manner for the fpace of two hours, the ebbings fucceeding each other at the diftance of about feven minutes, and gradually leffening, till the water fettled into its ordinary level. During the whole time that this phenomenon was obferved, the weather was calm. It could fcarcely be perceived that the direction of the clouds was from north-eaft." On the 13th of July, 1794, the loch experienced agitations fimilar to thofe defcribed by Mr. Fleming, but they were neither fo violent nor fo long continued.—Beauties of Scotland, vol. iv. Perthfhire.

Tay, a river of Ireland, in the county of Waterford, which runs into the fea, 7 miles W.N.W. from Dungarvan bay.

TAYA, a river of Auftria, which rifes near Schweigers, paffes by Drofendorf, and enters Moravia, paffes by Znaym, Laab, &c. and joins the Marfch, 4 miles N.N.E. of Hockenau.—Alfo, a fmall ifland in the Indian fea, near the weft coaft of Siam. N. lat. 7° 38′. E. long. 98° 30′.

TAYABO, a town on the eaft coaft of the ifland of Celebes, in Gunong-Tellu bay. S. lat. 1° 10′. E. long. 121° 30′.

TAYASAN, a town on the eaft coaft of the ifland of Negros. N. lat. 10° 18′. E. long. 123° 3′.

TAYBA, a ruined town in the deferts of Syria, which fhews in its prefent ftate, evident marks of its former magnificence.

TAYECUA, a town of South America, in the province of Darien; 30 miles W. of St. Marie de Darien.

TAYGETA, in *Ancient Geography*, a river of the Peloponnefus, in Laconia.

TAYGETUS, a mountain of Laconia, S.W. of Bryfées, being a portion of a fmall chain of mountains on the promontory of Tenarus, on the frontiers of Arcadia. It was famous for the abundance of its game. On this mountain was a place confecrated to the fun, called by Paufanias "Talet." Here they facrificed, among other victims, horfes.

TAYKYATT, a long and ftraggling town of the Birman empire, on the W. fide of the Irawaddy; 5 miles W.N.W. of Yeoungbenzah.

TAYL, in *Heraldry*. See Tail.

TAYLOR, Brook, LL.D. and F.R.S., in *Biography*, an eminent mathematician, was born of a good family, at Edmonton, near London, in the year 1685. In early life he devoted himfelf to mufic, drawing, and painting, in which he was reckoned to excel. At the fame time he purfued his classical studies and mathematics under a private tutor; and in 1701, at the age of 15, he was entered a fellow-commoner at St. John's college, in the university of Cambridge. Such was his assiduity in the prosecution of mathematics, that in 1708 he composed his treatise "On the Centre of Oscillation," which was published in the Phil. Transf. In the next year he took his degree of bachelor of laws, and in 1712 he was elected fellow of the Royal Society. By a letter addressed to Mr. Machin, dated in this year, it appears that he had then given a solution of Kepler's famous problem, pointing out its importance and use. He also at the same period presented to the Society three papers, *viz.* "On the Ascent of Water between two Glass Planes;" "On the Centre of Oscillation;" and "On the Motion of a stretched String." In consideration of his services to the Society, and distinguished qualifications for the office, he was elected their secretary in 1714, taking in the same year his degree of doctor of laws at Cambridge. In 1715, he published his "Methodus Incrementorun;" a curious essay, preserved in the Phil. Transf. entitled, "An Account of an Experiment for the Discovery of the Laws of Magnetic Attraction;" and also a treatise, of high value and reputation, "On the Principles of Linear Perspective." His correspondence this year with count de Montmort on the tenets of Malebranche was ably conducted, and gained for him an eulogy from the French academy; and in 1716, on his visit to Paris, he was treated with great personal respect. Upon his return to London, in 1717, he composed three treatises, published in the 30th volume of the Phil. Transf.; the titles of which are, "An Attempt towards an Improvement of the Method of approximating in the Extraction of Roots of Equations in Numbers;" "A Solution of Demoivre's 15th Problem, with the Assistance of Combinations and infinite Series;" and "A Solution of the Problem of G. G. Leibnitz proposed to the English." His health being impaired by intense application, he was obliged to seek relief at Aix-la-Chapelle. Upon his return, in 1719, he directed his attention to studies very different from those to which he had been accustomed; and the fruits of these studies have been found among his papers by his grandson sir William Young, in detached fragments of a treatise on the Jewish sacrifices, and a dissertation on the lawfulness of eating blood. His leisure hours were still devoted to the application of mathematics in the improvement of the arts; and with this view he revised his treatise on Linear Perspective, which appeared in a new and enlarged form. Drawing was also a favourite amusement. His treatise on Linear Perspective, which has been held among mathematicians in the highest estimation, produced at this time a controversy, which terminated in a very serious misunderstanding, between him and J. Bernouilli. This treatise, abstruse to those who consult it for mere practical purposes, was rendered more plain and perspicuous by Mr. Kirby, in an edition, entitled "Brook Taylor's Perspective made easy." Our author's answer to Bernouilli is preserved in the 30th volume of the Phil. Transf. Soon after his return to England in 1721, he published the last paper that appears with his name in the Phil. Transf. entitled "An Experiment made to ascertain the Proportion of Expansion of Liquor in the Thermometer, with regard to the Degree of Heat."

Dr. Taylor was twice married: his second wife was a daughter of John Sawbridge, esq. of Olantigh in Kent. On the death of his father, in 1729, he succeeded to the family estate of Bifrons in Kent, and in the following year his wife died in child-bed. About this time he probably wrote the essay, entitled "Contemplatio Philosophica," published by sir W. Young in 1793. But though his mind might have thus obtained temporary relief, he survived his wife little more than a year, and died of a decline in the 46th year of his age, December 1731. "I am spared," says his descendant, "the necessity of closing this biographical sketch with a prolix detail of his character, in the best acceptation of duties, relative to each situation of life in which he was engaged; his own writings, and the writings of those who best knew him, prove him to have been the finished Christian, gentleman, and scholar." Life by his grandson, sir William Young, prefixed to his Posthumous Works.

Taylor, Jeremy, an eminent divine and prelate of the established church in Ireland, was the son of a barber at Cambridge, where he was born in the early part of the 17th century. At the age of 13 he was admitted at Gonville and Caius college in the university of that place, where he remained till he took the degree of M.A. Having taken orders, he occasionally preached in London, and obtained by the interest of archbishop Laud, in 1636, a fellowship of All Souls' college, Oxford. Here he resisted attempts that were made to proselyte him to popery, and became more established in Protestant principles. Laud appointed him one of his chaplains, and procured for him the rectory of Uppington, in which he settled about the year 1640, at which time he surrendered his fellowship and married. In 1642 he was chaplain in ordinary to Charles I., and served his cause by writing in defence of the church of England. When the parliament became victorious, his living was sequestered, and he retired into Wales, where he was kindly received by the earl of Carbery, of Golden Grove, near Llandilo, in Carmarthenshire; under whose protection he exercised his ministry, and kept a school for the support of his family. In this state of retirement, he composed those discourses, which caused him to be held in high estimation, as one of the first writers in the English language, "with respect to fertility of conception, eloquence of expression, and comprehensiveness of thought." At this period the death of three hopeful sons disturbed his tranquillity, and rendered it necessary for him to change the scene and to remove to London, where he exposed himself to considerable danger by officiating in a private congregation of loyalists. Invited by Edward lord Conway to his seat at Portmore in the county of Antrim, he remained in Ireland until the Restoration. On that event he came over to England, and in January 1660-1, his services were recompensed by the promotion to the sees of Down and Connor. He was also made privy-counsellor of Ireland, and appointed to the administration of the bishopric of Dromore, and honoured with the office of vice-chancellor to the university of Dublin. In these high and responsible stations he paid sedulous attention to his official duties, exhibited an example of piety, humility, and charity; and employed so great a part of his income in doing good, both privately and publicly, that when he died at Lisburne in 1667, he left only moderate portions to his three daughters. His person was comely, his manners were polite, his voice was melodious, and his conversation was agreeable. Of his works, which were numerous, consisting chiefly of sermons and devotional pieces, and printed in four, and also in six volumes, folio, the most remarkable is entitled, "Theologia Eclectica, or a Discourse on the Liberty of Prophesying; shewing the unreasonableness of prescribing to other men's faith, and the iniquity of persecuting different opinions," 4to. first published in 1647. The author, when this book was written, belonged to a vanquished and persecuted party; and he strongly and boldly pleads for liberty of conscience, and the rights of individuals to judge for themselves in matters of religion.

religion. This work, confidering the time in which it was written, and the connections of the author, indicates a very enlightened mind with regard to the fubjects of difcuffion; and it is perufed with no fmall degree of intereft in the prefent period of greater knowledge and liberality. With refpect to toleration, however, we obferve, that he limits it to fuch doctrines as are not inconfiftent with fociety or the public good;—a limitation which is capable of being much mifconftrued and mifapplied. Having afferted, as a firft principle, that "the duty of faith is completed in believing the articles of the Apoftles' creed," he could not confiftently approve the impofition of ftricter creeds. Of the Athanafian creed he thus fpeaks: "If I fhould be queftioned concerning the fymbol of Athanafius, I confeffe I cannot fee that moderate fentence and gentleneffe of charity in his preface and conclufion, as there was in the Nicene creed. Nothing there but damnation and perifhing everlaftingly, unleffe the article of the Trinity be believed, as it is there with curiofity and minute particularities explained. Befides, if it were confidered concerning Athanafius's creed, how many people underftand it not, how contrary to natural reafon it feems, how little the fcripture fayes of thofe curiofities of explication, and how tradition was not clear on his fide for the article itfelfe, much leffe for thofe forms and minutes,—and after all this, that the Nicene creed itfelfe went not fo farre, neither in article, nor anathema, nor explication, it had not been amiffe if the final judgment had been left to Jefus Chrift."

This celebrated work did not efcape invidious criticifm and fevere animadverfion. Among others we may mention Anthony Wood, who, with cenfurable illiberality, fuggefted, that Taylor in this book, and Hales in his tract on Schifm, employed their arguments as a ftratagem by way of raifing factions among the Prefbyterians, and diffolving their union. The moft popular of Taylor's other writings, have been his "Golden Grove, or Manual of daily Prayers;" his treatife on "Holy Living and Dying;" and his "Ductor Dubitantium, or Rule of Confcience." Dr. Dodwell long fince obferved, and not unjuftly, that "Dr. Taylor, in his voluminous writings, faid many lively things, which will not bear a ftrict examination." Biog. Brit. Gen. Biog.

Taylor, John, D.D. a learned and highly refpectable divine among Proteftant Diffenters, was born in the year 1694, at or near Lancafter. After having received his education at Whitehaven under Dr. Dixon and others, he was nominated by one of the Difney family to the chapel of Kirkftead, in Lincolnfhire, exempt from ecclefiaftical jurifdiction, and which had been occupied from the latter end of the preceding century by diffenting minifters. Here he lived, on a fmall falary aided by a fchool, for 18 years; and laid a foundation for the theological celebrity, which he afterwards acquired by a diligent ftudy of the fcriptures in their original languages. In this obfcure and retired fituation he did not efcape notice; and in the year 1733, he complied with an invitation from the Prefbyterian congregation at Norwich. To his congregation, which had been before his fettlement ferved by Calviniftic minifters, he recommended the perufal of Dr. Clarke's Scripture-Doctrine of the Trinity. His firft publication was "A Prefatory Difcourfe to Mr. Jofeph Rawfon's Cafe," who, in 1736, had been excluded from communion with the congregational church at Nottingham, for refufing his affent to a declaration required of him concerning the Trinity; in which he ably defended the right of Chriftians to deduce their faith from the fcriptures, without the intervention of creeds and fubfcriptions. His firft avowed attack upon Calviniftic theology, was the publication of his "Scripture-Doctrine of Original Sin," which firft appeared in 1740. This excited alarm and animadverfion. (For an account of this controverfy, fee the article *Original* Sin.) Dr. Taylor's fupplement was publifhed in 1741. This was fucceeded, in 1745, by "A Paraphrafe on the Epiftle to the Romans, with a Key to the Apoftolic Writings." This "Key" was well received, and has been highly commended. The late learned Dr. Watfon, bifhop of Llandaff, has given it a place in his "Theological Tracts;" and archdeacon Paley recommends a careful perufal of the Paraphrafe on the Romans to candidates for priefts' orders. The labours of his fubfequent years produced feveral fmall tracts, and particularly his "Scripture-Doctrine of Atonement;" but his opus majus, as we may juftly denominate it, was his "Hebrew Concordance," in folio, the firft volume of which appeared in 1754, and the fecond in 1757. This work, which does immortal honour to the critical fkill and indefatigable affiduity of the author, was encouraged by a great number of fubfcribers, among whom we may enumerate twenty-two Englifh, and fifteen Irifh bifhops. Soon after the publication of this performance, the author was prefented by the univerfity of Glafgow with the degree of D.D. In 1754 he publifhed a pamphlet, entitled "The Lord's Supper explained upon Scripture Principles," and in 1757 appeared a defence of infant baptifm, entitled "The Covenant of Grace." Dr. Taylor was happily fituated at Norwich, and received every teftimony of refpect to which his learning and character entitled him; but a fcene of more public and general ufefulnefs was opened to him in the year 1757, when he was invited to fupply the place of divinity-tutor at the newly-founded academy of Warrington, in Lancafhire. But here his fituation was rendered unpleafant to him; and fome events occurred which affected his health and fpirits. Although he performed his official duties for fome time amidft the difquiets which he experienced, he was at length carried off, by an unperceived death, during the night of March 5, 1761, at the age of 66 years. At Warrington he publifhed two pamphlets, *viz.* "An Examination of the Scheme of Morality advanced by Dr. Hutchefon, late Profeffor of Morality in the Univerfity of Glafgow," and "A Sketch of Moral Philofophy," for the ufe of his clafs. He alfo prepared for the prefs "The Scripture Account of Prayer, in an Addrefs to the Diffenters in Lancafhire," in confequence of the introduction of a liturgy at Liverpool, an innovation in the accuftomed mode of worfhip among Diffenters which he difapproved. His pofthumous work, entitled "A Scheme of Scripture Divinity," was publifhed by Mr. Richard Taylor of Norwich, his eldeft furviving fon; and it was held in fuch eftimation by the late bifhop of Llandaff, as to form a part of his Collection of Tracts. As a preacher, Dr. Taylor was plain and fimple in his language, but dignified and impreffive; and he excelled in a critical explanation of difficult paffages of fcripture. He had the merit of introducing into the congregation at Norwich a fpirit of liberal enquiry, which, we are informed, ftill continues. Memoir on the Life of Dr. John Taylor of Norwich.

Taylor, John, LL.D., the fon of a barber at Shrewfbury, was born about the year 1703, and diftinguifhed himfelf as a fcholar and critic. After a courfe of preparatory education in his native town, he was entered at St. John's college in Cambridge, and became a fellow of it in the year 1730, in which year he publifhed two Latin academical orations. In 1732 appeared propofals for an edition of Lyfias. He was firft librarian and afterwards regiftrar of the univerfity. His "Lyfias," Gr. and Lat., with the conjectures of Markland, was publifhed from the prefs of

Bowyer,

Bowyer, in 1739; and a new edition, with Taylor's verfion and notes, was printed at Cambridge in the following year. Upon taking his degree of LL.D. he delivered and publifhed a differtation under the title of "Commentarius ad legem decemviralem de inope debitore in partes diffecando." In 1743, he publifhed "Orationes duæ; una Demofthenis contra Meidiam; altera Lycurgi contra Leocratem," Gr. and Lat. with notes and emendations; and in the following year, "Marmor Sandvicenfe, cum Commentario et Notis," being a differtation on an Athenian marble brought to England by lord Sandwich, bearing the oldeft infcription of known date.

In 1741, Dr. Taylor had been admitted an advocate in Doctors' Commons, and in 1744 he was made chancellor of Lincoln. He afterwards took orders, and printed a fermon preached at Bifhop-Stortford in 1749. He was prefented to the archdeaconry of Buckingham, to the rectory of Lawford, Effex; and in 1757 to a refidentiaryfhip of St. Paul's. In 1755, ftill profecuting his legal ftudies, he publifhed "Elements of the Civil Law," 4to. reprinted in 1769. An abridgment of this learned work, entitled "A Summary of the Roman Law," was publifhed in 1773.

Dr. Taylor held alfo the offices of commiffary of Lincoln and of Stowe: he was a member of the Royal and Antiquarian Societies; and of the latter he was one of the vice-prefidents. At the time of his death, his long-promifed edition of Demofthenes was juft finifhed, in two vols. 8vo. at the univerfity prefs, Cambridge; and the notes were afterwards added, together with part of an appendix to Suidas. The character of Dr. Taylor was that of an amiable and difinterefted man; and the world was deprived of his learned labours in April 1766. To the works already mentioned, we may add fome remarks inferted in Fofter's "Effay on Accent and Quantity," and various pieces of poetry, printed in the Gentleman's Magazine, and in Nichols's "Select Collection of Poems." Anecd. of Bowyer. Month. Rev. Gen. Biog.

Taylor, Henry, A.M. a very refpectable clergyman of the eftablifhed church, was the fon of William Taylor, merchant of London, and born at Southweald, in Effex, in May 1711. The rudiments of his education he received at Mr. Newcome's fchool, in the parifh of Hackney, and there he formed an early friendfhip with Mr. John Hoadly, fon of Dr. Benjamin Hoadly, bifhop of Winchefter. From Hackney he removed to Queen's college, in the univerfity of Cambridge, and having completed his education with a view to the church, he took orders, and commenced the exercife of his minifterial duties as a preacher with fingular acceptance. His talents and acquirements, as well as his voice and manner of delivery, which were peculiarly pleafing, recommended him to public notice, and he ranked high in the eftimation of thofe friends with whom he intimately affociated. His firft preferment was the rectory of Whitfield, in Oxfordfhire, which he held for a minor. In 1755 he was prefented by bifhop Hoadly to the rectory of Crawley, in Hampfhire, which he afterwards held in connection with the vicarage of Portfmouth, in exchange for a living in Hampfhire, which he had held with Whitfield. He married Mifs Chriftian Fox, daughter of the Rev. Francis Fox, rector of St. Mary's, Rotherhithe, who died in the year 1769; and by her he had four fons and two daughters. His courfe of literary and clerical labour terminated in April, 1785, and he was interred at Crawley.

Having recited the few particulars which we could collect concerning the private life of Mr. Taylor, we fhall now fubjoin a lift of his publications, fome having his name and others being anonymous. In 1760 he publifhed "An Effay on the Beauty of the Divine Economy; being the Subftance of a Sermon (with many and large Additions) preached at the Vifitation of the Lord Bifhop of Winchefter, held by the Worfhipful and Reverend Dr. John Hoadly, Chancellor of the Diocefe, on Tuefday September 18, 1759, at the cathedral Church of Winchefter, and publifhed at the Defire of Mr. Chancellor and the Clergy."—"A full Anfwer to a late View of the internal Evidence of the Chriftian Religion, in a Difcourfe between a rational Chriftian and his Friend," 1771.—"A Tract againft Warburton," 1772.—"Confufion worfe confounded, Rout on Rout; or the Bifhop of G——ter's Commentary upon Rice or Arife Evans's Echo from Heaven, examined and expofed by *Indignatio*," London, 1772. Anonymous. "Two Letters; *viz.* 1. A Letter to the Earl of Abingdon, in which His Grace of York's Notions of Civil Liberty are examined by *Liberalis*, publifhed in the London Evening Poft, November 6, 1777. 2. *Vera Icon;* or a Vindication of His Grace of York's Sermon, preached on February 21ft, 1777; proving it to contain a fevere Satire againft the Miniftry, and a Defence of civil and religious Liberty, upon the well-known Principles of Whiggifm; in anfwer to a Letter from *Liberalis* to the Earl of Abingdon, by *Myftagogus Candidus.*"—"The Apology of Benjamin Ben Mordecai to his Friends, for embracing Chriftianity; in feven Letters to Elifha Levi, Merchant of Amfterdam; with Notes and Illuftrations, by the Author and the Editor." Lond. 1771. 1773, 1774, 4to. The firft of thefe letters contains an account and examination of the various opinions among Chriftians, concerning the nature and perfon of Chrift. In the fecond, third, and fourth letters, it is propofed to fhew from fcripture, that the Logos was the angel of the covenant, and to prove the fame from the moft approved commentators on fcripture, both ancient and modern, both Jewifh and Chriftian; and to demonftrate that Jefus was the Meffiah. The fifth, fixth, and feventh letters contain preparatory principles to the Chriftian fcheme of redemption; giving the fcheme of Chriftianity itfelf, and fhewing it to be one, plain, regular, and confiftent fyftem of divine economy, from the beginning of the world to the end; and containing proofs, illuftrations, anfwers to objections, and an examination of Mr. Hume's notion of miracles.—"Thoughts on the Nature of the Grand Apoftacy, with Reflections and Obfervations on the Fifteenth Chapter of Mr. Gibbon's Hiftory of the Decline and Fall of the Roman Empire; to which are added three differtations: 1. On the Paroufia of Chrift; 2. On the Millennium; 3. On the late Rev. Mr. Richard Wood, on Prophecy," 1781.—"Farther Thoughts on the Nature of the Grand Apoftacy of the Chriftian Churches, foretold by the Apoftles; with Obfervations on the Laws againft Herefy, the Subfcription to Articles of Human Compofition, and other Subjects of the utmoft Importance to the Religion of Proteftants, and to Chriftianity in general," 1783.—"Confiderations on Ancient and Modern Creeds compared; the Supremacy of the Father; the perfonal Exiftence of the Holy Spirit; the Pre-exiftence of Chrift and his Divinity, &c." publifhed after the author's death by his fon, the Rev. Henry Taylor, rector of Spridlington, Lincolnfhire, 1788.

Mr. Taylor, who was of a fprightly, cheerful difpofition, occafionally amufed himfelf in writing verfes; fome of which, particularly his "Paradife Regained," are publifhed in Dodfley's Collection.

On Mr. Taylor's principles and character it is needlefs to enlarge. His conduct in private and focial life correfponded to his clerical profeffion: to the fentiments of bifhop Hoadley, in church and ftate, he was invariably attached; he joined the

petitioning

petitioning clergy in their application for an enlargement of the terms of conformity; and he avowed himſelf on all occaſions, without diſguiſe, the friend and advocate of civil and religious liberty. In his theological opinions, he conſidered himſelf as coinciding more nearly with Apollinaris, than with any other.

TAY-MING, in *Geography*, a city of China, of the firſt rank, in Pe-tche-li; 232 miles S.S.W. of Peking. N. lat. 36° 20′. E. long. 114° 49′.

TAYNG, a town of Corea; 25 miles S.E. of Haimen.

TAYWAN, or TAI-OUAN, the capital of *Formoſa;* which ſee.

TAZ, a river of Ruſſia, which riſes from two lakes, Ku and Din, and runs into the Tazovſkaia gulf, N. lat. 67° 35′. E. long 80° 14′.

TAZABUCO, a town of Peru; 46 miles E.N.E. of La Plata.

TAZATA, in *Ancient Geography*, an iſland of the Caſpian ſea, near the coaſt of Hyrcania. Pliny. It is called Talca by Ptolemy, and Talga by Mela.

TAZEE, in *Geography*, a town of Candahar; 70 miles E. of Candahar.

TAZEWELL, a poſt-town of Tenneſſee; 517 miles W.S.W. of Waſhington.

TAZINA, in *Ancient Geography*, a town of Aſia, in Media.

TAZLA, or SALATO, in *Geography*, a lake of Aſiatic Turkey, 36 miles long, and 2 broad; 30 miles N. of Cogni.

TAZLA, a town of Aſiatic Turkey, in Caramania; 28 miles N. of Cogni.

TAZOVSKAIA, a gulf or bay in the Obſkaia gulf, formed by the waters of ſeveral rivers of Siberia, and joined to the Obſkaia gulf, about 140 miles in length, and 3 in breadth. N. lat. 67° 40′ to 69°. E. long. 76° to 80°.

TAZREE, a town of Perſia, in the province of Lariſtan; 15 miles N.E. of Tarem.

TAZUS, TACHELY, in *Ancient Geography*, a town in the interior of the Tauric Cherſoneſus, E. of Portacra, mentioned by Ptolemy.—Alſo, a town of Aſiatic Sarmatia, upon the northern coaſt of the Euxine ſea.

TAZZETTA, in *Botany*, the ſpecific name choſen by Linnæus, who ſpells it incorrectly, for the Polyanthus Narciſſus. (See NARCISSUS.) The word is Italian for a ſmall cup, and De Theis ſuppoſes it was firſt applied in Italy to this flower, which is much cultivated there, and uſually imported from thence, in its higheſt perfection, by our floriſts. Still we do not ſee how Linnæus came to adopt this name, nor, indeed, how it fell in his way.

TCHA. See TEA.

TCHA, or *Cangua*, in *Geography*,. See CANGA.

TCHABA, a town of Aſiatic Turkey, in Natolia; 18 miles E. of Boli.

TCHABAR, a river of Chineſe Tartary, which runs north into the Songarie.

TCHABISCHI, a town of Ruſſia, in the government of Irkutſk, on the Amur; 40 miles N.N.E. of Stretenſk.

TCHACAHAMAR, a town of Thibet; 10 miles W. of Orto.

TCHACAOSO, a town of Thibet; 25 miles S. of Chatcheou.

TCHACA-TCHOUTCHI, a town of Thibet; 30 miles N.W. of Tchontori.

TCHACA-TOHOI, a town of Chineſe Tartary, in the country of Hami; 15 miles N.W. of Quatcheou.

TCHADOBSKO, a town of Ruſſia, in the government of Tobolſk, on the Tunguſka; 212 miles E. of Eniſeiſk.

TCHAGANSKOI, a fortreſs of Ruſſia, on the Ural; 16 miles S. of Uralſk.

TCHAGODO, a town of Ruſſia, in the government of Novgorod, on the lake Voz; 240 miles N.E. of Novgorod. N. lat. 60° 30′. E. long. 38° 44′.—Alſo, a river of Ruſſia, which riſes near Suchotzkoi, in the government of Novgorod, and runs into the Mologa, 16 miles N. of Uſtiuzna.

TCHAHAN HOTUN, a town of Chineſe Tartary; 260 miles N. of Peking. N. lat. 43° 58′. E. long. 117° 29′.

TCHAHAN *Hamer*, a town of Chineſe Tartary; 38 miles S.W. of Coucou.

TCHAHAN *Soubarkan Hotun*, a town of Chineſe Tartary; 163 miles N.N.E. of Peking. N. lat. 41° 38′. E. long. 118° 44′.

TCHAHASOU HOTUN, a town of Chineſe Tartary; 683 miles N.N.E. of Peking. N. lat. 49° 34′. E. long. 127° 42′.

TCHAHI, a town of Perſia, in the province of Choraſan, or Khoraſſan; 258 miles N. of Herat.

TCHAIA, a river of Ruſſia, which runs into the Lena, near Tchamſka, in the government of Irkutſk. N. lat. 58° 5′. E. long. 109° 34′.

TCHAICAN, a town of Corea; 28 miles W. of Outchuen.

TCHAI-YAM, a river of China, which joins the Lo, 15 miles W.S.W. of Pao-king.

TCHAKAN-TOTOHO KIAMEN, a poſt of Chineſe Tartary, in the country of the Monguls; 18 miles S.E. of Kara-Hotun.

TCHAKET, a town of Aſiatic Turkey, in Aladulia; 15 miles N. of Adana.

TCHAKTELA, a town of Aſiatic Turkey, in Caramania; 27 miles N. of Akſhehr.

TCHAL, a town of Kurdiſtan, or Curdiſtan; 28 miles E. of Amadieh.

TCHALBISCHEVO, a town of Ruſſia, in the government of Tobolſk; 20 miles S. of Eniſeiſk.

TCHALMOZA, a town of Ruſſia, in the government of Olonetz, on the north-eaſt coaſt of lake Onezſkoe; 32 miles S.E. of Povenetz.

TCHAM, a town of Corea; 420 miles E. of Peking.

TCHAMDSOU-TIGAC, a lake of Thibet, about 36 miles in circumference. N. lat. 31° 30′. E. long. 81° 26′.

TCHAMNAGOM-DOU, a lake of Thibet, about 36 miles in circumference. N. lat. 30° 50′. E. long. 93° 54′.

TCHAMSKA, a town of Ruſſia, in the government of Irkutſk; 64 miles E.N.E. of Kirenſk.

TCHAM-TCHIM HOTUN, a town of Corea; 415 miles E. of Peking. N. lat. 40° 9′. E. long. 124° 46′.

TCHAM-TIEN, a town of Chineſe Tartary; 43 miles N.W. of Siao-ku-leou.

TCHAMTOU, a town of Thibet; 54 miles S.W. of Contchoudſong.

TCHANG, a lake of China, about 20 miles in circumference; 40 miles N.E. of Tcin-tcheou.

TCHANG-CHAN, or CHAN-SAN, a ſmall iſland in the Chineſe ſea, and moſt ſoutherly of thoſe called Mi-a-tou; 18 miles N.W. of Teng-tcheou.

TCHANG-FONG, a town of Corea; 63 miles E.S.E. of King-ki-tao.

TCHANG-HOA, a town of China, of the third rank, in the iſle of Hainan; 42 miles S.W. of Tchen-tcheou.

TCHANG-ING, a town of Corea; 40 miles S. of Kang.

TCHANG-KIA-KEOU, a gate on the great wall, which separates China from Tartary, in the northern part of Pe-tche-li, the principal passage by which the Tartars enter China; 90 miles N.N.W. of Peking.

TCHANG-PING, a town of Corea; 15 miles E. of Koang-tcheou.—Also, a city of China, of the second rank, in Pe-tche-li; 20 miles N.N.W. of Peking. N. lat. 40° 14'. E. long. 115° 37'.

TCHANG-SING, a town of Corea; 35 miles S. of Koang-tcheou.

TCHANG-SONG, a town of Corea; 33 miles N.W. of Kang-tcheou.

TCHANG-TCHA, a city of China, of the first rank, in Hou-quang, on the Heng river. The inhabitants of this city have given occasion to a great festival, which is celebrated in the fifth month throughout the empire. The mandarin who governed this city, and was much esteemed and beloved by the people for his probity and virtue, happening to be drowned in the river, they instituted a festival to his honour, which is celebrated by sports, and feasts, and fights upon the waters, as if they intended to search for the mandarin, the object of their love and grief. This festival, which was at first peculiar to this city, came afterwards to be observed throughout the empire; 742 miles S. of Peking. N. lat. 28° 11'. E. long. 112° 25'.

TCHANG-TCHEOU, a city of China, of the first rank, in Fo-kien; 950 miles S. of Peking. N. lat. 24° 32'. E. long. 117° 34'.—Also, a city of China, of the first rank, in Kiang-nan; 525 miles S.S.E. of Peking. N. lat. 31° 50'. E. long. 119° 29'.

TCHANG-TE, a city of China, of the first rank, in Hou-quang; 717 miles S.S.W. of Peking. N. lat. 29° 2'. E. long. 111° 2'.

TCHANG-YUEN, a town of Corea; 60 miles W.S.W. of Ho-ang-tcheou.—Also, a town of Corea; 30 miles S.E. of Kang-tcheou.

TCHANI, a lake of Russia, in the government of Kolivan, upwards of 200 miles in circumference; 100 miles W.N.W. of Kolivan.

TCHANKOUR, a town of Thibet; 105 miles S.E. of Sourman.

TCHAN-TE, a city of China, of the first rank, in Ho-nan. This is one of the most northern cities of the province. Two things are here remarkable: the first is a fish resembling a crocodile, the fat of which is of such a singular nature, that when once kindled it cannot be extinguished; the second is a mountain in the neighbourhood, so steep and inaccessible, that in time of war, it affords a place of refuge to the inhabitants, and a safe asylum from the insults and violence of the soldiery. Tchan-te contains in its district one city of the second class, and six of the third; 255 miles S.S.W. of Peking. N. lat. 36° 6'. E. long. 114°.

TCHAO-KING, a city of China, of the first rank, in Quang-tong, on the river Si; 1062 miles S.S.W. of Peking. N. lat. 23° 3'. E. long. 111° 44'.

TCHAO-NAIMAN-SOUMI-HOTUN, a town of Chinese Tartary; 198 miles N. of Peking. N. lat. 42° 28'. E. long. 115° 44'.

TCHAO-TCHEOU, a city of China, of the first rank, in Quang-tong, on the Pe-kiang; 1007 miles S. of Peking. N. lat. 23° 37'. E. long. 116° 21'.

TCHAOUTCHE-AGHISI, a town of Asiatic Turkey, in Natolia, on the Black sea; 12 miles N.W. of Erekli.

TCHAPIE-DSAKE-TOMPSOU, a lake of Thibet, about 54 miles in circumference. N. lat. 32° 12'. E. long. 84° 34'.

TCHARKAZ. See ZARCHAS.

TCHARONDA, a town of Russia, in the government of Novgorod, on the Sula; 188 miles E.N.E. of Novgorod. N. lat. 59° 40'. E. long. 37° 34'.

TCHASIRCONG, a town of Thibet, near the Ganges; 24 miles E. of Latac.

TCHASTIJA, an island of Russia, in the government of Irkutsk, on the Lena; 112 miles N.E. of Kirensk.

TCHAT, a mountain of Thibet, on the frontiers of Yarkan. N. lat. 33° 10'. E. long. 78° 44'.

TCHATELI, a town of Chinese Tartary, in the country of Hami; 38 miles N.W. of Hami-Hotun.

TCHAUNSKAIA, a gulf on the northern coast of Russia, in the Frozen sea. N. lat. 71° to 72°. E. long. 166° to 169°.

TCHAUSI, a town of Russia, in the government of Mogilev, on the Soz; 40 miles S.E. of Mogilev. N. lat. 53° 36'. E. long. 31° 14'.

TCHAZMIUNSKOI, a cape on the east coast of Kamtschatka; 52 miles S. of Verchnei Kamtschatskoi. N. lat. 55° 48'. E. long. 160° 15'.

TCHEBAKSAR, a town of Russia, in the government of Kazan, on the Volga; 64 miles W.N.W. of Kazan. N. lat. 56° 24'. E. long. 46° 30'.

TCHEBARKULSKAIA, a fortress of Russia, in the government of Upha; 132 miles E. of Upha.

TCHECHUI, a river of Russia, which runs into the Lena, nearly opposite Ilinska.

TCHECO, a town of Thibet; 93 miles E.S.E. of Lassa.

TCHEFTKAN, a town of Asiatic Turkey, in Aladulia; 45 miles N.N.W. of Adana.

TCHEGEN, an island in the Caspian sea; 144 miles S. of Astrachan.

TCHEGOTCHINA, a river of Russia, which runs into the Kolima, N. lat. 68°. E. long. 150° 14'.

TCHEGUEDE HOTUN, a town of Chinese Tartary, on the east bank of the Amur, opposite Teldom; 673 miles N.N.E. of Peking. N. lat. 49° 26'. E. long. 127° 37'.

TCHEHARSHEBEH, a town of Asiatic Turkey, in Natolia; 30 miles S.E. of Alah Shehr.

TCHEKENAGUR, a town of Asiatic Turkey, in Caramania; 21 miles S. of Kirshehr.

TCHE-KIANG, a province of China, bounded on the north and north-west by Kiang-nan, on the east by the sea, on the south by Fo-kien, and on the south-west by Kiang-si; about 200 miles in length from north to south, and from 120 to 180 broad. This province, which was formerly the residence of some of the emperors, is one of the most considerable in the empire, on account of its maritime situation, extent, riches, and the number of its inhabitants. The air is pure and healthful; the plains are watered by a number of rivers and canals, kept in good order; and the springs and lakes, with which it abounds, contribute greatly to its fertility. The natives are mild and lively, and very polite to strangers; but they are said to be extremely superstitious. A prodigious quantity of silk-worms is bred in this province; whole plains may be seen covered with dwarf mulberry-trees, which are purposely checked in their growth: they are planted and pruned almost in the same manner as vines. Long experience has taught the Chinese, that the leaves of the smallest trees procure the best silks. The principal branch, therefore, of the trade of this province, consists in silk-stuffs; those in which gold and silver are intermixed are the most beautiful, and most esteemed in the empire. With regard to their common pieces, an immense quantity is sent to every part of China, to Japan, the Philippines, and to

Europe ; and, notwithſtanding this exportation, ſo much is left, that a complete ſuit of ſilk may be bought here as cheap as one of the coarſeſt woollen-cloth in France. Excellent hams are brought from this province, and thoſe ſmall gold fiſh with which ponds are commonly ſtocked. The tallow-tree grows here, and a ſpecies of muſhrooms, which are tranſported to every province of the empire. In Tche-kiang there are reckoned to be 11 cities of the firſt claſs, 72 of the third, and 18 fortreſſes, which in Europe would be accounted large cities. (Groſier's China, vol. i. p. 64.) According to ſir George Staunton, the number of inhabitants amounts to 21 millions, and the province includes 39,150 ſquare miles, or 25,056,000 acres. See CHINA.

TCHELAO, a town of Perſia, in the province of Chorafan, or Khoraſſan : near it is a narrow defile in a mountain, called, by the orientaliſts, Hell, from the difficulty of the paſſage.

TCHELBOSCH, a river of Ruſſia, which joins the Biſuga, and runs with it into the ſea of Azof ; 40 miles S.W. of Eiſkoi.

TCHELEH-DAGHI, a mountain of Natolia, N.E. of Boli.

TCHELGA, a town of Abyſſinia ; 20 miles N.W. of Gondar. N. lat. 12° 44′. E. long. 37° 18′.

TCHELIABINSK, a town of Ruſſia, in the government of Upha ; 188 miles E. of Upha. N. lat. 54° 50′. E. long. 62° 4′.

TCHELMINAR, or TCHILMINAR. See CHILMINAR.

TCHEMURTAESKOI, in *Geography*, a fortreſs of Ruſſia, in the government of Irkutſk ; 60 miles S.W. of Selenginſk.

TCHEN, a town of Corea ; 13 miles N.N.E. of Ping-hai.—Alſo, a city of China, of the ſecond rank, in Ho-nan ; 416 miles S.S.W. of Peking. N. lat. 34° 46′. E. long. 110° 36′.—Alſo, a city of China, of the ſecond rank, in the iſland of Hai-nan ; 57 miles S.W. of Kiong-tcheou. N. lat. 19° 32′. E. long. 108° 49′.

TCHEN-AN, a town of Corea ; 35 miles S.S.E. of Hetſin.

TCHENBAR, a town of Ruſſia, in the government of Penza ; 80 miles W.S.W. of Penza. N. lat 52° 52′. E. long. 43° 30′.

TCHENDEI, a river of Ruſſia, which runs into the Yana, near its mouth.

TCHENE, a town of Egypt, on the right bank of the Nile ; 18 miles N. of Enſeneh.

TCHENG-TCHANG, a town of Corea ; 30 miles S.S.E. of Haimen.

TCHENG-TE, an iſland in the Eaſtern ſea, near the ſouth coaſt of Corea ; about 10 miles long, and 6 broad. N. lat. 34° 20′. E. long. 128° 37′.

TCHEN-HAI, a town of Corea ; 30 miles S. of Tſin-tcheou.

TCHENJEE. See HÆMUS.

TCHEOU-CHAN, or CHU-SAN, an iſland in the Chineſe ſea, near the weſt coaſt of China, belonging to the province of Tche-kiang, about 24 miles long, and from 4 to 10 broad.

TCHEPAGIRSKOI, a town of Ruſſia, on the Pod-kamonſkaia Tunguſka. N. lat. 61° 20′. E. long. 96° 44′.

TCHEPETKINA, a river of Ruſſia, which runs into the Kolima, 88 miles N. of Verchnei Kovimſkoi. N. lat. 67° 35′. E. long. 148° 14′.

TCHER, a river of Ruſſia, which runs into the Don, near Tcherkovſkaia, in the country of the Coſſacks.

TCHERDAKLI, a town of Ruſſia, in the government of Ekaterinoſlav ; 32 miles N. of Mariupol.

TCHEREDOVA, a town of Ruſſia, in the government of Tobolſk, on the Irtiſch ; 16 miles N. of Tara.

TCHEREMISSES and TCHEUWASSES, tribes of people occupying the vicinity of the Volga, in the government of Regen. Theſe people uſe the horſe in their facrifices, and chiefly white ones, eſpecially in their great annual ſolemnities in autumn, of which none can partake, unleſs he has firſt bathed and put on a clean ſhirt.

TCHEREMSCHAN, a river of Ruſſia, which runs into the Volga, near Singiliev, in the government of Simbirſk.

TCHEREPOVETZ, a town of Ruſſia, in the government of Novgorod, on the Sula ; 188 miles E.N.E. of Novgorod. N. lat. 59° 40′. E. long. 37° 34′.

TCHERGONA, *Valley of*, a ſequeſtered beautiful valley of the Crimea, inhabited by the richeſt Tartars, who, from their vicinity to Aktiar, find a ready market for the produce of their lands ; carrying thither honey, wax, fruit, and corn. This valley is deſcribed as the retreat of health and joy ; the pipe and tabor ſounding merrily among mountains, thick ſet with groves, which cloſe them on every ſide. The performers conſiſt of parties of Tzigankies, or gipſies, who, as mendicant artificers, muſicians, and aſtrologers, are very common all over the ſouth of Ruſſia. They have alſo a wind-inſtrument reſembling a haut-boy, made of the wood of cherry-tree, and they carry with them the large Tartar drum, characteriſtic of the Cimbri in the time of Strabo. Theſe gipſies are much encouraged by the Tartars, who allow them to encamp among their villages and to exerciſe their various occupations. Many of them are rich, poſſeſſing fine horſes and plenty of other cattle ; but rich or poor, their mode of life is the ſame.

TCHERIKOV, a town of Ruſſia, in the government of Mogilev, on the Soz ; 80 miles S. of Mogilev. N. lat. 52° 36′. E. long. 30° 54′.

TCHERKASK, a town of Ruſſia, in the country of the Coſſacks, on the Don. The appearance of the town, viewed from the river, affords a moſt novel ſpectacle. Although not ſo grand as Venice, it ſomewhat reſembles that city. The entrance to it is by broad canals, interſecting it in all parts. On each ſide, wooden houſes, built on piles, appear to float upon the water : to theſe the inhabitants paſs in boats, or by narrow bridges only two planks wide, with poſts and rails, forming a cauſeway to every quarter of the town.

The town of Tcherkaſk is divided into eleven ſtanitzas, and contains 15,000 inhabitants, occupying about 3000 houſes, and allowing, upon an average, five perſons to each houſe. Here are ſeven churches, four built of ſtone and three of wood. One of theſe churches is appropriated to the Mahometan worſhip of the Tartars. The firſt erected in this place was founded by Peter the Great, and in this they keep what they call their regalia, applying the term to republican, rather than to regal, enſigns of diſtinction. Another church is built in the Grecian taſte, with fourteen Corinthian columns, covered entirely with burniſhed gold. Almoſt all the other public edifices are conſtructed of wood. Here are ſix priſons, four for males and two for females ; and the priſoners are allowed to go about begging in their chains. The ſhops are very numerous, kept chiefly by Greeks, and containing the produce of Turkey, as pearls, cloth, ſhawls, tobacco, fruit, &c. Here are two public baths, and each ſtanitza has its reſpective tavern. The inhabitants, according to Dr. Clarke in his Travels (vol. i.), are cleanly in their appearance, poliſhed in their manners, well inſtructed, hoſpitable, generous, and diſintereſted, humane to the poor, good huſbands, good brothers, good wives, good mothers, virtuous daughters, valiant and dutiful sons. "A Cossack," he says, "placed by the side of a Russian, what a contrast!" 32 miles E.N.E. of Azof.

TCHERKASSES, or TSCHERKASSIANS, a tribe of people, who inhabit that part of Caucasus which is called the Great and Little Kabardia, the islands of the lower Kuban, and the southern bank of that river. (See CIRCASSIA.) These people are famous for their horses, which are about the size of the Kalmuck horse, ill-made, without elegance or proportion, and for the most part ewe-necked, but of such strong and hardy natures, as to be able to run five or six hundred English miles in three days.

TCHERKESH, a town of Asiatic Turkey, in Natolia; 45 miles W.S.W. of Castamena.

TCHERKIN, a town of Abyssinia; 36 miles N. of Gondar. N. lat. 13° 15′. E. long. 37° 40′.

TCHERMAEVSKOI, a town of Russia, in the government of Tobolsk; 32 miles E.N.E. of Turinsk.

TCHERNAIA, a river of Russia, which runs into the Anadir, 100 miles below Anadirskoi.

TCHERNAIAGRIADA, a fortress of Russia, on the Volga; 32 miles N.N.W. of Astrachan.

TCHERNIGOV, a town of Russia, and capital of a government, on the Desna; 344 miles S.S.W. of Moscow. N. lat. 51° 24′. E. long. 31° 14′.

TCHERNIGOVSKOE, a government of Russia, bounded on the N. by Mogilevskoe, on the N.W. by Novgorod Sieverskoe, on the E. by Charkovskoe, on the S. by Kievskoe, and on the W. by Poland: about 180 miles long and 40 broad. N. lat. 49° 50′ to 51° 5′. E. long. 31° to 35°.

TCHERNIKEH, a town of Asiatic Turkey, in the government of Sivas, at the union of the Tosanlu and Jekil-Ermak; anciently a city of Pontus, and called Eupatoria, from Mithridates, surnamed Eupator; 24 miles N. of Amasia. N. lat. 40° 26′. E. long. 36° 38′.

TCHERNITZ. See CZERNITZ.

TCHERNOIYAR, a town of Russia, in the government of Saratov, defended by a ditch and chevaux-de-frieze, with some cannon; 200 miles N.W. of Astrachan. N. lat. 47° 54′. E. long. 46° 4′.

TCHERNOLUTZKAIA, a town of Russia, in the government of Tobolsk; 20 miles W. of Omsk.

TCHERNOMORSKI, or *Cossacks of the Black Sea*, a tribe of Cossacks, whose territory is separated by the river *Ae* or *Yea*, from that of the Grecian or Malo-Russian inhabitants, whose number does not exceed 700 persons, and the boundary of whose district is formed by the river Ae towards the S. and by the sea of Azof to the N. The Tchernomorski are a brave but rude and warlike people, and hospitable to strangers. Their original appellation was Zaporogztzsi or Zaporagians, denoting their former situation "beyond the cataracts" of the Dnieper. From the banks of this river they were removed by the late empress Catharine to those of the Kuban, in order to repel the incursions of the Circassians and Tartars from the Turkish frontier. In consequence of the service they rendered to Russia in Catharine's last war with Turkey, the empress, by an ukase of the 2d of June, 1792, ceded to them the peninsula of Taman, and all the countries between the Kuban and the sea of Azof, as far as the rivers Ae and Laba; an extent of territory comprehending upwards of 1000 square miles. They had also a constitution allotted to them in all respects similar to that of the Don Cossacks, and received the appellation of "Cossacks of the Black sea." They were also allowed the privilege of choosing an Ataman; but their numbers have been considerably diminished. They could once bring into the field an army of 40,000 effective cavalry: but at present, their number of troops does not exceed 15,000. They now occupy the whole country from the Ae to the Kuban, and from the Black sea to the frontier of the Don Cossacks. (See COSSACKS.) The Tchernomorski do not resemble the Cossacks of the Don in habits, disposition, or any other characteristic quality. The latter wear the true uniform; the former wear any habit according to their caprice. The Don Cossack is mild, affable, and polite; the Black-sea Cossack is blunt and even rude, from the boldness and martial hardihood of his manners. If he is poor, he appears clad like a primeval shepherd, or the wildest mountaineer; at the same time having his head bald, except one long braided lock from the crown, placed behind the right ear. This lock distinguishes the Tchernomorski Cossack from the Cossack of the Don, as well as from every other tribe of Cossacks in the Russian empire. If the Euxine Cossack is rich, he is very lavish in the costliness of his dress, which consists of embroidered velvet, and the richest silks and cloths of every variety of colour. The Tchernomorski are more cheerful and noisy than the Don Cossacks; turbulent in their mirth; vehement in conversation; somewhat querulous; and if not engaged in dispute, they are generally laughing or singing. Both these Cossacks hold one another in low estimation. The metropolis of the Tchernomorski Cossacks is "Ekaterinedara," or "Catherine's Gift." It has no resemblance to a town; but is rather a grove, or forest of oaks, in which a number of straggling cottages, widely separated, are concealed, not only from general observation, but from the view of each other. The country is covered with tumuli, which are very ancient, and appear by their remains to have been sepulchres. The government is wholly exercised by the Ataman and his officers, who wear theatrical and splendid habits. Their breasts are covered with chains of gold and gold-lace; their sabre is Turkish; their boots of red or yellow-coloured leather; their cap of black velvet, ornamented with lace and silver chains, or fine black Tartarian wool, taken from lambs in an embryo state. They bind their waist with silken sashes, sustaining pistols of the most costly workmanship. A small whip, with a short leathern thong, is attached to their little finger. The lower extremity of their lance is supported by the right foot; and from the powder-flask, pendent in front, are suspended silver coins, and other trinkets. The Circassians and Tchernomorski carry on trade by a peculiar kind of barter. The exchange of corn, honey, mats, wood, and arms, for the salt of the Cossacks, is transacted without contract; the wares of the Circassians being placed on the ground where they find the salt ready stationed for barter. The Tchernomorski who are employed in guarding their cattle in the steppes, amounting to many thousands, from the depredations of the Circassians, pass the night upon the bare ground; and in order to protect themselves from the mosquitoes, which are both numerous and troublesome, creep into a kind of sack, sufficient only for the covering of a single person; beneath this they lie upon the thistles and other wild plants of the steppes. In order to avoid the excessive irritation and painful swelling occasioned by the stings of these ferocious insects, they light a number of fires to drive them from the cattle during the night; but their thirst of blood is so insatiate, that swarms will attack a person attempting to shelter himself even in the midst of smoke. See Clarke's Travels, vol. ii. 8vo.

TCHERNORIEGENSKAIA, a fortress of Russia, in the government of Upha, on the Ural; 12 miles W. of Orenburg.—Also, a fortress of Russia, in the government of Simbirsk, on the river Sak; 80 miles S.E. of Simbirsk.

TCHERPLINSKOI, a fortrefs of Ruffia, in the government of Upha, on the Ural; 124 miles E. of Orenburg.

TCHERTCHI, a town of Thibet; 20 miles S.W. of Harachar.

TCHERTOVSKA, a town of Ruffia, in the government of Irkutfk; 32 miles S.W. of Kirenfk.

TCHERVLENA, a fortrefs of Ruffia, in the government of Caucafus, on the Malka; 64 miles E. of Ekaterinograd.

TCHESKAIA, a gulf or bay in the Frozen ocean, on the N. coaft of Ruffia. N. lat. 66° 50′ to 77° 40′. E. long. 45° to 47°.

TCHESUCHINSKOI, a fortrefs of Ruffia, on the borders of China; 104 miles S.W. of Nertchinfk.

TCHE-TAN, a river of China, which runs into the Tom, 12 miles W. of Yeou.

TCHE-TCHEOU Hotun, a town of Chinefe Tartary, in the country of Hami; 983 miles E. of Peking. N. lat. 40° 29′. E. long. 94° 21′.

TCHETIRDAGH, a mountain of the Crimea, the *Trapezius* of Strabo, the height of which Pallas ftates to be about 1200 feet, and Dr. Clarke fays, that it does not exceed 1300 feet; though the rapidity of its rife from the coaft about Alufta makes its elevation appear to be much greater. Almoft the whole of the Crimea may be feen from its fummit in clear weather. The higher parts of this mountain exhibit a mafs of lime-ftone, very compact and of a grey colour. Its ancient name, *Trapezius*, was probably derived from the table-form of its fummit. The lower diftrict is covered by groves impenetrable to the rays of the fun.

TCHEUISKOI, a town of Ruffia, in the government of Tobolfk, on the Oby; 48 miles N.N.E. of Kolivan.

TCHEVTZA, a river of Ruffia, which runs into the Viatka, near Slobodfkoi, in the government of Viatka.

TCHIATAM, a town of Thibet; 510 miles E. of Laffa. N. lat. 28° 3′. E. long. 99° 20′.

TCHICOU, a town of Corea; 18 miles S.S.E. of Long Kouang.

TCHICSE, a town of Thibet; 12 miles E. of Latac.

TCHICTAMA, a town of Thibet; 15 miles N.E. of Pi-tchan.

TCHIEIN, a town of Ruffia, near the ftraits which feparate the continent of Afia from America. N. lat. 65° 40′. E. long. 188° 24′.

TCHIGLING, a river of North America, which runs into the Frozen fea, oppofite to the ifland of Chichitfi.

TCHIKIRI, a river of Chinefe Tartary, which runs into the Amur, 15 miles N. of Saghalien Oula Hotun.

TCHILINSKOI, a town of Ruffia, in the government of Irkutfk, on the Ingoda; 60 miles E. of Doroninfk.

TCHILLDIR Mountains, a name which is given to a very high ridge, formed by fome branches of mount Caucafus, which taking an oppofite direction of thofe known by the name of the "Mountains of Ceraunii," pafs towards the S. and S.W., crofs Ahgaz and Mingrelia, and encircle the Euxine to the E. and S.E. Thefe unite in the abovenamed high ridge on the northern frontier of Immeretia, and again open into the Turkifh province of Akifha. Here they affume the appellation of Tchilldir, and would appear to feparate into three branches, the moft northern of which follows in a S.E. line the banks of the Cyrus, and ultimately produces an immenfe range, which running parallel with the Cafpian, feparates Irak from Ghilan and Mazanderan, and to the N. of Mefhed is loft in the deferts of Khoraffan. In the neighbourhood of Sultanea and Cazween this range receives the name of Khai Caucafan, and in the vicinity of Tehraun it is called Elbourz. The middle ridge of the Tchilldir mountains, under the denomination of the Moffian hills, traverfes the province of Georgia, and bounds on the N. the delightful plain of Erivan. It then enters the Ruffian diftricts of the Karabaug and Karadaug, and gradually finks into the plains of Mogan. The laft and moft fouthern branch of the Tchilldir mountains, bending to the S. and E., paffes the town of Kars, and forms a junction with mount Taurus. Kinneir's Mem. of the Perfian Empire.

TCHINDAT Turukuevskoi, a fort of Ruffia, in the government of Irkutfk; 72 miles S. of Nertchinfk.

Tchindat *Turukuevfka*, a fortrefs of Ruffia, in the government of Irkutfk; 80 miles S.W. of Nertchinfk.

TCHINEH, a town of Afiatic Turkey, in Natolia; 15 miles W.N.W. of Moglah.

TCHING, a city of China, of the fecond rank, in Honan; 382 miles S. of Peking. N. lat. 33° 49′. E. long. 114° 38′.—Alfo, a city of China, of the fecond rank, in Ho-nan; 340 miles S.S.W. of Peking. N. lat. 34° 50′. E. long. 113° 29′.

TCHI-NGAM, a city of China, of the fecond rank, in Se-tchuen; 780 miles S.W. of Peking. N. lat. 28° 32′. E. long. 107° 4′.

TCHING-CANG, a city of China, of the fecond rank, in Yun-nan; 1302 miles S.W of Peking. N. lat. 24° 12′. E. long. 99° 16′.

TCHING-CHAN, a town of Corea; 30 miles S.S.E. of Ou-tchuen.

TCHING-HE, a town of Corea; 30 miles N.N.E. of Kang-tcheou.

TCHING-HIANG, a city of China, of the firft rank, in Se-tchuen; 910 miles S.W. of Peking. N. lat. 27° 18′. E. long. 104° 26′.

TCHING-KIANG, a city of China, of the firft rank, in Kiang-nan, on the fouth fide of the river Yang-tfe. This is not one of the largeft cities of the province, for it is not above a league in circumference, and has authority over only three cities of the third clafs, but it is one of the moft confiderable for its fituation and commerce; it is the key of the empire towards the fea, and is alfo a fortrefs, where there is alfo a ftrong garrifon; the walls are above 30 feet in height in feveral places. The ftreets of the city and fuburbs are paved with marble; 470 miles S.S.E. of Peking. N. lat. 32° 14′. E. long. 118° 55′.—Alfo, a city of China, of the firft rank, in Yun-nan; 1082 miles S.S.W. of Peking. N. lat. 24° 44′. E. long. 102° 40′.

TCHING-NING, a city of China, of the fecond rank, in Koei-tcheou; 1017 miles S.S.W. of Peking. N. lat. 26° 3′. E. long. 105° 23′.

TCHING-TCHEOU, a city of China, of the firft rank, in Hou-quang. This city is fituated on an angle made by two rivers; the country is watered by a great number of brooks, which make the vallies exceeding fruitful; it is very full of mountains, which yield plenty of quick-filver, lapis lazuli, and green-ftones for painting. There are alfo mines of filver and gold. The people who inhabit the mountains are not fo polite as the reft of the Chinefe; on the contrary, their rude and favage manners make them to be looked upon as barbarians. The diftrict of this city contains one of the fecond order, and nine of the third; 765 miles S.S.W. of Peking. N. lat. 28° 23′. E. long. 109° 40′.—Alfo, a city of the province of Kiang-nan, fituated near the canal through which all barks going from Sou-

T C H

Sou-tcheou to Kiang muſt paſs. It is celebrated on account of its trade, and water which gives tea a pleaſant taſte: dependent on it are five cities of the third claſs, in which a particular kind of earthen-ware is manufactured, highly valued by the Chineſe, and preferred to the moſt elegant porcelain.

TCHING-TEOU, a town of Corea; 30 miles S.S.W. of Kang-tcheou.

TCHING-TING, a city of China, of the firſt rank, in Pe-tche-li. Tching-ting is a large city, about four miles in circumference. Its juriſdiction is very extenſive, and comprehends 32 towns; five of which are of the ſecond, and 27 of the third claſs. Northward from it lie ſeveral mountains, where the Chineſe ſay many ſimples and curious plants are to be found; on theſe mountains there are alſo ſeveral monuments or temples, erected in honour of deceaſed heroes; among which is one conſecrated to the memory of the firſt emperor of the dynaſty of Han; 137 miles S.S.W. of Peking. N. lat. 39° 9′. E. long. 114° 20′.

TCHING-TOU, a city of China, of the firſt rank, in Se-tchuen. This was formerly the reſidence of the emperors, and one of the largeſt and moſt beautiful cities in China; but in 1646, it was almoſt entirely deſtroyed, during the civil wars which preceded the laſt invaſion by the Tartars. Its temples, bridges, and the ruins of ancient palaces, are objects of admiration to ſtrangers; neither its commerce, nor the manners of its inhabitants, have any thing to diſtinguiſh it from other cities, nor its ſituation, which is, however, exceedingly pleaſant. It has under its juriſdiction ſix cities of the ſecond claſs and 25 of the third; 810 miles S.W. of Peking. N. lat. 30° 40′. E. long. 103° 44′.

TCHIN-HOA, a town of Corea; 50 miles E.N.E. of King-ki-tao.

TCHINKITANY Bay, a bay on the W. coaſt of North America, called by the Spaniards Baya de Guadaloupe.

TCHIN-NAN, a city of China, of the ſecond rank, in Yun-nan; 1187 miles S.W. of Peking. N. lat. 25° 16′. E. long. 101° 4′.

TCHIN-NGAN, a city of China, of the firſt rank, in Quang-ſi; 1150 miles S.S.W. of Peking. N. lat. 23° 21′. E. long. 106°.

TCHIN-YUEN, a city of China, of the ſecond rank, in Quang-ſi; 1145 miles S.S.W. of Peking. N. lat. 23° 14′. E. long. 106° 49′.

TCHIRAKI, a town of Chineſe Tartary, in the country of the Kalkas. N. lat. 48° 36′. E. long. 115° 16′.

TCHIRINKOUTAN, one of the ſmall Kurile iſlands. N. lat. 49° 20′. E. long. 153° 4′.

TCHIRNOOI, one of the ſmall Kurile iſlands. N. lat. 47° 8′. E. long. 151° 50′.

TCHIRON. See Shiron.

TCHISEGI Daghi, a mountain of Aſiatic Turkey, in the government of Sivas, near Divriki.

TCHISTAY, a town of Bohemia, in the circle of Boleſlau; 4 miles N.W. of Jung Buntzel.

TCHISTIAKOVA, a town of Ruſſia, in the government of Perm; 36 miles N. of Perm.

TCHISTOKOLSK, a town of Ruſſia, in the government of Kazan; 36 miles S.E. of Kazan. N. lat. 50° 16′. E. long. 49° 54′.

TCHI-TCHEOU, a city of China, of the firſt rank, in Kiang-nan; 570 miles S. of Peking. N. lat. 30° 45′. E. long. 117°.

TCHI-TCHOUAN, a town of Thibet; 20 miles N. of Chao-ma-ing Hotun.

TCHIUNA, a river of Ruſſia, which riſes ſix miles from Bratſkoi, in the government of Kolivan, lat. 56° long. 101°, and runs into the Tunguſka, 56 miles S.E. of Eniſeiſk. N. lat. 57° 54′. E. long. 93° 34′.

TCHIURAC, a river of Natolia, which runs into the Meinder near Tcheharſhebeh.

TCHI-YUEN, a town of Corea; 15 miles S.E. of Tſin-tcheou.—Alſo, a city of China, of the firſt rank, in Koei-tcheou; 1000 miles S.S.W. of Peking. N. lat. 27° 1′. E. long. 107° 51′.

TCHO, a city of China, of the ſecond rank, in Chan-ſi, on the river Fuen; 298 miles S.W. of Peking. N. lat. 36° 36′. E. long. 111° 23′.

TCHOCOU, a town of Thibet; 18 miles E. of Harachar Hotun.

TCHOHA Kiamen, a poſt of Chineſe Tartary; 45 miles S.W. of Kara.

TCHOI. See Palcati *Nor*.

TCHOKA. See Saghalien.

TCHOL, a river of Chineſe Tartary, which riſes in lat. 48° 20′, long. 120° 34′, and runs into the Noupi, N. lat. 46° 28′. E. long. 123° 31′.

Tchol *Hotun*, a town of Chineſe Tartary, on a river of the ſame name; 500 miles N.N.E. of Peking. N. lat. 46° 41′. E. long. 123° 35′.

TCHOL-ABADI, a town of Aſiatic Turkey, in Caramania; 32 miles S.W. of Aſkſhehr.

TCHOM-COU-CHO, a town of Chineſe Tartary; 25 miles S.W. of Ning-yuen.

TCHOM-YUEN, a town of Chineſe Tartary; 15 miles N. of Geho.

TCHONG, a town of Corea; 68 miles from Kin-naitchan.—Alſo, a city of China, of the ſecond rank, in Quang-ſi; 1175 miles W. of Peking. N. lat 22° 26′. E. long. 107° 4′.

TCHONG-HOTOC, a town of Thibet; 90 miles S.S.W. of Horatoubé.

TCHONG-KIANG-CHE, a town on the W. coaſt of Formoſa. N. lat. 24° 40′. E. long. 138° 2′.

TCHONG-KING, a city of China, of the firſt rank, in Se-tchuen. This is one of the moſt commercial cities of the province. It is in a great meaſure indebted for its trade to its ſituation at the confluence of two remarkable rivers; one of which, called *Hin-cha-kiang*, or *Golden-ſand*, receives in its courſe all the ſtreams from the mountains, which riſe on the neighbouring confines of Tartary. The other is Ta-kiang, which has its ſource beyond the boundaries of China, and is commonly called *Yang-tſe-kiang*. Tchong-king is built upon a mountain, and riſes in the form of an amphitheatre: the air round it is wholeſome and temperate. This city is celebrated for its fiſh, and a particular kind of trunks, made with canes, interwoven in the manner of baſket-work. It has in its diſtrict three cities of the ſecond claſs, and eleven of the third; 750 miles S.W. of Peking. N. lat. 29° 42′. E. long. 106° 19′.

TCHONG-KOUE, or the *Middle Kingdom*, the name which the Chineſe give to this empire; the weſtern Moguls call it Catay; the Mantchew Tartars, Nican-courou; the Japaneſe, Thau: and the people of Cochinchina and Siam, Cin, from which laſt appellation that of China is probably derived.

TCHONTORI, a town of Thibet; 175 miles S.E. of Hami. N. lat. 40° 24′. E. long. 96° 34′.

TCHORRO-TOHON-KIAMEN, a poſt of Chineſe Tartary; 23 miles N. of Odoli.

TCHORS, a town of Perfia, in the province of Adirbeitzan, inhabited by Curds, fubject to Perfia; 78 miles W.N.W. of Tauris.

TCHOSCHO, a fmall river of Ruffia, which runs into the Tchefkaia galf, 40 miles N.N.E. of Mezen.

TCHOUĆDOU, a town of Chinefe Tartary; 20 miles N.N.W. of Petouné-Hotun.

TCHOUCHAN, a town of Corea; 38 miles S. of King-ki-tao.

TCHOUCHLOMA, a town of Ruffia, in the government of Koftrom; 76 miles N.E. of Koftrom. N. lat. 58° 35′. E. long. 42° 40′.

TCHOUCTEY-KIAMEN, a poft of Chinefe Tartary; 10 miles N.E. of Tchol.

TCHOUDSONG, a town of Thibet, on the borders of China; 340 miles S.E. of Laffa. N. lat. 27° 22′. E. long. 96° 50′.

TCHOUKIA-POURAN, a town of Thibet; 69 miles S.S.E. of Laffa.

TCHOU-KIONG, or YUNG, a city of China, of the firft rank, in Yun-nan; 1187 miles S.W. of Peking. N. lat. 25° 6′. E. long. 101° 20′

TCHOULGUE-HOTUN, a town of Chinefe Tartary; 745 miles E.N.E. of Peking. N. lat. 44° 1′. E. long. 131° 47′.—Alfo, a town of Chinefe Tartary; 840 miles E.N.E. of Peking. N. lat. 44° 48′. E. long. 133° 49′.

TCHOUMOU, a town of Thibet; 63 miles E.S.E. of Laffa.

TCHOUMOURTI, a town of Thibet, near the Ganges; 225 miles E.S.E. of Latac.

TCHOURHATAI, a town of Chinefe Tartary. N. lat. 43° 4′. E. long. 119° 45′.

TCHOUSOR, a town of Thibet; 36 miles S.W. of Laffa.

TCHOU-TAN, a river of China, which runs into the Yuen, near Hong-kiang-fe.

TCHOU-TCHAN-TCHE, a town of the ifland of Formofa. N. lat. 24° 48′. E. long. 120° 21′.

TCHUDSKOI, a lake of Ruffia, between the governments of Peterfburg and Riga; about 64 miles in length, and from 8 to 24 in breadth. N. lat. 58° to 59° 10′. E. long. 27° to 27° 28′. See PEIPUS.

TCHUGUEV, a town of Ruffia, in the government of Charkov; 12 miles E. of Charkov. N. lat. 49° 58′. E. long. 36° 14′.

TCHUKOTCH, a river of Ruffia, which runs into the Icy fea, N. lat. 71° 30′. E. long. 155° 14′.

TCHUKOTSKIJA, the moft eaftern province of Ruffia, in the government of Irkutfk, extending from N.W. to S.E., about 740 miles in length, and nearly 520 from N. to S. N. lat. 63° to 73° 20′. E. long. 157° to 159°.

TCHUKOTSKOI, a cape of the N.E. extremity of Siberia, at the entrance of the ftraits which divide the Pacific ocean from the Frozen fea, and the continent of America from Afia. N. lat. 66° 15′. E. long. 199° 14′.

TCHULIM, a river of Ruffia, formed by the union of feveral rivers, which runs into the Oby, near Moltchanovka.

TCHUMARA-STANITZ, a town of Ruffia, in the government of Irkutfk, on the Lena. N. lat. 61° 12′. E. long. 125° 14′.

TCHUMISCH, a river of Ruffia, which runs into the Oby, 6 miles S.S.E. of Kolivan.

TCHURKINO, a lake of Ruffia, 320 miles N.N.W. of Zafhiverfk. N. lat. 72° 30′. E. long. 134° 4′.

TCHUSOVAIA, a town of Ruffia, in the government of Perm; 28 miles N. of Perm.—Alfo, a town of Ruffia, in the government of Perm, at the union of the Tchufovaia and the Kama; 16 miles N. of Perm.—Alfo, a river of Ruffia, which joins the Silva, and runs into the Kama, about 12 miles above Perm.

TCHUSOVOI, a town of Ruffia, in the government of Perm; 40 miles N.E. of Perm.

TCHU-TCHEOU, a city of China, of the firft rank, in Tche-kiang; 730 miles S.S.E. of Peking. N. lat. 28° 36′. E. long. 139° 33′.

TCI-NAN, or TSI-NAN, a city of China, of the firft rank, in the province of Chan-tong, fituated fouth of the river Tfing-ho, or Tfi: this city is large and populous, and is much refpected by the Chinefe, on account of its having been formerly the refidence of a long feries of kings, whofe tombs, rifing on the neighbouring mountains, afford a beautiful profpect. Tci-nan has under its jurifdiction four cities of the fecond clafs, and 26 of the third; 235 miles S. of Peking. N. lat. 36° 46′. E. long. 116° 46′.

TCIN-CHOUI, a lake of China, about 37 miles in circumference; 25 miles N.N.E. of Tfin-tcheou.

TCING, a city of China, of the fecond rank, in Pe-tche-li; 130 miles S.S.W. of Peking. N. lat. 38° 8′. E. long. 114° 6′.

TCI-NGIN, a city of China, of the fecond rank, in Chang-tong; 275 miles S. of Peking. N. lat. 35° 34′. E. long. 116° 24′.

TCIN-TCHEOU, or TSIN-TCHEOU, a city of China, of the firft rank, in Chang-tong. The principal branch of its commerce is fifh, which are caught in fuch abundance, that, we are affured, the profit arifing from their fkins only is very confiderable. It has in its diftrict one city of the fecond clafs, and 13 of the third; 230 miles S.S.E. of Peking. N. lat. 36° 46′. E. long. 118° 20′.

TCITCICAR-HOTUN, a town of Chinefe Tartary. This is the ufual refidence of a Tartarian general, and capital of a diftrict. This city was built to guard the frontiers of the Chinefe empire from the Ruffians. The city is fortified by clofe palifades, and a wall conftructed of earth. The fpace inclofed by the former contains the tribunals and the houfe of the Tartar general; that which is between the palifades and the earthen wall is occupied by the foldiers of the Tartar garrifon, merchants, and tradefmen, moft of whom are Chinefe invited hither by hopes of gain, or condemned to exile, and whofe houfes are only of earth, forming pretty large ftreets. The jurifdiction of the general who commands here extends over the new cities of Merguen and Saghalien-oula (city of the Black river): the latter being, on account of its fituation, the moft populous, the richeft, and the moft important. It is fituated on the fouthern bank of the river Saghalien, commands a plain in which feveral villages have been built, and fecures to the Mantchew Tartars the poffeffion of extenfive deferts covered with woods, in which a great number of fables are found.

The diftrict to which this city belongs is the moft northerly of the three departments of Eaftern Chinefe Tartary. It is occupied by different Tartar tribes, the principal of which are the Mantchews, Solons, and the Tagouris, the ancient inhabitants of the country. The two latter tribes fubmitted to the Mantchews, and implored their affiftance againft the Ruffians or Mufcovites, who, with armed barks, paffing from the Saghalien-oula into the Songari-oula, infefted all the rivers which flow into them, and made themfelves formidable to the Tartar nations who inhabited their banks. The Ruffians would foon have become mafters of the valuable forefts in which the fables are found, if the fort of Yafca, which they built on the river Saghalien, had been fuffered to remain; but, by the treaty of peace concluded in 1689,

 between

between the Ruffians and Chinefe, it was agreed that it fhould be demolifhed, that no caufe of umbrage or complaint might be left to the Tartar hunters.

The Tagouris, who appear to be the oldeft inhabitants of the country, are tall, ftrong of body, and accuftomed to labour; they build themfelves houfes, fow corn, and cultivate their lands, although they have always been furrounded by Tartars who live under tents, and are entirely ignorant of agriculture.

The Solon Tartars are ftill more robuft, braver, and of greater ingenuity; they are almoft all hunters; their women mount on horfeback, handle the bow and the javelin, and follow in the chace ftags and other wild animals. It is generally about the beginning of October that thefe Tartars depart to hunt fables, clad in a fhort clofe garment of wolf's fkin: they cover their heads with a cap made of the fame, and carry their bows fufpended at their backs.

They take along with them feveral horfes loaded with facks of millet, and their long cloaks made of foxes' or tygers' fkins, which they wrap round them to defend themfelves from the cold, efpecially during the night. Their dogs are trained to this kind of hunting; they are accuftomed to climb the fteepeft rocks, and know all the ftratagems of the fables.

The fables' fkins of this country are highly valued. Some of the rivers that run into the Saghalien-oula furnifh pearls; 335 miles N.E. of Peking. N. lat. 47° 25'. E. long. 123° 30'.

TE, a city of China, of the fecond rank, in Chan-tong, on the grand canal; 150 miles S. of Peking. N. lat. 37° 35'. E. long. 115° 50'.

TEA-*Tree*, in *Botany*. See THEA.

TEA, in *common language*, denotes the leaves of the tea-tree, as they are imported into this country, and the infufion of them in boiling water. The term is more extenfively applied to any other infufion of ordinary roots or herbs.

Dr. Lettfom, in his botanical defcription of the tea-plant, thinks it moft probable, that there is only one fpecies, and that the difference between the green and bohea teas depends on the nature of the foil, culture, age, and the manner of drying the leaves. He adds, that it has even been obferved, that a green tea-tree, planted in the bohea tea country, will produce bohea, and on the contrary; and that on his examining feveral hundred flowers, brought both from the bohea and green tea countries, their botanical characters have always appeared uniform. We are principally indebted to Kæmpfer, Le Compte, and Du Halde, for an authentic hiftory of the culture of this exotic fhrub, and the manner of preparing or curing its leaves.

The particulars of greateft importance that have been recited, have lately been judicioufly collected, and the fubject further illuftrated by additional obfervations by Dr. Lettfom.

The tea-tree loves to grow in vallies, at the foot of mountains, and upon the banks of rivers, where it enjoys a fouthern expofure to the fun; though it endures confiderable variations of heat and cold, as it flourifhes in the northern clime of Peking, as well as about Canton; and it is obferved that the degree of cold at Peking is as fevere in winter as in fome of the northern parts of Europe. However, the beft tea grows in a mild temperate climate, the country about Nanking producing better tea than either Peking or Canton, betwixt which places it is fituated.

The root refembles that of the peach-tree; the leaves are green, longifh at the point, and pretty narrow, an inch and half long, and jagged all round. The flower is much like that of the wild rofe, but fmaller. The fruit is of different forms, fometimes round, fometimes long, fometimes triangular, and of the ordinary fize of a bean, containing two or three feeds, of a moufe-colour, including each a kernel. Thefe are the feeds by which the plant is propagated: a number from fix to twelve or fifteen being promifcuoufly put into one hole, four or five inches deep, at certain diftances from each other. The feeds vegetate without any other care, though the more induftrious annually remove the weeds, and manure the land. The leaves which fucceed are not fit to be plucked before the third year's growth, at which period they are plentiful, and in their prime.

In about feven years the fhrub rifes to a man's height, and as it then bears few leaves, and grows flowly, it is cut down to the ftem, which occafions an exuberance of frefh fhoots and leaves the fucceeding fummer; fome, indeed, defer cutting them till they are of ten years' growth. In Japan, the tea-tree is cultivated round the borders of the fields, without regard to the foil; but as the Chinefe export confiderable quantities of tea, they plant whole fields with it. The leaves are not collected from the cultivated plant till it is three years old; and after growing feven or ten years, it is cut down, in order that the numerous young fhoots may afford a greater fupply of leaves.

The beft time to gather the leaves of tea is while they are yet fmall, young, and juicy; and the different periods in which they are gathered are particularly defcribed by Kæmpfer. The firft gathering of the tea-leaves, according to this author, commences about the latter end of February, when the leaves are young and unexpanded. The fecond collection is made about the beginning of April, and the third in June. The firft collection, which confifts only of the fine tender leaves, is moft efteemed, and is called Imperial tea. The fecond is called Tootsjaa, or Chinefe tea, becaufe it is infufed and drunk after the Chinefe manner. The laft, which is the coarfeft and cheapeft, is chiefly confumed by the lower clafs of people. Befides the three kinds of tea here noticed, it may be obferved, that by garbling or forting thefe, the varieties of tea become ftill further multiplied. The leaves are plucked carefully one by one, and notwithftanding the feeming tedioufnefs of this operation, the labourers are able to gather from four to ten or fifteen pounds each in one day. The tea-trees that yield often the fineft leaves, grow on the fteep declivities of hills, where it is dangerous, and in fome cafes impracticable to collect them. The Chinefe are faid to vanquifh this difficulty by a fingular contrivance. The large monkies which inhabit thefe cliffs are irritated, and in revenge they break off the branches, and throw them down, fo that the leaves are thus obtained. The leaves fhould be dried as foon as poffible after they are gathered.

The buildings, or drying-houfes, that are erected for curing of tea, contain from five to ten or twenty fmall furnaces, about three feet high, each having at the top a large flat iron pan. There is alfo a long low table covered with mats, on which the leaves are laid, and rolled by workmen, who fit round it: the iron pan being heated to a certain degree by a little fire made in the furnace underneath, a few pounds of the frefh-gathered leaves are put upon the pan; the frefh and juicy leaves crack when they touch the pan, and it is the bufinefs of the operator to fhift them as quick as poffible with his bare hands, till they become too hot to be eafily endured. At this inftant he takes off the leaves with a kind of fhovel refembling a fan, and pours them on the mats before the rollers, who, taking fmall quantities at a time, roll them in the palm of their hands in one direction, while others are fanning them, that they may cool the more fpeedily, and retain their curl the longer. This procefs is repeated two or three

three times, or oftener, before the tea is put into the ſtores, in order that all the moiſture of the leaves may be thoroughly diſſipated, and their curl more completely preſerved. On every repetition the pan is leſs heated, and the operation performed more ſlowly and cautiouſly. The tea is then ſeparated into the different kinds, and depoſited in the ſtore for domeſtic uſe or exportation.

The Chineſe know nothing of *imperial tea*, *flower of tea*, and many other names, which in Europe ſerve to diſtinguiſh the goodneſs and the price of this faſhionable commodity; but, beſide the common tea, they diſtinguiſh two other kinds, *viz.* the *voui* and *ſoumlo*, which are reſerved for people of the firſt quality, and thoſe who are ſick. We have two principal kinds of tea in Europe; *viz.*

Tea, *Green*, which is the common tea of the Chineſe, &c. F. le Compte calls it *bing* tea, and ſays it is gathered from the plant in April. It is held very digeſtive, and a little aſtringent; it gives a paliſh-green tincture to water, and its leaves are much twiſted.

Tea, *Bohea*, which is the *voui* tea, or *bou tcha* of the Chineſe. F. le Compte makes this only differ from the green tea, by its being gathered a month before it, *viz.* in March, while in the bud; and hence the ſmallneſs of the leaves, as well as the depth of the tincture it gives to water. Others take it for the tea of ſome particular province; the ſoil being found to make an alteration in the properties of the tea, as much as the ſeaſon of gathering it. It is all bought at Nankin, and thence brought into Europe, where it is now much in vogue.

As to the differences in colour and flavour peculiar to theſe two kinds, and to their varieties, Dr. Lettſom thinks that there is reaſon to ſuſpect that they are, in ſome meaſure, adventitious, or produced by art. He has been informed by intelligent perſons, who have reſided ſome time at Canton, that the tea about that city affords very little ſmell while growing. The ſame is obſerved of the tea-plants now in England, and alſo of the dried ſpecimens from China. We are not, however, as he obſerves, to conclude from hence, that art alone conveys to tea, when cured, the ſmell peculiar to each kind; for our vegetable graſſes, for inſtance, have little or no ſmell till they are dried and made into hay.

As to the opinion, that the green tea owes its verdure to an effloreſcence acquired from the plates of copper on which it is ſuppoſed to be cured or dried, he ſhews that there is no foundation for this ſuſpicion. The infuſions of the fineſt imperial and bloom teas undergo no change on the affuſion of a volatile alkali, which would detect the minuteſt portion of copper contained in them, by turning the liquors blue.

The fine green colour of theſe teas, with as little reaſon, hath been attributed to green copperas; as this metallic ſalt would, on its being diſſolved in water, immediately act on the aſtringent matter of the leaves, and convert the infuſion into ink, as happens when a chalybeate water has been employed in the making of tea.

On the whole, Dr. Lettſom thinks it not improbable, that ſome green dye prepared from vegetable ſubſtances, is employed in the colouring of the leaves of the green teas. And Neumann ſuſpects, that the brown colour and the flavour of the bohea ſorts are introduced by art. Both the grean and bohea teas have an agreeable ſmell, and a lightly bitteriſh ſubaſtringent taſte: with ſolution of chalybeate vitriol, they ſtrike an inky blackneſs. They give out their ſmell and taſte both to watery and ſpirituous menſtrua; to water, the green ſorts communicate their own green tincture, and the bohea, their brown; but to rectified ſpirit, they both impart a fine deep green. The extracts, obtained by gently drawing off the menſtrua from the filtered tinctures, are very conſiderably aſtringent, and not a little ungrateful; but the ſpirituous moſt ſo.

Savary alſo ſpeaks of a ſort of *red* tea, or *Tartar* tea, called *Honan tcha*, which tinges the water of a pale red, and which is ſaid to be extremely digeſtive: by means of it the Tartars are ſaid to be able to feed on raw fleſh. Its taſte is earthy, and much the leaſt agreeable of them all: but this is ſcarcely known in England.

Tea is to be choſen of the briſkeſt ſmell, and as whole as poſſible: and the greateſt care is to be taken that it have not been expoſed to the air to pall and evaporate.

The drink, tea, is made in China, and throughout the greateſt part of the Eaſt, after the ſame manner as in Europe; *viz.* by infuſing the leaves in boiling water, and drinking the infuſion hot. Indeed, among us, it is uſual to temper its bitterneſs with ſugar, but the Orientals uſe it without the addition of ſugar or milk.

However, the Japaneſe are ſaid to prepare their liquor in a ſomewhat different way, *viz.* by pulverizing the leaves, ſtirring the powder in hot water, and drinking it as we do coffee.

From the account given by Du Halde, this method is not peculiar to the Japaneſe, but is alſo uſed in ſome provinces of China.

The common people, who have a coarſer tea, boil it for ſome time in water, and make uſe of the liquor for common drink. Early in the morning, the kettle, filled with water, is regularly hung over the fire for this purpoſe, and the tea is either put into the kettle encloſed in a bag, or by means of a baſket of proper ſize preſſed to the bottom of the veſſel, that there may be no hindrance in drawing off the water.

The Bantsjaa tea only is uſed in this manner, whoſe virtues, being more fixed, would not be ſo fully extracted by infuſion.

The Chineſe are always taking tea, eſpecially at meals: it is the chief treat with which they regale their friends. The moſt moderate take it at leaſt thrice a day; others ten times, or more; and yet it is computed, the conſumption of tea among the Engliſh and Dutch is as great, in proportion, as among the Orientals.

With regard to the commercial hiſtory of tea, we may obſerve that it was firſt introduced into Europe by the Dutch Eaſt India Company, very early in the 17th century, and that a quantity of it was brought over from Holland by lord Arlington and lord Oſſory, about the year 1666, at which time it was ſold for 60*s.* a pound. But it appears, that before this time, drinking of tea, even in public coffee-houſes in this country, was not uncommon; for in 1660, a duty of 8*d. per* gallon was laid on the liquor made and ſold in all coffee-houſes.

The preſent conſumption of it is immenſe, both among the rich and poor. Dr. Lettſom tells us, that he has been informed, that at leaſt three millions of pounds are allowed for the annual home conſumption, not including the incredible quantity ſmuggled into the kingdom; and that the Eaſt India Company have generally in their warehouſes a ſupply for three years.

In the appendix to ſir George Staunton's Account of Lord Macartney's Embaſſy to China, we have ſeveral ſtatements relating to the tea-trade with China. The average of teas exported from China to Europe in foreign ſhips, for nine years, *viz.* from March 1772 to 1780, the average of the number of ſhips being twelve, was 13,198,201 lbs.; in Engliſh ſhips, at the average of nine, 5,639,939 lbs.: the total average of ſhips is twenty-one, and of exported tea 18,838,140 lbs

18,838,140 lbs. The annual confumption of tea by foreigners in Europe is eftimated at 5,500,000 lbs.; and the confumption of Great Britain and her dependencies is at leaft 13,338,140 lbs., which, at 700,000 lbs. *per* fhip, would employ thirty-eight large fhips conftantly in the China trade, inftead of eighteen fhips, as above, moft of which were fmall, one fleet going out when another is coming home.

The above is exclufive of private trade teas, brought legally and illegally into Europe. It is faid, upon the authority of confidential information, that the Englifh fhips have often fmuggled from 1000 to 3000 chefts of tea each; and alfo that the foreign captains bring a large quantity of tea, which they either fmuggle at fea, or throw into the fea, the punifhment being fevere. The lofs to the public on 1000 chefts of hyfon tea fmuggled, is above 20,000*l.*

The average quantities for one year of each fort of tea fold by the Eaft India Company in ten years, from March fale 1773 to September fale 1782 inclufive, exclufive of private trade, which was trifling, are as follow:

Bohea - - -	3,075,307 lbs.
Congou - -	523,272
Souchong and Pekoe	92,572
Singlo - - -	1,832,474
Hyfon - -	218,839
	5,742,464

See COMMUTATION *Aa.*

As to the properties of tea, they are ftrangely controverted: the Eaftern nations are at leaft as much poffeffed with an idea of their extraordinary virtues as the Europeans; but it is, perhaps, becaufe imagination bears as great a fway there as here. The reafon why the gout and ftone are unknown in China, is afcribed to the ufe of this plant.

Tea is extolled as the greateft of all medicines: moderately and properly taken, it acts as a gentle aftringent and corroborative: it ftrengthens the ftomach and bowels, and is good againft naufeas, indigeftions, and diarrhœas. It acts alfo as a diuretic and diaphoretic. The immoderate ufe of it, however, has been very prejudicial to many, who have been thereby thrown into the diabetes.

And alfo in Europe, infufions of tea-leaves have been extravagantly condemned by fome, and commended by others. From the contradictory opinions, even of medical writers, on this fubject, the natural inference feems to be, that they poffefs neither noxious nor beneficial powers, in any very confiderable degree. They feem, when moderately ufed, to be for the moft part innocent; in fome cafes they feem to be falutary; in fome they are apparently prejudicial. They dilute thick juices, and quench thirft more apparently, and pafs off by the natural emunctories more freely, than more watery fluids: they refrefh the fpirits in heavinefs and fleepinefs, and feem to counteract the operation of inebriating liquors.

From their manifeft aftringency, they have been fuppofed to ftrengthen and brace up the folids, but this effect experience does not countenance; as it is in diforders, and in conftitutions in which corroborants are more ferviceable, that the immoderate ufe of tea is peculiarly hurtful; in cold indolent habits, cachexies, chlorofis, dropfies, and debilities of the nervous fyftem. Lewis's Mat. Med.

Dr. Lettfom has particularly inquired into the medical qualities and effects of tea; and having obferved that infufions of bohea and green tea contribute to preferve fweet fome fmall pieces of beef immerfed in them, he infers that they poffefs an antifeptic power, when applied to the dead animal fibre, and from their ftriking a purple colour with falt of iron, he deduces their aftringent quality.

From other experiments he concludes, that the activity of tea chiefly refides in its fragrant and volatile parts; and that if the ufe of it be beneficial or injurious to any particular conftitution, it becomes fo principally by means of this odorous fragrant principle. He apprehends that it is the fafeft courfe to ufe the infufion of the more ordinary kinds of this plant, which abound lefs with this fragrant principle. Or the tea may be boiled a few minutes, in order to diffipate this volatile part, which ftands charged as the caufe of thofe nervous affections that are faid to be produced, or aggravated, by the ufe of this liquor. By this procefs may likewife be extracted more copioufly the more fixed, bitter, and ftomachic parts of this vegetable.

Dr. Lettfom, who feems to be thoroughly perfuaded of the occafionally noxious effects of this volatile principle, in the finer teas efpecially, recommends this laft mentioned mode of making tea, or the fubftitution of the extract inftead of the leaves; by the ufe of which the nervous relaxing effects, which follow the drinking of tea in the ufual manner, would be in great meafure avoided. This extract has been imported hither from China, in the form of fmall cakes, not exceeding a quarter of an ounce each in weight, ten grains of which might fuffice one perfon for breakfaft; but it might eafily be made here by fimple decoction and evaporation, by thofe who experience the noxious qualities of the volatile principles of this plant.

It may be farther obferved, that the effect of drinking large quantities of any warm aqueous liquor would be to enter fpeedily into the courfe of circulation, and pafs off as fpeedily by urine or perfpiration, or the increafe of fome of the fecretions.

Its effects on the folid parts of the conftitution would be relaxing, and thereby enfeebling.

If this warm aqueous fluid were taken in confiderable quantities, its effects would be proportionable, and ftill greater if it were fubftituted inftead of nutriment. The infufion of tea, however, has thefe two peculiarities. It is not only poffeffed of a fedative quality, but alfo of a confiderable aftringency; by which the relaxing power, afcribed to a mere aqueous fluid, is in fome meafure corrected on this account. It is, perhaps, lefs injurious than many other infufions of herbs, which, befides a very flight aromatic flavour, have very little, if any, ftypticity, to prevent their relaxing debilitating effects.

So far, therefore, tea, if not too fine, if not drank too hot, nor in too great quantities, is perhaps preferable to any other known vegetable infufion. And if we take into confideration, likewife, its known enlivening energy, our attachment to it will appear to be owing to its fuperiority in tafte and effects to moft other vegetables. See Dr. Lettfom's Natural Hiftory of the Tea-tree, with Obfervations on the Medical Qualities of Tea, and Effects of Tea-drinking, 4to. 1772.

Tea may be confidered as a very powerful aphrodifiac; and accordingly, a phyfician of confiderable eminence in his profeffion, imputes the amazing population of China, amongft other caufes, to the general ufe of it. Percival's Eff. p. 63.

We fhall clofe this part of the article with a tranfcript of its medicinal powers, as they are ftated by Dr. Cullen (Mat. Med. vol. ii.) "With refpect to its qualities as a medicine, that is, its power of changing the ftate of the human body, we might fuppofe it afcertained by the experience of its daily ufe; but from the univerfality of this ufe in very different conditions of the plant, and in every poffible condition of the

the perfons employing it, the conclufions drawn from its effects muft be very precarious and ambiguous, and we muft attempt by other means to afcertain its qualities with more certainty.

"To this purpofe it appears, from the accurate Dr. Smith's experiments 'De Actione Mufculari,' No. 36, that an infufion of green tea has the effect of deftroying the fenfibility of the nerves, and the irritability of the mufcles; and from the experiments of Dr. Lettfom, it appears that green tea gives out in diftillation an odorous water, which is powerfully narcotic.

That the recent plant contains fuch an odorous narcotic power, we might prefume from the neceffity which the Chinefe find of drying it with much heat before it can be brought into ufe; and that, even after fuch preparation, they muft abftain from the ufe of it for a year or more, that is, till its volatile parts are ftill farther diffipated: and it is faid, that unlefs they ufe this precaution, the tea in a more recent ftate manifeftly fhews ftrong narcotic powers. Even in this country, the more odorous teas often fhew their fedative powers in weakening the nerves of the ftomach, and indeed of the whole fyftem.

"From thefe confiderations we conclude very firmly, that tea is to be confidered as a narcotic and fedative fubftance; and that it is efpecially fuch in its moft odorous ftate, and therefore lefs in the bohea than in the green tea, and the moft fo in the more odorous, or what are called the finer kinds of the latter.

"Its effects, however, feem to be very different in different perfons; and hence the different, and even contradictory accounts that are reported of thefe effects. But if we confider the difference of conftitution, which occafions fome difference of the operation of the fame medicine in different perfons, and of which we have a remarkable proof in the operation of opium, we fhall not be furprifed at the different operations of tea.

"If to this we add the fallacy arifing from the condition of the tea employed, which is often fo inert as to have no effects at all; and if we ftill add to this the power of habit, which can deftroy the powers of the moft powerful fubftances, we fhall not allow the various and even contradictory reports of is effects to alter our judgment, with refpect to its ordinary and more general qualities in affecting the human body.

"From the experiments above-mentioned, and from the obfervations which I have made in the courfe of fifty years, in all forts of perfons, I am convinced that the qualities of tea are narcotic and fedative.

"It has been often alleged, that fome of the bad effects imputed to tea are truly owing to the large quantity of warm water which commonly accompanies it, and it is poffible that fome bad effects may arife from this caufe: but from attentive obfervation I can affert, that wherever any confiderable effects appear, they are in nine of every ten perfons entirely from the qualities of the tea; and that any like effects of warm water do not appear in one of a hundred who take in this very largely.

"But while we thus endeavour to eftablifh the poifonous nature of tea, we do not at the fame time deny that it may fometimes fhew ufeful qualities. It is very poffible, that in certain perfons, taken in moderate quantity, it may, like other narcotics in a moderate dofe, prove exhilarating, or, like thefe, have fome effect in taking off irritability, or in quieting fome irregularities of the nervous fyftem.

"As its bad effects have been often imputed to the warm water that accompanies it, fo we have no doubt that fome of its good effects may alfo be afcribed to the fame caufe, and particularly its being fo often grateful after a full meal."

By 9 Geo. II. c. 35, if a veffel, coming from foreign parts, and having 6 lbs. or more of tea on board, fhall be found at anchor, or within two leagues of the fhore, &c. all fuch tea, with cheft and package, fhall be forfeited. The importer of any coffee, tea, or cocoa-nuts, fhall within thirty days enter the faid tea, &c. and warehoufe it. (10 Geo. c. 10. 5 Geo. III. c. 43.) That which is landed without entry and warehoufing fhall be forfeited. But this fhall not extend to any coffee or tea imported by the Eaft India Company. The coffee and tea intended for home confumption fhall be entered and the duty paid. (10 G. c. 10.) A permit fhall be given for the removal of tea from any warehoufe, whether it be bohea, congou, fouchong, or pekoe tea; and fuch tea fhall in the permit be fpecified under the denomination of *black* tea; and if the tea be neither bohea, congou, fouchong, nor pekoe tea, then fuch tea fhall be fpecified under the denomination of *green* tea. 43 Geo. III. c. 129.

By 13 Geo. III. c. 44. no licence fhall be granted to the Eaft India Company to export tea, unlefs there remain in the warehoufes a quantity not lefs than ten millions of pounds weight.

No tea is allowed to be imported, except from the place of its growth, on pain of forfeiture. (11 Geo. c. 30.) And by 24 Geo. III. c. 38. all the duties upon tea imported, fold, or ufed in this kingdom, fhall ceafe from September 15, 1784; at which period the Eaft India Company is difcharged from the payment of duties on tea in their warehoufes; and afterwards there fhall be paid a duty of 12*l.* 10*s.* *per cent.* computed upon the grofs prices for all tea delivered by the Company to the purchafers, which duty fhall be drawn back on exportation to any place where the drawback is already allowed. The Company is required to make four fales in the year, and to fell fuch quantity as fhall be fufficient to fupply the demand, provided an advance of 1*d.* *per* lb. be bid upon the prices at which the teas fhall be put up; and at the four firft fales after paffing the act, thefe prices fhall not exceed the following rates; *viz.* for bohea tea, 1*s.* 7*d.* *per* lb.; congou tea, 2*s.* 5*d.* *per* lb.; for fouchong tea, 3*s.* 3*d* *per* lb.; for finglo tea, 3*s.* 4*d.* *per* lb.; and for hyfon tea, 4*s.* 11*d.* *per* lb.: and afterwards the whole price at which the teas are put up, fhall not exceed the prime coft, with the freight and charges of importation, lawful intereft from the time of the arrival of fuch tea in Great Britain, and the common premium of infurance. In lieu of the duties on tea, this act fubftitutes an additional duty on windows. See Commutation *Act.*

By this fame act, the inland duty upon cocoa-nuts and coffee fhall ceafe from September 15, 1784, and the following additional duties be paid; *viz.* for every pound of cocoa-nuts, the produce of Britifh America, 6*d.* and the produce of any other place, 1*s.* 6*d.*; and for every pound of coffee, the produce of Britifh America, 6*d.* and the produce of any other place, 2*s.* 6*d.*; and thefe duties are fubject to an additional impoft of 5 *per cent.* and 5 *per cent* thereon impofed by 19 Geo III. c. 25. and 22 Geo. III. c. 66.

If coffee or tea are intended to be taken out for exportation, they fhall be delivered out on fecurity that they fhall be exported, and not relanded. 13 Geo. c. 10.

No drawback fhall be allowed on tea exported, except to Ireland, &c. where the whole duty on exportation fhall be allowed. 18 Geo. II. c. 26. 17 Geo. III. c. 27. 43 Geo. III. c. 69.

Every perfon having in his cuftody more than fix pounds weight of tea, is a dealer; and felling without a licence, to be be had for 12*d.*, shall forfeit 5*l.* a month. (11 Geo. c. 30.) If any person offer any tea to sale without a permit, or a pedlar with one, the person to whom it is offered may seize the same, &c. 9 Geo. II. c. 35. See COFFEE.

Every person dealing in tea, &c. shall cause to be painted or written over the door of his shop, the words *dealer in coffee, tea, cocoa-nuts*, or *chocolate*, on pain of 200*l.* (19 Geo. III. c. 69.) And any dealer buying of any person who has not this inscription, incurs forfeiture of 100*l.*, and any other person 10*l.* By 20 Geo. III. c. 35. no person shall trade in coffee, tea, or chocolate, without a licence, at the price (by 43 Geo. III. c. 69.) of 5*s.* 6*d.*, under penalty of 20*l.* The adulteration of tea is subject to a penalty of 100*l.* besides the forfeiture of the same, and for every pound of dyed leaves of tea, 5*l.* 11 Geo. c. 30. 17 Geo. III. c. 29.

At the East India Company's sale of teas, an account shall be taken of the buyers and prices, and the best bidder shall within three days deposit with the Company, or their clerks, 40*s.* for every tub or chest of tea, on pain of six times the value, and such sale shall be void, and the same shall in 14 days after be put up again. (18 Geo. II. c. 26.) And by 13 Geo. III. c. 44. the deposit for every tub and chest of bohea tea shall be 4*l.* By 13 Geo. III. c. 44. tea may be exported. No tea shall be received, with or without a permit, within the limits of the bills of mortality; and no tea, exceeding 20lbs. weight, shall at one time be received, with or without a permit, out of the said limits, on pain of forfeiture. (21 Geo. III. c. 55. 22 Geo. III. c. 68. 23 Geo. III. c. 70.) All tea seized and condemned shall be sold to the best bidder. (24 Geo. III. sess. 2. c. 47.) Tea carried in the night, with or without a permit, except in certain circumstances, shall be forfeited, and may be seized by any officer for the inland duties as tea. 21 Geo. III. c. 55.

TEA, *Buckthorn.* See RHAMNUS.

TEA, *German.* See SPEEDWELL.

TEA, *Mexico, Chenopodium ambrosioides* of Linnæus, is a species of chenopodium, which, as well as the Jerusalem oak, or chenopodium botrys, are natives of the southern parts of Europe, and sown annually with us in gardens. Infusions of the leaves and flowery heads of both these plants, which are not unpalatable, drank as tea, are said to be of service in humoral asthmas and coughs, and other disorders of the breast; they are supposed to be antispasmodic and antihysteric. Lewis's Mat. Med.

TEA, *New Jersey.* See CEANOTHUS.

TEA, *New Zealand.* See PHILADELPHUS.

TEA, *Oswego.* See MONARDA.

TEA, *Paraguay*, or *South Sea.* See PARAGUAY.

TEA, *West Indian.* See SIDA.

TEA *Soup*, in *Rural Economy*, that which is prepared from the tea, liquid, or infusion of some sort of vegetable substance or other, such as hay, cut straw, or haulm, &c. by thickening it a little with some sort of mealy material, or mashed potatoes, or other such roots, after being boiled or steamed.

TEA, in *Geography*, a river of England, in the county of Buckingham, which runs into the Ouse near Stony Stratford.

TEAHOWRAY. See PORTLAND *Island.*

TEAK, or TEEK, a species of timber that occurs frequently in various parts of the East Indies, and which is applied to a variety of domestic and nautical purposes. Extensive forests of these trees border on the banks of the Godavery within the mountains, and supply abundance of ship-timber for the adjacent ports. The teak forests, from which the marine yard at Bombay is furnished with that excellent species of ship-timber, lie along the western side of the Gaut mountains, and other contiguous ridges of hills, as the N. and N.E. of Basseen; the numerous rivulets that descend from them affording water-carriage for the timber. Major Rennell reproaches the unpardonable negligence with which Europeans are chargeable for delaying to build ships of war for the service of the Indian seas. They might be freighted home, without the ceremony of regular equipment, as to masts, sails, and furniture; which might be calculated to answer the purpose of the home-passage at the best season; and crews could be provided in India. Teak ships of 40 years old and upwards are not uncommon in the Indian seas, while an European ship is ruined there in five years. The teak is called the Indian oak. See TECTONA.

TEAKI, in *Geography*, an island in the Mediterranean; twenty miles long, and four broad. This island was anciently called "Ithaca," and is memorable in Grecian history for being the kingdom of Ulysses; some Europeans call it "Val de Compare." N. lat. 38° 47′. E. long. 21° 40′.

TEAL, QUERQUEDULA, in *Ornithology*, the *Anas crecca* of Linnæus, the smallest of all the duck kind. Its beak is black, and its head, and upper part of its neck, of a reddish-brown; but there runs on each side of the head a green streak from behind the eyes quite to the back part, and between these is a black spot under the eyes; there is a white line which separates the reddish colour from the green. The lower part of the neck, the shoulders, and the sides, are very beautifully variegated with black and white streaks; the breast and belly are of a dusky greyish-white; the first beautifully spotted with black; the vent black; the tail sharp-pointed and dusky; the coverts of the wings brown; the greater quill-feathers dusky; the exterior webs of the lesser marked with a glossy green spot, above which is another of black, and the tips white; the irides whitish, and the legs dusky. The female is of a brownish ash colour, spotted with black, and has a green spot on the wing, like the male. Ray and Pennant. See DUCK.

TEAL, *Crested, Querquedula cristata*, a name given by Belonius and some others to a species of duck, remarkable for a tuft of feathers an inch and half long, hanging down from the back part of the head, and thence called the *tufted* duck; but more known among authors by the name of *capo negro.* See DUCK.

TEAL, *Summer, Anas circia* of Linnæus, is apprehended by Mr. Pennant to be no other than the female of our teal, though Linnæus has described it as a distinct species. See DUCK.

Summer teal is also a name given in some places to the garganey.

TEAM, THEAM, or *Thame*, in our *Ancient Customs*, signifies a royalty granted by the king's charter to a lord of a manor, for the having, restraining, and judging bondmen, neifs, and villeins, with their children, goods, and chattels, in his court.

TEAM, in *Agriculture*, the number of horses, oxen, or other animals which are drawing together at once in the same plough, cart, waggon, or other carriage. There is a great variety of different sorts of teams employed in field, road, and other sorts of labour, which is carried on by means of domestic animals; and it is of very great importance to ascertain which of them is of the greatest advantage, and the cheapest in the different uses and intentions.

In all sorts of farming work, in the field as well as on the road, the heavier kinds of strong horses, and those of the close, short, compact, punch breeds, have hitherto, for the most part, been employed for the purpose of team labour; and for

for the dray, and every fort of fimilar heavy work, where a flow, fteady, ftrong draught is required, they are alfo unqueftionably the moft proper and fuitable, as long experience has fully proved. But a confiderable alteration has lately taken place in the kinds which are made ufe of as teams for carrying on the lighter forts of road-work, whether by means of carriages or other vehicles.

It has been found that the ftouter fort of horfes, poffeffing a little blood, are by much the beft adapted to this kind of labour of any, being much more active and expeditious, as well as more durable, and lefs liable to fatigue and to become tired out on the road. On this account they form the teams for moft forts of coach and other carriage labour, and in many inftances for various heavier defcriptions of it: and it is not improbable but that, in fome cafes, they might be fubftituted as teams for farming work with great propriety and advantage, in confequence of their quicker pace, and having what is commonly called more bottom.

Among farmers it has long been a difputed point, whether horfes or oxen form the moft economical and advantageous team for the purpofe of the cultivator in performing his work, and it remains ftill undecided, though many intelligent agriculturalifts now incline to the fide of horfe-teams, except in particular circumftances and fituations. And a late writer has remarked, that the circumftances in which the latter have been chiefly fuppofed to be more advantageous than the former, are in their being kept at lefs expence, and their not declining in value. But that thefe, when examined, are perhaps not fo decifive of their fuperiority, as they may at firft fight appear; for where the work of the farm is done by the younger fort of horfes, which is perhaps the beft method, the decline in value cannot be of any material confequence, while the fuperiority in point of the difpatch of work is very great. And in regard to the keep, as oxen cannot perform their labour well in continuance without oats, or fome other fuftenance of a fimilar kind, it would feem not improbable but that young horfes may pay nearly as well as oxen, and be kept with little difference in the expence. Indeed the common opinion, that oxen are fuperior to horfes in the tillage of heavy lands, does not at all appear to be well founded, efpecially when drawn in *yokes* and *bows*, as the poaching muft be greater than by horfes working at length. But when in harnefs, they may, from their greater fteadinefs, be preferable; of courfe, under different management, they are capable of being employed in both ways. But in all fuch cafes, as where quick motion is of more importance than the fteady drawing of heavy weights, the horfe is much fuperior to the ox, as well as in carting, where great fpeed is required in the unloaded ftate, and wherever the roads or lands are rough, fharp, and ftony, as oxen cannot be fhod fo well as horfes to ftand fuch roads. And in harrowing with light harrows, where a jumping irregular motion is neceffary, it has been fhewn in the Annals of Agriculture, that horfes are the moft proper, and to be conftantly preferred. In fhort, that teams of the ox-kind may be made ufe of with benefit in many cafes in bufineffes about the farm, but they are incompatible with all forts of diftant work, and efpecially on the road, and in ftony fituations.

It has been remarked, in a late Calendar of hufbandry, that there are two cafes in which oxen are certainly more beneficial than horfes: firft, when a farmer lives in a diftrict where there is a breed of cattle well adapted to work; and, fecondly, when his farm is fo large, that he can buy in a lot of cattle annually, at a fmall expence *per* head, and feel no inconvenience in turning out fuch beafts from the teams to fatten as do not work well. In both thefe cafes, the writer has little doubt of the fuperiority of oxen to horfes. But in countries that do not poffefs a breed of cattle well adapted for work in the ftate of oxen; and on fmall farms, whence fairs muft be attended at the diftance of a hundred miles to purchafe a few, and confequently at a great expence *per* head, and poffibly without land for fattening any, the benefit will be very queftionable.

It has been fuggefted by the writers of the Agricultural Survey of the Weft Riding of Yorkfhire, that from the circumftances of ox-teams being almoft univerfally given up in thofe places where they were formerly in repute, a fufpicion arifes, that working them is not attended with profit.

In regard to the national advantages to be derived from a change from horfes to oxen, there does not appear to be any great benefit, as it has been fhewn by Mr. Pitt in an excellent paper in the fifth volume of Communications to the Board of Agriculture, that as thofe ufed in agriculture are in a great meafure a nurfery for thofe wanted for other purpofes; the extent of fuch change can take place no farther than about the work of 100,000 horfes.

To afcertain what general effect fuch a change might produce in increafing food for mankind, as what he calls the higher kept farm-horfes are generally, or at leaft a part of them in preparation for fale, for the road, or harnefs; he muft fuppofe the deduction made, from what he has called moderately kept farm-horfes; now fupported at four acres and a half *per* head; then the deduction of

	Acres.
100,000 of thofe would fave the landed produce of - - - - -	450,000
And the deduction of young ftock, in the fame proportion, one-ninth of the whole, would fave one-ninth of 250,000 acres, to preferve even numbers, fuppofe -	30,000
In all faved - - - - - - -	480,000

The idea in all the midland counties is, it is obferved, that two oxen will be required to do the work of each horfe; 200,000 working oxen will therefore be wanted inftead of the horfes thus deducted. To give the oxen a fair chance in this calculation, he will fuppofe them fit to work at three years old, and the workers to be of the ages of three, four, five, and fix refpectively, 50,000 of each; the fame number coming one, two, and three years old, will be wanted for fucceffion ftock; and 50,000 annually fatted off; the land neceffary for their fupport may be nearly as follows:

	Acres.
Keep of 50,000 fteers, of the ages of coming one, two, and three years old refpectively, 150,000 acres in all, at one acre each *per* head *per annum* - - -	150,000
200,000 working oxen, of full three, four, five, and fix years old, 50,000 of each, at two and a half acres *per* head *per annum* - - - - -	500,000
Lefs land cannot, it is believed, be poffibly allowed to keep them in working condition; they muft have hay and fometimes corn when clofely worked, 50,000 fatting, at three acres *per* head - -	150,000
Land neceffary for the oxen - - - -	800,000
Deduct for the horfes - - - -	480,000
Difference - - - - - - - -	320,000

These 320,000 acres of land will produce 50,000 fat oxen, or 32 acres will produce five fat oxen; suppose them 270lbs. *per* quarter each, or 5400lbs. of beef from 32 acres; this is 168¾lbs. of beef *per* acre *per annum*: but a dairy will, it is said, produce more, and a flock of sheep well managed quite as much human food *per* acre. Little advantage, therefore, would, it is said, be derived from this change of substituting oxen for horses in agriculture, unless the use of horses on the road, and for purposes of pleasure, luxury, pomp, amusement, trade, mining, manufactures, commerce, and war, could be abolished or lessened.

Accordingly, Mr. Malthus thinks the advantages of luxury, when it falls short of actual vice, are certainly great: it cannot be denied, but it contributes to the comforts, enjoyments, and consequent happiness of a nation; but if carried too far, it will completely defeat its own purpose; the surest way is to stop short of the mark.

In the clear, full, and excellent account of the state of agriculture in the county of Middlesex, the very able and experienced author has brought together into one point of view a great number and variety of the different objections and reasons, which either operate against or wholly prevent the use of oxen for the purpose of performing team-labour; and which the inquirer, who wishes for more full information on so important a subject, may do well to consult, as they place the question with much clearness and decision greatly in favour, and on the side, of the horse.

In fact, the writer thinks it very clear, that those persons who prefer horses to oxen, for the purpose of labour, display superior knowledge in agriculture. This opinion, he says, is sanctioned by the practice of nine-tenths of the best husbandmen in the nation. In proportion as Britons become enlightened, they lay aside ox-teams; and experience has now so completely established the superiority of horses, as to render their employment almost universal. And under this system, the science and practice of agriculture have improved more rapidly than at any former period of time. "The number of horses used in husbandry are nearly," says the writer, "1,200,000. If half this number were to be superseded by oxen, in the proportion of two oxen to one horse, it would require 1,200,000 such cattle to do the same quantity of labour as is now done by 600,000 horses. The difference of these two numbers would be an increase to that extent of our labouring cattle. The other 600,000, in the place of so many horses, as well as the increased number, feed in the same manner as cows, and on a similar herbage; consequently the whole 1,200,000 would deprive us of the means of supporting so many cows. So unwise a measure would reduce the number of our cows to one-fourth of their present number. The veal, milk, butter, and cheese, would be diminished in that proportion; and in consequence of this scanty produce of the dairy, the price would be so exorbitant, that none but the most wealthy could afford to eat of these things.

"After what has been said, need I add, that every ox used in husbandry at this time deprives the nation of a cow, and of all the comforts which that animal is calculated to bestow. The introduction of oxen, to do one half the labour now done by horses, would deprive the labourers of the greater part of their diet: a dearth would be the inevitable consequence, until the numbers of our people were reduced to equal the scantiness of their food, or until the oxen could be fattened and slaughtered, to make way for the return of the more valuable cow. Hereafter I shall expect the farmers in theory only, who are advocates for ox-teams, to change their notes, and write in favour of a team to be drawn by cows."

Upon the whole, the writer is of opinion, that the very few advantages which oxen possess are not by any means of such consideration, as to compensate for the damage which their being used would do upon some kinds of land; nor are they so proper for the general purposes of a farm as horses, and the general substitution of labouring oxen in lieu of horses would be vastly injurious to the nation.

It is allowed that those who have argued in favour of the superior advantage of oxen may be correct in all their reasonings, so far as they are deduced from their own experience; but that the experience of others may furnish arguments as strong on the other side. Circumstances vary in every district, and render the good or the bad of any practice altogether relative. In the county of Chester, for instance, the farmer has not only to fallow his corn land, and lead manure to his meadows, but he has often to send his team to distances of ten or fifteen miles, to take his corn to market, to fetch lime or coal, and for various other purposes, on hard turnpike roads; and the time in which such services are performed is to him of essential consequence. Would oxen be as well able to accomplish such journies as horses? Are oxen used in any county where circumstances are precisely similar? Do not oxen require more rest than horses? Will they stand hard work as well? Are they as ready for every different kind of work on a farm as horses? Unless these questions can be answered in the affirmative, we have to place in opposition to the saving of expence in keeping them, convenience and time, which are as valuable as corn and money. It is also further argued, that the diminution in the use of corn, from employing oxen, is an object of great national importance; all that the horse consumes being so much loss as the food of man; and the loss of animal food, occasioned by the preference given to horses, is likewise urged. But if, in the same portion of time, horses will do more work than oxen, the earth will be enabled to yield a greater produce, and the additional portion of food gained may more than counterbalance what is lost. The consumption of food, however, is not an argument which should be brought forward against the farmer, who, by every proper artificial means, should be induced to raise the greatest quantity possible from his ground. On what principle is it that the legislature, by bounties, endeavour to encourage exportation, when the prices of corn sink below a certain sum? Is it not that more may be produced, in the ordinary course of seasons, than the nation can consume, in order to secure a sufficiency when the harvests are below their average? The more horses are kept, the greater the consumption of corn, and the greater the demand; and is it not better to have it increased by such means, than by exportation? The horses, in the year of scarcity, may be fed entirely on hay or grass; and, at all times, their existence is so much real national wealth. May it not be doubted too, whether, if farmers could dispense with the use of horses, a sufficient number would, as hinted at above, be reared for the mere purposes of pleasure or luxury, to answer the demand of government, in cases of emergency? Numbers of them, of all descriptions, whether for the increase of cavalry, or the draught of artillery, are surely desirable in every country that must trust its defence exclusively to its own exertions. Even now the breeding of them is attended with so much hazard, that very many are fearful of encountering the risk: what then would be the consequence, if the demand was considerably lessened?

In respect to the feeding of teams, whether of horses or oxen, it is a point that requires much thought, care, and attention; as where a want of economy prevails, it may lessen the profits of the farmer in a very high degree,

gree, as is obvious from the vaſt conſumption of expenſive food that muſt take place. The yearly expence of keeping a labouring horſe and an ox, previous to the late riſe in the different articles that are made uſe of as food, has been ſtated, in the ſixteenth volume of the Annals of Agriculture, to be in the general amount as follows: *viz.* that of a working horſe, 17*l.* 10*s.* 6*d.*; and that of a working ox, 13*l.* 1*s.* 10*d.*: ſo that the difference of expence in favour of the ox is 4*l.* 8*s.* 8*d.*

The difference in the expences of food, ſince the above period, may have probably demanded the addition of rather more than one-third to theſe accounts; though they are at preſent much lowered.

The training or breaking in the oxen for team-labour is commonly performed by firſt confining them by means of a halter or rope, while the yoke or harneſs is put on, and then placing them between a pair of old ſteady oxen both before and behind, ſo that they can neither puſh forward nor backward in an improper manner; and another, perhaps better, way is to yoke them ſingly with an old team-ox, which is not a free worker, as they are leſs liable to be hurt in hot weather in this way. They may alſo be firſt broken in, by being employed in other ſorts of labour before they are put to the plough.

Oxen are more apt to tread, poach, and injure the land, eſpecially where it is of a heavy, clayey, moiſt nature, when worked in yokes, than when in harneſs; yet ſome diſtricts prefer the ſyſtem of yokes and bows, either ſingle or double, to the harneſs method, which is a later practice. And there is a wide difference of opinion among practical farmers about the ſuperiority of the one or the other method. Some very ſenſible men, who have tried both ways, contend that three in harneſs are equal to as much work as four in the other mode, and that they are more quick in their motions, and work with more eaſe: while others, equally well experienced, are decidedly of opinion that the old eſtabliſhed method is ſuperior to the new, and that any number in yokes are equal to the ſame number in collars. The queſtion is, of courſe, not yet well decided: however, it is agreed, that it is unfavourable to work them too hard in any method.

The neceſſary proportion of horſes to the extent of the farm, is alſo a circumſtance that is of much intereſt to the farmer; but which muſt of neceſſity vary greatly, according to the nature, ſituation, and ſtate of the land, as well as the mode of huſbandry under which it is conducted.

In deciding the neceſſary proportion of team, the farmer muſt likewiſe well conſider the extent which the ſward or graſs-land bears to that which is in the ſtate of tillage; as where the proportion of the former is conſiderable, there will be much leſs team-work to be executed, of courſe a much leſs ſtrength may be ſufficient. Where the farm is under the hay ſyſtem, as there is ſeldom much team-work, except in conveying the produce and carting manure, a ſmaller extent of team is moſtly ſufficient, in proportion to the quantity of land, than in other caſes. And in the dairy management, the ſame is the caſe; but as in this caſe it becomes neceſſary to raiſe green crops as cattle food, a ſomewhat ſtronger team may be required than in the former caſe.

In perfectly tillage farms, whether conducted under the naked fallow ſyſtem, or the more improved management under the convertible huſbandry, a much greater force of team will be required, in proportion to the extent of land that is to be cultivated. Some reduction of team-labour may, however, be effected in both caſes, by having recourſe to green ſmothering crops in the place of the fallowings, which ſhould always be done as much as poſſible.

There can be no doubt but that there are ſome other ſorts of animals, beſides thoſe of the horſe and ox kind, that may be occaſionally employed in team-labour. The mule is an animal well calculated for this purpoſe, from its being more hardy, and enduring work a greater length of time, or to a more advanced age, than the horſe. In ſome caſes, the ſmaller ſorts of mules have been recommended, as more hardy and uſeful; but in Worceſterſhire, large mules have been found more beneficial for team purpoſes.

The aſs may likewiſe be employed for team-labour with advantage, in ſmall concerns, from its hardy nature, and being capable of living on more ſcanty fare than the horſe; and it is very uſeful for numerous purpoſes about the farm-houſe.

Whatever ſort of teams may be made uſe of upon farms, they ſhould always be well attended to, and no neglect of any kind ſuffered in regard to them; and when attacked by diſeaſe, recourſe be had as quickly as poſſible to proper remedies.

TEAN, in *Geography*, a river of England, which runs into the Dove, 2 miles N.E. of Uttoxeter.

TEANO, a town of Naples, in Lavora; 14 miles N.W. of Capua.

TEANUM, Tiano, in *Ancient Geography*, a town of Italy, in Campania, towards the ſouth-eaſt. It was a Roman colony, and a conſiderable town.—Alſo, a town Italy, ſurnamed Apulum by Strabo, and Apulen Pliny.

TEAP, in *Rural Economy*, provincially a tup c . See Ram.

TEARNE, in *Geography*, a river of England, w runs into the Severn, near Shrewſbury.

TEARPOUR, a town of Hindooſtan, in the circar of Sumbul; 13 miles N.N.E. of Sumbul.

TEARS, in *Phyſiology*, the peculiar limpid fluid ſecreted by the lacrymal gland. This fluid is deſtined to preſerve the tranſparency of the cornea, by keeping it moiſt, and removing from it foreign ſubſtances. In man a preternatural flow of tears is excited by different paſſions of the mind, eſpecially grief; but it is doubtful if this takes place in any inferior animal. See Eye, Man, and Passion.

The fluid of tears has been examined *chemically* by Fourcroy and Vauquelin, but their account of its properties is not ſo complete as could be wiſhed. It is colourleſs and tranſparent, without any ſmell, but of a perceptibly ſaline taſte. Its ſpecific gravity is ſomewhat greater than that of water. It tinges vegetable blues green. It unites with water, both cold and hot, in every proportion. The mineral acids produce no change upon it. When evaporated to dryneſs, a number of cubic cryſtals of muriate of ſoda are obtained; and there are alſo diſtinct traces of a free alkali, which is ſoda. One hundred parts, when evaporated, leave only four of ſolid matter, of which about one is ſaline matter, and the reſt a peculiar animal ſubſtance, which theſe chemiſts conſidered as a ſpecies of *mucus*, and which is ſeparated likewiſe from tears in their fluid ſtate, in the form of flakes, when alcohol is poured upon them. This peculiar animal matter, on expoſure to the air, is ſtated to poſſeſs the property of gradually abſorbing oxygen, which renders it thick and viſcid, and of a yellow colour. In this ſtate it is inſoluble in water, and remains long ſuſpended in it without alteration. Hence, ſays Berzelius, if theſe obſervations are to be depended upon, this ſubſtance bears a conſiderable affinity to the mucus of the noſe, which probably, like that

 of

of tears, is fecreted in a fluid ftate, and afterwards converted, by the action of the air during refpiration, into the ftate we ufually fee it. The folid matter of tears obtained by evaporation, when burnt, leaves fome traces of the phofphates of lime and foda. Journ. de Phyfique, t. xxxix. p. 256.

TEASARRAH, in *Geography*, a town of Bengal; 72 miles W. of Midnapour.

TEASEL, or Teazel, in *Botany*. See Dipsacus.

Befide the common wild fpecies of this plant, there is a large kind of it, the heads of which are of fingular ufe in raifing the nap upon woollen cloth, for which it is propagated in great quantities in many parts of the weft of England.

The foils moft adapted to the growth of this plant are thofe of the more ftrong and deep kinds, but which are not too rich; as loamy clays, and fuch as have ftrong marly bottoms, and are fit for the growth of wheat crops.

The moft favourable fituations are thofe that are rather elevated, open, and incline a little to the fouth; and the higher grounds, particularly where the country is inclofed, are the moft advantageous.

For the preparation of the ground, where it is a lea, it fhould be ploughed up deeply in the early part of the year, as in the beginning of February; and where it is inclined to moifture, it fhould be executed in narrow ridges of not more than three bouts each, the furrow flices being laid over in as even and regular a manner as poffible, the fine mould from the furrows being raifed by the plough or fpade fo as to cover the furface. But in lands that are fufficiently dry, and which are broken up from ftubble, the ploughing may be deferred to a later period, and be laid in ridges of much greater breadths, and in a more flat form.

Mr. Billingfley, in his Agricultural Report of Somerfetfhire, has remarked, that in the providing feed, it fhould conftantly be taken from fuch plants as are the moft perfect of their kind, and the moft productive in heads; as there is much difference in the quantity that is afforded by different plants, fome producing nearly a hundred, while others do not afford more than three or four. It fhould be fuffered to remain till it becomes perfectly ripened, and be ufed while frefh.

With refpect to the proportion of feed, that which is moftly employed on the acre is from about one to two packs, according to the above writer; but fome make ufe of a larger quantity, as two pecks, or more.

It may be noticed, in regard to the feafon of putting in crops of this fort, that it is commonly about the middle of March or beginning of April. The common method of putting this fort of crop into the ground is the broad-caft, it being fown evenly over the furface, in the manner that is practifed for turnips, fown in this way. But before this is done, the land fhould be well harrowed down, in order to afford a fine ftate of mould as a bed for the feed. It is then to be covered in by a flight harrowing with a light fhort-tined harrow, fuch as is ufed for grafs-feeds. Some, however, prefer a light bufh-harrow for this purpofe.

However, this fort of crop may be fown in rows in the drill method, at the diftance of eight, twelve, or more inches from each other, in the fame way as that of the drilled turnip. But this method is not, we believe, yet much employed by thofe who are in the practice of raifing crops of this nature.

In the after-culture of crops of this kind, much depends on the land between the plants being kept perfectly clean and free from weeds; in having them fet out to proper and fufficient diftances, as about twelve inches; and in having them well earthed up. Some cultivators perform frequent diggings, that the ground may be rendered cleaner and more mellow, confequently the growth of the plants be the more effectually promoted. This bufinefs has ufually the name of fpaddling, or fpittling, and is executed with great difpatch by labourers that are accuftomed to perform it. When thefe diggings have been finifhed, nothing further is neceffary till the period of cutting, which is generally about the end of the month of July in the fecond year, which is known by fome of the uppermoft heads beginning to blow; as when the bloffoms fall, they are ripe, and in a ftate to be cut and fecured.

This cutting is moftly executed at three different times, at the diftances of about ten days or a fortnight from each other. It is performed by means of a knife, contrived for the purpofe, with a fhort blade, and a ftring attached to the haft. This laft is done, in order that it may be hung over the hand or wrift, when the leaves are to be ftripped from the ftem parts. A pair of ftrong gloves is likewife neceffary. Thus prepared, the labourer cuts off the ripe heads along the rows or lines, or otherwife, with about nine inches of ftem, and ties them up in handfuls with the ftem of one that is more perfectly ripened, or otherwife. And on the evening of the day on which they are cut, they fhould be put into a dry fhed; and when the weather is fine, and the air clear, they fhould be taken out and expofed to the fun daily, till they become perfectly dry. As foon as they are completely dried, they fhould be laid up in a dry room, in a clofe manner, till they become tough and of a bright colour, and ready for ufe. They fhould then be forted or feparated into three different kinds, by opening each of the fmall bundles. Thefe are diftinguifhed into *kings*, *middlings*, and *fcrubs*, according to their different qualities. They are afterwards, the author of the above report fays, made into packs, which, of the firft fort, contain nine thoufand heads; but when of the fecond, twenty thoufand; the third is a fort of very inferior value. By fome, before forming them into packs, they are done up into what are termed ftaves, by means of fplit fticks, when they are ready for fale.

The produce in crops of this nature muft be very uncertain, there being fometimes fifteen, or fixteen, or more packs on the acre; and at other times fcarcely any. The produce is difpofed of to the cloth manufacturers in Somerfetfhire, Wiltfhire, and Yorkfhire.

It has been ftated, that formerly an acre of land, if well grown, and what is deemed a full crop, often produced nine packs of *kings*, nineteen of *middlings*, and two of *fcrubs*.

In the county of Effex, they have a fingular practice of cultivating and growing teafel crops with feeds, fuch as coriander and carraway, producing thereby a fort of treble crop. It is ftated, that the feeds of thefe feveral plants are fown together, very early in the fpring, upon a ftrong old lay, once ploughed; and generally yield very confiderable returns.

It is noticed, that the head of the teafel is of a conical form, two or three inches in length, and one or one and a half in diameter at the bottom, or largeft end; armed on every part with fmall ftrong points, turned a little downwards; and are bought by the woollen manufacturers, who fix them upon frames, calculated to cover a cylinder, which is made to turn round, and flightly catch their fays, bays, and other fuch articles, which another part of the weaver's machine draws againft them; by which means the knap is raifed to almoft any length the manufacturer wifhes.

The largeft burs, and thofe moft pointed, are efteemed the

the beſt, and are now called *male* teaſels; they are moſtly uſed in the dreſſing and preparing of ſtockings and coverlets; the ſmaller kind, properly called the *fullers'* or *drapers'* teaſels, and ſometimes the *female* teaſel, are uſed in the preparation of the finer ſtuffs, as cloths, rateens, &c. The ſmaller kind ſometimes, called *linnots heads*, are uſed to draw out the knap from the coarſer ſtuffs, as bays, &c.

The leaves of the common wild teaſel dried, and given in powder or infuſion, have been commended by ſome as a powerful remedy againſt flatuſes or crudities in the ſtomach.

TEATE, Chieti, in *Ancient Geography*, a town of Italy, in Samnium, ſeated on a mountain, at a ſmall diſtance from the Adriatic gulf. It was the capital of the people called Marrucini. Ptol. In the Itinerary of Antonine, this town is marked on the route from Rome to Hadria, by the Valerian way.

TEATHE, in *Agriculture*, a term applied to the dung of cattle in feeding off green crops; or which, in a more particular ſenſe, ſignifies the ſoil or improvement left upon the paſture lands in feeding them with live-ſtock, or the fertilizing effects which are produced on them, in conſequence of ſuch cattle or other live-ſtock being foddered upon them with any ſort of food, whether ſuch improvements be cauſed by their dung, urine, treading, breath, perſpiration, warmth of their bodies, or other ſimilar cauſes. It is a term much made uſe of in the huſbandry of Norfolk.

TEATHING, the practice of eating turnips, or other ſuch matters, off, upon young wheat crops, or in other ways, in the early ſpring months, by live-ſtock, as ſheep and bullocks. It is often written *tathing* by farmers.

It is a ſingular huſbandry, which the writer of the Norfolk Agricultural Report met with on entering the diſtrict of Fleg, in coming from Yarmouth. It conſiſts in carting turnips on to wheat in February and March; they call it *pull and throw* on wheat, eating them on that crop by ſheep and bullocks, if ſheep are kept; if not, by bullocks alone.

The outfield graſs-land in ſome of the ſheep diſtricts in the northern parts of the iſland, which are incloſed in a temporary manner, and intended to be broken up for tillage, are ſometimes teathed, by confining black cattle and ſheep upon them in ſomething of the fold manner.

TEATINOS, in *Geography*, a ſmall iſland in the Pacific ocean, between the iſland of Chiloe and the coaſt of Chili. S. lat. 43° 35′.

TEATS, Sore, in *Neat Cattle*, an affection in thoſe of the cow-kind, to which ſome are much more ſubject than others; eſpecially ſuch as have newly or lately calved. When the teats of theſe animals are affected during the ſummer months, they often become ulcerated, and by the teazing of the flies, the cattle are rendered difficult to be milked: they alſo become a very great nuiſance at the periods of milking, as the diſcharges from them are apt, without much attention, to paſs between the fingers of the operator into the milk-pail, and ſpoil the milk.

The affection is cauſed by inflammation, irritation, and too much diſtention of the parts by the milk.

In order to the removal of it, the milk ſhould be firſt frequently drawn, and the parts well waſhed with ſoft ſoap and warm water; after which, a ſubſtance compoſed of elder ointment and wax melted together, to which is then added a little alum and ſugar of lead, in fine powder, may be uſed to the parts after milking at night and in the morning; or a weak ſolution of white vitriol and a little ſugar of lead, in ſoft water, may be made uſe of in the ſame way, in ſome caſes, with more advantage. The addition of a little aſſafœtida, and ſuch like ſubſtances, in powder, is, it is ſaid, beneficial in the ſummer ſeaſon in driving away the flies.

Great care is to be taken to keep the teats as clean as poſſible during the time of cure.

TEBALA, in *Geography*, a town of Arabia, in the province of Hedsjas; 128 miles S.S.E. of Mecca.

TEBALDEO, Antonio, in *Biography*, an Italian poet, was born at Ferrara in 1463. Although brought up to the medical profeſſion, he chiefly devoted himſelf to poetry, and it was his cuſtom to accompany his verſes with his lute. Of theſe, which were much admired, a collection was publiſhed by his couſin Jacopo, in 1499, and often reprinted. In Latin verſe he ſucceeded better than in thoſe of his native language; and it is ſaid, that pope Leo X. gave him 500 gold ducats for a ſingle epigram. After the death of Leo, whoſe favour he enjoyed, he was reduced to the neceſſity of begging 30 florins of cardinal Bembo. He died at Rome in the year 1537. Specimens of his compoſitions in both languages are given in Mr. Roſcoe's Life of Leo X. Gen. Biog.

TEBECRIT, in *Geography*, a town of Algiers, near the Mediterranean; 2 miles from Ned Roma.

TEBELBELT, a town of Africa, in the country of Tafilet; 100 miles S. of Sugulmeſſa.

TEBENDA, in *Ancient Geography*, a town of Aſia, in the interior of Pontus Galaticus. Ptolemy.

TEBESTA, in *Geography*, a town of Africa, in the kingdom of Tunis, on the borders of Algiers, where are found ſeveral beautiful ruins. It was anciently very ſtrong; but, in the year 1057, was laid waſte by Muley Mahomet. Tebeſta is well ſupplied with water, and the environs abound in almonds and nuts; 130 miles S.S.W. of Tunis.

TEBET, or Thevet, the fourth month of the civil year of the Hebrews, and the tenth of their eccleſiaſtical year. It anſwered to part of our December and January, and has but twenty-nine days. The ſecond day of this month is the laſt of the octave of the dedication of the temple, after it was purified by Judas Maccabæus. See 1 Macc. iv. 59. John, x. 22.

The tenth day of this month is obſerved by the Jews as a faſt, in memory of the ſiege of Jeruſalem by Nebuchadnezzar, in the ninth year of Zedekiah.

TEBIQUARI, in *Geography*, a river of South America, which riſes in S. lat. 27°, and joins the Iquay, to form the Rio Grande, in S. lat. 30° 55′.—Alſo, a river of South America, which runs into the Paraguay, 8 miles below Aſſumption.

TEBOOA. See Hood's *Iſland*.

TEBSEN, a town of Egypt, on the Nile; 16 miles N. of Cairo.

TEBUÇ. See Tahuk.

TEBUHASAN, a town of Africa; 15 miles S.E. of Sugulmeſſa.

TECALA, a town of European Turkey, in Theſſaly; 30 miles W. of Lariſſa.

TECALETH, a town of Morocco; 121 miles W.N.W. of Morocco.

TECALIA, in *Ancient Geography*, a town in the northern part of Germany. Ptolemy.

TECEUT, or Techeit, in *Geography*, a town of Africa, in the country of Sus, ſituated in a fertile ſoil, abounding with grain, dates, figs, grapes, and ſugar-canes. Here is a manufacture of Morocco leather; 150 miles S.W. of Morocco.

TECH, a river of France, which riſes in the Pyrenées, and runs into the Mediterranean, near Elne.

TECHE, a river of Louiſiana, which connects with the Vermillion; and theſe are the principal rivers of the Attakapas. Their general courſes are nearly the ſame to the lake

lake Taffe; their channels are deep, and they are connected by ftreams from the lake Taffe. The Teche is much larger and longer than the other, being upwards of 200 miles in length. The Taffe is a beautiful lake of clear water, about 10 miles in circumference. The principal fettlements of the Attakapas are on each fide of the Teche, moftly weftern, and on the Vermillion. Befides the culture of cotton, maize, &c. they have the advantage of extenfive natural meadows to fupport their herds, which, on account of the natural mildnefs of the climate, are kept without much trouble. The inhabitants of the Attakapas are generally wealthy, and live as luxuriantly as the planters of the Miffifippi. Upon the whole, this part of Louifiana feems deftined to become one of its richeft diftricts.

TECHIA, a town of the Arabian Irac; 160 miles N. of Bagdad.

TECHNICAL, Technicus, formed of τεχνικος, *artificial*, of τεχνη, *art*, fomething that relates to art.

In this fenfe we fay, *technical words*, *technical verfes*, &c. And in this fenfe Dr. Harris entitles his dictionary of arts and fciences, Lexicon Technicum.

Technical is more particularly applied to a kind of verfes, in which are contained the rules or precepts of any art, thus digefted to help the memory to retain them. See *Artificial* Memory.

Technical verfes are ufed in chronology, &c. Such, *e. gr.* are thofe expreffing the order and meafure of the calends, nones, &c. thofe expreffing the feafons, and thofe expreffing the order, &c. of the figns.

F. Labbé has compofed a fet of technical Latin verfes, including all the epochas in chronology; and F. Buffier, after his example, has put both chronology and hiftory into French verfe, and even geography alfo.

Technical verfes are commonly compofed in Latin; they are generally wretched ones, and often barbarous; but utility is all that is aimed at in them: to give fome idea of which we will here add a few inftances. The cafuifts include all the circumftances which make us partakers with another in a theft, or other crime, in thefe two technical verfes.

"Juffio, confilium, confenfus, palpo, recurfus,
Participans, mutus, non obftans, non manifeftans."

The firft of F. Buffier's technical verfes of the hiftory of France, are thefe:

"Ses lois en quatre cents Pharamond introduit,
Clodion Chevelu, qu' Aetius vanquit.
Merovée; avec lui combatit Attila;
Childeric fut chaffé, mais on le repella."

Technical *Words*, are what we otherwife call *terms of art*.

TECHUKS, in *Geography*, the moft remote people of Afiatic Ruffia, who fcarcely exceed 1000 families, are generally found in fmall camps, pitched by the fides of rivers. Their rude tents are fquare, confifting of four poles, fupporting fkins of rein-deer, which alfo form the covering: before every tent are fpears, and arrows, fixed in the fnow againft any fudden attacks of the Koriaks, who, though of the fame face, are a more malicious and enterprifing people. In the midft is a ftove, and the bed confifts of fmall branches of trees fpread on the fnow, and covered with deer-fkins. Their habitations and food are dirty and difgufting; and the drefs of the women confifts only of a fingle deer-fkin faftened on the neck, fo that on loofening one knot the body remains naked. The features are coarfe, but they have not the flat nofes, nor little hollow eyes of the Kamtchadales; and Leffeps pronounces their countenances to have nothing of the Afiatic form, in which affertion he had been preceded by Pallas and Tooke. The Koriaks are fuppofed not to exceed 2000 families.

TECKLENBURG, a town of Weftphalia, and capital of a county to which it gives name; 7 miles S.W. of Ofnabruck. N. lat. 52° 15'. E. long. 7° 35'.—Alfo, a county and principality, bounded on the north and eaft by the bifhopric of Ofnabruck, and on the fouth and weft by the bifhopric of Munfter; about 20 miles in length, and 10 in breadth. This county was formerly more extenfive, including the county of Lingen, and part of the bifhopric of Munfter. The foil is fertile, and yields good corn, and paftures for cattle: the river abounds in fifh, and in feveral places are quarries of ftone: the chief manufactures are linen cloth. It is now annexed to Weftphalia.

TECLITIUM, or Teglitium, in *Ancient Geography*, a town of Lower Mœfia, upon the route from Vininatium to Nicomedia, along the Danube. Anton. Itin.

TECOANTAPEQUE, in *Geography*, a fea-port town of Mexico, in the province of Guaxaca, fituated at the foot of a volcanic mountain, near the Pacific ocean; 160 miles S.E. of Acapulco. N. lat. 16° 2'. W. long. 99° 10'.

TECOLATA, or Tetolata, in *Ancient Geography*, a town of Gallia Narbonnenfis, upon the Valerian way, between Ad Turrem and Aquæ Sextiæ. Anton. Itin.

TECOLITHOS, in *Natural Hiftory*, the name of a gem, otherwife called *Syriacus lapis*, and *Judaicus lapis*, good for diffolving the human calculus. See Syriacus and Judaicus.

It has this name from τηκω, *I diffolve*, and λιθος, *a ftone*; becaufe it diffolves ftones.

TECOMA, in *Botany*, fo called by Juffieu, from the Mexican appellation *Tecomaxochitl*, under which one of the fpecies appears in Hernandez.—Juff. 139. Brown Prodr. Nov. Holl. v. 1. 471. (Tecomaxochitl alia; Hernand. Mex. 409.)—Clafs and order, *Didynamia Angiofpermia*. Nat. Ord. *Perfonatæ*, Linn. *Bignoniæ*, Juff. *Bignoniaceæ*, Brown.

This genus is feparated from *Bignonia* by Juffieu, folely becaufe the partition of the capfule or pod is contrary, not parallel, to the valves; and he enumerates as fpecies the *B. ftans*, *radicans*, and *pentaphylla* of Linnæus, befides the above plant of Hernandez from Mexico. Mr. Brown adds to thefe the *B. pandorana*, Andr. Repof. t. 86; which is *B. Pandoræ*, Curt. Mag. t. 865; *B. pandorea*, Venten. Malmaif. t. 43; though the laft-mentioned author fays he found the partition of the capfule parallel to the valves, and therefore this fpecies is a *Bignonia* according to Juffieu. So indeed it remains in Mr. Aiton's Hort. Kew. v. 4. 34, with the fpecific name of *auftralis*, by the fubftitution of which Mr. Brown has happily got rid of the above *pandorean* confufion; and there we fhall readily leave it, only remarking that it is, according to Mr. Brown, a native of Port Jackfon, and of the tropical part of New Holland, not of Norfolk ifland. The *ftem* is twining. *Leaves* pinnate, with an odd leaflet, fmooth. *Flowers* panicled, white, with a purple throat. For the other fpecies above named, fee Bignonia, n. 11, 14 and 15. We doubt whether the tribe in queftion is fufficiently well known at prefent for botanifts to undertake its generic reformation. Nor can we permit the above name of our diftinguifhed friend Juffieu to pafs without animadverfion, as nothing can be more contrary to found principles of nomenclature, nor to his own declaration againft barbarous names in his preface. The prefent is peculiarly ill applied, as the original *Tecomaxochitl* of Hernandez appears to be *Solandra grandiflora*, or very like it, having fimple leaves.

TECONA,

TECONA, in *Geography*, a town of Hindooſtan, in Dowlatabad; 21 miles W. of Poonah.

TECONIC FALLS, a cataract in the river Kennebeck, about 65 miles from its mouth.

TECORIPA, a town of New Mexico, in the province of Sonora; 70 miles E. of Pitquin.

TECRIT, a town of Aſiatic Turkey, in the government of Moſul, ſituated on a rock near the weſt ſide of the Tigris, on the borders of the Arabian Irak. Tecrit is thought to be the Birtha or Vitra of the ancients, deſcribed as a very ſtrong fortreſs, and ſaid to have been conſtructed by Alexander the Great. It was choſen in the ſeventh century for the abode of a Jacobite primate, and increaſed to a conſiderable town. In 1393, it was taken by Timur Bec, who put all the ſoldiers that defended it to death. The ruins are extenſive, and the number of houſes amount to about five or ſix hundred, with a caravanſera and two coffee-houſes; 120 miles S. of Moſul. N. lat. 34° 37′. E. long. 42° 37′.

TECTONA, in *Botany*, a name altered by Linnæus from the Eaſt Indian name of this valuable timber-tree, *Tek*, *Tekka*, *Theka*, or *Teak*, and made claſſical, according to a method which he ſometimes uſed, from τεκτων, *a carpenter*, or τεκτονια, *a piece-work in timber, or iron*, both derived from τευχω, *to build*; alluding to the uſe of the wood in building houſes as well as ſhips.—Linn. Suppl. 20. Schreb. 141. Willd. Sp. Pl. v. 1. 1088. Mart. Mill. Dict. v. 4. Thunb. Nov. Gen. diſſ. 4. 71. Ait. Hort. Kew. v. 2. 11. Gærtn. t. 57. (Theka; Juſſ. 108. Lamarck Illuſtr. t. 136.)—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Perſonatæ*, Linn. *Vitices*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, bell-ſhaped, its margin in five, occaſionally ſix, ovate blunt ſegments, permanent. *Cor.* of one petal, funnel-ſhaped; tube ſhorter than the calyx; limb in five, occaſionally ſix, deep, obovate, crenate ſegments, incurved at the point, twice as long as the tube. Nectary a glandular ring, at the baſe of the germen. *Stam.* Filaments as many as the ſegments of the corolla, inſerted, alternately therewith, into the tube, decurrent, thread-ſhaped, erect, rather longer than the limb; anthers heart-ſhaped; two-lobed, erect. *Piſt.* Germen ſuperior, nearly globular, downy; ſtyle thread-ſhaped, downy, ſlightly curved, the length of the corolla; ſtigmas two, revolute, obtuſe. *Peric.* Drupa nearly globoſe, depreſſed, dry, ſpongy, hairy, concealed in the enlarged, inflated, membranous calyx. *Seed.* Nut bony, the ſhape of the drupa, with a terminal knob, of four cells, with ſolitary kernels.

Eſſ. Ch. Corolla five-cleft. Stigma divided. Drupa dry, ſpongy, within the inflated calyx. Nut of four cells.

Obſ. The terminal flowers are often ſix-cleft.

1. T. *grandis*. Teak-wood, or Indian Oak. Linn. Suppl. 151. Willd. n. 1. Ait. n. 1. Roxb. Coromand. v. 1. 10. t. 6. (Theka; Rheede Hort. Malab. v. 4. 57. t. 27. Jatus; Rumph. Amboin. v. 3. 34. t. 18.)—Native of the mountainous parts of the Malabar and Coromandel coaſts, as well as of Java, Ceylon, and other countries of the Eaſt Indies, flowering during the hot ſeaſon; but not till the tree is arrived at a conſiderable age and magnitude, ſo that there is little chance of ſeeing it bloſſom in our ſtoves, where young plants are ſometimes introduced. The *trunk* in its native country grows erect, to a vaſt height, with copious ſpreading oppoſite *branches*, croſſing each other, quadrangular when young. *Leaves* ſpreading, oppoſite, ſtalked, elliptic-oblong, acute, entire, ſlightly waved, with one rib and many tranſverſe veins, whoſe ſubdiviſions are finely reticulated; their upper ſide rough like a file; lower finely downy: their length is generally about a ſpan, but the leaves on young branches ſometimes meaſure eighteen inches or two feet, and are nearly half as much in breadth. *Panicles* terminal, hoary, very large and ſpreading, repeatedly ſubdivided in an oppoſite manner, with lanceolate *bracteas*. *Flowers* very numerous, comparatively ſmall, being ſcarcely half an inch long; externally hoary; internally yellow, dotted with red. *Anthers* yellow. *Fruit* the ſize of a ſmall cherry, rough, brown, in a large membranous, brown, bladdery *calyx*, reſembling the *Phyſalis Alkegengi* in general ſhape, but hardly ſo large.

The wood of this tree is, as Dr. Roxburgh remarks, by far the moſt uſeful timber in Aſia; it is light, eaſily worked, and though porous, both ſtrong and durable. For ſhip-building it is peculiarly excellent for its lightneſs, and its durability either in or out of the water. Pegu affords the largeſt quantity of this timber, which is eaſily brought down the rivers of that country, and ſold cheap. The ſame author mentions that the banks of the Godavery, in Hindooſtan, afford a teak which is beautifully veined, much cloſer in the grain, and heavier, than uſual. This ſort is peculiarly fitted for furniture, and gun-carriages.—Teak-wood, according to Thunberg, fetches a conſiderable price at the Cape of Good Hope, on account of its great utility, in a country where large timber-trees are rare.

TECTOSAGES, or *Volcæ Tectoſages*, in *Ancient Geography*, a people included amongſt thoſe who inhabited the ſouthern part of Gaul, belonging more particularly to Languedoc.

TECTRICES, in *Ornithology*, are the leſſer coverts of the wings of birds, or the feathers which lie on the bones of the wings.

TECUCZI, or TECUTSCH, in *Geography*, a town of European Turkey, in Moldavia, on the Birlat; 70 miles W.N.W. of Galatz.

TECULET, a town of Africa, in the empire of Morocco, ſituated near the coaſt of the Atlantic, on the edge of a mountain. In the year 1514, this town was ſacked by the Portugueſe, and a great number of inhabitants carried away for ſlaves. It has been ſince re-peopled; 15 miles E. of Mogodor.

TECUM DUCES. See DUCES.

TED, in *Agriculture*, a term made uſe of to ſignify the ſpreading abroad new-mown graſs, which is the firſt thing done in order to its being dried, and made into hay. Much in the proceſs of hay-making depends upon good and complete tedding of the graſſy hay in the beginning of the work.

TEDANIUM, TEDONIUS, or *Tidanus*, in *Ancient Geography*, a river of Illyria, which ſerved as a boundary between this province and Japygia. Pliny.

TEDBURY, in *Geography*. See TETBURY.

TEDDER, TEDDOR, or *Tether*, in *Agriculture*, a rope or chain by which an animal is tied, and confined in the fields, that it may not paſture on too wide a range. This is very ſeldom a good practice, or one that ſhould be much followed.

TEDELER, or TEDLIS, in *Geography*. See DELLYS.

TEDESCHI, or TUDESCHI, NICCOLO, in *Biography*, an eminent canoniſt, ſometimes called "the abbot," and ſometimes "Panormitanus," from the city of Palermo, the city in which, as ſome ſay, he was born, in 1386, though others make Catania his native place. At the age of fourteen he took the habit of St. Benedict in Catania, and afterwards purſued his ſtudies at Bologna. We ſhall not follow him through all the ſtages of his advancement from one degree of reputation, and from one ſtation of honour and truſt to another; but obferve, that he accepted a cardinal's hat from pope Felix V., favoured by Alphonfo, king of Sicily, and openly embraced his party during the contefts about the papal throne. In 1442 he was pope's legate to Frederic, king of the Romans; but when Alphonfo took part with pope Eugenius, Tedefchi retired to his church at Palermo, of which he was archbifhop. He would not diveft himfelf of the purple, though received from an anti-pope, but died poffeffed of it in 1445. Of the erudition of this ecclefiaftic, however fluctuating and temporifing he was in his politics, we have ample evidence in his works, an edition of which was publifhed at Venice, in 9 vols. fol., in 1617.

TEDESCHINI, Christiani, a buffo tenor finger in the comic opera, who came hither from Berlin at the fame time as the Paganini, 1760. He appeared firft in an under character in "Il Mondo nella Luna," compofed by Galuppi. Nor was his figure (which was *gobbo*) or voice fit for a more important part. He was, we believe, by birth a German, whence he had his name; but he had been in Italy, and his language on the ftage, and manner of finging, were perfectly Italian.

He fung on our opera ftage but one year, and afterwards devoted his time totally to fcholars, and became a very fafhionable and ufeful finging-mafter. Among his numerous pupils he made many good fingers, the Mifs Fitzpatricks, Mifs Sloper, &c. &c.; and was of ufe to many of our ftage-fingers. After accumulating a confiderable fum of money by diligence and hard labour, he returned to the continent to end his days.

TE DEUM, a kind of hymn, or fong of thankfgiving, ufed in the church, beginning with the words *Te Deum laudamus, We praife thee, O God.*—It is ufually fuppofed to be the compofition of St. Auguftine and St. Ambrofe.

It is cuftomarily fung in the Romifh church with extraordinary pomp and folemnity upon the gaining of a battle, or other happy event: and fometimes even to conceal a defeat.

This hymn was likewife fung in Proteftant churches on days of thankfgiving for a victory, peace, or other national event. Purcell compofed his Te Deum for the opening of the cathedral of St. Paul's, but did not live till that ftructure was finifhed.

In Boyer's Annals of Queen Anne, vol. iv., 1704, it is faid that the hymn Te Deum, with other anthems, were admirably performed at St. Paul's, when her majefty went thither in great ftate on the day of thankfgiving for the victory at Blenheim. We are not informed by whom the mufic was compofed; it is only faid that it was performed with great folemnity by the three choirs of her majefty's chapel, Weftminfter Abbey, and St. Paul's. There was no inftrumental band on this occafion, or any other accompaniment to the voices than the organ, which feems to have been the cafe in all former times, when any of our fovereigns went in ftate to St. Paul's.

But in 1706 we are told in the fame Annals, vol. v. p. 333, that at a public thankfgiving for the battle of Ramillies, her majefty went in great ceremony to St. Paul's, accompanied by both houfes of parliament, and all the great officers of ftate; when Te Deum was performed "with vocal and *inftrumental* mufic, after the compofition of the famous Mr. Henry Purcell." And this feems the firft time that an inftrumental band was allowed to accompany the voices in our metropolitan church of St. Paul.

In 1708, Te Deum was fung to excellent mufic at St. Paul's, compofed by Dr. Crofts for the victory at Audenarde, whither her majefty went in great folemnity.

We were extremely curious to learn when and where Handel's grand Te Deum for the peace of Utrecht was firft performed. It was natural to imagine that it was firft heard at St. Paul's, and that queen Anne went thither in ftate on the occafion, which fir John Hawkins pofitively afferts, telling us that, "in 1713, the treaty of peace at Utrecht being finifhed, a public thankfgiving was ordered for the occafion, and Mr. Handel received from the queen a command to compofe a Te Deum and Jubilate, which were performed at St. Paul's cathedral, her majefty herfelf attending the fervice." Hift. Muf. vol. v. p. 269.

But though in a paragraph of the Poft Boy, July 2, 1713, it is announced that "her majefty goes the 7th to St. Paul's, being the day appointed for the thankfgiving, accompanied by the houfes of the lords and commons;" yet in the fame newfpaper, from Saturday July 4, to Tuefday July 7, 1713, the public was informed that "her majefty does not go to St. Paul's July 7, as fhe defigned, but comes to St. James's (from Windfor) to return thanks to God for the bleffings of peace."

If Handel's elaborate compofition had been executed at St. Paul's, a ftyle of mufic fo new, forcible, and mafterly, muft have had a great effect on an Englifh congregation, who had never heard ecclefiaftical mufic fo accompanied. Purcell's voice parts, always pleafing, well accented, and expreffive, had little affiftance from an inftrumental band. Inftrumental mufic, except organ playing, was but little cultivated in our country during his time. But Handel, befides his experience in Germany, had heard operas and maffes performed by great bands in Italy, with fuch precifion and effects, as were unknown in our country till he came hither to teach us.

Handel's Te Deum for the battle of Dettingen, 1743, and Graun's for the king of Pruffia's victory at Colin, in 1757, are the moft celebrated compofitions to that facred hymn of the laft century, and the moft likely to furvive the prefent.

TEDIASTUM, in *Ancient Geography*, a town placed by Ptolemy in the interior of Liburnia, near Aruciæ.

TEDJEN, or Tedyen, in *Geography*. See Tedzen.

TEDIF, a town of Syria, in the pachalic of Aleppo. Here is a Jewifh fynagogue; and the inhabitants have a tradition that one of the minor prophets refided here. On a hill near this town are fome fepulchres and aqueducts cut in the rock; 21 miles E. of Aleppo.

TEDINGHAUSEN, a town of the duchy of Bremen; 9 miles S. of Otterfberg.

TEDIUM, in *Ancient Geography*, a town of Arabia Deferta, near Mefopotamia. Ptol.

TEDLA, or Tedila, in *Geography*, a province of the empire of Morocco, in the kingdom of Fez, which extends along the eaftern fide of Mount Atlas, and has to the weft the province of Shavoya, and to the S. Morocco. This is a rich province, abounding in fheep, whofe wool is fo fine, that no filk is fofter: it is ufed in the manufacture of caps worn by the opulent, and is fold at Fez at a very high price: its exportation being prohibited, it is confumed by the inhabitants. The province contains 450,000 inhabitants.

TEDNEST, or Tedoest, a town of Africa, in the empire of Morocco. This town was deftroyed by the Portuguefe in the year 1514, and in part rebuilt by the Jews; 40 miles N.E. of Mogador.

TEDONG. See Tirun.

TEDSI, a town of Africa, in the country of Sus, fituated to the eaft of Tarudant; 90 miles S.W. of Morocco.

TEDZEN, a town of Perfia, in Khoraffan, on a river of the fame name; 32 miles E. of Mefghid.—Alfo, a river of Perfia, in the province of Khoraffan, fuppofed to be the ancient Ochus, and next in fize to the Oxus. It has its fource near Saraks; and after receiving many ftreams, and in the number Mefhed river, falls into the Cafpian fea, in N. lat. 38° 41′.

TEE, in the *Manege*. See BREAST-*Plate*.

TEE-*Square*. See SQUARE.

TEEBAKAN, in *Geography*, a fmall ifland in the Eaft Indian fea, near the N. coaft of Borneo. N. lat. 7° 52′. E. long. 117° 39.

TEECHA, a town of Bengal; 45 miles E. of Calcutta.

TEEDIA, in *Botany*, fo named by Perfoon, we know not with what meaning.—"Perf. Syn. v. 2. 166." Brown in Ait. Hort. Kew. v. 4. 47. See CAPRARIA, fp. 3, *lucida*, on which alone this genus is founded, being diftinguifhed by having a *berry* inftead of a *capfule*, as is remarked in the place indicated. We have not had an opportunity of examining whether this be really the cafe, or whether it be a capfule with or without a pulpy coat; nor do we know how far Willdenow's fuggeftion, that all the Cape fpecies poffibly have a fimilar feed-veffel, is well founded.

TEEFEE, in *Geography*, a town of Africa, in Kaffon; 30 miles N.W. of Kooniakary.

TEEHEENGAN, a fmall ifland in the Eaft Indian fea, N. of Borneo. N. lat. 7° 49′. E. long. 117° 30′.

TEEKOOL, a fmall ifland in the Sooloo Archipelago. N. lat. 6° 6′. E. long. 120° 25′.

TEELNA, a town of Bengal; 10 miles W. of Conchong.

TEEMBIE, a town of Africa, in the country of Foota. N. lat. 10° 28′. W. long. 10° 48′.

TEEMBOO, a town of Africa, in the country of Foota. N. lat. 9° 59′. W. long. 10° 18′.

TEEN-TALLOW, a town of Hindooftan, in Guzerat; 20 miles S.E. of Brodera.

TEERAH, a province of Candahar, W. of Paifhawar.

TEERANDAZEE, a town of Candahar; 8 miles E. of Suffa.

TEERRAWHITTE, the fouth-weft point of the northernmoft ifland of New Zealand, in the South Pacific ocean, and the N. fide of Cook's Straits.

TEERWISCH, a town of Pruffia, in the province of Oberland; 8 miles N.N.W. of Ortelfburg.

TEES, a river of England, which rifes on the borders of Cumberland, and runs into the German ocean, about ten miles below Stockton, N. lat. 54° 42′. The whole courfe forms a boundary between the counties of York and Durham.

TEESDALIA, in *Botany*, received that name from Mr. R. Brown, in memory of the late Mr. Robert Teefdale, F.L.S., who died on Chriftmas-day, 1804. This accurate Englifh botanift was, for many years, a feedfman in the Strand, but retired from bufinefs fome time before his death, refiding firft at Ranelagh, near Chelfea, and afterwards at Turnham-Green. He was the author of "*Plantæ Eboracenfes*; or a Catalogue of the more rare Plants, which grow wild in the neighbourhood of Caftle Howard, in the North Riding of Yorkfhire, difpofed according to the Linnæan Syftem;" publifhed in the Tranfactions of the Linnæan Society, v. 2. 103. The author compofed this catalogue whilft he was gardener to the earl of Carlifle.—Brown in Ait. Hort. Kew. v. 4. 83. Sm. Tr. of Linn. Soc. v. 11. 283. Compend. Fl. Brit. ed. 2. 98.—Clafs and order, *Tetradynamia Siliculofa*. Nat. Ord. *Siliquofæ*, Linn. *Cruciferæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of four elliptical, concave, fmall, fpreading, equal, deciduous leaves. *Cor.* Petals four, obovate-oblong, obtufe, fpreading, with fhort broad claws. *Stam.* Filaments fix, flightly club-fhaped, afcending, each with a dilated ovate fcale attached to its inner fide, a little above the bafe, the two lateral ones fhorteft and moft diftant, in one fpecies wanting; anthers vertical, of two round lobes, diftant at their bafe. *Pift.* Germen fuperior, feffile, roundifh, emarginate, tumid at one fide, flat at the other; ftyle fcarcely any; ftigma capitate. *Peric.* Pouch erect, inverfely heart-fhaped, tumid, with a longitudinal furrow in front; concave, with an elevated ridge, at the back, two-celled; partition lanceolate; valves boat-fhaped, oblique, keeled. *Seeds* two in each cell, ovate.

Eff. Ch. Pouch emarginate, inverfely heart-fhaped. Seeds two in each cell. Filaments with a fcale on their inner fide, near the bafe.

1. T. *nudicaulis*. Naked-ftalked Teefdalia. Ait. n. 1. Sm. Tr. of L. Soc. v. 11. 286. (Iberis nudicaulis; Linn. Sp. Pl. 907. It. Oeland. 139. Sm. Fl. Brit. 692. Engl. Bot. t. 327. Curt. Lond. fafc. 6. t. 42. Fl. Dan. t. 323? Burfa paftoria minima; Ger. Em. 276. Shepherd's Crefs; Petiv. Herb. Brit. t. 50. f. 2.)—Petals unequal.—Native of dry gravelly fituations in the northern parts of Europe, flowering in April or May. It occurs about London, Norwich, and Bury, but is not a general Englifh plant. The *root* is fmall, tapering, annual. *Herb* varying much in luxuriance and number of ftalks. *Leaves* feveral, almoft entirely radical, pinnatifid in a lyrate manner, ftalked, roughifh principally at the edges. *Stalks* unbranched; the central one always erect and naked; the reft afcending, fpreading or decumbent, often bearing a leaf or two. *Flowers* white, very fmall, corymbofe. *Calyx* fmooth, often purplifh. Two inner or upper *petals* as long as the calyx; outer ones full twice as long; all entire. The remarkable fcales on the *ftamens* were firft particularly noticed in *Englifh Botany*. On thefe Mr. Brown founds his principal generic character, omitting the irregularity of the petals, in which this plant agrees with IBERIS, though very little in its habit, which is rather that of a LEPIDIUM. (See thofe articles.) The writer of the prefent article has, in the Tranfactions of the Linnæan Society above quoted, critically inveftigated the hiftory of this fpecies and the following, and has firft brought them together under one genus.

2. T. *regularis*. Regular-flowered Teefdalia. Sm. as above, 286. (Lepidium nudicaule; Linn. Sp. Pl. ed. 1. 643. ed. 2. 898. Loefl. It. Hifp. 155. Nafturtium minimum vernum, foliis tantùm circa radicem; Magnol. Bot. Monfp. 187. t. 186. N. foliis pinnatifidis, caule nudo floribus tetrandris; Gerard Gallopr. 347, excluding the *Iberis* of Linnæus.)—Petals equal. Stamens but four.—Native of dry elevated gravelly places in the fouth of France, and above the convent of St. Bernard at Madrid, flowering in the early fpring. The *root* is annual. Whole *herb* fo precifely refembling the foregoing, except in being ufually rather lefs luxuriant, that it is fcarcely poffible to diftinguifh them, except by the *flowers*. The *petals* of the prefent are all of equal fize, fpreading, longer than the *calyx*. *Stamens* only four, two at each broad fide of the germen, each bearing a white expanded fcale, as in the *T. nudicaulis*; the two fhorter, or more fpreading *ftamens* entirely wanting. It is much to be wifhed that feeds of this fpecies could be procured from Montpellier, that we might compare both in a living ftate. Linnæus was always perfuaded of their being diftinct.

TEESEE, in *Geography*, a town of Africa, in Kajaaga. N. lat. 14° 50′. W. long. 9° 27′.

TEESHOO LOOMBOO, or LUBRONG, a town and large monaftery of Thibet, confifting of three or four hundred habitations of the Gylongs, befides temples, maufolea, and the palace of the fovereign pontiffs, all built of ftone; 2 miles S.W. of Sgigatchee.

TEESTA, or YO SANPOO, a river of Afia, which rifes in Thibet, and runs into the Ganges by two ftreams, one 25 miles N., the other 80 E.S.E. of Moorfhedabad.

TEETBADDY, a town of Bengal; 27 miles N.E. of Dacca.

TEETH, *Difeafes of the.* The difeafes which affect the teeth and the parts connected with them, are ufually divided into two kinds; namely, into fuch as are termed *common*, becaufe they are alfo met with in other parts; and into thofe which are called *proper*, being obferved only in the teeth. Hence, as the celebrated Plenck has remarked, the fubject may be conveniently treated of under the following heads. Doctrinâ de Morb. Dentium, &c. Lovanii, 1796.

Of Natural Dentition.—The procefs by which the teeth make their way through the gums, is named *dentition*, (fee DENTITION,) which may be divided into the *firft* and *fecond*.

1. *Of the Firft Dentition.*—In the fixth or feventh month after birth, the *firft* or *milk* teeth make their appearance through the gums. The two middle incifores of the lower jaw are thofe which moft frequently firft come out, and, in the courfe of a few weeks, they are generally followed by the two middle incifor teeth of the upper jaw. At length, after fome months more, the lateral incifors and the canine teeth fhew themfelves. The anterior molares, or front grinders, do not commonly pafs through the gums until the child is a twelvemonth old.

The third and fourth grinders are cut about the tenth or twelfth year, and the dentes fapientiæ at the age of twenty, or even at a more advanced period of life.

The *firft* dentition, therefore, lafts from the fixth month to the fecond or third year. The *fecond* from the ninth to the thirteenth year.

But it is to be obferved, that the interval betwixt the periods when the teeth are actually cut, is fubject to very great variety, both with refpect to different teeth and different children. Sometimes a month, fometimes half a year, and, on other occafions, a whole twelvemonth will elapfe between the firft appearance of one tooth and that of another.

The cutting of each tooth has two diftinct ftages; the firft of which has been called the *periodus ingreffus*; the fecond, the *periodus egreffus.*

The firft ftage is ufually obferved in the fourth month, or about fix weeks before the tooth paffes through the gums. It happens when the tooth, in confequence of its augmented fize, begins to prefs againft the bony laminæ of the focket, fo as to make them recede. At this period the child feels a degree of itching in the gums, and hence it is that he now frequently puts into his mouth his fingers, or other hard bodies, and compreffes them by ftrongly biting them between the gums. The fecretion of the faliva is increafed. The gums become red, and fwell in the fituation of the tooth which is about to be cut. When the child fucks, he irritates and bites the nipple; he is alfo commonly troubled with a purging and a cough; he is watchful, cries frequently, and becomes feverifh.

Sometimes, however, dentition takes place fo eafily, that none of the preceding fymptoms are remarked.

After a few days, the above complaints generally ceafe, but not unfrequently come on again in about a fortnight or a month, that is to fay, about the commencement of the fecond ftage, or that in which the tooth makes its egrefs. Then the gum grows white, or exhibits whitifh points in the fituation of the tooth which is about to be cut. Thefe are caufed by the tooth itfelf, and difappear as foon as it has paffed through the gum.

2. *Of the Second Dentition.*—In the feventh or eighth year, the milk-teeth, amounting in number to twenty, become loofe, and gradually fall out, generally in the fame order in which they were cut. Soon afterwards, the fecond or permanent teeth rife out of the gums. It hardly ever happens, that the fecond dentition produces any dangerous fymptoms, the paffage through the alveolary procefs and gum being now fufficiently capacious.

After the milk-teeth have fpontaneoufly fallen out, or been extracted, they are almoft always found to be deftitute of fangs. This is a circumftance which has puzzled many eminent writers, and has even given birth to the erroneous doctrine, that the milk-teeth are never furnifhed with fangs. Suffice it here to fay, that in the opinion of the beft informed modern furgeons, the difappearance of the fangs is the effect of abforption.

Sometimes children, but more frequently adults, cut their teeth a third time. It is faid that dentition has been obferved to happen thrice in an infant five years of age; and Plenck was acquainted with a man, who was born with two of the grinding teeth, which were afterwards changed twice. (Doctrinâ de Morbis Dentium, p. 10.) Even a fourth dentition has been noticed by fome very experienced men. Halleri, tom. viii. l. 30. p. 22.

Of Difficult Dentition.—The advance of the teeth out of the fockets or gums may be attended with the moft alarming fymptoms. But experience proves, that in numerous children, the whole femicircle of each jaw becomes furnifhed with teeth, without the flighteft mark of indifpofition either before, or during the progrefs of the teeth through the gums. In other inftances the worft fymptoms prevail, both while the teeth are making their way out of the fockets, and through the gums; fuch as an inflammatory fwelling of the gums, tonfils, and parotid glands; rednefs of the eyes and cheeks; vomiting, griping pains, tenefmus, profufe diarrhœa with green evacuations, and fometimes obftinate coftivenefs and retention of urine. Fever, accompanied with cough and other catarrhal affections, hiccough, univerfal or partial tetanus, convulfions, &c. are the fymptoms by which, according to the eftimate of feveral writers, nearly a third of children are deftroyed in difficult dentition.

Thefe are the *common* fymptoms of difficult dentition; but occafionally *peculiar* ones arife, which not unfrequently fubfide as foon as the tooth is cut; as, for inftance, gutta rofacea (Lorry, Tract de Morb. Cutaneis, 1777, p. 411.); deafnefs; amaurotic blindnefs; enlargement of the knees; paralyfis; and lamenefs of one or both legs. (Pafch, Abhandlung aus der. Wundarzney von. den Zahnen, S. 25. 36.) Aphthæ of the mouth; an inflamed tubercle over the tooth which is about to be cut; fuppuration, ulceration, and even floughing of the gums. Rachitis is alfo alleged to have its origin fometimes from difficult dentition.

Thefe effects are particularly met with in very plethoric and irritable children; or in infants whofe bowels are overcharged with irritating excrementitious matter. Too much laxity, or too great hardnefs of the gums, is hardly ever the fole caufe of fuch fymptoms.

With regard to the prognofis, it may be remarked, that favourable dentition is a fign of future health. Ricketty children almoft invariably cut their teeth with difficulty. The

The more numerous the teeth are which are making their way out together, the more fevere are generally the fymptoms, and the greater is the danger.

Bloated, coftive, heavy children are extremely liable to be carried off by dentition.

The incifors and grinders ufually come out with more eafe than the canine teeth. Thin children, who are affected with acute fever, and whofe bowels are open, are in lefs danger from dentition. Infants who have a cough during this procefs, are often a long while in cutting their teeth. The foregoing prognofis accords with what was pronounced upon the fubject by Hippocrates, whofe accuracy remains unimpeached.

As the fymptoms of dentition are partly *inflammatory*, being accompanied with a ftrong determination of blood towards the head and brain; and partly *fpafmodic*, in confequence of the fympathy of the teeth with other parts, the treatment requires that antiphlogiftic and antifpafmodic means be employed. It is neceffary, therefore,

1. That the bowels be kept open with emollient clyfters.

2. That leeches be applied behind the ears.

3. That the fyrup of poppies, with nitre and one or two drops of laudanum be internally adminiftered.

4. That the red part of the gum over the tooth which is about to be cut, be rubbed with a mixture of lemon-juice and honey, or cream.

5. That in the event of there being a tendency to convulfions, in addition to the other fymptoms, a divifion of the gum be made over the tooth. By the majority of practitioners, indeed, the laft is confidered as by far the moft ufeful and efficient means of relief.

This incifion is to be made through the gum with the common inftrument, well known by the name of the gum-lancet, which is far better for the purpofe than an ordinary lancet, which is apt to cut the tongue and lips, efpecially when the child moves about much. The grinding teeth require a crucial incifion: all the others a fimple tranfverfe cut completely through the gum. The wound is then to be examined with the finger, in order to afcertain that no tenfe fibre over the tooth continues undivided. In this country, practitioners feldom apply any thing to the incifion; but abroad, it is not uncommon to put to it a mixture of lemon-juice and honey.

Internally, antifpafmodics may be exhibited, particularly the fyrup of poppies, with the fpiritus ammoniæ fuccinatus.

In order to promote dentition, and render its effects on the conftitution as mild as poffible, the celebrated Plenck recommends, that as foon as the infant is five months old, its gums be rubbed feveral times a day with a mixture of lemon-juice and honey, firft over the middle incifors of the lower jaw, and when thefe have come out, over thofe of the upper jaw.

Emollient remedies are faid to relax the gums too much, the confequence of which is, that the loofe gum is flowly and difficultly perforated by the tooth, as inftead of ulcerating, it is only raifed and rendered tenfe.

The ufe of hard applications, as biting the root of marfhmallows, fmooth corals, boars' tufks, &c. render the gums callous; but more good might, perhaps, be derived, if fubftances with rough furfaces were employed.

A premature incifion of the gum foon clofes again, and therefore does little fervice; but we do not believe that the cicatrix, thus produced, can be any impediment afterwards to dentition, as many have imagined; for it is an eftablifhed fact, that cicatrices in general are more difpofed to ulcerate and be abforbed, than the original parts of the body. We would never fuffer any idle apprehenfions of the above fort to deter us from dividing the gum, were there any chance of benefit from the proceeding. At the fame time, we do not recommend this as a prophylactic meafure, but as being proper only when illnefs, fufpected to arife from dentition, actually exifts.

Premature Dentition.—This is ftated to happen, when the milk-teeth come out before the infant is fix months old. Sometimes children are even born with their teeth already cut. Rzafcynky, Rhodius, l'Eclufe, and Stoerck, mention a boy, who had the molares at the time of birth. Alfo in an abortion of fix months, and another of feven, teeth have been obferved. (Halleri Elementa Phyfiol. t. vi. p. 19.) Van Swieten met with two incifors in an abortion of five months. (Comm. t. iv. p. 742.) In a very weak male child, born at eight months, Arnold faw two perfect teeth rife out of the lower jaw on the feventh day after birth, and grow with extraordinary quicknefs; but they fell out in the eighth week from their firft appearance. Obf. Phyfico-Med. p. 70.

In general it is to be concluded, that early dentition indicates great conftitutional vigour and ftrength.

Of Backward Dentition.—Backward dentition is when the milk-teeth are not cut, though the child is a twelvemonth old, or even older. The proximate caufe of this delay is generally referred by medical writers to languor and weaknefs of the conftitution. But late dentition is of feveral kinds.

1. Backward dentition from an unknown caufe fometimes happens, the teeth not making their appearance for a year after birth, notwithftanding the children have not any appearance of debility. Van Swieten met with a moft healthy female child, who was nineteen months old when fhe cut the firft tooth. Comm. t. iv. p. 742.

2. Backward dentition from the rickets. It is univerfally known, that in ricketty children the cutting of the teeth is a long while delayed. In thefe fubjects the gums are always much relaxed, and we have already ftated, that this circumftance is by no means favourable to dentition. It is probable, alfo, that in ricketty infants the teeth themfelves are a long while before they are perfectly formed, it being well afcertained, that in fuch conftitutions the depofition of the phofphate of lime takes place with extraordinary flownefs and difficulty.

3. Backward dentition of the dentes fapientiæ. The wife teeth are feldom cut before the twentieth year, and fometimes they firft come out in perfons confiderably advanced in years. Halleri Element. Phyfiol. t. vi. p. 28.

4. Late dentition in adults. Sometimes this takes place a third time, chiefly with refpect to the incifores; and inftances are actually recorded, in which thefe teeth were cut in adults, or even in old perfons. Haller quotes examples, in which they were cut at the ages of 90, 95, 100, 118, 120, and later. Halleri, l. c. t. viii. l. 30.

Wrong Situation of the Teeth.—This happens when the teeth make their appearance in the palate, or in any place not comprifed in the alveolary arches. The proximate caufe of this unpleafant occurrence is the preternatural formation of the young tooth in an erroneous fituation.

The cafes may be of different kinds, in regard to the place which the tooth occupies.

1. When a tooth grows out of the palate, it obftructs maftication, and by rubbing againft the tongue, often makes it ulcerate. The inconvenience can only be remedied by extracting the difplaced tooth.

2. The tooth may come out under the tongue. This cafe produces the fame grievances as the preceding, and requires the fame mode of relief.

3. The

3. The next curious circumftance which we have to notice, is the growth of teeth in the ovaries. It is now believed, that the teeth fometimes found in thefe organs, are not always the relics of a previous embryo, but may be formed there as a lufus naturæ. An inftance, in which a tooth was formed in an encyfted fwelling in the orbit, has been lately recorded by Mr. Barnes of Exeter. See Medico-Chir. Tranf.

4. Albinus records an example, in which a tooth grew out of the maxillary procefs below the orbit. It was concealed until it made its way out in this extraordinary fituation. Annot. Acad. t. i. p. 54.

5. The teeth have fometimes been obferved inverted, their bodies being fituated towards the jaw. Poilich, Increm. Offium, p. 25. Albin. c. 9. Palfin, c. 9.

Extraordinary Diftance of the Teeth from each other.—Sometimes the teeth are placed too diftant apart, fo that between their crowns large interfpaces are left.

1. In children three years of age, the crowns of the milk-teeth are fo clofe to each other, that they are laterally as it were in contact; but in children feven years old, there are wide interfpaces between them. The reafon of this is owing to the jaw increafing in fize, while the dimenfions of the teeth undergo no alteration. The fecond or permanent teeth, on the other hand, (at leaft the firft twenty of them,) have larger bodies than the milk-fet.

2. Frequently the tartar infinuates itfelf between the crowns of the teeth, and occafions a confiderable feparation of them. We need fcarcely obferve, that the cure requires that the tartar fhould be taken off, and the teeth reduced into their natural pofition.

3. The deformity of which we are now treating, is occafionally afcribable in adult fubjects to the preternatural breadth of the jaw, in which circumftance it is abfolutely incurable.

Extraordinary Clofenefs of the Teeth.—The teeth may be too crowded together, fo that their crowns are laterally in contact. This defect may extend to fome or all the teeth. The frequent confequence is, that the lateral margins of thefe parts become carious.

There are two fpecies of the diforder.

1. The firft arifes from the great width of the crowns of the teeth, and it may be afcertained by ocular examination. In fome inftances, all the bodies of the teeth are preternaturally wide; in others, only a certain number of them.

The mode of cure confifts in filing off a little of the lateral edges of the teeth affected.

2. The fecond fpecies is caufed by the uncommon fhortnefs of the jaw. It may be known by obferving that the crowns of the teeth are not too large, and that the alveolary arches are ftrikingly diminutive.

Here the mode of relief is the fame as in the foregoing cafe.

Extraordinary Number of Teeth.—Sometimes the number of the teeth exceeds what is the ufual fhare of the human fpecies in general; and this particularly occurs whenever the number amounts to more than thirty-two. Columbus has feen thirty-three (p. 34.); Fauchart, thirty-three and thirty-four (edit. 2. tom. i. p. 3.); Bourdet, thirty-fix (p. 25.); and Ingraffias, thirty-fix, including twenty-four grinders. Text 2.

1. With refpect to the redundant number of each clafs, it is when there are fix incifores, or four canine teeth, or more than ten molares in one jaw. The cafe is incurable.

2. In fome inftances, the exceffive number is owing to there being a double row of teeth. This malformation may happen to both jaws, or be confined to one. It has been noticed in both jaws by Munick, p. 144; Plinius, c. xi. p. 623; C. Bartholinus, p. 464, &c.

Arnold met with a boy, fourteen years old, who had altogether feventy-two teeth in his mouth. There was a double fet of the incifores, canine teeth, and three pofterior grinders; but the anterior grinders were triple: confequently there were counted in each jaw eight incifores, two canine on each fide, and twelve molares. The incifores were not arranged in an even double row, but each row feemed irregular, and its order as it were promifcuous. The arrangement of the canine and grinding teeth was more regular. None of thefe teeth were affected with caries. Obf. Phyf. Med. p. 69.

3. There may be a larger number of teeth than common, in confequence of the prefence of one of the milk-teeth; for when the latter does not fall out at the ufual period, the corrづfponding permanent teeth come out in the vicinity of it.

Here the cure confifts in drawing the fuperfluous milk-tooth.

Deficient Number of Teeth.—Sometimes the number of the teeth falls fhort of what is ufual; and this happens whenever they are fewer in the adult fubject than thirty-two.

1. The defective number may be owing to a preternatural fhortnefs of the jaw. Sometimes one or more teeth remain concealed during life. Thus, the dentes fapientiæ are never cut in perfons who have the upper or lower alveolary arch not fufficiently long.

2. The fex alfo makes a difference; women, generally fpeaking, having fewer teeth, than belong to men. Riolan, p. 38, and 39.

3. The deficiency in the number may proceed from a tooth having been drawn, or dropped out. This is evidently a cafe which can only be remedied by the infertion of an artificial tooth.

4. Laftly, the limitation of the number may be owing to infancy; for, in children under feven years of age, the natural number of the teeth does not exceed twenty.

Obliquity of the Teeth.—The pofition of fome or all the teeth may be oblique; an inconvenience which may be caufed by the milk-teeth not being fhed, by tartar infinuating itfelf into the interfpaces of the teeth, by loofenefs of the alveoli, and, laftly, by a forcible luxation of the teeth affected. The milk-teeth feldom grow obliquely; the permanent ones do fo much more frequently. The molares hardly ever rife in a wrong direction; and, in general, they are only the incifores and canine teeth which deviate from the right pofition.

With regard to the effects of fuch obliquity, we have to obferve, that the teeth affected impede maftication, interfere with the articulation of words, ferioufly disfigure the countenance, and, unlefs drawn, or replaced in their natural pofition, may occafion incurable ulcers on the tongue, lips, or cheeks.

The differences of the obliquity make thefe cafes divifible into feveral kinds.

1. The obliquity forward is when the tooth projects anteriorly, fo as to hurt the cheek or lips. Such a tooth may caufe ulceration of thefe parts, as already mentioned. The parotid duct has been known to be perforated, and a falivary fiftula brought on, by an oblique tooth in the upper jaw. Pafch, l. c. p. 71.

2. The obliquity backward is when the pofition of the tooth inclines towards the centre or pofterior part of the mouth, fo as to be capable of hurting the tongue. Teeth, fo circumftanced, have fometimes been the caufe of ulcers on the tongue, which in point of obftinacy and malignancy have truly vied with cancer. Plenck informs us, that by drawing

ing the left eye-tooth, he once cured an ulcer, which had exiſted half a year on the left edge of the tongue. P. 20.

3. The converging obliquity is when the crowns of the teeth converge in their ſituation, or even croſs each other.

4. The diverging obliquity is when they diverge.

5. The lateral obliquity is when the ſide of the body of the tooth is turned more or leſs forwards or backwards.

6. Obliquity of the fang. Sometimes the fangs of the teeth are curved ſo obliquely backwards or forwards, that the bottom of the ſockets either projects like a ſmall exoſtoſis, or is completely perforated.

Of the Reduction of an oblique Tooth.—With reſpect to one of the permanent teeth, which is rendered oblique by the preſence of one of the firſt ſet, the treatment conſiſts in immediately extracting the latter.

The milk-tooth may be known by its pearl colour, its more poliſhed ſurface, and its ſmaller ſize. The permanent tooth is longer, whiter, ſtronger, and of greater breadth. The crowns only of the ſecond ſet of grinders are ſhorter than thoſe of the milk-ſet. Albini, Annot. Acad. l. ii. p. 19.

But an oblique permanent tooth may be replaced in its right poſition, by the following means.

1. When the child is very young, and the tooth quite recent, it may be reduced into its proper ſituation, by frequently preſſing upon it with the finger in the courſe of the day.

2. Or the reduction may be effected with a double ſilk-thread, ſmeared with wax and maſtich. A nooſe is to be made at each end of the thread, and faſtened to the adjacent teeth. The thread, being then divided into two, is to be made to croſs two or three times firmly over the oblique tooth.

3. By a metallic plate. The length of the plate ſhould exceed the meaſure of the two neighbouring teeth, together with the oblique one. Its width ſhould be leſs than the height of the teeth. It is to be applied to the inſide of ſuch teeth as incline inwards, and to the outſides of thoſe which incline outwards. At the ends of the plate are two holes, through which the ſilk-threads, ſmeared with wax, are to be paſſed, and, after croſſing each other, are to be tied over the oblique tooth.

4. By Bruner's machine. When the tooth does not admit of reduction by the preceding means, Bruner's machine may be tried. See A Bruneri Einleitung zur Wiſſenſchaft eines Zahnarztes, p. 83.

When ſeveral of the teeth are oblique, the cure is to be attempted by the ſame operations; but when the ſide of a tooth inclines forward, it is neceſſary to uſe the forceps to bring the part into its right poſition.

Looſeneſs of the Teeth.—Sometimes the teeth become looſe and moveable in their ſockets. The proximate cauſe of this affection may depend upon the loſs of the elaſticity of the alveoli and gums, upon the too great or too ſmall ſize of the ſockets, or upon the abſorption or waſting of the fangs. Looſe teeth are very inconvenient in maſtication, and eaſily drop out.

Of this complaint there are ſeveral ſpecies, the differences of which are referrible to the cauſes.

1. Looſeneſs of the teeth from ſecond dentition. After the ſeventh year, the twenty milk-teeth begin to grow looſe, and fall out, nearly in the ſame order in which they were cut.

2. Looſeneſs of the teeth from age. In old perſons the ſockets become contracted, and the canal in the fangs being obliterated, theſe parts alſo diminiſh. Hence we ſee the reaſon why the teeth frequently become looſe in ſubjects advanced in life.

3. Looſeneſs of the teeth from violent concuſſions. A forcible concuſſion, ſuch as happens in falls againſt the teeth, diminiſhes the elaſticity of the gums and ſockets, and of courſe may be a cauſe of the preſent diſorder.

The cure requires corroborant waſhes: the tinctura laccæ, aſtringent decoctions, red wine, ſpirit of wine, or the terra catechu or ſanguis draconis, diſſolved in camphorated ſpirit.

4. Looſeneſs of the teeth from relaxation of the gums. There are people whoſe gums are pale and relaxed, at the ſame time that there is no appearance of ſcurvy.

Here the cure is to be accompliſhed by the means recommended for the preceding caſe.

5. Looſeneſs of the teeth either from caries of the ſocket or fang. This caſe may be known by the emiſſion of pus from the ſocket of the looſe tooth. Sometimes a cure may be effected by gargles; but, in general, if the tooth is alſo painful, it ought to be extracted.

6. Looſeneſs of the teeth from ſcurvy of the gums. In ſubjects with ſcurvy, the gums become looſe and fungous, and the ſockets filled with a fetid purulent matter: hence the teeth are looſened.

The cure requires the internal exhibition of antiſcorbutic medicines, and the uſe of antiſcorbutic waſhes.

7. Looſeneſs of the teeth from mercury. Mercury acts ſpecifically upon the gums, deſtroying their tone, and promoting the ſecretion of ſaliva. Hence, perſons uſing mercury, either outwardly or inwardly, are liable to have their teeth rendered looſe.

The cure demands purgative medicines, the expulſion of the mercury from the ſyſtem, and the uſe of tonic gargles.

Defect of Teeth.—When the teeth are entirely wanting, ſeveral very unpleaſant effects are neceſſarily the conſequence. The proper maſtication of the food being then abſolutely impoſſible, cardialgia, and other complaints connected with difficult digeſtion, are produced. The deficiency of the grinding teeth occaſions a collapſe of the cheeks, and of courſe an unſightly emaciation of the countenance; while the want of the inciſores ſpoils the voice.

1. It is natural for all young infants to be without teeth, until they are ſeven or eight months old; but when the teeth do not begin to come through the gums after a child is a twelvemonth old, then the backwardneſs of dentition may be conſidered as morbid.

2. In old perſons, the teeth naturally fall out, and the alveoli contract into a kind of ſharp edge, covered with the callous membrane of the gums, by which the ſofter ſpecies of food may yet be chewed.

3. Want of teeth from rickets. When the rudiments of the permanent teeth are deſtroyed with the milk-teeth, then of courſe no ſecondary teeth ever make their appearance.

4. Loſs of teeth from violent cauſes. Under this head we comprehend the defect of one or ſeveral teeth, drawn, or beaten out.

5. Loſs of teeth from necroſis. Every form of this diſorder makes the teeth fall out in little pieces.

6. Loſs of teeth from ſcurvy. In ſituations where the ſcurvy is prevalent, it is common to meet with numerous perſons who have loſt their teeth in the very prime of life.

Every kind of deficiency of teeth, except that which belongs to infancy, cannot be remedied in any other way but by the inſertion either of artificial or natural teeth.

Of the Inſertion of Teeth.—There are various ſpecies of this operation, but all of which may be included under the following heads.

1. The inſertion of a healthy proper tooth. When a tooth that has been extracted, or beaten out, appears to be entirely ſound, it is to be immediately replaced in the ſocket, and tied with thread to the adjacent teeth. Sometimes it ſpon-

ſpontaneouſly becomes fixed again, if care be taken to uſe an aſtringent gargle with a view of making the gum contract.

2. The inſertion of a proper tooth that has a carious fang. When the tooth, which has been removed from the alveoli, is merely carious in the fang, it may be replaced again, after the carious part has been filed away.

3. The inſertion of a proper tooth, which has a caries of its body or crown. When a very ſmall portion of the crown is carious, it may be removed with a file, and the tooth can then be put into its ſocket again. But if the whole body be diſeaſed, it may be cut off tranſverſely from the root; a ſmall hole may be drilled acroſs the latter part, and, with the help of a golden wire, an artificial crown or body, having alſo a tranſverſe hole for the paſſage of the wire, may be faſtened to the root. In this ſtate, the tooth may be replaced.

4. The inſertion of a tooth taken from the mouth of another living ſubject, or from a dead ſubject. The perſon, to whom the tooth is to be transferred, ſhould not be above the age of forty; but the ſubject, from whom it is to be taken, ought not to be more than four-and-twenty. The tranſplanted tooth ſhould belong to the ſame jaw and ſide of the face, and be of the ſame ſhape and ſize, as the tooth that is extracted.

The canal of the tooth, which is to be inſerted, muſt be cloſed with gold; and the tooth muſt be every where rendered free from inequalities, ſo that it may be the more likely to adhere.

5. The inſertion of an artificial tooth. The form and ſize which ſhould be given to the artificial tooth muſt be determined by a model of ſoft red wax, which has been preſſed into the gap made by the loſt tooth. In order that the white colour of the artificial tooth may correſpond to the light yellowiſh colour of the reſt of the teeth, the new tooth ſhould be macerated in ſtrong coffee, or in the lees of red wine.

Artificial teeth ought to be made of ivory, or of the tooth of the hippopotamus. Each of them ſhould be grooved on both ſides, and perforated tranſverſely, ſo as to admit of being tied to the neighbouring teeth. The nooſes of two threads are to be faſtened on the neighbouring teeth, and the ends having been drawn tranſverſely through the hole of the artificial tooth, and there made to decuſſate, they are to be tied in a ſurgeon's knot. The tooth having been placed in the ſocket, the threads betwixt the artificial and old teeth muſt be tightened and made faſt. Laſtly, an aſtringent gargle muſt be uſed for a few days.

6. The inſertion of ſeveral artificial teeth. When two, three, or a larger number of contiguous teeth are wanting, an equal number muſt be formed of one piece of ivory, or other ſubſtance, and faſtened at once to the neighbouring teeth.

7. The inſertion of a whole ſet of artificial teeth. When all the teeth of the upper and lower jaws are loſt, a complete ſet may be fixed on the margins of the alveolary arches. Should any of the natural teeth remain, they may often be of great aſſiſtance, in rendering the lodgment of the artificial ones more firm and ſecure. When the whole, or the greater part, of the teeth of either jaw is loſt, an artificial ſet may alſo be inſerted.

The cuſtom of wearing ivory teeth, and of binding them in with a gold wire, is very ancient: Lucian and Martial ſpeak of it as practiſed among the Romans. But ligatures of wire have been found to hurt the natural teeth, with which the artificial are connected; whereas ſilken twiſt cannot affect them to any conſiderable degree for ſeveral years.

Guilleman gives us the compoſition of a paſte for making artificial teeth, which will never grow yellow: the compoſition is white wax granulated, and melted with a little gum elemi, adding powder of white maſtich, coral, and pearl.

Thus whole ſets may be made for one or both jaws, ſo well fitted to admit of the neceſſary motions, and ſo conveniently retained in their proper ſituation, by means of ſprings, that they will anſwer every purpoſe of natural teeth, and may be taken out, cleaned, and replaced by the patient himſelf with great eaſe.

Wearing out of the Enamel.—(See CRANIUM.) The bodies of the grinding teeth being wide, exceſſively hard, and expoſed to perpetual friction, they become worn much ſooner than the reſt of the teeth, and flat in conſequence of the deſtruction of their points. Halleri Element. Phyſiol. t. vi. p. 29.

With reſpect to the effects of the loſs of the enamel, it is to be obſerved, that the teeth which are deprived of it become ſo ſenſible, that painful ſenſations are produced in them by heat and cold, and by ſolid as well as liquid aliment. In the end, alſo, they readily become carious.

The ſpecies of this affection depend upon the cauſes.

1. Loſs of the enamel from age. After the age of thirty, almoſt all the teeth in the human ſubject have been ſomewhat worn by long maſtication. Some writers aſſert, that in youth, the waſte of the enamel may be repaired by nature; but if the teeth be deſtitute of vaſcularity, the evil muſt be always irreparable. See CRANIUM.

2. Loſs of the enamel from gnaſhing of the teeth. Perſons who in the night are in the habit of gnaſhing their teeth deſtroy the enamel. For the purpoſe of preventing the ill conſequences of this practice, it has even been recommended to cover the teeth in the night-time with a thin gold plate.

3. Deſtruction of the enamel by the uſe of tobacco-pipes. Plenck informs us, that in the inciſor teeth of men, who had for many years been accuſtomed to ſmoke pipes, he has ſeen the diſtinct impreſſion of a black ſemicircle.

4. Loſs of the enamel from long and violent bruſhing of the teeth. They who daily rub and bruſh their teeth forcibly with a rough hard tooth-powder, or too ſtiff a bruſh, inevitably deſtroy, in the courſe of a few years, all the enamel on the front ſurface of the teeth. Here the cure obviouſly depends upon the avoidance of the cauſe.

5. Loſs of the enamel from applying the file to the teeth. Whenever this operation is carried to too conſiderable a depth, the enamel is removed by mechanical violence.

6. Loſs of the enamel from biting a very hard body. This ſort of violence ſometimes ſplits the enamel, which immediately falls off in pieces, at the very time of making the bite.

7. Loſs of the enamel from its being preternaturally brittle. When the enamel is thus affected, it is apt to break in chewing and biting ſubſtances without the exertion of any particular degree of force.

8. Loſs of the enamel from the projection of an oppoſite tooth. A tooth which juts out conſiderably, ſo wears the correſponding tooth in the oppoſite jaw, as to make a deep impreſſion in it. The treatment conſiſts in ſhortening the tooth, which is injurious on account of its length, with a file.

Concretion of ſeveral of the Teeth into one Maſs.—A true anchyloſis of the teeth cannot happen from any proceſs like oſſification, becauſe they poſſeſs no vaſcularity; and ſome of the caſes, referred to by writers, were probably original malformation.

There are ſeveral varieties ſpecified.

1. The

1. The true concretion of the teeth, which happens when the teeth are connected together by a ſubſtance reſembling bone.

2. The ſpurious concretion, or that ariſing from the exceſſive cloſeneſs of the teeth to each other, in which ſtate they ſeem as if they had actually grown together.

3. The concretion from tartar. Sometimes the interſpaces of the teeth are ſo filled up with tartar, that the teeth cohere in ſuch a degree, as to cauſe an appearance reſembling what may be ſuppoſed to proceed from an actual bony concretion of thoſe bodies. The mode of treating this caſe will be conſidered in ſpeaking of the tartar of the teeth.

4. The cloſe contact of the fang of the tooth with the ſocket. In this circumſtance, the tooth either cannot be extracted, or, in the event of great force being uſed, the tooth is broken away from the jaw.

Elongation of the Teeth.—Sometimes one or more of the teeth appear to become longer.

1. Elongation of a tooth from the deficiency of the oppoſite one. Thus, when one of the molares of the upper jaw is drawn out, the correſponding tooth of the lower jaw ſeems lengthened; becauſe after a time the neighbouring teeth are worn down by the friction which they continually exerciſe againſt each other.

2. Elongation from preternatural ſoftneſs of the tooth. Plenck informs us, that he has ſeen in a female child eight years old, the right canine tooth of the lower jaw elongated, and which, after being extracted, was found ſo ſoft, that the crown and fang could be compreſſed with the finger.

3. Elongation of a tooth from exceſſive growth is mentioned by writers; but this caſe cannot be poſſible, as the teeth are known not to be vaſcular.

4. Imaginary elongation. Perſons whoſe teeth are affected with ſtupor, are apt to fancy that their teeth are longer than natural; but without real cauſe. The cure conſiſts in removing the ſtupor.

Foulneſs of the Teeth.—The teeth are often ſeen covered with a ſordid, fetid, yellowiſh, or dark-brown mucus.

The proximate cauſe is the adheſion of the mucus of the mouth and fauces to the ſurface of the teeth.

1. Morning foulneſs. In almoſt all men, the teeth become coated in the night during ſleep with a dirty mucus, and appear foul in the morning. The reaſon is, becauſe during ſleep the ſaliva is more ſlowly ſecreted in the mouth; and, on account of the motionleſs ſtate of the tongue and jaws, it is not waſhed off the teeth.

This ſpecies of foulneſs is eaſily removed by waſhing the mouth every day with cold water, and the teeth with a bit of rag, the finger, or a wet ſponge.

2. Foulneſs of the teeth from neglect to clean them. They who are not in the daily habit of waſhing their mouths and teeth with cold water, by degrees have the interſtices and fangs of their teeth incruſted with mucus in the morning, and with the remaining particles of the food.

With reſpect to the treatment, merely waſhing the mouth in this inſtance is not enough; it is alſo requiſite to clean the teeth occaſionally with tooth-powder.

3. Foulneſs of the teeth from fever. This is remarkably ſeen in caſes of putrid fever, in which, owing to the ſtate of the ſaliva, the teeth become covered with a yellow or dark-brown coat.

Here the teeth ſhould be frequently waſhed and cleaned with vinegar.

4. Foulneſs from ptyaliſm, eſpecially that produced by mercury. In the beginning of a ſalivation, the teeth become coated with mucus. The beſt treatment is to waſh and clean them frequently with a honey gargle.

5. Scorbutic foulneſs. In perſons labouring under ſcurvy, the teeth are invariably covered with a purulent kind of mucus, iſſuing from the ſockets of the looſened fangs.

The cure demands the internal and external employment of anti-ſcorbutic remedies.

6. Foulneſs of the teeth from tartar. In the early ſtate of the formation of tartar, the ſurface of the teeth becomes covered with a mixture of earth and gluten.

The treatment conſiſts in removing the tartar with a thick tooth-powder.

Of cleaning the Teeth.—In perſons whoſe teeth are perfectly ſound, it is only neceſſary to waſh their mouths every morning with water that has had the chill taken off it, and that contains a few drops of the ſpirit of lavender; the mucus being wiped from the teeth with a bit of rag, or ſponge. The ſame ſhould alſo be done after meals, and the fragments of meat lodged between the teeth muſt be removed with a tooth-pick, which inſtrument ſome recommend to be made of juniper wood.

But in perſons in whom a depoſition of tartar readily takes place, the tartar ought to be removed with a tooth-ſcraper, and the teeth well cleaned every week with tooth-powder.

Charcoal, or carbon, is uſed for cleaning the teeth, and the beſt is made from the ſhell of the cocoa-nut. We are informed by hiſtorians that the ladies among the ancient Britons uſed the charcoal made with the wood of the common hazel-nut for this purpoſe. See DENTIFRICE.

The abſorbent earths are uſed for dentifrices; they mechanically cleanſe the teeth from the thick mucus and tartar, and at the ſame time preſerve the tone of the gums. Therefore,

1. The baſis of dentifrice powders may be prepared ſhells, red corals, mother-of-pearl, powdered crabs' claws, bone of the cuttle-fiſh, lapis hæmatites, &c.

2. For communicating an agreeable colour to the powder, carmine or cochineal may be added.

3. For giving an agreeable odour, ambergris, cinnamon, or cloves may be uſed.

4. For ſtrengthening the gums, armenian bole, ſanguis draconis, or terra catechu, is the beſt ingredient.

Rough tooth-powders, like that containing pumice-ſtone, gradually wear away the enamel, eſpecially when they are employed every day.

Acid applications, particularly the mineral ones, do indeed whiten the teeth; but when long uſed, render them brittle.

Hence crude and burnt alum ought to be rejected from every kind of dentifrice. The nitric, muriatic, and ſulphuric acids in tinctures are ſtill more hurtful.

Of the Tartar of the Teeth.—This ſubſtance is an earthy cruſt, which adheres to the teeth. As it fills up the interſpaces of ſeveral of the teeth, and occupies their external ſurfaces, it is ſeldom obſerved upon their inſides. By the Greeks it was called *odontolithos*, from ὀδοὺς, *a tooth*, and λίθος, *a ſtone*. By others it has been termed *tophus*, vel *calculus* dentium.

With regard to the effects of the tartar, it diſplaces the teeth, and renders them looſe and painful; it alſo ſeparates the gums from the fangs, producing caries in the latter, and a bad ſmell in the breath.

In reſpect to colour, the tartar of the teeth is of three kinds, namely, dark-brown, yellow, and black.

Since many perſons who never clean their teeth at all are not diſfigured with theſe depoſitions of tartar, it appears that a peculiar diſpoſing cauſe is neceſſary for the occurrence of the complaint. The ſpecies are:

1. Tartar

1. Tartar from neglect to wafh the mouth. It originates from the gluten of the faliva, which, in uncleanly fcorbutic fubjects, and great wine-drinkers, adheres to the teeth, becomes putrid with the heat, and in putrefying depofits a fort of earthy matter upon the teeth. People who drink chiefly water are feldom troubled with earthy incruftations on their teeth.

The cure requires the removal of the tartar. Small portions of tartar may be taken off by means of a brufh and a thickifh tooth-powder.

But when the tartar is abundant, thick, and grown, as it were, to the teeth, it muft be cut with a fuitable inftrument placed obliquely, beginning from the neck, and carrying the inftrument towards the upper part of the tooth. The tartar having been cut, is then to be removed piecemeal.

Any remaining particles of tartar may afterwards be gradually got rid of by the ufe of a brufh and tooth-powder.

2. Spontaneous tartar. There are certain perfons, whofe teeth are conftantly incrufted with tartar, notwithftanding they are in the continual habit of wafhing their teeth and mouths.

This peculiar diathefis feems to confift in an extraordinary quantity of earthy matter in the faliva.

Berdmore relates a furprifing example of this fort of tartar. A man, thirty-two years of age, had the teeth of each jaw coated with folid tartar, half an inch in thicknefs, both on the outfide and infide of the teeth, and on the furface of the gums, fo that the interftices of the teeth were altogether invifible. The gums were every where pufhed off the teeth, and painful. The incruftations upon the incifor teeth were fo thick, that the lower lip was rendered more prominent. During a fortnight, Berdmore removed every day fome of the tartar from the teeth with an inftrument, and at length employed a dentifrice and brufh. The retracted gums were fcarified, and thus made to adhere to the necks of the teeth. The patient was obliged to brufh his gums and teeth three times a day, partly with a view of preventing the new formation of tartar, and partly in order that the regeneration of the gums might be ftill more promoted. But although the patient ftrictly followed this plan, his teeth and gums, in the courfe of half a year, became again covered with an extremely thick coat of tartar. Berdmore was therefore under the neceffity of recommending the ufe of a ftiffer brufh, and a dentifrice made of fhells, for the purpofe of removing the tartar. P. 56.

With refpect to the treatment of tartareous incruftations of the teeth in general, it is effential to remove the tartar and clean the teeth well every day.

The internal and external remedies alfo, which are ufually advifed for diffolving ftones in the bladder, may be employed, as lime-water, pure potaffa, &c.

Sometimes peppermint-water, with a few drops of nitrous acid, is ufed with advantage.

3. Tartar from the porofity of the furface of the teeth. Perfons who are in the habit of ufing acrid tinctures or powders which diffolve the enamel, and make it porous, are frequently troubled with tartareous incruftations.

The caufe being avoided, the mode of treatment is the fame as in the preceding cafes.

Of Blacknefs or Necrofis of the Teeth.—This is a very peculiar affection of all the teeth, making them appear black, rough, and eroded.

Sometimes only the upper part of the crown exhibits a dark-coloured erofion; while, in other inftances, the whole fubftance of the tooth is eroded.

The proximate caufe of this difeafe is imputed by Plenck to injury of the nutrient veffels of the pulp by difeafe, before the growth of the tooth is thoroughly completed; and, therefore, it is a totally different diforder from necrofis of the bones, which is attended with phenomena, connected with the vafcularity of the parts themfelves.

Hence it is only in infants that feveral of the teeth are ufually thus diftempered.

Necrofis of the milk-teeth is indeed much more frequent than of the permanent fet.

The following varieties of the complaint, depending on the difference of the caufe, have been diftinguifhed.

1. Blacknefs of the teeth from rachitis. In ricketty infants, the milk-teeth come out of the jaw more tardily, and they foon afterwards turn black and friable, and fall out piecemeal. The fecondary teeth alfo, when rachitis is not cured between the firft and fecond dentition, are affected with the fame deftructive change, fo that fubjects of this defcription are either deftitute of teeth during the whole of their lives, or only have in their mouths teeth which have a black eroded appearance.

As for the cure of rachitis, we do not intend to confider it in the prefent place, and fhall merely ftate that the pure milk of a healthy nurfe, falubrious air, a great deal of exercife, good food, abforbent medicines, white alkaline falts, bark, fteel, fea-bathing, &c. are the remedies principally recommended.

2. Scorbutic blacknefs of the teeth. When the fcurvy attacks children before the offification of the teeth is completed, the milk-teeth, as foon as cut, either appear to be already eroded, or in a fhort time afterwards become fo, and put on a black colour.

The cure demands the immediate exhibition of anti-fcorbutic medicines, with the affiftance of which the fecond teeth are fometimes perfectly healthy.

3. Blacknefs of the teeth from the fmall-pox. In children who are feized with malignant fmall-pox during the firft or fecond dentition, a black erofion of the teeth is frequently obferved.

The cure requires the repeated adminiftration of purgatives, and then the Peruvian bark.

4. Blacknefs of the teeth from meafles. The fame black erofion of the teeth has been remarked after fevere cafes of meafles.

The cure is the fame as in the foregoing inftance.

All the preceding fpecies of necrofis, when they affect the milk-teeth, are to be ftopped by their proper fpecific remedies, in order that the fecond fet of teeth may not be affected; but when thefe are difordered, the cafe is irremediable.

5. Blacknefs of the teeth from tartar. The tartar itfelf fometimes turns black, and even after its removal, the teeth often remain of a blackifh colour, which cannot be effaced.

6. Blacknefs of the teeth from the application of mineral acids. Nitrous acid diluted with water, in a fhort time, whitens the teeth; but foon afterwards renders them black and friable. Plenck has feen the lateral edges of the teeth turned black and corroded by the employment of mercurial cofmetics.

7. Blacknefs of the teeth from cancer. Plenck has twice noticed in men, who were afflicted with ulcerated cancers of the lower lip, the teeth disfigured with a deep black colour. But it is to be remarked, that the affection was confined to the enamel, and did not extend to the bony fubftance of the fangs.

Preternatural Colour of the Teeth.—This is a change of the natural colour of the teeth to a yellow or afh-colour.

1. Difcolouration from neglect to clean the teeth. The fordes,

fordes, which collect upon the teeth, diminifh their glofs and whitenefs, and render them yellow or afh-coloured.

The cure confifts in removing the fordes.

2. Difcolouration from age. The whitenefs and polifh of the teeth, peculiar to youth, change in the advanced period of life into a dull yellow, which is totally irremediable.

3. Difcolouration from the ufe of mercury. The teeth are difcoloured not only by the internal, but alfo by the external ufe of mercury. Hence gilders, and other artizans who make ufe of mercury, have their teeth ftained of a leaden colour. Plenck has feen the fame fort of disfigurement occafioned by cofmetics containing quickfilver.

The cure requires that the mercury be got out of the fyftem as expeditioufly as poffible.

4. Difcolouration from fcurvy, &c. Scorbutic perfons are efpecially noticed as having the colour of the teeth fpoiled. Venereal and ricketty fubjects are alfo frequently affected in the fame way.

To this head muft likewife be referred the difcolouration of the teeth obfervable in mariners.

5. Difcolouration of the teeth from pregnancy. In pregnant and fuckling women, the luftre of the teeth is often remarked to leffen, and thefe parts to be difcoloured. Lorry, Tract. de Morb. Cutaneis, p. 61.

It is fuppofed that this change of the teeth is frequently connected with the bad ftate of the milk, the evacuation and correction of which are the means of cure advifed by feveral authors.

6. Difcolouration from taking hot food. Perfons who make a practice of drinking very hot liquids, or of chewing fubftances which are too warm, have the luftre and whitenefs of their teeth deftroyed. It is queftionable, whether the beautiful white colour of the teeth of animals in general may not be owing to their abftaining from hot aliments?

7. Difcolouration from dentifrice powders and tinctures containing mineral acids. Thus, burnt alum and fpirit of nitre for a fhort time whiten the teeth; but a little while afterwards, the enamel turns pale and falls off in bits.

8. Difcolouration from the fmoke of tobacco. The oil of this plant is well known to have the effect of turning the colour of the teeth to a dark brown or black.

9. Difcolouration from thinnefs of the enamel. When the vitreous fubftance is in a certain degree worn away, the bony fubftance, which is yellow, can be feen through it. The defect is incurable.

10. Difcolouration from an internal caries of the tooth. Such a tooth lofes its luftre and whitenefs, and becomes pale, afh-coloured, dark-brown, and at length black.

Here the only mode of cure is to extract the difeafed tooth.

11. Difcolouration from the ufe of madder. It is remarked, that only the bony part of the tooth is ftained red by this root, but not the enamel. The rednefs alfo does not extend itfelf to the portion of the tooth already formed; but only to the part formed while the animal is fed with madder. This colour likewife never difappears: circumftances much againft the doctrine of the teeth being vafcular.

12. Golden difcolouration of the teeth. This fpecies is brought on by art.

Fragility of the Teeth.—In this affection, the cohefion of the fubftance of the teeth is fo flight, that a very inconfiderable force makes it break.

The proximate caufe of this fragility of the teeth is probably connected, in many examples, with fome imperfections in their original growth.

The varieties defcribed by writers are as follow:

1. The fcorbutic fragility. In people afflicted with the fcurvy, the bodies of the teeth by degrees become fo fragile that they drop out piecemeal.

2. Fragility from rickets. In children thus affected, the milk-teeth, foon after they have been cut, become dark-coloured, are eafily broken, and ufually fall out in pieces.

3. Fragility from old age. In old age the teeth are apt to be broken in biting with force, and to fall out piecemeal.

4. Fragility from the application of mineral acids or burning oils. The abufe of fuch medicines, too long continued, brings on a fpecies of fragility, which admits of no mode of cure.

5. Fragility from caries. Teeth, which are excavated by caries, and rendered thin, are readily broken in maftication, and drop out in pieces.

All the different fpecies of fragility are incurable.

Mollities, or Preternatural Softnefs of the Teeth.—This difeafe is fo remarkable a foftnefs of the fubftance of the teeth, that it can almoft be compreffed together by the fingers.

The proximate caufe is faid to be either too great a quantity of the gluten, which connects the earthy particles together, or elfe a deficiency of the earth.

The fpecies are:

1. Softnefs of a milk-tooth. Plenck extracted from a girl feven years of age, a canine milk-tooth of the lower jaw, which was livid and foft, like cartilage, and was compreffible by the fingers, efpecially at the fang. De Morb. Dentium, p. 39.

2. Softnefs of the teeth from farcoftofis of the fang. Sometimes the fang of a tooth is abforbed, and a fungous fubftance fills up its place. This cafe has been abfurdly inftanced as a fpecimen of mollities of the teeth.

3. Softnefs of the teeth from fcurvy. It is afferted, that in the fcurvy, the teeth have been fometimes foftened and enlarged. (Grainger Hift. Febris Anom. p. 6.) But fuch accounts muft be incorrect, fince they imply a vafcular organization of the teeth. It merits attention alfo, that in certain dead fubjects, whofe bones are all affected with mollities, the teeth are found perfectly hard.

Preternatural Angles, or Sharpnefs of the Teeth.—Sometimes the form of a tooth is fo acute, that it hurts the neighbouring parts by pricking them.

The effects of fuch a tooth are irritation of the tongue, or of the inner furface of the lips, or cheek. Hence inflammation of thefe parts, or an ill-conditioned ulcer oppofite the fharp portion of the tooth, curable by no means whatfoever, except the removal of the angle or fharpnefs.

The fpecies are afcribable to the particularity of the caufe.

1. Irritating angles, or fharpnefs from malformation of a tooth. In this cafe the tooth has a found appearance, and the crown is felt to be too pointed or fharp.

2. Irritating angles, or fharpnefs from an oblique fracture of a tooth; as fometimes happens from biting hard nuts and other fubftances. The cafe can be detected on ocular examination.

3. Irritating angles, or fharpnefs from the tooth being worn obliquely. This is the moft common cafe.

The cure requires that the pointed or fharp part of the tooth be removed either with a file or a pair of cutting forceps; but if this cannot be accomplifhed, the tooth fhould be pulled out.

Fractures of the Teeth.—A fracture of a tooth is a folution of it into two or more fragments.

The folution of continuity may be tranfverfe, oblique, or comminuted. The moft common kind of fracture is the feparation of a particle of the enamel from the reft.

The effects are, confiderable pain in the tooth, and fometimes convulfions; an unpleafant fenfation in the tongue upon its touching the fracture. An oblique fracture hurts the tongue, lips, or cheek, by its pointed form. The broken furface of a tooth not unfrequently becomes carious.

The fpecies are:

1. Fracture from violence; as occurs in a fall upon the teeth, a blow on them, or in biting the hard ftones of fruits, or in an imperfect extraction of a tooth.

2. Fracture from previous caries, or fragility of a tooth. When either of thefe caufes is prefent, a very inconfiderable force will break the tooth, and fplit it into feveral pieces. The furface of the fractured part ought to be kept covered for feveral days with maftich.

The fracture of a tooth is an incurable accident.

Fiffures of the Teeth.—A fiffure of a tooth means a folution of continuity, like a mere line, or a crack in the enamel.

For the moft part, the caufe originates from biting the ftones of fruit, or other hard fubftances.

The effects are pain and tendernefs of the tooth, and, in confequence of the entrance of fordes into the fiffure, caries is frequently produced.

The treatment confifts in filling up the fiffure, while recent, with gum maftich.

Luxations of the Teeth.—The luxation of a tooth means the difplacement of it from its natural pofition in the focket, occafioned by violence.

The caufes are biting hard or refifting bodies with extreme force; falls or blows upon the teeth; but, moft commonly, the accident is brought on by an imperfect and unfuccefsful attempt to draw a tooth.

The disfigurement, arifing from the wrong pofture of the tooth, is the chief effect. The tooth may be put into its right pofition again with the aid of a pair of forceps.

Stupor of the Teeth.—This is a very fingular fenfation in the teeth, which cannot be defcribed by words. It was called by the Greeks *hæmodia*, from αἱμωδιάω, *obftupefco:* the French term it *l'agacement des dents.*

The proximate caufe is a peculiar affection of the nerves of the teeth.

With regard to the effects, this annoying fenfation prevents maftication, and excites a preternatural fecretion of the faliva; while it is exafperated by the entrance of air into the cavity of the mouth. For the moft part, the complaint is only of a tranfient nature.

The fpecies are:

1. Stupor of the teeth from eating unripe fruit. Hence we find, the affection is often caufed by eating four cherries, currants, goofeberries, &c.

This cafe may be relieved by chewing fweet almonds, or applying fomentations to the teeth.

2. Stupor of the teeth from vomiting dark bilious matter from the ftomach. The fecretions thrown up from the ftomach are fometimes of an auftere acid kind, and therefore may give rife to this affection of the teeth. Plenck has many times noticed the occurrence in hypochondriacal fubjects. Doctrina de Morb. Dentium, p. 42.

The cure demands emetics and abforbents, or mild alkaline remedies.

3. Stupor of the teeth in ricketty fubjects. The teeth of perfons who labour under rachitis, are, on account of their greater fenfibility, particularly expofed to the attack of this complaint.

Befides the radical cure of rachitis, which is to be attempted by tonic and abforbent medicines, external palliative means are not to be omitted

4. Stupor of the teeth from harfh noifes. Thus the painful fenfation is brought on by the acute rough found made by filing various fubftances, fcraping flate, fawing ftone, &c. In a fright, the gnafhing of the teeth has been obferved to have a fimilar effect.

Odontalgia, or Tooth-ache.—This fignifies pain in one or more of the teeth; the etymology being ὀδοὺς, *dens*, and ἀλγέω, *doleo.*

The proximate caufe is an irritation of the nerves which are diftributed to the teeth and gums.

As for the effects, the pain in the teeth fometimes rifes to fuch a degree, that reftleffnefs, fever, delirium, fpafms, convulfions, faintings, &c. are produced, efpecially in perfons of irritable conftitutions.

The cheek of the painful fide very often fwells upon a little abatement of the complaint taking place; the patient drivels confiderably; and maftication cannot be performed without an increafe of fuffering.

The different fpecies of the complaint are as follows:

1. Odontalgia rheumatica, or the tooth-ache occafioned by the rheumatifm affecting the gums and teeth.

The fymptoms of this cafe are, pain in the teeth, without any thing ailing the gums, as far as can be detected by ocular examination.

The cure demands purgative medicines, and afterwards fudorifics.

Externally, wine and water; or vinegar, in which the radix pyrethri has been boiled; the fmoking of tobacco; finapifms to the cheek; or blifters upon the temples, or nape of the neck; are efteemed amongft the moft eligible means of relief.

2. Odontalgia catarrhalis. This cafe is moftly brought on by a cold damp atmofphere and the fuppreffion of perfpiration, or from fudden expofure to cold while the body is very much heated.

This fpecies may be known by the prefence of the ufual fymptoms of catarrh, the difcharge of mucus from the noftrils, cough, &c.

It admits of relief by the fame means which are proper for a catarrh, or the rheumatic fpecies of tooth-ache.

3. Odontalgia inflammatoria. The complaint is brought on by inflammation of the gums. Such inflammation oftentimes affects, at the fame time, all the neighbouring parts, as the cheeks, ears, eyes, and indeed fometimes the whole head.

Frequently the cafe brings on, in a flow manner, the formation of abfceffes between the gums and cheek, which abfceffes, after a great deal of violent pain, burft.

This tooth-ache is exafperated by every kind of warm medicine, whether given inwardly, or ufed as an external application.

The cure of the complaint in its early ftage demands venefection, purgatives, nitre, and other antiphlogiftic remedies.

Externally, there is no better application than the aqua plumbi fuperacetatis.

4. Odontalgia arthritica, or odontagra, arifes on the abatement of a gouty affection of the joints, but fubfides again as foon as the latter difeafe recommences.

5. Odontalgia venerea. Both the venereal difeafe itfelf, and the mercury which is adminiftered for its cure, not unfrequently give rife to fevere tooth-ache. In each of thefe cafes, purgatives are indicated, and afterwards an emulfion of gum arabic, the warm bath, and the compound decoction of farfaparilla.

Here drawing the teeth is faid to be extremely dangerous, as it is apt to bring on inflammation of the throat, and even fatal confequences.

6. Odontalgia fcorbutica. This cafe may be known by the

the exiftence of the ufual fymptoms of the fcurvy. In addition to an intolerable itching in the gums, very acute pain is alfo often experienced.

With refpect to the cure, topical remedies muft be employed, together with fuch external and internal medicines as are generally requifite for the fcurvy.

7. Odontalgia gaftrica is an acute pain in the teeth and gums, arifing from a wrong ftate of the primæ viæ.

It may be cured by emetics, purgatives, and other medicines calculated to put the bowels and ftomach into order again.

Odontalgia gaftrico-verminofa. People who have worms are frequently tormented with the tooth-ache. Authors attempt to explain the fact as follows: they ftate that worms in the inteftines irritate the great intercoftal nerve, which has a ftrong fympathetic connection with the nerves of the teeth.

The cure demands purgatives and anthelmintic remedies.

8. Odontalgia a ventriculi debilitate, feu irritabilitate. It fometimes happens that men and hyfterical women, whofe ftomachs are weak and irritable, are afflicted with excruciating tooth-aches, which yield to no remedies but antifpafmodics, ftomachics, and tonics.

9. Odontalgia gravidarum. In the tooth-ache originating from pregnancy, the pain often fhifts from one tooth to another, and comes on very repeatedly, although the teeth are frequently perfectly found. Sometimes the pain is merely fympathetic; but, in moft inftances, it is connected with that plethoric ftate of the female conftitution known to prevail during pregnancy. Venefection is, therefore, the chief means of relief, and then topical applications may be ufed.

It is a queftion, whether the operation of drawing a tooth fhould ever be performed on pregnant women. There are fome women who have fuch a dread of the inftruments for this purpofe, that the very fight of them brings on the danger of convulfions and a mifcarriage. But, on the other hand, the pain may be fo violent as to create a chance of the fame evils. Here much addrefs is requifite to perfuade the patient to undergo the operation, and at the fame time great prudence not to advife it, unlefs rendered abfolutely indifpenfable by the feverity and obftinacy of the pain.

10. Odontalgia nutricum. Women who fuckle are alfo particularly fubject to be afflicted with excruciating tooth-ache, whether the teeth be found or carious. When the pain refifts the ufual means, efpecially opium and venefection, the tooth muft be extracted. This cafe has been fuppofed to depend upon a certain fympathy between the mammæ and the teeth.

11. Odontalgia from cutting the dens fapientiæ. Sometimes great and long-continued pain, delirium, and other alarming fymptoms take place, until the tooth has made its way out, or the gums have been divided.

12. Odontalgia hyfterica. This fpecies of tooth-ache often affects hyfterical women a long while, notwithftanding the teeth may be perfectly healthy; nor does it always yield to opium, nor even to the operation of extracting feveral of the painful teeth.

The treatment requires the warm bath, emollient fomentations to the cheeks, and gargles of the fame quality to the mouth.

13. Odontalgia from the teeth being worn away. The bony fubftance of the teeth is fo fenfible, when deprived of the enamel, that on coming into contact with air, or food, at all too warm, or cold, the moft intolerable pain is excited.

14. Odontalgia from tartar on the teeth. The tartar feparates the gums from the neck and fang of the tooth, fo as to expofe the latter parts to the cold air, and the ftimulating quality of the food. Hence, it is obvious, pain muft be the confequence.

The radical cure can only be accomplifhed by removing the tartar. The complaint may be palliated by the common applications for the relief of tooth-ache.

15. Odontalgia from a fracture of the body of the tooth. In this cafe the nerves of the remaining portion of the tooth are expofed to the air, and fometimes become affected with extreme pain.

Writers recommend for the purpofe of relieving this complaint, either applying the cautery to the furface of the fractured tooth, or elfe covering it with wax, or gum maftich.

16. Odontalgia verminofa. Whether the tooth-ache can ever really arife from the prefence of worms in a carious tooth, is doubtful. Plenck conceives the occurrence poffible, and he propofes as a means of cure the employment of a gargle containing the muriates of ammonia and foda.

17. Odontalgia periodica fignifies that form of the tooth-ache, which comes on every other day, and refembles in its periods of attack an intermittent fever.

In the treatment, authors recommend the ufe of purgatives, emetics, and the Peruvian bark.

18. Odontalgia cariofa. It is not every fort of caries of the teeth which is accompanied with pain; but only the internal or external humid kind of caries. In the dry caries, and alfo in the humid, when all the nervous filaments of the bone of the tooth have been deftroyed by it, the carious tooth remains free from pain.

In the tooth-ache from caries, the following modes of relief are recommended:

1. Preffure upon the nerve which comes out of the infra-orbitary canal of the fuperior maxillary bone.

2. Preffure upon the nerve which paffes out of the canalis mentalis of the lower jaw-bone.

3. Sulphuric acid applied to the carious part of the tooth by means of a probe. Plenck has fometimes found this plan ufeful.

4. Vinum pyrethri, vel rutæ, or ftrong vinegar.

5. Sinapifms to the cheek.

6. Blifters to the nape of the neck, and behind the ears.

7. The application of a magnet to the painful tooth.

8. Oil of cloves introduced into the carious tooth.

9. Camphorated milk retained for a time in the mouth.

10. Burning the nerve with a heated probe.

11. Opium applied to the carious tooth, or adminiftered internally.

12. Luxating the painful tooth is another mode of relief which has been propofed. With the aid of a fuitable inftrument the tooth is to be turned a little round in its focket, and then turned back again into its natural pofition. Thus, the fmall nerve, which enters the hole in the fang, is either broken or rendered paralytic.

Caries of the Teeth.—This fignifies an erofion of the fubftance of the teeth.

The dentes molares are more frequently than the reft of the teeth affected with caries, and the dentes fapientiæ oftener than any of the other grinders.

Caries of the teeth varies in refpect to its fituation, figure, nature, and caufe.

In regard to fituation, the caries may take place in one, in feveral, or in all the teeth. It may occur upon the external

ternal or internal furface of a tooth; upon the body or the fang of a tooth; or it may affect every part of it.

As to caufes, the caries may proceed from fuch as are properly called external, as a fiffure; a wearing away of the enamel; fordes adhering to the teeth; tartar; a detachment of the gums; a violent effort to bite, by which the apex of the fang, or the bottom of the focket, is contufed; the ufe of mercury; cofmetics; the application of acids, efpecially thofe which are termed mineral; dentifrice powders containing alum; cold damp air; fmoking, or chewing tobacco, &c.

Sugar has been imagined to be hurtful to the teeth; but probably without real foundation. General de Beaufort ate every day for forty years a pound of fugar, and lived to the age of feventy. After death, his vifcera were found free from difeafe, and his teeth found. (Anecdotes de Médécine, tom. ii. p. 35.) Plenck put a healthy tooth into fome fyrup diluted with water, and kept it there two months, at the end of which time it was taken out, and found to have undergone no change. Doctrinâ de Morb. Dentium, p. 52.

The internal caufes are fcurvy, rachitis, fcrofula, &c.

In relation to the particular nature of caries of the teeth, there are two fpecies; one termed humid, which quickly deftroys the tooth affected with it; the other is the dry caries, which advances flowly, lafts a long while, is altogether indolent, and cannot be palliated by any known remedy.

The effects of caries are fetor of the breath; repeated attacks of tooth-ache; infection of the neighbouring teeth; and not unfrequently the correfponding tooth on the oppofite fide of the mouth becomes alfo affected with caries, as feveral authors whimfically fuppofe, from nervous fympathy. In the fituation of the difeafed tooth, efpecially, over the carious fang, the gum is moft commonly attacked with a parulis, or epulis. Sometimes chronic ophthalmy originates from the irritation of the difeafed fang (Journ. de Méd. tom. xxxvi.); or elfe a fiftula of the gums or cheek, or an ozæna of the antrum Highmorianum. Even a locked-jaw has been known to arife from carious teeth. Truka Com. de Tetano, p. 151.

In refpect to figure or form, the following fpecies of caries may be eftablifhed.

1. Caries foraminofa, or a carious canal, which runs from the external furface of the crown, and penetrates the fubftance of the tooth.

In the treatment, it is proper to clean out the carious canal with a needle, and by injecting a fluid into it. Then it is to be burnt with a heated needle; and, laftly, clofed with wax, maftich, gold, or lead.

2. Caries of the whole crown or body of a tooth. When the middle of the crown of a tooth is eroded in fuch a manner, that the caries is wider fuperficially than it is more deeply, then the gold, or lead, or whatever is ufed for filling it up, cannot be retained in its place.

In this circumftance it becomes neceffary to burn the carious furface with a fuitable inftrument; or to deftroy it with cauftic applications; or to apply antifeptics.

But when, notwithftanding all thefe means, the caries yet fpreads, the tooth ought to be extracted, in order to remove the pain, prevent the occurrence of other difeafes, and not incur the rifk of the tooth breaking in pieces in the attempt to take it out at a later period, when it may be excavated and rendered too thin.

3. Caries maculofa. If the fuperficial fpot only appear upon the external furface of the tooth, it may be removed with a file.

4. Caries ftriata. When the caries occurs in the form of a longitudinal black ftreak, it is either in the middle of the crown, or on the lateral margins of the tooth. This cafe may be occafioned by the teeth being placed too clofely together, and alfo by the ufe of cofmetics. It admits of being taken off with a file.

5. Caries of the fang of a tooth. The body of fuch a tooth is fometimes found. The tooth, however, is frequently painful, the cheek of the affected fide, and the gum near the painful tooth fwell, and an abfcefs is formed, which is lefs common in the other fpecies of caries.

The cure requires that the tooth fhould be drawn out as foon as the inflammation has fubfided. It is reckoned dangerous to perform the operation while the parts are much inflamed.

6. Internal caries of a tooth. In this complaint the tooth is painful, and exhibits a leaden colour, and if it be fhaken with an inftrument the pain is confiderably exafperated. Thus the difeafed tooth may be detected amongft many which are healthy, even when feveral of them are thought by the patient to be unfound.

The cure requires the tooth to be extracted.

7. Caries of all the teeth. This affliction is fometimes induced by the fcurvy, and rachitis. The radical cure is of courfe impoffible; but the progrefs of the caries can be checked by the internal ufe of antifcorbutic medicines, the remedies againft rachitis, and by giving affa-fœtida.

Externally, antifeptic wafhes may be ufeful.

Plumbatio dentis is the filling of the carious cavity with thin fheet-lead, tin, or gold. Gold is preferable to lead, which is apt to be acted upon and diffolved by acid food, and may therefore produce the faturnine colic; but, on the other hand, lead is more eafily introduced into the tooth, and it can be more firmly fixed there. Some dentifts give the preference to tin.

The operation is proper, if the carious tooth has a narrow entrance. It can only be performed on the incifors, canine teeth, and firft grinders, which are furnifhed with but one fang.

The operation is contraindicated, when the orifice of the caries is wider than its bottom, as the lead cannot then be retained. Alfo, when pain and inflammation are prefent, the introduction of the lead muft be deferred until thefe fymptoms have fubfided.

The inftruments for this operation are,

1. The introductor.
2. The perforator.
3. The planatorium.
4. The file.
5. The plates or leaves of gold, about three or four times as thick as thofe commonly met with.

As for the operation itfelf,

1. A thin plate of lead, tin, or gold, is to be put into the hollow of the tooth, by means of the inftrument called the introductor.

2. The lead or gold is to be gradually compreffed more and more clofely, fo that it may fill up well the fides of the cavity. This is to be done with the planatorium. Then fome holes are to be drilled in the metal with the perforator, and thefe are to be filled with lead. Laftly, the place is to be rendered even and fmooth with the file.

The lead, for fome days after the operation, proves rather difagreeable to the tongue; but, in a fhort time, the patient is habituated to it, and he experiences no longer any fuch inconvenience.

Sometimes pain and inflammation follow; in which cafe, the lead muft be taken out for a few days with a pointed inftrument.

There have been perfons who have had lead in their teeth feventy years, and upwards, without any annoyance from it.

Of drawing or extracting a Tooth.—We fhall conclude this article with a few obfervations upon the furgical operation of extracting a tooth from its focket.

The following cafes make the performance of it neceffary.

1. A carious tooth, producing a fevere degree of pain, which can be abated by no remedies.

2. A fharp tooth, which irritates and hurts the tongue, and does not admit of being amended with the file.

3. An ulcer, or abfcefs of the maxillary finus.

4. A tooth which renders the focket carious, or caufes abfceffes, or excrefcences of the gums, fiftulæ of the jaw, or fome other troublefome complaints.

5. A milk-tooth not being fhed at the ufual period, and its prefence forcing one of the permanent fet to grow in a wrong direction.

6. A tooth growing out of the palate, or in any other unnatural place.

On the other hand, the operation is contraindicated, when the gums are highly inflamed; or when a tooth-ache, excited by mercury, or the fcurvy, is prefent. Drawing a tooth, in thefe circumftances, might give rife to extenfive inflammation and angina in a dangerous degree.

The common inftruments are,

1. The odontagra.
2. The pelicanus.
3. The clavis, or key.

Thefe three inftruments are objectionable in one refpect: namely, they pull the tooth out of its focket obliquely; and hence they often break the alveolary procefs, or the tooth itfelf.

4. But the tooth-inftrument which Aitken has defcribed, draws the tooth out of the focket perpendicularly; and, on this account, has an advantage. See Effays on feveral important Subjects in Surgery, London, 1771, p. 196.

5. The tooth forceps.

6. The pes caprinus, or punch.

The molares, when they can be firmly taken hold of, may be extracted with either of the firft four inftruments.

The incifores, canini, and firft molares, may be drawn out with the forceps.

Stumps and fangs cannot be taken hold of with thefe inftruments; they muft, therefore, be pufhed out of the alveolary procefs with the pes caprinus, or punch, and then be removed with a pair of forceps.

The patient and furgeon are to place themfelves as follows.

1. If the tooth be in the upper jaw, and it is to be taken out with the odontagra, pelicanus, or punch; or if the tooth, which is to be drawn, is in the lower jaw, the patient muft be feated in a low chair, or on the ground, the furgeon ftanding behind him.

2. But if the tooth is to be taken out with the key, or from the upper jaw with the forceps, the patient is to fit in a common chair, and the furgeon is to ftand in front of him.

The following are the different methods of performing the operation.

1. Of extracting a tooth with the odontagra.

The inner gum of the tooth about to be drawn, is to be depreffed with the claw of the inftrument nearly down to the alveolary procefs. The other part of the inftrument is to be applied to the crown of the tooth.

While the thumb is employed in making firm preffure upon the claw, the handle is to be held with the fingers, and, under the direction of the palm, the tooth is to be raifed perpendicularly from its focket.

By means of the fcrew, which admits of being turned, the inftrument may readily be adapted to the larger teeth.

2. Of drawing a tooth with the key.

The key is applied to the tooth nearly in the fame way as the odontagra, except that the thumb of the other hand is placed upon the claw. At the commencement, the key is to be turned very gradually; and the tooth, when it yields, is to be cautioufly and flowly raifed, left it flip away, and remain adherent to the gum.

3. Of drawing a tooth with the pelicanus.

The claw of this inftrument is to be applied to the infide of the neck of the tooth, while the rotula is to be put upon the two neighbouring teeth. The thumb of the hand not holding the inftrument is to be applied to the infide of them, fo as to counteract the refiftance of the rotula.

4. Of the extraction of a tooth with the forceps.

The neck of the tooth being firmly grafped with the forceps, is to be gradually moved, until it is fufficiently loofened to admit of being taken out perpendicularly.

5. Of taking out a tooth with the pes caprinus, or punch.

The two points of the inftrument are to be firmly applied, under the gum, to the lower part of the neck of the remaining portion of the tooth. The thumb of the hand not thus employed is to be covered with fome linen, and applied internally. The fang is then to be pufhed out of the focket, and removed with a pair of forceps.

With regard to the fymptoms arifing after the operation: a flight hæmorrhage, and a fwelling of the gums and cheek, are the ufual confequences. Thefe, however, are free from danger, and, when the mouth is wafhed with a gargle of tepid vinegar, they are foon relieved.

The more ferious confequences, which fometimes occur after the extraction of a tooth, are,

1. A violent and dangerous degree of hæmorrhage.

2. Alarming inflammation of the gums and cheek.

3. Abfceffes of the gums; very apt to take place, when the gums have been confiderably bruifed by the inftrument, or when fplinters of bone are left behind.

4. A fracture of the alveolary procefs, or of the palate. This accident is moft liable to happen, when the fangs of the teeth diverge, or when the fang and focket have grown together by the procefs of offification. The exiftence of the laft cafe may be known by the neck of the tooth being curved. Here the tooth fhould always be drawn out towards its concave fide.

5. Diflocation of the jaw. This may occur, if the mouth be too much open, or the lower jaw be brought too much forward, in the operation. The luxation ought to be immediately reduced. See Luxation.

6. Fracture of the jaw. See Fracture.

7. Caries of the focket.

8. Laftly, fracture and luxation of the tooth may be the confequences of an unfuccefsful attempt to perform the operation.

In the preceding remarks, we have been chiefly affifted by Plenck's excellent compendium, entitled "Doctrina de Morbis Dentium," &c. Lovanii, 1796.

Some interefting obfervations on the difeafes of the teeth, particularly with a view to the queftion whether thefe parts are vafcular, will be found in the article Cranium.

For a defcription of the difeafes of the gums, we refer to Gums, *Difeafes of.*

A Danifh

A Daniſh phyſician, named Hagerup, maintains in certain theſes that one may hear with the teeth.

As to animals, there are ſome fiſhes which have teeth on their tongues, as trouts; others have them at the bottom of the gullet, as the cod-fiſh; ſome, as the great ſea-dog or ſhark, called *canis carcharias*, have three, four, or five rows of teeth on the ſame jaw; the crocodile three, and thoſe all inciſors; vipers have two large crooked canine teeth, which are moveable, and ordinarily lie flat, only being raiſed when they would bite; and the rana piſcatrix, ſea-frog, or ſea-devil, has whole rows of the like moveable teeth. The toad and cuttle-fiſh have no teeth, and yet they can bite. See *Anatomy of* FISH.

TEETH, *Chemical Analyſis of.* The teeth cloſely reſemble bone in their compoſition. The bodies conſiſt of a cartilaginous baſis, united with phoſphate of lime, and ſmall proportions of other earthy ſalts. The enamel differs ſo far only from the bodies, that it contains no cartilaginous matter, but conſiſts entirely of earthy ſubſtances. The teeth have been often examined, and with various reſults, according to the ſtate of chemical knowledge at the period of examination. We do not think it neceſſary to give an account of all that has been ſaid on the ſubject, but ſhall confine our attention principally to the lateſt and moſt perfect analyſes. We ſhall begin with the analyſis of Mr. Pepys: he found the enamel of teeth compoſed of

Phoſphate of lime - - -	78
Carbonate of lime - - -	6
Loſs and water - - -	16
	100

The bodies of the teeth, according to the ſame chemiſt, conſiſt of the following proportions.

	Roots of the Teeth.	Teeth of Adults.	Firſt Teeth of Children.
Phoſphate of lime -	58	64	62
Carbonate of lime -	4	6	6
Cartilage - -	28	20	20
Loſs - - -	10	10	12
	100	100	100

A much more complete analyſis, however, of the enamel of teeth has lately been made by Berzelius. He gives the following table of his reſults, compared with the compoſition of the bones of the ſame animals.

	Dried Human Bones.	Enamel of Human Teeth.	Bones of Oxen.	Enamel of Ox Teeth.
Cartilage - -	32.17	—	} 33.30	} 3.56
Blood-veſſels -	1.13	—		
Fluate of lime -	2.00	3.2	2.50	4.00
Phoſphate of lime -	51.04	85.3	55.85	81.00
Carbonate of lime -	11.30	8.0	3.85	7.10
Phoſphate of magneſia - -	1.16	1.5	2.05	3.00
Soda, muriate of ſoda, water, &c.	1.20	2.0	2.45	1.34
	100	100	100	100

Thus confirming a diſcovery made many years before by Morichini, an Italian chemiſt, namely, that the enamel of teeth contains fluoric acid; a circumſtance which had been called in queſtion by later inquirers.

Foſſile ivory and bone have been found by Fourcroy and Vauquelin to retain proportions of animal matter, varying from 45 to 15 *per cent.*; a curious fact, and highly illuſtrative of the powers of intimate mixture, or rather perhaps chemical union, in preventing the deſtruction of organic ſubſtances.

TEETH, *Artificial*, are thoſe ſet in lieu of natural ones, which are wanting. See TEETH, *Diſeaſes of.*

TEETH, *Mark of*, in the *Manege.* See MARK and EYE *of a Bean.* See alſo TEETH, *infra.*

TEETH *of Fiſh.* See *Anatomy of* FISH.

TEETH, in *Rural Economy*, little bones fixed in the jaws, which ſerve not only to reduce the food and nouriſhment, but ſhew the age in ſome animals. The horſe has forty teeth, including the tuſhes, which are thus diſtinguiſhed. Twenty-four are called *grinders*, being placed at the bottom of the mouth, beyond the bars, twelve on each ſide of the channel, *viz.* ſix above, and ſix on each ſide. Theſe teeth continue, and do not give place to new teeth in their room, ſo that they are of no uſe in diſtinguiſhing a horſe's age; and they are ſubject to wolves teeth. In regard to the other ſixteen, twelve of them are called in their infancy *milk* or *foal* teeth, and the remaining four go by the name of *tuſhes.* The twelve foal teeth are ſhort, ſmall, and white, and are ſeated on the fore-part of the mouth, ſix above, and ſix below: and theſe change and caſt, to give place to others; which, in proceſs of time, become long, large, and yellowiſh.

Theſe new teeth are diſtinguiſhed by different names given them, according to their putting forth; and it is the manner of their coming forth that gives the knowledge of the firſt years of a horſe's age.

Of theſe twelve, four are called *nippers*, four *middling* teeth, and four go by the name of *corner* teeth. The four nippers are ſeated on the fore-part of the mouth, two above, and two below. When a horſe has put forth theſe, he is concluded to be from two and a half to three years old.

The middling teeth are placed near the nippers or gatherers, one above, and one below, on each ſide of the jaws. They come out and appear between three and a half and four years.

The corner teeth are placed ſtill more forward in the mouth, one above, and one below, on each ſide of the jaws.

They begin to ſhoot between the fourth and the fifth year, and are got above the gum at five years; and when ſurmounting the gum at that age, they become hollow, and mark commonly till ſeven or eight years. By marking is meant, that in the hollow or cavity of the corner teeth a little black ſpeck is formed, which, from its reſemblance, is called the bud or eye of a bean, or the mark. But when the horſe paſſes ſix, the cavity begins to fill, and the black mark diſappears by degrees; yet this diminution of the cavity and the mark continues from ſix to ſeven and a half. However, at eight years, the cavity is filled up, and the black mark gone; and the tooth is then full, and even as if it had been ſhaved. It is then ſaid, that the horſe has *raized*, which happens a little before the eighth year; and after that, the horſe does not mark; ſo that the ſureſt knowledge of his age is then formed from his tuſhes.

The tuſhes are placed beyond the corner teeth, upon the bars, two on each ſide below, without being preceded by any foal teeth. The two under tuſhes cut ſometimes at three years, ſometimes at three and a half, ſometimes at four;

four; but the two upper tuſhes ſometimes at four, ſometimes at four and a half; ſometimes before and ſometimes after the corner teeth, without any certain rule; and till the age of ſix they are chamfered within. And at about ten years of age the two under tuſhes appear much worn, which ſerves for that age. After that they grow out in length, and become bare of fleſh, becauſe the gum ſhrinks and retires; and at laſt, about the fifteenth or ſixteenth year, the horſe *ſhells.*

It is ſometimes ſaid, that a horſe is not capable of any great fatigue till his tuſhes have cut the ſkin. See AGE, in *Horſemanſhip.*

The teeth in ſheep are divided into two kinds, the *inciſores* and the *molares*, or the cutting and dividing, and the rubbing and grinding teeth. Such ſheep as are full-mouthed have eight of the firſt ſort of teeth; throwing up two every year, conſequently loſe their ſucking teeth. The inciſores are found to wear down in proportion to the action which they have; but the molares, having more ſtrength, and a different form, do not ſuffer ſo much in this way.

It has been ſuggeſted by an experienced ſheep-farmer, that theſe ſorts of young animals moſtly renew their firſt two teeth at from about fourteen to ſixteen months of age; and after that, every year nearly at the ſame time, until they are turned three years old, or, in the technical language of the ſheep-maſter, three ſhear, when they become full-mouthed; for although they have eight teeth before in the under jaw, it is commonly believed that they only caſt and renew the ſix inſide ones. Shepherds, however, differ much on this point, ſome contending that they only ſhed the ſix fore-teeth, while others maintain that they caſt the whole eight fore-teeth. The matter is, therefore, not yet well aſcertained. Some properly remark, that ſheep are very uncertain in their throwing up their teeth; much depending upon their being early or late lambed, well or ill fed, and other ſimilar circumſtances. Tups have been known to have four broad or renewed teeth, when by the age, as ſhewn in the above manner, they ought to have had only two. Some ſheep are remarked to be more backward than others, by ſeveral months, in proportion to their ſtrength of conſtitution, and other matters.

In Romney Marſh the teeth of ſheep are found to decay much faſter, it is believed, than in any other part of the country. Cloſe feeding wears the teeth exceedingly; of courſe, the teeth of the ſheep of thoſe who ſtock the hardeſt commonly decay the ſooneſt. The ſheep graziers in this diſtrict are very particular in mouthing their ſheep, which are kept or rejected according as their mouths are found to be good or bad; as, where the latter is the caſe, they have great difficulty in maintaining themſelves during the winter ſeaſon.

It is noticed that ſheep, about the time of renewing their teeth, are very tender in their mouths, and do not thrive ſo well as they do at other ſeaſons. At one ſeaſon a teg, it is ſuppoſed, may ſtarve any ſheep by cloſe feeding; but on the renewal of its broad teeth, any ſheep may ſtarve it.

In the above diſtrict, the barrens or old breeding ewes are generally caſt off when they have had their third lamb; though ſometimes, if their mouths be good, and they are often better than thoſe that have had only one lamb, they are kept for the fourth lamb: nor is this ſuppoſed a bad practice, ſince by it ſome valuable ewes may be reſerved.

Sheep are ſeldom kept here to any great age: ſome favourites are, however, kept till ten years old, without a tooth in their heads. Some have heard of their living twenty years. In the county of Hereford they are ſaid to live to a great age: they live on long graſs in the ſummer ſeaſon, and peaſe-ſtraw and other ſimilar matters in the winter, which do not wear their teeth ſo much as when they labour hard on a cloſe ſhort-ſet turf. See SHEEP.

The teeth of the various other ſorts of domeſtic animals have hitherto been but little noticed or attended to by ſtore or ſtock maſters, though they are probably, in many caſes, as much changed, and ſerve to mark the ages and growths of the animals as much and as certainly, as in the inſtances and caſes which have been given above.

TEETMOW, in *Geography*, a town of Bengal: 40 miles S.S.E. of Curruckpour.

TEFEE, a town of Braſil, in the government of Para, on the river of the Amazons; 220 miles W. of Fort Rio Negro.

TEFELSDORF, a town of Tranſylvania; 7 miles N. of Scheſburg.

TEFEN, a town of Aſiatic Turkey, in Natolia; 28 miles S.W. of Amaſieh.

TEFESSAD, or TFESSAD, a town of Algiers, whoſe ruins extend along the coaſt of the Mediterranean near a league, ſuppoſed to have been the ancient Tipaſa; 32 miles S.S.W. of Algiers. N. lat. 36° 32′. E. long. 2° 54′.

TEFETHNE, or TEFTANE, a town of Morocco, on the coaſt; 60 miles W. of Morocco.—Alſo, a river of Morocco, which runs into the ſea near Mogodor.

TEFFEREG, a town of the archbiſhopric of Salzburg; 1 mile S. of Windiſch Matray.

TEFLIS, a town of Aſia, capital of the principality of Georgia, and ſee of a biſhop, founded, according to an old inſcription in the citadel, by a certain prince Sarang, A.D. 1063, is ſituated on the N.W. ſide of the great plain of Karajoes, at the foot of a hill, occupying both banks of the river Kur, over which is a bridge. This city is ſurrounded with ſtrong walls, except towards the river; and has a large fortreſs at the declivity of the mountain, which contains a garriſon, and is often made uſe of as a place of refuge for criminals and debtors. All the houſes are of ſtone, with flat roofs, which ſerve, according to the cuſtom of the Eaſt, as walks for the women. The buildings are neat and clean; but the ſtreets are exceedingly dirty and narrow. The town contains one Roman Catholic, thirteen Greek, and ſeven Armenian churches. Near it are ſome warm ſprings, and hence it is called Theleſtokar, or Warm town. In the year 1386, this town was taken by Tamerlane, and the king of Georgia made priſoner. In 1723 it was taken by the Turks; and in 1734 retaken by Kouli Khan. Before it was taken by Aga Mahomed Khan, in 1797, it contained 4000 houſes, and 22,000 inhabitants. Although moſt of the houſes, which are neatly built, are now ſtanding, the population does not exceed 15,000 ſouls. It was for many years the reſidence of prince Heraclius, and is at preſent that of the Ruſſian governor and commander-in-chief, who has at all times a large force ſtationed in the city, to the diſguſt of the inhabitants, who ſhudder at the thoughts of their wives and daughters being conſtantly expoſed to the view and importunities of ſtrangers. This circumſtance tends to render the Ruſſian name deteſted by the Georgians: 100 miles N.N.E. of Erivan. N. lat. 42° 45′. E. long. 45° 20′.

TEFTERDAR, the name of an officer of dignity in the Eaſtern nations. In Egypt he is lord high treaſurer of the tribute paid out of the lands to the grand ſignior. He is named for

for a year by the Porte, but is generally continued in his office many years. This office is sometimes given to one of the poorer beys, to help him to support his dignity; and frequently to a quiet one, who is not likely to enter into intrigues. For one party never cares that a stirring man of the opposite party should be invested with an office of this dignity. See Deftardar.

TEFUT, in *Geography*, a town of Africa, in the country of Darah, formerly the capital of the ancient kings of Darah, now gone to decay.

TEFZA, a town of Morocco, built by the Arabians on the side of a mountain: the surrounding walls are composed of blocks of marble; 70 miles N.E. of Morocco. N. lat. 31° 40'.

TEFZRA, a town of Algiers; 15 miles S. of Tremecen.

TEG, a term used in some parts of the kingdom by the farmers, to express a lamb of a year old. Among sportsmen it denotes a roe of two years old. When a flock of ewes and lambs are turned into a turnip-field, the young lambs of three weeks old will immediately fall to eating the turnips, and scoop them very prettily; but these tegs will not touch them for several days. They usually stay till almost starved to death before they begin, but when they have begun, they soon grow fat.

In the Romney Marsh system of management, both the ewe and the wether tegs are kept upon the upland grass farms during the winter season, by which advantages are gained in various ways. They are by this means enabled to keep more ewes and fattening sheep on their marsh-lands, and to have the tegs when the pastures require them. See Sheep.

TEGADOO Bay, in *Geography*, a bay on the east coast of the most northern islands of New Zealand, discovered by captain, then lieutenant Cook, in 1769. S. lat. 38° 10'. W. long. 181° 14'.

TEGÆA, Jimmel, in *Ancient Geography*, a town of Africa, mentioned by Hirtius, situated S.W. of Leptis.

TEGANAN, an island of the Mediterranean, in the vicinity of that of Rhodes.

TEGAPATAM, in *Geography*. See Fort *St. David*.

TEGAREE, a town of Bengal; 11 miles N. of Kishenagur.

TEGAZA, a town of Africa, capital of a district in Zenhaga; near it is a salt-mine, about 300 miles from the Atlantic, and 400 S. of Cape Non. N. lat. 22° 20'.

TEGE, in *Ancient Geography*, a town of Africa Propria, between the two Syrtes. Ptol.

TEGEA, a town in the S.E. part of Arcadia, at a small distance from the Argolide; and placed by M. D'Anville on the scite of the modern Moklia. In this place was a famous temple of Minerva Alea, in which was a statue of the goddess, which was removed to Rome by Augustus. This temple contained a number of other curiosities; and the priesthood in it was exercised by a young female under fifteen years of age. Near this temple was a stadium, in which were celebrated games in honour of Minerva, and others in memory of a victory gained over the Lacedæmonians. The public place was ornamented with statues, and particularly one of Mars Gynecothoene, (γυνηκοθοινε,) sculptured upon a column. The epithet served to maintain the remembrance of a victory obtained by the valour of the females of Tegea. At a small distance from the public place was a magnificent theatre, encompassed with bronze statues. This city suffered much in the wars which raged in Arcadia in the time of the Achæan league. Pausanias says that here was a temple of Venus Urania, near that which was dedicated to Ceres and Proserpine. The Tegeates were a valiant people. Herodotus (l. i. c. 61.) mentions them with commendation. The Lacedæmonians ravaged the territory of Tegea, and at length obtained a superiority over its inhabitants.

Tegea, a town of the isle of Crete, said to have been inhabited by Agamemnon.—Also, a town of Macedonia.

TEGEHET, or Tegegilt, in *Geography*, a town of Africa; 120 miles S.S.W. of Fez.

TEGEL, Eric, in *Biography*, a Swedish historian, and principal secretary to Eric XIV. His father, having incurred the just resentment of Eric, as the cause of the misfortunes that occurred during his reign, was apprehended by Charles, duke of Sudermania the brother of Eric, and put to death at Stockholm in 1568. Charles, however, took the son under his protection, and sent him to Germany for improvement; and when he had visited Spain and Poland, appointed him his secretary. In 1614 he was nominated by Gustavus Adolphus historiographer of the kingdom, and in 1617 a privy-counsellor. He died at Stockholm in 1636, and left several works, of which the following were printed in Swedish: *viz.* "The History of Gustavus I. in two Parts." Stockholm, 1622, fol. "The History of Eric XIV. with Stiernman's Remarks;" 16-1721, 4to.

TEGENUM, or Tegianum, in *Ancient Geography*, a town of Lucania.

TEGERHY, or Teigarea, in *Geography*, a town of Africa, in the country of Fezzan; 80 miles S.W. of Mourzouk. It is a small town, and collects from its lands little produce besides dates and Indian corn. N. lat. 26° 17'. E. long. 15° 5'.

TEGERN, a town of Bavaria, on a lake called the Tegern See, anciently Lacus Tigurinus. Here is a celebrated abbey, founded by Albert and Ockar, two Bavarian princes; 28 miles S.S.E. of Munich.

TEGESSUS, in *Ancient Geography*, a town of the island of Cyprus.

TEGEWSE, in *Geography*, a town of Africa, near the lake of Marks, anciently called Tichasa; 38 miles S.S.W. of Gafsa.

TEGHURI, a large river of Mingrelia, which rises between the Alani and Soanni hills, and disembogues into the Phasis, 10 versts above the Scharistkali.

TEGIANUM, in *Ancient Geography*, a town of Italy, in Campania, according to Cluvier; though others assign it to Lucania, and call it Tegenum

TEGIUM, a town of Asia Minor, in the Troade.

TEGLA, in *Geography*. See Tuggala.

TEGLIO, a town of Italy, in the Valteline, situated upon the top of a mountain, is a long straggling place, containing about 300 houses, about 9 miles from Tirano, and 12 from Sondrio. Close to the town are the ruins of a fortress, standing upon an insulated rock, and formerly esteemed of great strength. This elevated spot commands a rich and extensive prospect from Tirano to the lower part of the valley, beyond Sondrio, as far as Morbegno. The government of Teglio is said to contain the 12th part of the Valteline; it is the most populous district, and contains about 8000 souls. In a good season, it produces much more corn than is sufficient for the consumption of the inhabitants, and rivals Sondrio and Tirano in the goodness of its wine.

TEGNA, in *Ancient Geography*, a town of Gaul, on the banks of the Rhone, not far from Valentia, to the north; the modern Tein.

TEGOMA, in *Geography*, a town of Africa, in the country of Asoudan; 50 miles S. of Agades. N. lat. 19° 10'. E. long. 12° 20'.

TEGORARIN, a town of Africa, in Biledulgerid; 70 miles N.N.W. of Gardeiah.

TEGUCO, a town of New Mexico, in the province of Culiacan; 40 miles N. of Culiacan.

TEGUIXIN, in *Zoology*, a fpecies of *lizard;* which fee.

TEGULA, in *Ancient Geography*, a town of Sardinia, on the route from Sulci to Nora. Anton. Itin.

TEGULET, in *Geography*, a town of Abyffinia; 180 miles S. of Gondar. N. lat. 9° 54′. E. long. 38° 35′.

TEGUMENT. See INTEGUMENT,

TEGYRA, in *Ancient Geography*, a town of Greece, in Bœtica.

TEHAE′, in *Geography*, a town of Curdiftan; 30 miles E. of Amadieh.

TEHAMA, a fandy belt which encompaffes the peninfula of Arabia, beginning at Suez, and terminating at the mouth of the Euphrates. It is of various breadth; for the moft part about two days' journey from the fea-fhore to the rife of the hills; or at leaft this is the breadth of the plain adjacent to the Red fea. It bears every mark of having been anciently a part of the bed of the fea. Its bottom foil is a greyifh clay, with a large proportion of fand, and having marine exuviæ interfperfed to a great diftance from the fea-fhore. It contains large ftrata of falt, which in fome places rife up to hills. Its regular inclination towards the fea indicates that it has emerged gradually. The fmall eminences on the confines of this plain are compofed of calcareous ftones, with a blackifh appearance, as if they had been burnt by the fun. The adjoining hills contain fchiftus and bafaltes. The fea, it is thought, ftill continues to recede, and the Tehama on that fide is gradually extending its limits. Hiftory confirms thefe appearances of the gradual receffion of the waters; and mentions, as fea-ports, feveral places which are at prefent inland, without noticing the prefent maritime towns, which muft have been of later origin than the formation of the land on which they ftand. Thefe newly-formed lands, however, are barren and unfruitful.

TEHRAUN, one of the five large diftricts of the province of Irak, in the Perfian empire: the other four being Ifpahan, Naen, Mullayer, and Kermanfhaw. Tehraun is alfo the name of the prefent capital of Perfia, which is rendered interefting by the furrounding fcenery. To the S. are the extenfive ruins of the grand and once proud city of Rae; to the E. the mountains of Elburz (famed in the Perfian traditions as the abode of dæmons); to the N. the fnow-clad fummit of the lofty Dumavend; and to the W. a plain enriched with cultivation and villages, and forming a delightful contraft with the rugged and ftupendous rocks which fkirt it on the N. and S. Tehraun is about four miles in circumference, furrounded by a ftrong wall, flanked by innumerable towers, and a noble dry ditch, with a glacis between it and the wall. The only building of confequence within the city is the citadel, which contains the palace of the fovereign and his officers. It was founded by Kurim Khan, enlarged by the late king, and beautified by the prefent fovereign. The fortifications can be confidered as formidable only in a country where the military art is unknown. The population is variable, being in fummer about 10,000, and in winter not lefs than 60,000 people. The environs of Tehraun are not unpleafant; the plain, to the E. and W., being covered with villages, and abounding in grain. On the N. fide the king has completed a palace, which, from its fituation, and the fine gardens that furround it, is a moft delightful refidence. There are many reafons which have probably induced the late king to fix upon Tehraun as the capital of his dominions. Its centrical fituation, and the eafy defence which it affords to the Perfian empire; the fertility and productivenefs of the furrounding country; the number of wandering tribes that have fettled round it, and that may be eafily and foon affembled; and above all, perhaps, its propinquity to Aftrabad, the native city of Aga Mahomed Khan, and alfo to Mazanderan and Daheftan, countries poffeffed by the Kajer tribe, of which he was the chief, and on whofe power and affection to his perfon his authority was in a great meafure founded;—all thefe confiderations might have induced him to make this city the capital of the empire. N. lat. 35° 40′. E. long. 50° 52′.

TEHROOT, or ZEHEROOT, a town of Perfia, in the province of Kerman, furrounded by numerous gardens; 8 miles N.W. by W. from Subziftan, and about 52 miles from the ruins of Bumm.

TEHUACAN, or TEGUACAN, a pleafant town of New Spain, between Oaxaca and Orizava. It is fituated in a delightful vale, near a river of the fame name, called alfo Rio Grande, of a nitrous quality, and fo petrifying a nature, that the fhores refemble ruinous walls. It has four churches; and the ftreets, fquares, and houfes are neat and modern. The chief market is that of wheat, which is excellent, and the pomegranates are highly efteemed. Befides numerous families of Spaniards and Mulattoes, here are about 2080 Indians. In the vicinity of this town are two wheat-harvefts, one in May, the other in September.

TEHUELS, a large lake of South America, towards the S. of Chili.

TEHUKHA, a town of Thibet; 4 miles S. of Jhanfu Jeung.

TEICHOPŒUS, τειχοποιος, among the Athenians, an officer who had the care of the city walls; their number was the fame with that of the tribes, every tribe having the choice of one.

TEIGN, in *Geography*, a river of England, in the county of Devon, which runs into the Englifh Channel at Teignmouth.

TEIGNMOUTH, a market-town in the hundred of Exminfter, and county of Devon, England, is fituated, as its name imports, at the mouth of the river Teign, and is fheltered on the eaft and north-eaft by a chain of hills, near the foot of which it ftands. It is diftant from Exeter 12 miles S. by E., and from London 187 W.S.W. A fmall rivulet divides the town into two parts or parifhes, called Weft and Eaft Teignmouth. The town is recorded to have been burnt in the tenth century by the Danes, who, having landed here, and defeated the king's lieutenant, ravaged the country to a confiderable extent. It was alfo nearly confumed in the reign of queen Anne, when the French landed and fet fire to it: one of the new ftreets, erected with the money procured by a brief for the diftreffed inhabitants, was named French-ftreet, as a memorial of the calamity. Since that period the town has become of much greater importance, and is now one of the moft fafhionable watering-places in the weftern part of England. The principal refort of company is Eaft Teignmouth, where the public rooms and theatre are fituated: the former, a neat building, contains tea, coffee, affembly, and billiard-rooms; the theatre has been recently built on a fpot of ground given by lord Courtenay, and was firft opened in the fummer of 1802. A walk or promenade leads from the public rooms towards the fouth, over an extenfive flat called the Den, on which is a fmall fort erected for the defence of the town. The view hence, up the river, is extremely beautiful; the ground gradually rifing on each fide into verdant hills, well cultivated, and adorned with woods. The cliffs overhanging the fea have a fingular appearance, being, with the exception of a few broad patches of verdure, of a deep red colour, and mount in rude irregular ſhapes to the height of ſeventy or eighty feet. Near the centre of Weſt Teignmouth is the church, a very ancient ſtone fabric, built in the form of a croſs: the roof is ſupported in a ſingular manner by the ramifications of a wooden pillar, that was formed from the trunk of a ſingle tree. Eaſt Teignmouth church is a venerable pile near the beach, and, from the appearance of its architecture, was probably one of the earlieſt ſtructures erected after the coming of the Normans. The trade of Teignmouth conſiſts chiefly of commercial intercourſe with Newfoundland; the exportation of clay, and the importation of coal; and is carried on principally in craft built at the place, where are conveniences for launching veſſels of a hundred tons. The clay exported is brought from Bovey, for the moſt part by a canal; and dug on the eſtate of James Templar, eſq., who, with true patriotiſm, is employed indefatigably in promoting the ſolid intereſts of his country, by improving agriculture, and encouraging manufactures. Weſt Teignmouth had anciently a chartered market, held on Sundays; but this was diſcontinued by order of the ſheriff in the reign of Henry III. The market is now held on Saturdays. Salmon, trout, whiting, mackarel, and various other kinds of fiſh, are taken here; and by ſome excellent local regulations, the inhabitants have the privilege of ſupplying themſelves before any can be ſold to the dealers. The lord of the manor holds a court-baron, or court-leet, in the town once every year: at which court a jury is nominated, two conſtables deputed and ſworn, and a portreve choſen, who is inveſted with conſiderable authority. In the population return of the year 1811, Weſt Teignmouth was ſtated to contain 441 houſes; Eaſt Teignmouth, 188; the inhabitants of the former being 2080; of the latter 813: making an aggregate of 2893 perſons, occupying 629 houſes.

Nearly oppoſite Teignmouth, and almoſt under the promontory called the Neſs, is the hamlet of Shaldon, the property of lord Clifford, which has lately become a favourite ſummer reſidence for many families who viſit the watering places on this coaſt. The chapel, erected about the year 1670, ſtands in a beautiful ſituation, a little above the Teign, about three quarters of a mile from the hamlet, and is approached by a level walk ſhaded with luxuriant trees.—Beauties of England and Wales, vol. iv. Devonſhire. By J. Britton and E. W. Brayley, 1803. Warner's Walk through the Weſtern Counties, 1800.

TEIJEUT, a town of Morocco; 15 miles S.E. of Mogodor.

TEIL, a river of France, which runs into the Atlantic, N. lat. 47° 39′. W. long. 3° 8′.

Teil, *Le*, a town of France, in the department of the Ardeche, on the Rhone; 12 miles S. of Privas.—Alſo, a town of France, in the department of the Ille and Vilaine; 15 miles S.E. of Rennes.

TEILLEUL, Le, a town of France, in the department of the Channel; 6 miles S. of Mortain.

TEIN, a town of Bohemia, in the circle of Pilſen; 6 miles N.E. of Tachau.

Tein, or *Teyn*, a town of Bohemia, in the circle of Bechin; 4 miles S. of Bechin.

TEINITZ, a town of Bohemia, in the circle of Pilſen; 26 miles S.W. of Pilſen. N. lat. 49° 30′. E. long. 12° 57′.—Alſo, a town of Moravia, in the circle of Brunn; 27 miles S.S.E. of Brunn.

Teinitz *Jungfern*, a town of Bohemia, in the circle of Schlan; 8 miles W. of Schlan.

TEINTS, and *Semi-Teints*, in *Painting*, denote the ſeveral colours uſed in a picture, conſidered as more or leſs high, or bright, or deep, or thin, or weakened, and diminiſhed, &c. to give the proper relievo, or ſoftneſs, or diſtance, to the ſeveral objects. See Colouring.

The word is pure French, where it ſignifies the ſame.

TEIRCE, or Teirs. See Tierce.

TEISBACH, in *Geography*, a town of Bavaria, on the Iſer; 1 mile W. of Dingelfingen.

TEISENDORF, a town of the archbiſhopric of Salzburg; 12 miles W.N.W. of Salzburg.

TEISKO, a town of Sweden, in Tavaſtland; 45 miles N.N.W. of Tavaſthus.

TEISSIER, Anthony, in *Biography*, a voluminous French writer, was born at Montpellier in the year 1632. Having ſtudied Greek and philoſophy at Orange, and being deſtined for the miniſtry among the Calviniſts, he applied to Hebrew and theology at Niſmes; and after ſpending ſome time in the academy at Montauban, he removed to that of Saumur. From thence he went to Paris, where he cultivated an acquaintance with ſeveral learned men; but giving up his deſigns for the miniſtry, on account of a diſorder under which he laboured, he turned his thoughts to juriſprudence, and took the degree of LL.D. at Bruges. In 1683 he married; but upon the revocation of the edict of Nantes, he was obliged to quit France. He then retired with his wife to Switzerland, and was recommended by Turretin and Heidegger to the family of Eſcher, a burgomaſter of Zurich. Declining to accept advantageous offers if he returned to France, he engaged with the ſenators of Berne for two years in conducting a French gazette in that city. In 1691 he quitted Berne and went to Zurich; and from thence he proceeded to Brandenburgh, where refugees enjoyed common privileges with thoſe of the natives of the country. At Berlin, the elector appointed him hiſtoriographer, with an annual penſion of 300 crowns, which was ſucceſſively augmented. He was alſo honoured with the title of counſellor of legation, and ordered by the elector to tranſlate into French the life of his father, Frederic William, written in Latin by Puffendorf. For this ſervice he was liberally rewarded, though his tranſlation was never printed. He was afterwards employed in compoſing many works for the inſtruction of the prince royal; and though his conſtitution was delicate, he enjoyed good health till his death, which happened in 1715, in the eighty-fourth year of his age. It would exceed our limits to enumerate all his works; an ample account of them may be found in the General Biography.

TEI-TCHANG, in *Geography*, a town of Corea; 13 miles N.N.E. of Haimen.

TEITEI, in *Ornithology*, the name of a Braſilian bird, a ſpecies of tanagra, in the Linnæan ſyſtem, called alſo *guiranheemegeta*, and *guraundi*.

It is of the ſize of our red-breaſt, and beautifully coloured.

It ſings very ſweetly, and is kept in cages, five or ſix together in the ſame cage. Marcgrave's Hiſt. of Braſil.

TEITH, in *Geography*, a river of Scotland, formed by ſtreams from ſeveral lakes, in the county of Perth, which runs into the Forth, two miles above Stirling.

TEJUCO, the capital of the Diamond diſtrict in Braſil, ſituated in a ravine at the foot of a mountain. Tejuco is ſeparated by the ſmall rivulet of St. Franciſco from the oppoſite mountains. The greateſt of the diamond works, called Mandanga, is ſituated on the river Izgitanhanha, and employs about 1000 negroes, ſometimes double this number. This rich river, formed by the junction of ſeveral ſtreams, is as wide as the Thames at Windſor, and in general from three to to nine feet deep. The part now working is a curve or elbow, from which the current is diverted into a canal cut acrofs the tongue of land round which it winds; the river being ftopped below the head of the canal by an embankment formed of feveral thoufand bags of fand. The deeper parts of the channel of the river are laid dry by large caiffons, or chain-pumps, worked by a water-wheel. The mud is then carried off, and the cafcalhão is dug up and removed to a convenient place for wafhing by machinery adapted to this purpofe. The contrivance for obtaining th· diamonds from the cafcalhão is particularly defcribed by Mr. Mawe, ubi infra. Tejuco is fituated in a fterile diftrict, which produces nothing for the maintenance of its inhabitants, whofe number is about 6000; and therefore depends for a fupply of provifions, on farms fituated at the diftance of feveral leagues. Neverthelefs, Tejuco may be called flourifhing, on account of the circulation of property created by the diamond-works in its vicinity. The annual fum paid by government for the hire of negroes, falaries of officers, and various neceffaries, fuch as nitre and iron, does not amount to lefs than 35,000*l.* and this, added to the demands of the inhabitants of the town and its neighbourhood, occafions a confiderable trade. The fhops are ftocked with Englifh cottons, baizes, and cloths, and other manufactured goods; alfo hams, cheefe, butter, porter, and other articles of confumption, which are brought on mules from Bahia and Rio de Janeiro. Tejuco, from its fituation on the fide of a hill, is very irregularly built; its ftreets are uneven, but the houfes in general are well conftructed, and in good condition, compared with thofe of other towns in the interior. Its name, fignifying in the Portuguefe language a muddy place, is derived from places of that defcription near it, which are rendered paffable by being covered with large pieces of wood. The diamonds are locked in the treafury under three locks; and thofe found in the diftrict are depofited every month, as they are received from the works; they are carefully weighed, and fome of them felected and kept feparate. The average quantity obtained may be eftimated at from 20,000 to 25,000 carats annually, which are fent under a military efcort to Rio, and there lodged in the treafury. The diamonds are tied up in black filk bags, and depofited in elegant inner cabinets, all which are locked up in ftrong chefts, bound with iron. Tejuco affords fome good barley, but grafs for cattle is fcarce and dear. Moft parts of the country abound in oranges, pines, peaches, guavas, and a great variety of indigenous fruits: ginger and pepper grow fpontaneoufly, and many fpices might probably be cultivated with fuccefs. Mawe's Travels in the Interior of Brazil, 1812.

TEJUGUACU, in *Zoology*, the name of a fpecies of lizard, common in the Brazils, and called alfo *temapara*.

It much refembles the iguana in its general figure, but differs from it in that its whole body is black, only variegated with fome white fpots. It lives principally on the fucking of eggs, but it is capable of bearing hunger a long time; Marcgrave having kept one alive feven months without eating. This fpecies afforded alfo a certain teftimony to that author of the reproduction of the tail when cut off. Ray.

TEIUM, in *Ancient Geography*, a town of Afia Minor, fituated on the Euxine fea, on the frontiers of Paphlagonia, near the fmall river Billis, 370 ftadia from the town of Heraclea. It was a Greek Ionian colony, which derived its name and its origin from *Tios*, a Milefian prieft, according to Arrian and Mela. The worfhip of Jupiter named Patarus was practifed in this town, according to Demofthenes. On the E. the territory of this town was bounded by the river Parthenius. The town was much augmented when the empire of the Perfians was deftroyed.

TEIUNHANA, in *Zoology*, the name of a fmall American lizard. It is about the thicknefs of one's little finger, and has a fharp nofe. Its tail is very flender, fix fingers breadth long, and terminates in a point almoft as fharp as a needle. Its head is covered with fcales; and its back, fides, and legs, with a tender fkin, as foft as fatin to the touch; and its tail is covered with extremely minute fcales, of a fquare figure. Ray.

TEKAT, in *Geography*, a town of Afiatic Turkey, in Natolia; 10 miles N. of Kiangari.

TEKEBI, a town of Egypt; 22 miles W.S.W. of Damietta,

TEKEH, a town of Turkifh Armenia; 40 miles S.E. of Trebifond.

TEKEREE, a town of Hindooftan, in Candeifh; 14 miles E. of Barrawnay.

TEKIN, a town of Afiatic Turkey, in Caramania; 100 miles W. of Tocat.

TE-KING, a city of China, of the fecond rank, in Quang-tong, near the river Si; 1064 miles S.S.W. of Peking. N. lat. 23° 12′. E. long. 111°.—Alfo, a city of China, of the fecond rank, in Quang-tong; 1065 miles S. of Peking. N. lat. 23° 12′. E. long. 110° 50′.

TEKKIUR DAG, a mountain of European Turkey, in Romania; 32 miles S.S.E. of Adrianople.

TEKLA, a town of Bohemia, in the circle of Chrudim; 6 miles S.W. of Leutmifchl.

TEKMABAD, a town of Perfia, in the province of Segeftan; 70 miles E.N.E. of Boft.

TEKOA, a village, and anciently a city of Paleftine, built by Rehoboam, king of Judah, and confiderable ruins appear of its ancient grandeur. It was the native place of the prophet Amos; 9 miles S. of Bethlehem.

TEKOLY, a town of Hindooftan, in Bahar; 53 miles S.S.W. of Patna.

TEKUPHÆ, or THEKUPHÆ, in the *Jewifh Chronology*, are the times in which the fun proceeds from one cardinal point to the next.

The fame term is alfo applied to the moment in which the fun enters a cardinal point: thefe four terms, or tekuphæ, into which the Jews divided their folar year, are obferved among the Jews with a great deal of ceremony; the reafon, as we are informed by Munfter, is this:

That people have a notion, that in each tekupha the fun has a feparate angel appointed to guard and direct it; and that in the very point where the fun finifhes one tekupha, and enters upon another, before the one director has taken place of the other, the devils have a power to exercife all kinds of tyranny in the water.

And hence, they fancy, that if any body drinks the fmalleft quantity of water at that time, he will infallibly have a dropfy, or fome other grievous diftemper.

The tekupha of Tifri correfponded to the autumnal equinox, that of Tebeth to the winter folftice, that of Nifan to the vernal equinox, and that of Tamuz to the fummer folftice

TEKY SOUND, in *Geography*, a road on the coaft of Georgia, fouth of the Savannah river, where a large fleet may anchor in ten or fourteen fathoms, and have fafe entrance over the bar of the river; the flood tide generally feven feet.

TEL ARESIAS, a town of Afiatic Turkey, on the Euphrates; 5 miles W.N.W of Diarbekir.

TEL *Gizir*, a town of Afiatic Turkey, in the province of Diarbekir; 16 miles W. of Merdin.

TEL *Kiaran*, a town of Afiatic Turkey; 30 miles S.S.W. of Diarbekir.

Tel *Muſet*, a town of Aſiatic Turkey, in the government of Diarbekir; 33 miles N.W. of Moſul.

Tel *el Judieh*, a town of Egypt, where the Jews had formerly a temple, deſtroyed by Veſpaſian; 17 miles N.E. of Cairo.

TELA, in *Ancient Geography*, a town of Spain, on the route from Aſturica to Saragoſſa, between Intercatia and Pintia. Anton. Itin.

Tela, or *Conſtantia*, a place of Aſia, in Meſopotamia, near the mountains, about N. lat. 37° 25′.

Tela *Celluloſa*, in *Anatomy*, the Cellular *Subſtance*; which ſee. It is ſometimes alſo called tela mucoſa.

TELACH, in *Geography*, an iſland of Ruſſia, in the Penzinſkoi ſea. N. lat. 61° 35′. E. long. 159° 14′.

TELAMON, in *Ancient Geography*, a promontory of Italy, in Etruria, at the foot of which was a port, between the rivers Almina and Alma. (Anton. Itin.) Pliny calls this port Telamon.

TELAMONE, in *Geography*, a town of the Stato del Preſidii, on the coaſt; 10 miles N. of Orbitello. N. lat. 42° 38′. E. long. 11° 6′.

TELAMONES, a name given by the Romans to what the Greeks called *Atlantes*; *viz.* the figures of men ſupporting entablatures, and other projectures. See Atlas.

The word, according to ſome, is derived from the Greek τελαμων, from τελαω, or τλαω, *I bear*.

Among the Greeks they were called *atlantes*, ατλαντες, which comes from the ſame word, ταλαω, or τλαω, by the figure metatheſis.

Telamones is alſo uſed by ſurgical writers ſometimes for lint, and ſometimes for the fillets or bandages which they apply over their dreſſings.

TELANA, in *Ancient Geography*, a very ancient town of Aſia, in Aſſyria. Steph. Byz. ſays that the king made it the place of his reſidence before Nineveh was built.

TELANADING Islands, in *Geography*, three ſmall iſlands lying eaſt and weſt, near the N.W. coaſt of the iſland of Gilolo. N. lat. 2° 18′. E. long. 127° 30′.

TELANDRIA, in *Ancient Geography*, an iſland on the coaſt of Lycia, in Aſia Minor. Pliny.

TELANDRUS, a town of Aſia Minor, in Lycia. Pliny.

TELAPSAR, in *Geography*, a town of Aſiatic Turkey, in the province of Diarbekir; 20 miles W. of Moſul.

TELARUSE, a river of Aſia, which forms the north boundary of the kingdom of Queda, ſeparating it from Lower Siam, and runs into the Eaſt Indian ſea, N. lat. 6° 55′. E. long. 99° 42′.

TELAUGIA, in *Natural Hiſtory*, the name of a genus of ſcrupi, of a glittering appearance, uſually containing flakes of talc, and emulating the ſtructure of the granites. Hill.

Of this genus we have twelve ſpecies.

TELCHINES, in *Ancient Geography*, a people who derived their origin from the iſle of Crete. They eſtabliſhed themſelves in Cyprus, and in Rhodes, where it is ſaid they invented the uſe of iron and braſs.

TELCOOTE, in *Geography*, a town of Hindooſtan, in Oriſſa; 20 miles S.E. of Jaypour.

TELDOM Hotun, a town of Chineſe Tartary, on the weſt ſide of the river Saghalien; 745 miles N.E. of Peking. N. lat. 49° 56′. E. long. 127° 33′.

TELE, τελη, among the Athenians, thoſe revenues that were brought in by lands, mines, woods, and other public poſſeſſions, ſet apart for the uſe of the commonwealth; as alſo tributes paid by ſojourners and freed-ſervants, and the cuſtoms laid upon certain trades and goods.

TELEBA, in *Ancient Geography*, a town of Albania, between the mouth of Soana and that of Garrus. Ptol.

TELEBOAS, a river of Aſia, in the environs of the ſources of the Tigris; ſurrounded, as Xenophon ſays, by a great number of villages.

TELEGRAPH, a machine adapted for communicating intelligence at a conſiderable diſtance, by making various ſignals, which have been previouſly agreed upon between two parties, to repreſent letters, words, or ideas. The means of making ſignals that are uſed in naval and military operations, are not called telegraphs, although they effect in a great degree the ſame object. See Signal.

The word telegraph, which is derived from two Greek words, τηλε, *at a diſtance*, and γραφω, *to write*, was brought into uſe about 1793 or 1794, when the French directory eſtabliſhed machines of this kind for communicating intelligence between Paris and all the principal towns in France. The Britiſh government ſoon after adopted the ſame meaſure, and it has ſince become very general.

No machine for making ſignals can with propriety be called a telegraph, unleſs it is adapted to expreſs a ſufficient number of letters or words to form a complete language, and which can therefore be made to communicate any information which can be expreſſed by oral or written language. Leſs perfect ſyſtems of ſignals, which extend only ſo far as to communicate intelligence of events which have been foreſeen, and the appropriate ſignals previouſly arranged, are ſtill called ſignal flags, ſignal lanthorns, ſignal guns, or fires, &c.

When people wiſh to tranſmit intelligence to others at a diſtance, in a quicker manner than by letters ſent by meſſengers or carrier-pigeons, it can be done only by ſignals. Theſe may be employed in three different ways: either by ſingle ſignals, which, according to previous agreement, convey whole ideas; or by ſeveral ſucceſſive ſignals, which, by repreſenting letters and words, anſwer the ſame purpoſe; or otherwiſe, by employing ſignals which expreſs numbers, each perſon being provided with a dictionary in which every word has a number affixed to it.

The firſt kind of ſignals were employed in the earlieſt periods, and ſome of them were ſuited to the ear as well as to the eye. For the making of viſible ſignals, the ancients employed fire and ſmoke, torches, flags, &c.; and in modern times, ſky-rockets have been uſed. For the audible ſignals, they employed drums and trumpets; and ſince the invention of gunpowder, the firing of cannon has been applied to the like uſe. But all theſe methods are incapable of expreſſing what could be communicated by ſpeech and writing; and the means of expreſſing all the poſſible variations and combinations of the letters of the alphabet, form, in a proper ſenſe, the true telegraphic art. Even the ſignals commonly uſed at ſea, as they extend only to particular circumſtances, are, when compared to ſignals by letters, only a kind of hieroglyphics.

The propoſed object of the telegraphic art is, therefore, to obtain a figurative language, the characters of which may be diſtinguiſhed at a diſtance. On the firſt reflection, we find that the practicable modes of ſuch diſtant communications muſt be confined to ſound and viſion; each of which is in a great degree ſubject to the ſtate of the atmoſphere: for independent of the wind's direction, it is known that the air is ſometimes ſo far deprived of its elaſticity, or ſome other quality that influences the conveyance of ſounds, that the heavieſt ordnance can ſcarcely be heard farther than the ſhot flies. It is alſo well known, that in thick hazy weather, the largeſt and

moſt

moſt defined objects become totally obſcured at a ſhort diſtance. No inſtrument, therefore, deſigned for the purpoſe can be perfect. We can only endeavour to diminiſh theſe irremediable defects as much as may be.

The moſt barbarous nations employed ſignals, which could quickly inform them of the approach of enemies, as appears by the teſtimony of ſeveral ancient authors; and there is reaſon to believe that ſome ſort of telegraphic communication was in uſe among the Greeks. The deſtruction of Troy was certainly known in Greece very ſoon after it took place, and before any perſon could have returned from it. A Greek play begins with a ſcene, in which a watchman deſcends from the top of a tower in Greece, and gives information that Troy is taken. "I have been looking out theſe ten years (ſays he) to ſee when that would happen, and this night it has been done."

In addition to the Stenterophonic tube which was known and uſed by Alexander the Great, the Romans had a method, in their walled cities, either of forming a hollow in the maſonry, or of applying tubes to the walls, ſo as to confine or augment ſound, and convey information to any part of their works. In lofty houſes and warehouſes, it is now a common cuſtom to have a pipe, by way of ſpeaking trumpet, to give orders from the upper apartments to the lower. By this mode of confining its volume, ſound may be carried to a very conſiderable diſtance; but beyond a certain extent the ſound will loſe all articulation, and only convey alarm, without giving directions.

Every city of the ancients had its watch-towers; and the caſtra ſtativa of the Romans had always ſome ſpot, elevated either by nature or art, from whence ſignals were given to the troops cantoned or foraging in the neighbourhood: but it appears that they had not arrived to any greater refinements in the telegraphic art, than that on ſeeing a certain ſignal they were immediately to repair to their appointed ſtations. Flags or enſigns, with their various devices, are of the earlieſt invention, eſpecially at ſea, where, from the firſt idea, which was moſt probably that of a vane, to ſhew the direction of the wind, they have been long adopted as the diſtinguiſhing marks of nations, and are now ſo perfected into a ſyſtem of ſignals, that every requiſite order and queſtion is received and anſwered by the moſt diſtant ſhips of a fleet.

The mode of ſignalling in uſe about half a century ago was very imperfect. It was a good deal amended and ſimplified by that lamented officer admiral Kempenfelt; and his ſyſtem, as it was called, continued in uſe till within theſe twenty-five years. It was ſuperſeded in the navy by ſir Home Popham's, who firſt brought into practical utility a plan originally, it is believed, ſuggeſted by Mr. Richard Gower, of the Eaſt India Company's ſervice, in his "Practical Seamanſhip," publiſhed in 1794. This was the ſubſtitution of ten or twelve numbered flags, for a great number of flags. It is ſurpriſing that this eaſy ſcheme ſhould not ſooner have been diſcovered and adopted. Inſtead of the immenſe "colour cheſt" that we and our naval cotemporaries can recollect, and the difficulty of finding and hoiſting the variety of flags required, it is pleaſing to witneſs the facility with which communications can be now made, by means almoſt as eaſy of application as the pen.

The *ſyſtem* now in uſe, originating, as we have ſtated, with an officer of the Eaſt India Company's ſervice, has recently been greatly improved by another of theſe officers. It is not eaſy to deſcribe the nature of thoſe improvements; nor proper, perhaps, were it otherwiſe; for the directors of the Eaſt India Company have deemed it expedient to keep them ſecret. The author of them is captain Thomas Lynn. His work was printed in 1814, at the Company's expence, in a conſiderable quarto volume, under the title of "Lynn's Improved Syſtem of Telegraphic Communication." It is adopted throughout the extenſive ſervice of the Eaſt India Company; and we are glad to ſee it noticed in the preface to the volume, that the highly reſpectable court of directors moſt liberally patronized the work and its author. We do not find, notwithſtanding the manifeſt advantage of the "Improved Syſtem," that it has yet been introduced into the royal navy; although every officer in that as well as the Eaſt India Company's ſervice, who have had opportunities of trying it, are loud in its praiſe. It adapts itſelf to every deſcription of telegraphic machinery now in uſe; or, as far as we can ſee, that can be uſed: it requires fewer flags than were heretofore neceſſary; and its powers are vaſtly greater than the other codes or ſyſtems. This paragraph, and perhaps this whole page of our dictionary, can be thus communicated, word for word, or phraſe by phraſe, without difficulty, and with a rapidity unattainable by any ſcheme hitherto publiſhed. The numbers, and powers, and meaning of the ſignals, may be changed at pleaſure: ſo that if the work fall into improper hands, it merely communicates the principle on which the ſyſtem is founded.

In applying this or a ſimilar mode of communicating intelligence in land ſervice, ſeveral objections preſent themſelves: the variety of communications neceſſary to be made is ſo much greater, that the combination would become too complicated; and if the perſon for whom the information is intended, ſhould be in the direction of the wind, the flag would then preſent a ſtraight line only, and at a little diſtance would be ſcarcely viſible. The Romans were ſo well aware of this inconvenience of flags, that many of their ſtandards were ſolid, and the name manipulus denotes the rudeſt of their enſigns, which was a truſs of hay fixed on a pole.

A beacon or bonfire, made of the firſt inflammable materials that offered, being the moſt obvious, is perhaps the moſt ancient mode of general alarm. By being previouſly concerted, the number of points where the fires appeared may have particular intelligence affixed. The ſame obſervations may be referred to the more modern plan of throwing up rockets, whoſe number, or the places from whence they are thrown, may have affixed ſignifications. Many of our hills ſtill retain the name of beacon hills, from the ſignals which uſed to be made upon them, by means of fire and ſmoke, which were the chief things employed during the dark ages, and in the times of the feudal ſyſtem. The fire was uſed by night, and the ſmoke by day. Within a few years, ſignals made by theſe means were very common amongſt the ſmugglers on our coaſt.

The machine of Æneas, who wrote a treatiſe on the duties of a general in the time of Ariſtotle, is deſcribed by Polybius to have conſiſted of two earthen veſſels, made exactly ſimilar in all their dimenſions: they were to be filled with water, and each was to have a cock or ſpout, which could be opened or ſhut at pleaſure, and would, when open, diſcharge an equal quantity of water from both veſſels, ſo that each of the veſſels would take preciſely the ſame period of time to diſcharge the whole, or any given proportion, of its contents. A float of cork was to be provided for each veſſel to reſt upon the ſurface of the water, and ſupport a perpendicular ſtem or index, which could be divided, and have certain ſentences written to correſpond with each diviſion. The apertures of the ſpouts of the two veſſels were to be previouſly adjuſted, and the veſſels filled with water to the ſame height, ſo that their floats and indices would correſpond in pointing out the ſame ſentences: then, if both cocks were opened at the ſame inſtant, the water would run out from each veſſel, and the floats of both would ſubſide together, ſo that when either index

ſtood

ſtood at a particular ſentence, the other index would, at the ſame time, point out the ſame ſentence. Now this operation could be equally well performed when the two veſſels were moved to any diſtance aſunder, provided the obſervers were within ſight of each other, to be able to make the requiſite ſignals for opening and ſhutting the cocks of both veſſels at the ſame moment. The author thus deſcribes the uſe of this inſtrument: The two veſſels being prepared and adjuſted, they muſt be carried to the two places where the ſignals are to made and obſerved; water is poured into each, and the floats and indices are put into the veſſels. When any of the events which are written upon the indices ſhall happen, a torch or light is raiſed, which muſt be held aloft till ſuch time as another is raiſed by the party to whom it is directed. (This firſt ſignal is only to give notice that both parties are ready and attentive.) Then the torch or other light muſt be taken away, and the cocks ſet open inſtantly by both parties. When the interval or diviſion on that part of the index where the event, of which notice is to be given or written, ſhall be fallen to a level with the veſſels, then the man who gives the ſignals lifts up his torch, and on the other ſide, the correſpondent ſignal maker immediately ſhuts the cock of his veſſel, and looks at what is written on that part of the ſtick which touches the mouth of the veſſel; on which occaſion, if every thing has been executed exactly and equally on both ſides, both parties will read the ſame thing.

The proper telegraphic art was not wholly unknown to the ancients. The Greeks and the Romans made uſe of pots filled with lighted twigs and ſtraw for ſignals, over which they poured oil; and theſe being placed in certain rows, expreſſed certain letters, according to the order in which each row was lighted.

Polybius deſcribes a new method of communication, which was invented by Cleoxenus, or by Democlitus, and which Polybius himſelf very much improved. It poſſeſſes the principal advantage of the modern telegraph, *viz.* that, by means of ſignals, it communicates the letters of the alphabet, and can therefore be uſed to expreſs any thing which can be required. It is only inferior to the telegraph in the means of making the ſignals, which is by the light of torches, and rather complicated, ſo that it would be tedious to tranſmit any thing more than ſhort ſentences. Polybius deſcribes this method, which he calls Pyrſia, in the following manner: Take the letters of the Greek alphabet, and divide them into five parts, each of which will conſiſt of five letters, except the laſt diviſion, in which there will be only four. Let theſe be fixed on a board, in five columns. The man who is to give the ſignals is then to begin by holding up two torches, which he is to keep aloft till the other party has alſo ſhewn two: this is only to denote that both ſides are ready: theſe torches are then withdrawn. Both parties are provided with boards, on which the letters are diſpoſed as formerly deſcribed. Then the perſon who gives the ſignal is to hold up torches on the left hand, to point out to the other party, from what column he ſhall take the letters as they are pointed out to him: thus, if the letter is to be from the firſt column, he holds up one torch; if from the ſecond, two; and ſo on for the others. He is then to hold torches on the right hand, to denote the particular letter of the column that is to be taken. All this muſt have been agreed on beforehand. The man who gives the ſignals muſt have an inſtrument (διοπτρον, *perſpective*), conſiſting of two tubes, and ſo placed, that by looking through one of them he can ſee only the right ſide, and looking through the other, he can only ſee the left-hand ſide of him who is to anſwer. The board muſt be ſet up near this inſtrument; and the ſtations on the right and left muſt each be ſurrounded with a wall ten feet broad, and about the height of a man, that the torches raiſed above it may give a clear and ſtrong light, and that when taken down they may be completely concealed.

The ſteganographia trithemiana of a Benedictine monk, in the fifteenth century, ſeems to have been ſomething of the ſame kind; but the firſt recorded experiment, after the manner of the Greeks, is deſcribed by Kircher, in his "Ars magna Lucis et Umbræ," under the title of *Cryptogamia catoptrica;* it was however imperfect, and could be employed only at a certain diſtance. Schott, in his "Technica curioſa," propoſes, after an anonymous author, to erect poſts upon an eminence, ſo as to be diſtinguiſhed through a teleſcope, and on which proper ſignals could be elevated, as might be neceſſary.

The marquis of Worceſter, who is ſo juſtly celebrated for having firſt diſcovered that the force of ſteam could be applied to mechanical purpoſes, brought telegraphic communication to a conſiderable degree of perfection, if at leaſt we give him credit for having really effected every thing which he mentions in his Century of Inventions. This little tract was publiſhed in 1663, and contains the following articles.

"No. 6. How at a window, as far as eye can diſcover black from white, a man may hold diſcourſe with his correſpondent, without noiſe made, or notice taken, being according to occaſion given and means afforded, *ex re natâ*, and no need of proviſion before-hand, though much better if foreſeen, and means prepared for it, and a premeditated courſe taken by mutual conſent of parties.

"No. 7. A way to do it by night, as well as by day, though as dark as pitch is black."

The marquis gives us no idea of the means which he uſed for exhibiting his ſignals, by which we can judge of the practicability of his plan for communicating any detailed intelligence.

Keſler, in his Concealed Arts, adviſes characters to be cut out in the bottom of a caſk, ſo as to appear luminous when a light is placed withinſide, and the characters muſt be changed ſucceſſively to expreſs words and ſentences.

Dr. Hooke's Telegraph.—The firſt idea of a telegraph upon a ſimilar conſtruction to thoſe uſed at preſent, was ſuggeſted by Dr. Hooke towards the end of the laſt century, the ſiege of Vienna by the Turks having turned his attention to the buſineſs. He gave the firſt complete deſcription of ſuch a machine, as appears by the following extract, from a paper of his, read before the Royal Society on the 21ſt of May, 1684. "I propoſed (ſays he) ſome years ſince, a method of diſcourſing at a diſtance, not by ſound but by ſight: I ſay that it is poſſible to convey intelligence from any one high and eminent place, to any other that is in ſight of it, though thirty or forty miles diſtant, in as ſhort a time almoſt as a man can write what he would have ſent; and as ſuddenly to receive an anſwer, as he that receives it has a mind to return it, or can write it down on paper. Nay, by the help of three, four, or more eminent places viſible to each other, lying in a ſtraight line, 'tis poſſible to convey intelligence almoſt in a moment, to twice, or thrice, or more times that diſtance, with as great a certainty as by writing.

"For the performance of this, we muſt be beholden to a late invention, which we do not find any of the ancients knew; that is, the eye muſt be aſſiſted with teleſcopes, that whatever characters are expoſed at one ſtation, may be made plain and diſtinguiſhable at the other.

"Firſt: For the ſtations, if they be far diſtant, it will be neceſſary that they ſhould be high, and lie expoſed to the ſky; that there be no higher hill or part of the earth beyond them, that may hinder the diſtinctneſs of the charac-

ters,

ters, which are to appear dark againſt the ſky, beyond them appearing white, by which means alſo the vapours near the ground will be paſſed over and avoided. Next, in chooſing theſe ſtations, care muſt be taken, as near as may be, that there be no hill that interpoſes between them, that is almoſt high enough to touch the viſible ray, becauſe in ſuch caſes the refraction of the air of that hill will be very apt to diſturb the clear appearance of the object. The ſtations being found convenient, the next thing to be conſidered is, what teleſcopes will be neceſſary for each ſtation. One of theſe teleſcopes muſt be fixed at each extreme ſtation, and two of them in each intermediate ſtation; ſo that a man for each glaſs, ſitting and looking through them, may plainly diſcover what is done in the next adjoining ſtation, and with his pen write down on a paper the characters there expoſed, in their due order; ſo that there ought to be two perſons at each extreme ſtation, and three at each intermediate one, that intelligence may be conveyed backwards and forwards at the ſame time. Next there muſt be certain times agreed on, when the correſpondents are to expect it; or elſe there muſt be ſet at the top of a pole, in the morning, the hour appointed by either of the correſpondents for acting that day.

"Next there muſt be convenient apparatus of characters, conſiſting of at leaſt as many diſtinct characters as there are neceſſary letters in the alphabet, (to be made uſe of as is expreſſed in *Plate Telegraph*, *fig.* 1.) And theſe muſt be either day characters or night characters. If they are to be made uſe of in the day-time, they may all be made of deals, and of a ſize convenient for the ſeveral diſtances, any one of which characters may ſignify any one letter of the alphabet, and the whole alphabet may be varied 10,000 ways, ſo that none but the two extreme correſpondents ſhall be able to diſcover the information conveyed. If the characters are for the night, then they may be made with links, or lights diſpoſed in a certain order, which may be covered or uncovered, according to the method agreed on. There will be alſo requiſite ſeveral other characters, which may for expedition expreſs a whole ſentence, ſuch as 'I am ready to communicate;' 'I am ready to obſerve.' I could inſtance a hundred ways of facilitating the method of performing the deſign with the more dexterity and quickneſs, and with little change, but that I think will be needleſs at preſent, ſince, whenſoever ſuch a way of correſpondence ſhall be put in practice, thoſe and many more than I can think of at preſent will of themſelves occur, ſo that I do not in the leaſt doubt but that with a little practice all things may be made ſo convenient, that the ſame character may be ſeen at Paris, within a minute after it hath been expoſed in London; and that the characters may be expoſed ſo quick after one another, that a compoſer ſhall not much exceed the expoſer in ſwiftneſs, and this not only at the diſtance of one ſtation, but of an hundred; for ſuppoſing all things ready at all of thoſe ſeveral ſtations for obſerving and expoſing as faſt as the ſecond obſerver doth read the characters of the firſt expoſer, the ſecond expoſer will diſplay them to the obſerver of the third ſtation, whoſe expoſer will likewiſe diſplay them for the fourth obſerver, as faſt as his obſerver doth name them to him or write them down. There may be many objections brought againſt this way of communication, becauſe it has not yet been put in practice, but hardly any that may not be eaſily anſwered and obviated."

Dr. Hooke illuſtrates his invention thus: Let A B C (*fig.* 2.) repreſent three very long maſts or poles erected, E the top piece that joins them together, D a ſcreen, behind which all the deal-board characters hang upon certain rods or lines, and may, by the help of ſmall lines connected with each of them, be expoſed at F, or drawn back at D, as occaſion may require.

This propoſal of our ingenious countryman is very complete and well ſtudied; it would be leſs convenient and expeditious than the modern telegraphs, but would certainly have anſwered very uſeful purpoſes, with the advantage of being very free from the uncertainties and errors of more complete machines, which, at the ſame time that they admit of making a greater variety of ſigns than the letters of the alphabet, are for the ſame reaſon more liable to miſtakes in exhibiting as well as in reading or tranſlating them. The only obvious improvement on Dr. Hooke's telegraph is, that, inſtead of concealing the characters behind the ſcreen D, they ſhould be kept down below in the houſe on which the machine is to be erected, and be hoiſted up into the frame when they are to be exhibited.

M. Amontons, an ingenious French academician who ſtudied mechanics, was born at Paris in 1663, and died in 1705, at the age of forty-two. He propoſed the following method: Let there be people placed in ſeveral ſtations, and at ſuch a diſtance from each other, that by the help of a teleſcope, a man at one ſtation may ſee a ſignal made in the next before him: he muſt immediately repeat the ſame ſignal, that it may be ſeen by perſons in the ſtation next after him, who are to communicate it to thoſe in the following ſtation, and ſo on. Theſe ſignals may be as letters of the alphabet, or as a cipher, underſtood only by the two perſons who are in the diſtant places, and not by thoſe who make the ſignals. The perſon in the ſecond ſtation making the ſignal to the perſon in the third the very moment he ſees it in the firſt, the news may be carried to the greateſt diſtance in as little time as is neceſſary to make the ſignals in the firſt ſtation. The diſtance of the ſeveral ſtations, which muſt be as few as poſſible, is meaſured by the reach of a teleſcope. M. Amontons is ſaid to have tried this method on a ſmall tract of land, before ſeveral perſons of the higheſt rank at the court of France; but we are not acquainted with the kind of apparatus he employed; all that we know of his method is preciſely the ſame as Dr. Hooke's.

Guyat, a long time after Dr. Hooke, propoſed tables, with letters cut out in them: and Paulian, in his Dictionnaire de Phyſique, deſcribes a tranſparent figure, conſiſting of one perpendicular and three horizontal ſtripes, forming ten compartments, each of which can be rendered viſible or inviſible at pleaſure, by blinds or ſhutters moveable from behind.

Mr. Richard Lovell Edgeworth, in a memoir which he preſented to the Royal Society of Ireland (ſee their Tranſactions, vol. vi. p. 125.), adduces proof, that in 1767 he tried an experiment of the practicability of communicating intelligence by a ſwift and unſuſpected mode; and for this purpoſe he employed a common windmill, and arranged a ſyſtem of ſignals, which could be made by the different poſitions of the arms of its ſails, the canvas being removed from one or more arms, as was required. Theſe ſignals were made to denote numbers, and both parties were provided with vocabularies, in which all the words were numbered.

French Telegraph.—Although the telegraph was thus fully explained in 1684, it does not appear that this valuable invention was at all practiſed or applied to any uſeful purpoſe until 1793 or 1794, when the events of the French revolution had directed all the energies of that ingenious people to the improvement of the art of war. A report made by Barrere to the ſitting of the French Convention in Auguſt 1794, attributes the invention of the telegraph which they uſed to citizen Chappe.

"The new invented telegraphic language of ſignals is an artful

artful contrivance, to tranfmit thoughts in a peculiar language from one diftance to another, by means of machines, which are placed at different diftances of from twelve to fifteen miles afunder, fo that the expreffion reaches a very diftant place in the fpace of a few minutes. This is now brought to fuch a ftate of perfection, that a correfpondence may be conducted with Lifle, upon every fubject and every thing: even proper names can be expreffed; an anfwer may be received; and the correfpondence thus be renewed feveral times a day. The only thing which can interrupt their effect is the weather, when the air is fo very bad and turbid that the objects and fignals cannot be diftinguifhed. By this invention, remotenefs and diftance almoft difappear, and all the communications of correfpondence are effected with the rapidity of the twinkling of an eye. By its aid the operations of government can be very much facilitated, and the unity of the republic confolidated much more by the fpeedy communications with all its parts.

"The greateft advantage can be derived from this mode of correfpondence, becaufe, if thought proper, its objects need only be made known to certain individuals, or to one individual alone, or to the extremities of any diftance; fo that the Committee of Public Welfare may at prefent carry on a correfpondence with the reprefentative of the people at Lifle, without any other perfons being acquainted with their objects. If Lifle was even befieged, we fhould know every thing at Paris that might happen in that place, and could fend thither the decrees of the Convention without the enemy being apprifed of it, or able to prevent it."

M. Chappe's or the French telegraph is reprefented in *fig.* 4, which is made from fome fketches taken from the telegraph on the palace of the Louvre, at the time of its firft eftablifhment, and publifhed in the Monthly Magazine, and other publications.

A B is a beam or ftrong maft of wood, erected perpendicularly from the centre of a cabin or fmall houfe fituated on a rifing ground: it muft be about 15 or 16 feet high above the top of the houfe. C D is a balance-beam, jointed to the top of the maft, fo as to be moveable on its centre, like a fcale-beam. This balance-beam, which is called the long indicator, may be placed vertically or horizontally, or any how inclined, by means of ftrong cords, which are attached to the central wheel or pulley D, which has two grooves in the edge to receive the cords. The long indicator is about 11 or 12 feet long, and 9 inches in breadth; and at each extremity it carries fecondary indicators F, G, which likewife turn upon centres or joints, by means of four cords, which are conducted through a hollow in the centre pin or axis of motion of the long indicator, otherwife the motion of the long indicator to put it into different pofitions, would derange the cords, and alter the direction of the fecondary indicators, which are capable of being placed in any pofition with refpect to the long indicator, by thofe cords being conducted by pullies down into the cabin, and there attached to other mechanifm, by means of which the whole machine is moved, and can be made to affume any of the pofitions reprefented by the fmall figures in the plate, in which pofitions it forms a variety of different characters, to denote the letters of the alphabet or numerals.

That the indicators may be very light, and at the fame time oppofe the leaft refiftance to the wind, they are formed by frames, the interior parts of which are filled up by fmall oblique and feparate boards, which however, being feen in front, appear contiguous. The ends of the fmall indicators are carried beyond the centres, and carry counter-weights to balance the weight of the indicators: but thefe ends and balances are made fo as to be invifible at a diftance.

It is eafy to find the number of fignals poffible to be made with this telegraph: for if we confider the great indicator as being fixed, we fhall find that each of the fmaller ones may diftinctly take five different pofitions: two where it makes a right angle with the great indicator; two where it makes an angle of 45°; and one where it falls back upon the great one, in which cafe it will difappear. Three other diftinct pofitions might alfo be created; one where the fmall indicator would be horizontal with the great one, and two where it would make an angle of 135° with it.

The leffer indicators then, confidered as fingle movers, will furnifh five times five, or twenty-five fignals. As the great indicator is alfo a mover, there are twenty-five times as many fignals as this indicator has diftinct pofitions; and as it has but four diftinct pofitions, one horizontal, one vertical, and two inclined, there are in all four times twenty-five, or one hundred fignals.

The manner of ufing the telegraph was as follows: At the firft ftation, which was on the roof of the principal pavilion of the Louvre at Paris, M. Chappe, the inventor, received in writing, from the Committee of Public Welfare, the words to be fent to Lifle, near which the French army was at that time ftationed. Each of the telegraphs in the line employed three perfons to work it: one to move the machine, which was done by a fingle motion of a winch, and could therefore be effected in a moment. A fecond perfon was employed with a telefcope to obferve the telegraphs of the two adjacent ftations, to receive the communications, and to know by their fignals, if they had underftood the communication made to them, and alfo to receive the anfwers. The third perfon was employed to write down the obfervations made by the fecond perfon, and to give orders to the firft. The ftations were about three or four leagues diftant, and an obfervatory was fituated near the Committee of Public Safety at Belleville, to obferve the laft telegraph.

The grammarian will eafily conceive that fixteen figns may amply fupply all the letters of the alphabet; fince fome letters may be omitted, not only without detriment, but with advantage. Thefe figns, as they were arbitrary, could be changed every week: fo that the fign for B one day, might be the fign for M the next; and it was only neceffary that the perfons at the extremities fhould know the key. The intermediate operators were only inftructed generally in imitating and repeating thefe fixteen fignals, which were fo diftinct, and fo marked, as different the one from the other, that they were eafily remembered. The conftruction of the machinery within the houfe was fuch, that each fignal was uniformly given in precifely the fame manner at all times. It did not depend on the operators' manual fkill, becaufe the pofition of the arms could never for any one fignal be a degree higher or a degree lower than was intended, their movements being regulated mechanically. M. Chappe, having received at the Louvre the fentence to be conveyed, gave a known fignal to the fecond ftation, which was Montmartre, to prepare: at each ftation the obfervers with telefcopes were on watch, and each telegraph immediately gave the fignal of preparation which he had received; and this being communicated fucceffively through all the line, all the machines were brought into a ftate of readinefs. The perfons at Montmartre then received, letter by letter, the fentence from the Louvre, which they repeated with their own machine, and this was again repeated from the next height, with inconceivable rapidity, to the final ftation at Lifle, where the obfervations were written down, and tranflated according to the key which had been before arranged to be ufed, either by previous concert, or by fome particular fignal made with the telegraph, to denote that key which was ufed. The time

taken

taken up for each movement was about twenty feconds ; of which the motion alone took up four feconds ; and during the other fixteen, the telegraph was kept ftationary, that it might be diftinctly obferved and written down by the people at the next ftation. The figns were fometimes made for words, and fometimes for letters : when in words, a fmall flag was hoifted ; and as the alphabet could be changed at pleafure, it was only the correfponding perfons at each end of the line who knew the meaning of the figns. In general, news was given every day about eleven or twelve o'clock ; but the obfervers were conftantly on the watch, and as foon as a certain fignal was given and anfwered, they begun from one end to the other to move their machines. All the moveable parts were painted of a dark-brown colour, to be more diftinctly vifible when viewed againft the bright fky.

Another line of telegraphs, from Paris to Landau, was completed in 1796 : the firft of them was erected on a pavilion of the palace of the Tuilleries. The conftruction was more complicated than the firft. A fixed black bar, fifty feet long, was fupported horizontally by four uprights. This bar carried five indicators, fimilar to the fmaller indicators of the machines before defcribed. Two of the upright pofts which fupported the horizontal bar, carried each a fimilar indicator : in this way the centres of the indicators were all ftationary, inftead of having the long indicator with fmaller ones at the extremities. Thefe feven indicators were moved by pullies, in the ufual way ; and there was none of the difficulty of conveying the communicating cords through the hollow axis of the central pulley. Each of the indicators could take feven diftinct pofitions ; *viz.* for thofe which were fupported by the horizontal bar, two vertical, four inclined, and one horizontal ; and for thofe indicators which were fupported by the upright pofts, one vertical pofition, four inclined, and two horizontal ones. The number of combinations which fuch a conftruction can make, is $7 \times 7 \times 7 \times 7 \times 7 \times 7 \times 7$, which gives the aftonifhing number of 823,543 fignals. This number, which is eight thoufand times larger than that of the fignals of the firft telegraph, is doubtlefs more than fufficient : it, however, allowed them to abridge confiderably the telegraphic language, and to tranfmit whole phrafes at a time.

The Englifh Telegraph.—M. Chappe's machine was known in England not long after it was fet up, and two working models were made at Frankfort, and fent to England, by which the plan and alphabet became known ; and its advantages were fo obvious, that the Britifh government tried various experiments on telegraphic communication, and at length lines were eftablifhed from the Admiralty-office to Deal, Portfmouth, and other points of the fea-coaft. Thefe machines are upon the conftruction reprefented in *fig.* 3, not being made with indicators, like the French, to move upon centres into different pofitions, but with fix octagon boards, each poifed upon an horizontal axis, and fupported in a frame in fuch a manner, that each can be placed vertically, and will then appear of the full fize ; or if they are placed edgeways, as fhewn at d, the narrow edge alone will be prefented, and this at a fmall diftance will be invifible. The boards are turned by means of cranks, r, upon the end of the axles, and from thefe, lines defcend into the cabin below, where each has a handle, which is confpicuoufly marked with the letter or character which will be indicated when the handle is drawn down.

By the changes in the pofition of thefe fix boards, thirty-fix changes may be eafily exhibited, and the fignal to reprefent any letter may be made. By certain pofitions, a variety of other things may be fignified, according to the will of the two perfons employed at the two extreme pofts in making the fignals. Thus, one board being in a horizontal pofition, and the others fhut, or in a perpendicular fituation, may denote the letter a ; two boards only being in a horizontal pofition may give the letter b ; three in the fame manner, the letter c, and fo on. As there may be made as many changes with thefe boards as with the fame number of bells, the letters of the alphabet may be made with eafe, and a fufficient number of fignals may be formed for extraordinary purpofes.

This number of changes is fufficient ; for as this telegraph is intended to convey information by reprefenting the fucceffive letters of each word, a greater number of changes than would exprefs all the effential letters of the alphabet, the numerals, and three or four more fignals, to fignify attention, repeat, period, error, &c. would be only embarraffing, and liable to error. It is a good fyftem to fpell every word, rather than attempt to communicate entire words or fentences, as by keeping always to one fyftem, miftakes are avoided. The communication is in itfelf fo rapid, that it is more important to attain certainty in the operation, than to make any facrifice for the fake of difpatch.

This telegraph was judicioufly contrived to have a fufficient number of combinations, without having more than neceffary. Five boards would have been infufficient, and feven more than were neceffary. But there are feveral ferious objections to it : the form renders it too bulky to admit of being raifed to any great height above a building ; and after all, the boards are lefs evident to the eye at a diftance than the indicators of the French machine. The ftations muft, therefore, be nearer together, to render the bars of the frame vifible as well as the boards. Neither can this telegraph be made to change its direction, but it can only be feen from one particular point. It was found neceffary to have two telegraphs at the Admiralty, one for each line, and alfo at any point of the line where it branched off.

To enable the telegraph to be ufed at night, the firft French telegraph which was fet up was furnifhed with Argand lamps, but the Englifh was never ufed in that manner. It would have required a great number of lamps ; becaufe it would have been neceffary to have fixed lamps to indicate the points of the frame in which the boards work, as well as the boards themfelves.

Thefe two forms of telegraph, the French and the Englifh, continued in ufe for fome years. The French made frequent changes in the details of their fyftem, though for a long time they preferved M. Chappe's machine ; and when Buonaparte affumed the fupreme command in France, the original machines were taken down. A number of machines were fet up on various parts of the French coaft, and were ufed in fome of their campaigns : they were of a very temporary nature, and compofed of the fimpleft materials, of mafts and yards, with large balls at the end ; the yards were inclined by cords, fo as to effect the fignals on the fame principle as M. Chappe's original machine. About 1806 a new fet of telegraphs was eftablifhed on the whole extent of the coaft of the French empire, of which the following defcription is given by captain C. W. Pafley, in the Philofophical Magazine. See *figs.* 5 and 6.

Modern French Telegraph.—Every telegraph confifts of an upright poft, R, to which are attached three arms, A, B, and C, exactly fimilar to each other, and each moving upon its own diftinct fpindle or axis. The axis of one of thefe arms, A, is near the head of the poft R ; and the diftance between the centres of motion of either of the two uppermoft arms, and the centre of the one immediately below it, is rather lefs than double the length of one arm. The higheft of the three arms, A, can exhibit feven diftinct positions, as is shewn by the dotted lines A 1, A 2, A 3, &c.; but the other two arms, B and C, can only exhibit six positions each, because they are hidden by the post when in a vertical position. The total number of combinations, or of distinct signals, which can be made by this telegraph, will constantly be three hundred and ninety-one; but as the arm A, when in the vertical position A 4, may appear to be part of the post, R, it is not safe to employ that position, and this will reduce the number of signals to three hundred and forty-two. As only three bodies are employed in this telegraph, it appears very superior to the Admiralty telegraphs used in England, which, by the combination of double that number of bodies, can only make sixty-three distinct signals. Captain Pasley observes, that the mechanism of the French telegraphs just described, must be either imperfect, or the men employed in working them must have been very unskilful, for the signals were made and repeated in an awkward manner, with what seemed to him much unnecessary loss of time. But these defects, it will be evident, detract nothing from its merit as an invention. In regard to the mechanical construction, he could only observe that the arms, which were painted black, and appeared solid at a distance, were made in the fashion of a Venetian blind, in order, it may be presumed, to diminish the action of the wind in bad weather. Each arm had a counterpoise of thin materials painted white, which, unless the observer be very near the telegraph, becomes invisible.

Fig. 5. shews the telegraph in a state of rest, the dotted lines marking the several positions in which the arms can be exhibited. *Fig.* 6. is a specimen of the telegraph at work. *Fig.* 7. shews the construction of one of the arms on a larger scale, D E being the part which is fashioned like a Venetian blind, and E F the counterpoise.

Sir Home Popham's Telegraph at the Admiralty. — The original telegraphs at the Admiralty, with the six boards, have been lately taken down, and a new kind substituted. It is on the same principle with the French, being an upright mast with two indicators, which move upon centres one above the other, in the manner of the last described. The mast is made to turn round on its vertical axis, so as to present its arms successively to all quarters, when required. The mechanism, which is the invention of sir Home Popham, is the best which has ever been contrived, the movements being very simple, and effected by iron spindles and endless screws, so that the indices below are certain to accompany the indicators exactly in their movements, and place them precisely in their required positions, which cannot be done by the old machinery with cords, because they are liable to expand and contract by wet or dry weather. The machinery for this set of telegraphs was constructed in the most substantial manner by Mr. Maudslay in 1816. (See *figs.* 8, 9, and 10.) L M is a tall mast of an hexagonal form, framed up from six fir planks put together at the angles, and bound by iron hoops at different places, so as to be hollow within. The lower end, L, terminates in a pivot, and the mast is retained in a vertical position by a circular collar at O, which embraces it, and is supported in the roof of the building. The two arms, P M and Q R, are moveable upon centres, one at the top of the mast and the other half way down. When the arms are placed in a vertical position, they shut up within the hollow of the mast, so as to be entirely concealed; and for this purpose, two of the six sides are cut away at the upper part, so as to leave an opening through the mast of sufficient width to admit the two arms to work in it. To communicate motion to the arms, a small toothed wheel is fixed upon each arm at the centre of motion, and close to the side of the arm. The teeth of these wheels are actuated by endless screws or worms, formed on the upper ends of the long spindles *d e* and *f g*, which descend down to the bottom of the hollow mast, and have small bevelled wheels upon them, which are actuated by wheels of similar size, fixed on the ends of short horizontal spindles, which have handles, *p*, *q*, applied at the extremities. (See *fig.* 11.) By turning these handles, motion is given to the vertical spindles *d* and *f*; and by means of the endless screws upon the upper ends of them, the wheels at M and R, on the centres of the arms, are turned round, and the arms are put into any required position. But in order that the people below may at all times know exactly what positions the arms stand in, two dials, *m* and *r*, are formed on the lower part of the mast, the upper one, *m*, being for the upper arm M, and the other, *r*, for the lower arm R; and each dial has an index or hand, which turns round with a motion exactly corresponding to the motion of the arms. For producing this motion, the axle of each hand or index has a small toothed wheel, *s* or *t*, (*fig.* 11.) fixed upon it in the middle; and an endless screw is formed upon the upright spindle to work in the teeth of the wheel. The wheels upon the centre of the arms, and those upon the axes of the indices, have the same number of teeth; and as every turn of the spindles and screws will move the wheels round one tooth, the angular motion of the arms, P M and Q R, and the hands, *m* and *r*, will in all cases be the same.

The dials are each divided into eight, corresponding with the eight positions in which the arms are to be exhibited: *viz.* pointing vertically; 1st, upwards; and 2d, downwards: pointing horizontally; 3d, to the right; and 4th, to the left: pointing upwards at an inclination of 45 degrees; 5th, to the right; and 6th, to the left: pointing downwards at an inclination of 45 degrees; 7th, to the right; and 8th, to the left. But of these eight positions, only the four last are made use of to represent characters; because, in the two vertical positions, the pointers enter within the mast, and cannot therefore be seen whether they are pointing upwards or downwards: the horizontal positions of the arms are reserved for the necessary signals of preparation, &c. Each arm, then, has four positions, in which it will express different signals; and these positions are all made with the pointer, at an inclination of 45 degrees from the horizontal line.

These signals either express the letters of the alphabet, or the numeral characters, according to previous arrangement, which must be made known by exhibiting a preparatory signal, before the communication is begun. The signal to prepare for receiving letters is the lower arm extended horizontally to the right; and for the numerals, both arms are extended horizontally to the left.

The upper pointer, P M, used by itself, at an elevation of 45 degrees, denotes,

A, or 1, when pointing upwards to the left.
B, or 2, when pointing downwards to the left.
C, or 3, when pointing upwards to the right.
D, or 4, when pointing downwards to the right.

The lower pointer, Q R, used by itself, at an elevation of 45 degrees, denotes,

E, or 5, when pointing upwards to the left.
F, or 6, when pointing downwards to the left.
G, or 7, when pointing upwards to the right.
H, or 8, when pointing downwards to the right.

It is easy to conceive, that, by repeating all these positions with both arms exhibited together, instead of one singly, various combinations may be made, which are sufficient

ficient to exprefs all the remaining letters, and fome other neceffary fignals.

The dial for each arm is double; that is, a dial is fixed at each fide of the maft, and the axles of the indices or hands proceed quite through the maft, fo as to have a hand at each end. Thefe dials are not numbered exactly fimilar to each other, but are reverfed; and the two indices on the oppofite ends of the fame axle, though they point in one direction, do not indicate the fame numbers on the two dials; becaufe each dial is adapted to indicate the meaning which the different pofitions of the arms will have, when the telegraph is viewed on that fide to which the dial faces.

For when a fignal is made, that arm which projects from the right-hand fide, if the telegraph is examined on one fide, will project on the left hand, when the telegraph is viewed on the other fide.

It was before ftated, that the telegraph can be turned round, fo as to prefent its arms to any direction. This is done by the pivot, L, at the lower hand; but to hold it faft in the defired direction, a circular iron plate is placed on the floor, with holes in it; and a bolt, W, is fitted into two eyes, which are fixed to the axle of the maft. The point of this bolt drops into any of the holes in the plate, and thus holds the maft firm; but if the bolt is lifted up, to draw its point out of the holes, it can be turned round. The arms are made with boards, like Venetian blinds; and each has a piece of caft-iron at the oppofite end, to counterpoife the weight, and make the arm move freely into all pofitions.

Since the telegraph has been brought into actual ufe, its great utility has been obvious; and many ingenious perfons have ftudied the means of fimplifying the methods of reprefenting the fignals, with a view to obtain the greater facility and rapidity of communication. This would enable us to avoid the danger of miftakes, by being able to repeat the whole communication feveral times, which at prefent is tedious. Many of thefe contrivances difplay great ingenuity; but it appears to us, that the defect or difficulty of communicating detailed intelligence by means of telegraphs, arifes from the complicated conftruction of all the languages at prefent in ufe, rather than from any defects in the machines, which have been propofed to exhibit the fymbols; and that to perfect telegraphic communication, it would be neceffary to invent a new and more perfect language, which would be a moft valuable acquifition, to facilitate all other modes of communicating ideas.

All languages originated in a very rude ftate of fociety, and were at firft limited to the expreffion of very fimple ideas. As men advanced in civilization, they found the neceffity of increafing the number of their words; and to enable them to exprefs more complex ideas, compound words were occafionally introduced; but, in all cafes, knowledge muft have made a confiderable advance, before any arrangement or claffification of words was imagined: becaufe the neceffity of any grammar would not be difcovered, until the number of words were fo multiplied, as to render the ufe of them troublefome, and liable to confufion. Before a fyftem of grammar was eftablifhed, no improvements could be made in a language, except by the addition of new words; and every fuch addition muft have introduced new difficulties in the ufe of the language. Even when a fyftem of grammar is completely eftablifhed, as is now the cafe in all the languages of civilized nations, the number of words which were invented, or introduced without any fyftem, is fo confiderable, as to prevent that perfection of expreffion which might be obtained, if the language had been wholly conftructed in an advanced ftage of fociety. There is no doubt but a new language might be contrived, which, with a very fmall number of words, compared with any of the known languages, might exprefs all ideas in a much more expeditious and definite manner than they do. In oral communication, this defective conftruction of language, and the want of precifion, is little experienced, unlefs by thofe who begin to learn a foreign language; becaufe the extreme rapidity of expreffion enables us to amplify and enlarge upon any fubject, fo as to elucidate any words or phrafes which are not directly applicable to the expreffion of an idea to be communicated, or which are at all indefinite. In writing or reading, the deficiency of language is more obfervable, from the greater difficulty of expreffion and communication. But when we attempt to converfe by fignals, we experience in its full force the great complexity of language, and find that it becomes a tedious operation to reprefent a fentence clearly by fignals, which is fpoken or written in a moment; and this muft continue to be the cafe, even if the mechanical operation of exhibiting the fignals is reduced to the utmoft poffible fimplicity. As no fuch fcientific language as that which we hint at has been perfected, we muft content ourfelves to find the beft means of communicating our ideas by fignals, which fhall indicate the letters and words of our prefent languages: and this may be done in two ways; firft, by characters or fignals, which fhall either exprefs the letters of the alphabet, or words, or, in fome cafes, complete fentences. The other method is to exhibit fignals, which fhall indicate numbers; and thefe numbers can be tranflated into words, by means of a dictionary in which every word is numbered. The telegraphs which we have defcribed are of the former clafs, and we have explained the manner of ufing them; but the latter kind requires a greater variety of fignals, becaufe they muft be capable of making as many fignals as there are words in the language in which the communication is intended to be made. There is fome difficulty in making a telegraph fo univerfal as this requires, otherwife the numeral method has decided advantages, in the convenience with which it can be carried on by means of a common dictionary, alphabetically arranged, and in which every word is regularly numbered from one end to the other. In this any word can be inftantly found, by its place in the alphabet; and the number correfponding to it being exhibited by the telegraph, and obferved by the oppofite party, he can as quickly find out the fame word in the dictionary by means of its number.

The numeral method is perhaps the eafieft of all others, and may be exhibited by fire and fmoke in the fimpleft manner, without any telegraph or complicated apparatus being made for the purpofe.

The meaning of a fignal is afcertained by the continuance or difappearance of fire and fmoke at a different place. In the day-time, the fmoke on a particular hill may give notice to an obferver on the next hill, that a communication is to be made: he of courfe will anfwer it by fmoke, to fhew that he is upon his watch. The fmoke will then difappear on both hills, by a cover being placed over the fire; which, being taken off and put on again repeatedly, will fhew a fucceffion of clouds of fmoke rifing at proper intervals in the air. The obferver notes the number of times that the fmoke rifes without a confiderable interval, fuppofe three times; and he then writes down the number 3. After a more confiderable interval, determined on by the parties, the fmoke rifes again, we will fuppofe four times; he writes down the number 4. He has now the number 34 to communicate by fignals to the next poft. At night this is done by a fucceffive appearance and difappearance of fire.

As the number denoted by the fucceffive appearance of

 fmoke

ſmoke or fire, or firing of guns, may, if it is a large number, be liable to miſtake, a learned profeſſor in Germany propoſed to ſhorten the numbers employed, by uſing a quaternary inſtead of the decenary arithmetic. Thus, according to his ſyſtem, the units were to be placed as in common arithmetic; a figure in the next place, to the left hand, inſtead of denoting the number of tens, was a multiple of 4, denoted by the figure, that is, it denoted the number of fours to be expreſſed; in the third place, the figure denoted the number of ſixteens inſtead of hundreds; and the fourth place of figures would be ſixty-fours inſtead of thouſands; and ſo on. *E. gr.* To write down 95, he placed his figures thus: 1133; the 3 in the place of units denoted 3, the next 3 denoted 3×4, or 12; the third figure, 1, denoted 4×4, or 16; the next figure, 1, denoted $4 \times 4 \times 4$, or 64; conſequently 1133, in the quaternary arithmetic, was equivalent to $64 + 16 + 12 + 3 = 95$ in the common decimal numeration. The advantage propoſed by thus changing the figures was, that in making the ſignals 95, there muſt be fourteen firings, or appearances of ſmoke, which, in the other mode, is done by eight firings. In this arithmetic, a greater number than four never appears; and there is leſs danger in miſcounting ſo ſmall a number. Some of the numbers in the dictionary muſt be devoted to the ſingle letters of the alphabet, as it is by means of them alone that proper names can be made out.

Mr. Edgeworth, who, we believe, firſt introduced the numeral ſyſtem of communication, gives the following account of its advantages, in point of ſecrecy, over the alphabetical method, which is a great object in telegraphic communication. Although the alphabet may be varied at pleaſure, and any arbitrary ſigns employed, yet theſe are poſſible to be deciphered by rules which depend upon the uſual arrangements of letters: thus, for inſtance, a ſingle character being exhibited as a word, muſt, in the Engliſh language, be either A or I. The proportion which exiſts between the number of words of one, two, three, or any greater number of letters, can be claſſed in catalogues, and from theſe the monoſyllables of any cipher are eaſily obtained; and from the letters of theſe monoſyllables, the letters of longer words are diſcovered. By ſimilar rules, ſome of which are very ingenious, and depend upon the philoſophy of language, any alphabetical cipher may be eaſily unfolded. (See CIPHER.) But theſe rules, excepting a few of them, are uſeleſs, when ciphers are employed to denote entire words; and the moſt obvious mode of diſcovery may be avoided, by omitting thoſe common words which occur ſo frequently in every language, as *the*, *and*, *that*, *to*, &c.; and even ſuppoſing that, from its frequent recurrence, any word ſhould be diſcovered, no progreſs can be made from ſuch data, for the cipher of any word is an iſolated fact which leads to nothing farther.

Suppoſe the knowledge of any particular vocabulary ſhould fall into hands for which it was not intended, a ſlight change in the numeration, without any actual change of the figures, would prevent diſcovery: for inſtance, ſuppoſe it is ſettled between the parties, that 6, or any other number, is to be added or ſubtracted from the numbers which are exhibited before referring them to the vocabulary. The advocates of the numeral ſyſtem ſtate, that a letter can be communicated much quicker by ſignals which expreſs words, than by ſignals which expreſs only letters. Words may be forwarded as faſt as they can be looked out in a dictionary, and even faſter, whilſt only an equal number of letters could have been communicated by the alphabetical mode. Another alleged advantage reſulting from the uſe of words in the telegraphic correſpondence is, that the words of the ſame meaning in different languages having the ſame number attached to each, a correſpondence could be carried on from one language into another, which, though not grammatically correct, yet would be ſufficiently intelligible. Proper names muſt be ſpelt, which may eaſily be done, every letter having a correſponding number.

Mr. Richard Lovel Edgeworth, in the Tranſactions of the Royal Society of Ireland, vol. vi. p. 125, has deſcribed his telegraph, which is ſimple, and admits of very numerous combinations: it is intended to repreſent numbers to which words may be referred.

The machinery conſiſts of four indices or pointers, each capable of revolving on a centre or axis, ſo as to aſſume different poſitions. The ſhape of each pointer is that of an iſoſceles triangle, of which the baſe is rather leſs than half the perpendicular. The four pointers are placed in a row, as ſhewn by *fig.* 12, and, as in common numeration, the right hand repreſents units; the ſecond from the right, tens; the third, hundreds; and the fourth, thouſands. It is eaſy to diſtinguiſh whether a hand moving vertically, points perpendicularly downwards or upwards, horizontally to the right or left, or to any of the four intermediate ſituations: this produces eight poſitions, which can be made by each pointer; but of theſe eight poſitions, ſeven only are employed to denote figures; the upright poſition of the hand or pointer being reſerved to repreſent 0, or zero. The figures thus indicated refer to a vocabulary, in which all the words are numbered. Telegraphs of this kind, which are to be fixed at permanent ſtations, which may be ſeen clearly with tolerable glaſſes at twenty miles diſtance, are to be mounted on ſtone or wooden pillars, ſixteen or twenty feet high; four of which muſt be ſolidly erected in a row; and on the top of each a moveable circle or platform turns horizontally upon a centre, in the manner of a moveable windmill head. Acroſs the platform an axis lies horizontally, and carries the arm or pointer, fixed vertically at one extremity of the axis, whilſt, at the other end, are eight handles to turn the pointer round by. The handles are fixed in their different poſitions by a catch or alidad. By means of the platform, the pointer may be turned to any part of the compaſs; and as one ſide of it is painted black, and the other white, either ſide may be employed, as the colour of the clouds, or the ſituation of the place, may require.

In managing a correſpondence by theſe machines, it is neceſſary to have certain ſignals eſtabliſhed; nor are theſe ſignals merely arbitrary; it is abſolutely neceſſary that they ſhould be made by the two external pointers of the row, *viz.* units and thouſands; or by the two internal pointers, *viz.* tens and hundreds; elſe they could not be repeated by the intermediate ſtations without confuſion; becauſe, in the middle ſtations, that pointer which repreſents thouſands, when conveying a meſſage eaſtwards for inſtance, muſt, when an anſwer is returned to an oppoſite direction, repreſent units. The ſame change will take place between the pointer that denotes hundreds and tens.

When any communication is to be commenced, the pointers that denote thouſands and units are to be whirled round till the ſame is done at the correſponding ſtation. When this ſignal has been anſwered, the perſon who gave it proceeds to ſend his intelligence. As ſoon as he begins, the pointer of hundreds at the oppoſite ſtation is turned to 2, and kept in that poſition till the word is made out from the vocabulary; the pointer is then turned round to 0, or zero. The perſon who is ſpeaking, when he perceives by this ſignal that he is underſtood, turns all the machines to 0, which is always to be done at the end of every word.

When all his machines are in this poſition, his correſpondent again turns his pointer belonging to the place of hundreds to 2, to ſhew that he is ready to receive the intelligence, and it it is to remain there till he receives another word, and fo on, till all that is meant to be faid is finifhed: the pointers of *thoufands* and *units* are then to be vibrated backwards and forwards, with the points downwards, like pendulums, till the famé is done at the oppofite ftation.

If any interruption takes place on either fide from a cloud, or fhower, or any accident, it is to be indicated by vibrating *thoufands* and *units*, with their points upwards; which fignal muft be repeated from the oppofite ftation; and whoever has made the fignal of interruption, muft make the fignal of recommencement, when he is ready to proceed. This fignal is by vibrating *hundreds* and *tens*, with their points upwards, and when this is anfwered, (but not before,) the bufinefs may proceed. It fhould be obferved in general, that every fignal fhould be acknowledged by the party to whom it is addreffed.

The vocabulary correfponding with the numbers denoted by this machinery is compofed of a large book, *fig.* 13, with mahogany covers, framed, to prevent them from warping. Its fize, when opened, is 47 inches by 21; it confifts of 49 double pages, that is to fay, each fheet is folded in the middle, and when it is opened forms one page.

The book is divided into feven parts by thin flips of mahogany, which ferve to open it eafily at each of thefe divifions, every one of which contains feven pages, and each page forty-nine words. No more than forty-nine words are contained in each page, becaufe the numbers 8 and 9, and zero, are not admitted. This omiffion arifes from the ftructure of the machinery, which points only to feven numbers, referving 0 for a point of reft, at which point the hands indicate nothing. In every hundred, therefore, only forty-nine numbers are ufed; and in every thoufand, only feven hundreds are counted. Each divifion of the book, feparated by the mahogany rulers, contains all the efficient numbers in feven hundred. Each of thefe rulers projects beyond the fides of the pages, and is numbered in fucceffion from 1 to 7; and they are fo placed below one another, as to permit the numbers on all fides of them to be feen at once, as in the figure.

When any number of thoufands is pointed out, it can, by means of thefe rulers, be immediately felected: the feries of feven pages, which one of thefe rulers opens, is cut, like the alphabet of a ledger, at the edge in feven divifions. By thefe means, the page containing the hundred which is wanted is inftantly found. In the page thus obtained, the tens, from 10 to 70 inclufive, are divided from each other, fo as to be inftantly diftinguifhable, and the units under each divifion are in like manner eafily felected.

The following is a fpecimen of feven lines of the firft page, and though it is but one-tenth of the real fize, it is fufficiently diftinct. Its contents are divided into eight claffes, the words in each clafs being numbered downwards, from 1 to 77, omitting all cyphers, or zero, and all eights and nines. When once the clafs required is afcertained, any number in the page can be found immediately. As for inftance, the reader will eafily felect Clafs VII. N° 11, Clafs IV. N° 15, and fo of the reft. Nothing remains to be explained but the manner in which the clafs in each page is pointed out by the machinery. For this purpofe, before the pointers are turned to any fet of figures, the pointer that reprefents thoufands is turned to the clafs that is wanted, and as foon as the correfpondent anfwers this fignal, thoufands is returned to 0. Then all the pointers are moved to the places which denote the figures required for any word or fentence. When the clafs is thus afcertained, an index, which flides on the mahogany cover of the book, is fet to the column belonging to this clafs. When an obfervation is made, the number of thoufands can be opened by the ruler. As foon as it is read off by the telefcope, the number of hundreds is opened by the pages, where they are cut away, and the number of tens and units is feen on the page. As the pointers are moved in fucceffion from thoufands to units, the different divifions of the book can be opened as faft as the pointers are moved.

The principal objection to Mr. Edgeworth's machine is, that it would be of a vaft fize, and each pointer would require a man to work it. He defcribes, at the end of his paper, a portable machine, which is made of fpars and poles jointed together, and braced by cords. We think the fecond kind of French telegraph, which was fet up between Landau and Paris, would anfwer the purpofe very well: it has five indicators, and the movements are made by machinery in the houfe below.

Major C. Le Hardy, in the Tranfactions of the Society of Arts for 1808, vol. xxvi. has defcribed a telegraph which is well adapted for exhibiting fignals which fhall indicate numbers. It has four indices or pointers, each confifting of a long arm, carrying a fquare index-board or pointer at the extremity. One of thefe pointers reprefents units; the fecond, tens; the third, hundreds; and the fourth, thoufands. All the four indices move on a common centre by the machinery; and to diftinguifh them one from another, each board is placed at a different diftance from the centre of motion, fo that in their motion they defcribe four circles of different radii. The pofition of the arm, with refpect to the horizon, is made to indicate the number which is to be expreffed by each index refpectively, and there are ten different pofitions for each, anfwering to the numeral characters.

To identify thefe ten pofitions, a large frame is fixed clofe behind the pointers, parallel to the plane of their motion; and

and this frame supports ten radial bars, which diverge from the common centre of motion. The radii are again interfected by other bars, forming four concentric arcs of circles, each correfponding in radius with the length of one of the four pointers or fignal-boards. By means of the radii, the pofitions of the pointers, and their correfponding numbers, are read off, whilft the arcs ferve to diftinguifh the different pointers of units, tens, hundreds, and thoufands, becaufe they always fhew the length of the arms from the centre. By this machinery, 10,000 can be exhibited; and for higher numbers, there are two fquare fignal-boards, which can be turned fo as to be invifible or vifible at pleafure; one reprefents 10,000, and the other 20,000, and both together 30,000, either of which numbers is to be added to the number fhewn by the arms, according as thefe fignal-boards are exhibited. By this addition, this telegraph can exhibit as high as 40,000.

The frame with radial bars is a good method of reading off the exact pofition of the arms; and it is fo much more certain than trufting to the eye alone, that by its aid the arms may be fhewn in a much greater number of pofitions; ftill, if each arm is diftinctly capable of exhibiting ten fignals, it will be fufficient for the numeral method. Mr. Edgeworth's pointers, as we have feen, were only capable of eight pofitions for each; and this obliged him to mutilate the fyftem of numbers, by taking away all the eights, nines, and zero.

The dial-plate of a clock has been propofed as a model, and would make a moft excellent telegraph, as it might exhibit 144 figns, fo as to be vifible at a great diftance. The dial fhould only be divided into fix divifions inftead of twelve; and this being raifed twenty or thirty feet above a building, and the indices and the dial being painted with very diftinct colours, would be clearly vifible. The dial, if fupported on one poft, might be always turned to the direction in which the information was to be conveyed.

In the Supplement to the Gentleman's Magazine for 1794, a telegraph is defcribed, which confifts of a femi-circle placed in a vertical pofition on a ftrong ftand. The circumference is divided into twenty-four divifions, which are rendered vifible by circular holes cut through the femi-circle. In the centre is an index, which can fucceffively be brought to point out any divifion, very much in the manner of the dial of a clock. In the night-time each divifion is to be furnifhed with a lamp, and the index is made fufficiently broad to eclipfe or hide any of the lamps at pleafure to which it is turned, and by this means the letters of the alphabet are to be defignated.

Mr. Garnet's Telegraph.—Of all the propofals for making a variety of fignals by the different pofitions of an index or pointer which moves on a centre, the following is the moft certain as to the identity of the pofitions, and hence it admits of the greateft number of fignals from each pointer. It has alfo a farther advantage, that there is no neceffity for any frame or dials, like the three laft defcribed machines, which, as their divifions are intended to be obferved at a diftance, muft be exceedingly large. The pointer or indicator of Mr. Garnet's machine is the fame as the foregoing, and its different pofitions reprefent different characters or letters: its length fhould be two and a half or three feet from the centre, for every mile of diftance. The diftant obferver can find out, and exactly read off thefe pofitions by a wire fixed acrofs the eye-piece of the telefcope with which he obferves, which eye-piece turns round on the end of the tube of the telefcope, fo as to bring the wire to be parallel to, or correfpond with the diftant pointer. This is as eafy to do as to look through the telefcope.

The index or pointer has a fmall circle fixed on its axis of motion, and turning round with it. This circle is divided into twenty-four divifions, or even more, and each divifion is lettered with a letter of the alphabet. A fixed index is alfo provided, to which any letter on the divided circle can be brought by turning the pointer round, and this determines the pofition of the pointer. Or, inftead of an index, the divided rim of the circle may be concealed in a box, with a hole at one fide juft fufficient to fee one letter or divifion at a time, and then there can be no miftake in fetting the pointer. The eye-piece of the telefcope is to be made to turn round upon the end of the tube, and is to have a circle fixed upon it fimilarly divided and lettered. A fine wire is alfo to be ftretched acrofs the centre of the eye-piece in the focus of its lenfes; and there muft be likewife an index or mark on the telefcope, to read the divifions of the circle on the eye-piece. If this circle be likewife enclofed in a box, having a hole to fee only one letter at a time, there will be lefs danger of miftake.

The inftrument being correctly adjufted, it is obvious that (the eye-piece of the telefcope being turned round till its wire covers or becomes parallel to the diftant pointer) the index on the telefcope will point out the fame letter on the divided circle of the eye-piece, as is indicated by the index and circle of the diftant pointer: hence the two parties have the fame letter or character prefented to them by their refpective inftruments.

The idea of reading the fignals by means of wires on the eye-piece of the telefcope is very valuable, and promifes many advantages. In intermediate ftations, there is always danger of confufion in making fignals to parties in both directions; becaufe an arm which inclines towards the right when the telegraph is viewed in one direction, in an oppofite direction will appear to incline to the left, and indicate a different thing: hence it is always neceffary for the parties to be informed, by a previous fignal, in what direction the communication is to be made, that the obfervers, when they fee a fignal made, may know whether it is intended for them, or for the next ftation beyond. Now when the telefcope is ufed, if the circle of each telefcope be figured to correfpond with the circle of the pointer which is to be obferved with it, all fignals will become intelligible to any party who obferves them.

The Rev. John Gamble fuggefted a form of telegraph, which confifted of four arms, each ten feet long, and furnifhed with a circular board at the end. All the four moved upon a common centre of motion, and independently of each other, fo that one, two, three, or four, could be exhibited at different degrees of elevation with refpect to the horizon, or with refpect to each other, fo as to afford a great number of fignals. One of thefe was erected in 1803 upon one of the towers of Weftminfter Abbey, but has long been removed. About the time when telegraphs were firft ufed, this gentleman publifhed a fmall pamphlet, entitled "Obfervations and Telegraphic Experiments," which contains fome good ideas.

Nocturnal Telegraphs.—In 1801, Mr. John Boaz of Glafgow obtained a patent for a telegraph, which effected the fignal by means of twenty-five Argand lamps. Thefe were arranged in five rows, with five in each row, fo as to form a fquare. Each lamp being provided with a blind, with which its light could be obfcured, the lamps could be made to exhibit letters and figures, the fame as Dr. Hooke's characters, by leaving fuch lamps only vifible as were neceffary to form the character. The machine is defcribed in the Repertory of Arts, Firft Series, vol. xvi. p. 223; and in the Philofophical Magazine, vol. xii. p. 84.

In

In the Philofophical Magazine, vol. xxix. Capt. Pafley has defcribed a telegraph, which is nearly the fame as Mr. Boaz's, but with fix lights only; alfo what is called a Polygramic telegraph.

The Chevalier Edelcrantz has defcribed a machine in the Tranfactions of the Society of Arts, which is for working the vanes of a telegraph with boards, like *fig.* 4, fo that by merely preffing keys, like an organ, and then turniug a haudle, the required fignals fhall be made. The telegraph was propofed with nine boards inftead of fix; but as we confider this form of telegraph decidedly inferior to thofe with arms moving on centres, we fhall not enter into any further defcription of it.

To conclude, we clafs the telegraphic art amongft thofe which are not carried to fuch a ftate of perfection as to be incapable of farther improvement: it is much to be wifhed that it could be fo fyftematized, that the communication of intelligence could be effected with the fame eafe and certainty as by writing. We are confident of the poffibility of this, from having obferved the abbé Sicard converfing with his deaf and dumb pupils by making figns of the fimpleft nature with the hands, in which manner he could communicate his ideas on any fubject with more rapidity than by writing.

TELEM, in *Ancient Geography*, a town of Paleftine, in the tribe of Judah, towards the extremity of this tribe, along the frontiers of Edom.

TELEMANN, Gio. Philip, in *Biography*, one of the greateft and moft voluminous mufical compofers during the firft fifty or fixty years of the laft century, in Germany. He was born at Magdeburg in 1681, and preceded Keifer as opera compofer at Hamburgh, for which city he produced thirty-five operas. His compofitions for the church and chamber are fuppofed to be more numerous than thofe of Aleffandro Scarlatti. In the year 1740, his overtures on Lulli's model amounted to fix hundred.

This compofer, like Raphael and fome other great painters, had a firft and fecond manner, which were extremely different from each other; in the firft he was hard, ftiff, dry, and inelegant; in the fecond, pleafing, graceful, and refined. Telemann, who lived to a great age, drew up a well-written narrative of his own life, in the early part of which he was an intimate acquaintance and fellow-ftudent with Handel.

The lift of Telemann's printed works, inferted in Walther's Mufical Lexicon in 1732, amounted to twenty-nine; and in Gerber's Continuation of Walther, fifteen or fixteen more are fpecified. But ftill double the number of thofe printed were long circulated in manufcript from the mufic-fhops at Leipfic and Hamburgh.

The beft account of Telemann's profeffional merit as a compofer, was publifhed at Hamburgh immediately after his deceafe at 85, in 1767, by profeffor Ebeling, an excellent mufical critic, a friend of Emanuel Bach, a man of a refined tafte, found judgment, and a perfect acquaintance with the merits and various ftyles of the great muficians of his country.

TELEMBO, in *Geography*, a river of South America, which joins the Patia, 8 miles N.W. of Baracoas.

TELENGUTES. See Teleutes.

TELENTO, a town of Perfia, in the province of Lariftan, on the fea-coaft; 10 miles S.W. of Congo.

TELEOLOGY, formed of τελος, *end*, and λογος, *difcourfe*, the fcience of the final caufes of things. This is an ample and curious field of inquiry, though pretty much neglected by philofophers.

TELEPHANES, in *Biography*, a celebrated performer on the flute in the time of Philip of Macedon. According to Paufanias he was a native of Samos, and had a tomb erected to him by Cleopatra, the fifter of Philip, in the road between Megara and Corinth, which was fubfifting in his time. The epitaph upon this mufician, which is preferved in the Anthologia, equals his talents to thofe of the greateft names in antiquity.

> "Orpheus, whom gods and men admire,
> Surpafs'd all mortals on the lyre:
> Neftor with eloquence could charm,
> And pride, and infolence difarm:
> Great Homer, with his heav'nly ftrain,
> Could foften rocks, and quiet pain:—
> Here lies Telephanes, whofe flute
> Had equal pow'r o'er man and brute."

Telephanes was clofely united in friendfhip with Demofthenes, who has made honourable mention of him in his harangue againft Midias, from whom he received a blow in public, during the celebration of the feaft of Bacchus. As this was a kind of mufical quarrel, we fhall relate the caufe of it.

Demofthenes had been appointed by his tribe to furnifh a chorus, to difpute the prize at this feftival; and as this chorus was to be inftructed by a mafter, Midias, in order to difgrace Demofthenes, bribed the mufic-mafter to neglect his function, that the chorus might be unable to perform their feveral parts properly before the public, for want of the neceffary teaching and rehearfals. But Telephanes, who had difcovered the defign of Midias, not only chaftifed and difmiffed the mufic-mafter, but undertook to inftruct the chorus himfelf.

TELEPHIASTRUM, in *Botany*, Dill. Elth. 375, fo called by Vaillant, from its refemblance to *Telephium*. See Talinum.

TELEPHIOIDES, Tourn. Cor. 50. t. 485. Dill. Elth. 377. t. 282. See Andrachne.

TELEPHIS, in *Ancient Geography*, a town of Afia, in Greater Armenia, fituated in the vicinity of the river Phafis.

TELEPHIUM, in *Botany*, a name adopted from Diofcorides, whofe τηλεφιον the plant we are about to defcribe was fuppofed, by Imperato, Clufius, and moft authors, to be. Dr. Sibthorp however fatisfied himfelf that the plant of Diofcorides was *Cerinthe minor*, and poffibly alfo the *afpera* of Willdenow. To this conclufion he was led, firft, by the authority of the famous old manufcript with drawings, at Vienna; and next, by obferving that *C. minor* is particularly common in Greece among vines in the fpring, as well as in other cultivated ground, as Diofcorides relates of his τηλεφιον. The yellow colour of the flowers alfo anfwers to his defcription, which our *Telephium*, in that point, does not, nor did Dr. Sibthorp obferve the latter in any part of Greece.—Linn. Gen. 149. Schreb. 201. Willd. Sp. Pl. v. 1. 1506. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 173. Juff. 313. Tourn. t. 128. Lamarck Illuftr. t. 213. Gærtn. t. 129.—Clafs and order, *Pentandria Trigynia*. Nat. Ord. *Holeraceæ*, Linn. *Portulaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of five oblong, obtufe, concave, keeled leaves, the length of the corolla, permanent. *Cor.* Petals five, oblong, obtufe, erect, tapering downwards, inferted into the receptacle. *Stam.* Filaments five, awl-fhaped, fhorter than the corolla; anthers incumbent. *Pift.* Germen fuperior, triangular, acute; ftyle none; ftigmas three, acute, fpreading. *Peric.* Capfule fhort, triangular, of one cell with three valves, and a central unconnected receptacle, half as long as the capfule. *Seeds* numerous, roundifh-kidneyfhaped.

Eff.

Eff. Ch. Calyx of five leaves. Petals five, inserted into the receptacle. Capsule with one cell, three valves, and many seeds.

1. T. *Imperati.* Green Orpine. Linn. Sp. Pl. 388. Willd. n. 1. Ait. n. 1. (T. legitimum; Cluf. Hift. v. 2. 67. Ger. Em. 520. Telephio di Diofcoride; Imperat. Hift. Nat. 662.)—Leaves alternate.—Native of Switzerland, Italy, and the fouth of France. A hardy perennial, kept in our botanic gardens, flowering in fummer. Numerous decumbent, round, herbaceous, leafy *ftems*, a fpan long, but flightly branched, fpring from the crown of the root, fpreading in all directions. The *leaves* are fcattered, nearly feffile, obovate, entire, fmooth, glaucous, rather fucculent, an inch long, more or lefs. *Cymes* terminal, folitary, convex, of numerous fmooth *flowers*, with white, or pale flefh-coloured, *petals*.

2. T. *oppofitifolium.* Barbary Orpine. Linn. Sp. Pl. 388. Willd. n. 2. (T. myofotidis foliis, amplioribus, conjugatis; Shaw Afric. n. 572. f. 572.)—Leaves oppofite.—Found by Shaw in Barbary. Nothing is known of this fpecies but from his rude figure, and fhort defcription. The *leaves* are elliptic-oblong, above an inch in length; the lower ones ftalked. Tops of the flowering *branches* recurved, as in the *Heliotropium*. *Petals* fmall. *Capfules* of three valves, with many feeds; fo that there feems no doubt of the genus.

Telephium, in *Gardening*, furnifhes a plant of the fmall hardy perennial kind, of which the fpecies ufually cultivated for garden ufe is the true orpine (T. imperati).

Method of Culture.—This plant is increafed by fowing the feeds in the autumn or fpring, in dry light mould, either where the plants are to remain, or in beds to be afterwards planted out. They appear in the fpring, when they fhould be kept clear from weeds, and they will flower the following year.

It is alfo capable of being increafed fometimes by offsets, flips, or cuttings, planted out in the fpring feafon.

It likes a dry light foil, in which it grows beft and lafts longeft. The plants afford variety in the common borders and clumps when placed in the fronts of thofe parts.

Telephium, a malignant dangerous ulcer. The term is derived from Telephus, who was wounded by Achilles, and whofe wound, it is faid, became before he died a difeafe of the above kind.

TELEPHORUS, in *Entomology*, the Necydalis *Cærulefcens;* which fee.

TELESCOPE, from τηλε, *at a diftance*, and σκοπέω, *I fee*, is an optical inftrument that enlarges the vifual angle fubtended by a diftant object, and thereby is faid to *magnify* it, fo as to render it vifible to the eye of an obferver. This property of making diftant objects appear clofe to the eye, never fails to excite the furprife of every one who looks through a telefcope for the firft time; but few, comparatively fpeaking, have their curiofity fully gratified, as it regards the means by which this wonderful phenomenon is effected. They are told, that the tube through which they look, contains magnifying glaffes, or polifhed fpecula, which, by a peculiar arrangement, produce the furprifing effect they witnefs, and there the explanation ufually ends; but it is our province to give our readers a better account of this aftonifhing inftrument, which we propofe to do in a fyftematic manner, firft by giving a fhort *hiftory* of its invention and improvements; fecondly, by giving a popular explanation of the theory of the dioptric conftruction, including the doctrine of aberrations; thirdly, by explaining the theory of the cata-dioptric conftruction; fourthly, by defcribing the moft approved inftruments, with reference to the drawings that reprefent their figures on their refpective ftands; fifthly, by fhewing how their magnifying *powers* may be meafured by *dynameters*, and varied by different arrangements; and laftly, by exemplifying their *ufes* in meafuring fmall angles and their correfponding terreftrial diftances. But before we proceed further with this fubject, we muft requeft our readers to perufe the articles Aberration, Catoptrics, Dioptrics, Lens, Mirror, Reflection, Refraction, and Speculum, in the preceding volumes of our work, in order that we may not have occafion to repeat what would otherwife have been neceffary to be introduced in this place, to render our account fufficiently full, particularly in that part of it which relates to the theory of fingle lenfes.

1. *The Hiftory.*—The invention of the telefcope, which was one of the nobleft that modern ages can boaft of, has enabled man to raife his eyes far above the furface of the globe he inhabits, in fearch of worlds that were invifible to the unaffifted eye; and the more perfect his inftrument is made, the more celeftial bodies he difcovers fcattered through the infinitude of endlefs fpace. Whether this invention was cafual, or the offspring of ratiocination, cannot perhaps be pofitively affirmed from any exifting document; but the probability is, that it was in a certain degree cafual: lenfes of both the concave and convex formation were ufed feparately to affift the human eye, antecedently to the conftruction of any telefcope; and the general belief is, that fome accidental placing of two lenfes, one convex and the other concave, of different focal lengths, at fuch diftance from each other, that the rays tranfmitted through them formed a picture on the retina of the eye, led to the difcovery that they poffeffed the wonderful property of rendering a diftant body apparently more large, and confequently more near, than it will appear to the unaffifted eye, or to an eye ufing any fingle lens whatever: this difcovery, once made, would obvioufly lead to the conftruction of an inftrument, in which this fimple combination of two lenfes would be the bafis.

The honour of having conftructed the firft telefcope, which was no doubt of the dioptric or refracting fort, (from διοπτρον, *a perfpective inftrument*,) has been attributed to various inventors, feveral of whom may have been equally entitled to the claim of originality, though only one can be confidered as the *firft* inventor. We profefs not to be in poffeffion of better information on this fubject than our predeceffors were, and therefore fhall fatisfy ourfelves with the enumeration of thofe perfons who appear to us worthy of being put on the lift of competitors for the honour of this noble invention. Mr. W. Molyneux has afferted, in his "Dioptrica Nova," that our countryman Friar Bacon well underftood the nature of all forts of optical glaffes, and how to combine them fo as to form fome fuch inftrument as the telefcope; and Samuel Molyneux, the fon, has affirmed, that not only the invention but conftruction of a telefcope is fairly attributable to Bacon, as may be collected from various Latin phrafes in his Opus Majus; and Dr. Jebb, who edited this work, adduces a paffage from Bacon's manufcript, to prove that he actually applied telefcopes to aftronomical purpofes fo long ago as in the 13th century; the friar having died in the year 1294.

The paffages to which Mr. Molyneux refers, in fupport of Bacon's claims, occur in his Opus Majus, p. 348, and p. 357. Jebb's ed. 1733. The firft is as follows: "Si vero non fint corpora plana, per quæ vifus videt, fed fphærica, tunc eft magna diverfitas: nam vel concavitas corporis eft verfus oculum vel convexitas:" whence it is inferred, that he knew what a concave and convex glafs was. The fecond is comprifed in a whole chapter, where he fays, "De vifione visione fractâ majora sunt; nam de facili patet per canones supra-dictos, quod maxima possunt apparere minima, et e contra, et longe distantia videbuntur propinquissime, et e converso. Nam possumus sic figurare perspicua, et taliter ea ordinare respectu nostri visûs et rerum, quod frangentur radii, et flectentur quorsumcunque voluerimus, ut sub quocunque angulo voluerimus, videbimus rem prope vel longe, &c. Sic etiam faceremus solem et lunam et stellas descendere secundum apparentiam hic inferius, &c.:" *i. e.* greater things than these may be performed by refracted vision; for it is easy to understand by the canons above-mentioned, that the greatest things may appear exceeding small, and on the contrary: also that the most remote objects may appear just at hand, and on the contrary: for we can give such figures to transparent bodies, and dispose them in such order with respect to the eye and the objects, that the rays shall be refracted and bent towards any place we please; so that we shall see the object near at hand or at a distance, under any angle we please, &c. So that thus the sun, moon, and stars, may be made to descend hither in appearance &c. Mr. Molyneux has also cited another passage out of Bacon's Epistle ad Parisiensem, of the Secrets of Art and Nature, cap. 5. to this purpose: "Possunt etiam sic figurari perspicua, ut longissime posita appareant propinqua, et e contrario: ita quod ex incredibili distantia legeremus literas minutissimas, et numeraremus res quantumque parvas, et stellas faceremus apparere quo vellemus:" *i. e.* glasses or diaphanous bodies may be formed, that the most remote objects may appear just at hand, and contrarily; so that we may read the smallest letter at an incredible distance, and may number things though never so small, and may make the stars appear as near as we please.

Dr. Smith, however, who must be considered as having been a competent judge of this subject, was unwilling to allow the inference, that Bacon actually made a telescope, and conjectures that he only conceived in his mind how such an instrument might be constructed; which, by the bye, is still allowing the invention, though not the construction, to have been his. But be this as it may, we find no further notice taken of any such instrument as a telescope until about the year 1560, when John Baptista Porta, a Neapolitan, is said by Wolfius to have made a telescope; but the description he gave of his invention in his Magia Naturalis is so defective, that Kepler declared it unintelligible; neither does it appear that this telescope was used in any celestial observation. Soon after this time, *viz.* in the year 1579, according to the account of Thomas Digges, in his Stratiticos, his father, Leonard Digges, had learned from a manuscript book of the learned Bacon, how to discover objects at a distance, by perspective glasses set at due angles, when the sun shone upon them; but it is not evident whether the construction resembled that of a telescope or of a camera obscura, nor whether it was of the dioptric or catoptric kind.

According to Descartes, James Metius, while amusing himself with making mirrors and burning-glasses, happened to look through two lenses, one concave and the other convex, placed by accident at a proper distance from each other, and thus discovered the property that such a combination of glasses possesses of shewing objects at a distance; this discovery is said to have been near the end of the 16th century. The same discovery has been also attributed to John Lippersheim, a maker of spectacles at Middleburgh; but Borellus, in his book entitled "De vero Telescopii Inventore," makes Jansen, or Hansen, (Zacharias Joannides,) another maker of spectacles at the same place, the real inventor of the telescope in the year 1590; and there seems to remain little doubt but that Jansen was entitled to the honour. The account is, that after having arranged the glasses in a tube, this ingenious mechanic hastened to present it to prince Maurice, under a persuasion that it would benefit him in his wars; but the secret soon became public, and Lippersheim immediately copied the invention. This first telescope magnified about fifteen or sixteen times, and its inventor viewed with it the spots of the moon, the body of Jupiter, and even saw some small stars above and below his disc, which appeared to move round him, and which therefore must have been his satellites. From this source, it is supposed that Metius gained his information, as well as Cornelius Drebell, of Alcmaer in Holland, who afterwards made similar instruments. We may also mention Francis Fontana, an Italian, as one who claimed the honour of this invention in the year 1608; but from what we have already said, of Jansen particularly, he cannot be considered as the first inventor, though it is possible that the report of such an invention having taken place might incite him to devise the means of effecting a similar contrivance. This, it is generally understood, was the case with the famous Galileo, who, when professor of mathematics at Padua, heard it reported at Venice, in the year 1609, that a Dutchman had presented count Maurice of Nassau with an optical instrument, which had the property of making distant objects appear as though they were near; but notwithstanding about twenty years had elapsed since the invention, the means used for producing the wonderful effect were not known; and Galileo, on his return to Padua, in a very few days not only contrived but constructed a telescope, which he presented to the doge Leonardo Donati, and to the senate of Venice, together with an account of the construction and uses which the instrument might be applied to, both by sea and land; for which service it is well known that his stipend as professor was thenceforth tripled. Among other discoveries that were made with Galileo's telescope in the heavenly regions, the four satellites of Jupiter were found by him to revolve round this planet in their respective periods, and were called the *Medicean stars*, in honour of the house of Medici. This discovery took place early in the year 1610, and Galileo, pursuing his favourite study till March, published at Venice his "Nuncius Sidereus," containing an account of all his discoveries, and dedicated it to Cosmo, the grand duke of Tuscany, who, in a letter written by himself, invited the astronomer to quit Padua for an increased stipend, without the labour of a lectureship. The first telescope which Galileo constructed had only a power of three times; his second was six times more powerful; and his third magnified thirty-three times, which, at so early a date, was no contemptible instrument.

Hence Galileo, though evidently not the first maker of a telescope, has been considered as entitled to all the merit that is due to such a noble invention, seeing he had no model before him, nor instructions how to proceed in the accomplishment of his ingenious work. But though Galileo was successful in the construction and uses of his telescope, which was of the refracting sort, with a concave eye-glass, as we shall shew presently, yet it remained for that sagacious mathematician Kepler to explain, on philosophical principles, the *rationale* of that construction. It was he who first explained the nature and effects of both the converging and diverging rays of light, after passing through the respective lenses, and who demonstrated the principles by which new arrangements might be made in the glasses, that would produce a superior instrument. He shewed that in small obliquities of incidence, the angle of incidence exceeds the angle of refraction about three times.

He alfo firft proved, that in a plano-convex lens, parallel rays are made to converge to a point which is diftant from the lens juft the diameter of the fphere of convexity; and that, if both fides of the lens are equally convex, this point will be at the centre of the circle of convexity. It remained however for Cavallieri to difcover and to prove, in cafes where the radii of curvature of the two fides of a double-convex lens are unequal, that as the fum of both the diameters is to one of them, fo is the other to the diftance of the focus: and it may be proper to notice here, that the fame rules are applicable to concave lenfes, except that the focus is at the contrary fide of the glafs.

It is remarkable, however, that Defcartes, the pupil of Kepler, makes no mention of his tutor's improvements, in the art of conftructing a telefcope, having been carried into execution for feveral years after Galileo's was brought into ufe. It was not till the year 1630, that Scheiner defcribes, in his "Rofa Urfina," the plan of fubftituting a convex inftead of a concave eye-glafs, as fuggefted by Kepler, to be ufed for aftronomical purpofes, where the inverfion of the object is a matter of no importance, but where the increafed field of view is of material confequence. The fame mechanician foon after adds a fecond convex glafs to his eye-tube, by means of which the objects become erect, which addition was no improvement to the vifion, but rather a detriment; and after him, Rheita gave an erect pofition to objects, by ufing three fimilar lenfes in the eye-tube inftead of two, which greatly improved the vifion, without other detriment than the lofs of a little light: and becaufe Rheita's telefcope was adapted for viewing objects on the earth, as well as in the heavens, it was diftinguifhed by the name of the *terreftrial* telefcope, by way of diftinction from Scheiner's *aftronomical* one. In both thefe telefcopes, as well as in Galileo's with a concave eye-glafs, the power is eftimated from the focus of the object-glafs divided by the focus of the eye-glafs, as will be feen hereafter.

The ftudy of dioptrics now became general, and feveral improvements were offered by different individuals in the conftruction of the refracting telefcope; but among the real improvers muft be placed the very ingenious Huygens, who, being well acquainted with the aberration of the rays of light arifing from the fpherical figure of the glaffes, contrived a better arrangement of the eye-glaffes than had before been devifed. It was however very foon found, that the power of a telefcope of any of the preceding conftructions, could not be increafed by fhortening the focus of the eye-glafs alone, beyond certain limits, without introducing great indiftinctnefs, arifing from the fpherical aberrations; and that the beft mode of gaining power, without diminution of light and diftinctnefs, is an increafe of the focal length, without much increafe of aperture of the object-glafs; and a little experience fhewed, that it is neceffary to increafe this length in the duplicate ratio of the propofed increafe of power: *i. e.* in order to magnify *twice* as much, the focus of the object-glafs muft be made *four* times as long as that of another telefcope that has the fame light and diftinctnefs; and for any other power in a fimilar proportion. The confequence of this difcovery was, that different makers began to vie with each other, with refpect fimply to the length of their telefcopes: among thefe may be mentioned Euftachio Divini at Rome; Campani at Bologna; fir Paul Neille, Mr. Reive, and Mr. Cox, in England; and in France, Borelli and Auzout. The laft-mentioned mechanician fucceeded in grinding an object-glafs of the aftonifhing length of 600 feet; and it is faid, that Hartfocker made them even longer than this.

It will here occur to the reader, that tubes of this enormous length, if practicable, could not be manageable by an obferver; and hence we find, that thefe very long object-glaffes were fixed on the top of long poles, or to growing trees, and fo contrived as to be capable of adjuftment for the axis of vifion when turned to different altitudes, agreeably to the required pofition of the remote eye-glafs.

But while the length of the telefcope was thus inconveniently increafed, and the trouble of making good obfervations therewith proportionably augmented, it became a queftion to determine in what proportion the aperture might be enlarged with the increafe of focal length of the object-glafs. Auzout wrote a paper, and delivered it to the Royal Society in the year 1665, in which he affirmed, that the diameter of the object-glafs ought always to be in a fubduplicate ratio of its focal length, or nearly fo; and accordingly drew up a table of apertures fuitable for all focal lengths, from 4 inches to 400 feet: upon which Dr. Hooke very properly remarked, that the fame glafs may have its aperture advantageoufly enlarged or diminifhed, according to the quantity of light proceeding from the object viewed.

While powerful telefcopes were thus obliged to be unmanageably long, and obtained the name of *aerial* telefcopes, from the circumftance of their having no tubes to be inclofed in, the immortal Newton had his penetrating mind occupied with meditated improvements on the figure and arrangement of lenfes, and proceeding, as he always did, on rational principles, difcovered, from the elongated and coloured fpectrum formed by rays of light paffing through a triangular prifm, and from experiments calculated to inveftigate the caufe of fuch an oblong form and coloured appearance, that light is not homogeneous, and that different rays are differently refrangible, when tranfmitted through the fame medium. This grand difcovery prefented difficulties ftanding in the way of the improvement of the refracting or dioptric telefcope, apparently much greater than thofe which had previoufly been difcovered, as arifing only out of the fpherical figure of the glaffes; and all hope of fuccefs in making fhort telefcopes of great power, and yet with fufficient light and diftinctnefs, but without an admixture of coloured rays, was given up.

Yet to a mind like Newton's, it naturally occurred, that what could not be practically effected by refraction, might probably be accomplifhed by reflection of the rays of light into a focus, where, as there would be no feparation of the colorific rays by a refracting medium, there would be no colour nor elongation of the focal point, arifing from any other aberration, than what might be caufed by the figure of the reflecting furface; he therefore abandoned his propofed plan of grinding lenfes after the figure of fome of the conic fections, (for which fir Chriftopher Wren contrived a machine,) to avoid the effects of fpherical aberration in dioptric telefcopes, and turned his mind to the improvement of catoptric or rather cata-dioptric telefcopes, which had been previoufly propofed to Defcartes by Merfenne, and actually conftructed by James Gregory of Aberdeen. The compofition for the beft metal for reflection, and the mode of grinding and polifhing, as propofed and practifed by Newton, we have already detailed under our article SPECULUM; but as reflecting telefcopes have been conftructed differently, we will here introduce a fhort account of the refpective differences, before we refume the remaining narrative of the improvements in dioptric telefcopes. The firft conftruction of the reflecting telefcope was the Gregorian, and moft of the portable reflectors continue to be of this conftruction at the prefent day: its large fpeculum is concave, perforated at the centre, and placed at the interior end of the large tube; and the fmall reflector is alfo concave,

placed

placed oppofite the central hole of the large one, in fuch an adjuftable manner, that the rays, after a fecond reflection, *crofs* one another, and come to the eye-glafs in fuch a way, that an *erect* picture of the object, or rather of the image of the object, is formed on the retina of the eye. In this conftruction, it has been fuppofed that the figure of the large concave fpeculum ought to be truly parabolic, becaufe this is the figure recommended by Newton for his conftruction; but this conclufion is erroneous; for it is the joint effect of both the fpecula that muft be adverted to in their refpective figures, fo that the rays may come without aberration to the eye-glafs after *both reflections;* and in order to produce this joint effect, the curve of the large fpeculum muft be fomewhat *more* than parabolic, *viz.* approaching to hyperbolic, becaufe the fmall fpeculum is alfo concave, and has its feparate aberration.

In the Newtonian conftruction, the large fpeculum is, or ought to be, truly parabolic, and the fmall one *plane,* fet diagonally at an angle of 45°; fo that the rays, after the fecond reflection, come to the eye-tube on the *fide* of the large tube, and near its aperture: the rays do not crofs here, but come to a focus at the eye-glafs, where the object is reprefented inverted and well defined, as well as bright; for when the rays fall obliquely on the fmall reflector, they are almoft all reflected without difperfion, which is an advantage that this conftruction has over the Gregorian. When the Newtonian telefcope was propofed to Huygens, he had the candour to acknowledge, which proved to be the fact, that there would not be that limit to the aperture of a reflector, that is prefcribed by natural neceffity to that of a refractor, and that the power as well as light may be made far to exceed thofe of the latter.

The next conftruction of a reflecting telefcope was that of Caffegrain, defcribed in the Philofophical Tranfactions of the year 1672. This differs from the Gregorian only in this particular, that the fmall fpeculum is *convex,* and the focus of the large or concave one may be longer than is required in the other, for the fame length of tube; the rays do *not crofs* after the fecond reflection, and confequently the object is feen inverted, as in the Newtonian: but here the curve of the large fpeculum is lefs than parabolic, in order that the joint effect of both the reflections may be an exemption from aberration. This adjuftment of the figures of the metallic furfaces is beft underftood and accomplifhed by the firft-rate opticians, and is but little known to mere theorifts.

Of the Herfchelian telefcope we fhall only fay, in this place, that it differs from the Newtonian in no other refpect, except in its fize and powers, and that the fecond reflector is difpenfed with, the length of the tube being equal to the focal diftance of the large fpeculum, and the head of the obferver being confequently placed at the upper end or aperture of the tube; fo that, in this conftruction, as little light as poffible is loft from the fingle reflection, the principal lofs being that which is intercepted, on its entrance into the tube, by the head of the obferver. The parabolic curve for the face of the fpeculum is equally proper for the Herfchelian as for the Newtonian telefcope.

From thefe fhort hiftorical notices it will be feen, that Merfenne firft fuggefted the hint for conftructing a reflecting telefcope, which muft have been before the year 1651, when his Catoptrics were printed; or, according to Defcartes' third and twenty-ninth letters, written in 1639, though not publifhed till 1666, before thefe letters were written. Gregory, who might or might not have feen Merfenne's fuggeftion, publifhed an account of his conftruction in his "Optica Promota," in the year 1663; but as he was not a fkilful mechanic himfelf, it is underftood that his telefcope was but an indifferent one, and that the theory of his conftruction was not completely realized to his wifh. At this juncture, fir Ifaac Newton, who was a good mechanician, as well as mathematician and experimental philofopher, took the fubject into his confideration, and, by his fuccefsful labours, prevented the invention from falling into oblivion. His proceedings met with interruption from the occurrence of the plague; but about the end of the year 1668, he began his experiments on fpeculum metal, and, in the year 1672, produced two fmall reflecting telefcopes. In thefe, the large fpecula were ground into a fpherical concave furface, as being the eafieft to execute; but he was aware that the parabolic curve, recommended by Gregory, would be preferable, when it could be accomplifhed by mechanical contrivances, which he judged to be within the reach of human ingenuity. The refult of thefe labours was communicated to the Royal Society of London; and, through the medium of their fecretary, Mr. Oldenburgh, to the ingenious Huygens, who teftified his approval of this conftruction in an account which was publifhed in the Journal des Sçavans for the year 1672: and in this way, nearly the whole of Europe became acquainted with the Newtonian conftruction. In the mean time, Caffegrain, a Frenchman, who had varied Gregory's conftruction, by fubftituting a convex inftead of a concave fmall fpeculum, as we have already ftated, in the fame journal (des Sçavans, 1672), contefted the honour of having been the firft improver of the original Gregorian telefcope; which claim drew from Newton feveral objections to Caffegrain's conftruction, that will indeed apply equally to the Gregorian. We have, however, recently witneffed in captain Kater an advocate for Caffegrain's telefcope, in preference to that of Gregory, (fee Phil. Tranf. of London, 1813 and 1814,) principally with refpect to the brightnefs and diftinctnefs of objects refpectively feen by them; and his conclufion is, that much of the light is diffipated by the *croffing* of the rays in the *focal point,* which is a doctrine waiting for confirmation. In Caffegrain's telefcope, the picture of the object itfelf is viewed by the eye; but in Gregory's, the picture of the image reprefenting the object at the point of croffing is only viewed; which circumftance conftitutes the effential difference in the two conftructions: and it is very probable that the light proceeding from the image of an object may not be fo vivid as that proceeding from the object itfelf, of which the image may be confidered as a lefs enlightened reprefentation.

It is remarkable that no improvement was made on Newton's fmall telefcopes till about the year 1723, when Hadley prefented to the Royal Society a reflecting telefcope of Newton's conftruction, in which the focus of the fpeculum was 10 feet $5\frac{1}{4}$ inches. Though Newton's were only fix inches long each, they were compared to the fix-feet refractors, fuch as were made at that time; but what muft have been the public feeling, when Hadley produced his enlarged inftrument! This was found at leaft equal in power to the famous Huygenian refractor of 123 feet; at leaft, its power and diftinctnefs were equal, though the light was not quite fo bright.

Since Hadley's time, the reflecting telefcope has experienced confiderable improvements from the labours of Mr. Short, Mr. Mudge, the Rev. John Edwards, Dr. Herfchel (now fir William Herfchel), and others who are our own contemporaries.

But while reflecting telefcopes were undergoing their various improvements, and were fuperfeding the ufe of the long refractors, the idea of correcting both the fpherical and prifmatic

prifmatic aberrations was not abandoned. We have already afferted, under our article CIRCLE, that Chefter More Hall, efq. of More Hall in Effex, fo long ago as in the year 1729, conftructed telefcopes of different glaffes; fome of which have been preferved, and found, on examination, to be of the achromatic kind, though not known by this defignation. But as we are not in poffeffion of any record refpecting the invention and mode of conftructing fuch telefcope, we do not prefume to fay that this was the archetype of the modern achromatic inftrument; and, therefore, we do not confider it as detracting from the merit of the philofophic optician, who afterwards deduced the principles of the invention from accurate and ingenious experiments, and made known his fuccefsful application of them at a time when his claim to originality might have been difputed, if the prior invention had been then divulged.

It was not till about the year 1747 that Euler, not knowing what had been done by Hall, and profiting by a hint that had been fuggefted by fir Ifaac Newton, conceived the plan of conftructing an object-glafs of two fuch materials, of different refractive powers, as might counteract, by repeated refractions, the difperfion of the differently refrangible rays, and thus bring all the rays into one focal point, fo as to admit of a highly magnifying eye-piece. Accordingly two object-glaffes were fo inclofed in a box, as to include clear water between them, to be ufed inftead of a fingle lens; and though the experiment failed of fuccefs, the memoir, written by Euler on the occafion, attracted the attention of the late Mr. J. Dollond, mathematical-inftrument maker of London, who foon after fet about making experiments, as Newton had done, to afcertain if the refractive and difperfive powers of various tranfparent fubftances are in a conftant ratio, with the view of compounding, which he at length effected, an object-glafs that would bring the rays of light tranfmitted through it to a focal point, without the prifmatic aberration.

In the memoir which Euler had written, and which was publifhed in the Berlin Memoirs of 1747, he affumed that the indices of refraction might be expreffed by the powers of a certain invariable root, and that the exponents of thofe powers are proportional for the different rays of light paffing through different media. This paper coming to the hands of the ingenious Dollond, excited his attention; and in the year 1753 he addreffed a letter to James Short, "concerning a miftake in M. Euler's theorem for correcting the aberrations in the object-glaffes of refracting telefcopes;" which letter was publifhed in the Philofophical Tranfactions of the fame year; the object of which was to prove that Euler had affumed an hypothefis, as the bafis of his calculations, which was contrary to both reafon and experiment, or, as Short obferves in his accompanying letter, "contrary to the eftablifhed principles of optics." To this Euler replied, and maintained that his optical principle was a true law of nature; but the practical teft of its truth was wanting, the *ufe* that it was intended to be put to.

In 1754, the Swedifh geometer Klingenftierna took up the fubject, which now attracted the attention of various mathematicians, and attempted to prove that the Newtonian principle, oppofed to Euler's, is in fome extreme cafes irreconcileable with natural phenomena, and therefore ought not to be received as a law of nature. Dollond, therefore, thus oppofed, had recourfe to actual experiment, agreeably to Newton's plan of philofophizing; and, rejecting the propofal of putting water between two menifci, with a view of correcting the prifmatic aberrations by a number of refractions, proceeded to inftitute a regular feries of experiments, in order to determine what could be done by the oppofite refractions of different diaphanous media; and as thefe experiments were the foundation of all the improvements that have followed in the conftruction of colourlefs, or what Dr. Bevis denominated *achromatic*, object-glaffes of a refracting telefcope, we fhall here introduce a fummary account of them.

In the firft place, Dollond contrived to form a hollow inverted pyramid with two oppofite fides of glafs, as in *fig.* 1, *Plate* XXIV. *Aftronomical Inftruments*, and placed in an inverted pofition, within a triangular and equilateral prifm of glafs, to reft as reprefented in the figure. The veffel was then filled with clear water, and a ray of light made to pafs through both the water and glafs prifm: the angle at the junction of the glafs plates, clofing the veffel, was capable of enlargement or diminution; and the glafs fides were made to recede or approach, until an object feen through the water and glafs prifm was in its true place, *i. e.* until the refraction of the water balanced the oppofite refraction of the glafs. The refult of this experiment proved contrary to what had been expected from Newton's experiments, *viz.* an external object feen through this compound prifm was fringed with colours. But to be quite fure that there was no deception in the appearance, a glafs prifm, formed to an acute angle of only 9 degrees, was fubftituted, which was alfo more convenient for the experiment, and then the veffel was clofed, as in *fig.* 2, until the oppofite refractions balanced each other as before; but ftill the object viewed through the compound prifm was tinged with the prifmatic colours. The mean rays in thefe trials proceeded in a ftraight line, after quitting the fecond wedge of water; but the extreme rays were deflected, or turned refpectively out from exact parallelifm.

After having thus afcertained that equal and oppofite refractions of glafs and water will not deftroy the *colours*, the author varied the experiment, by altering the wedges of water, till he found that the refraction occafioned by the water muft be to that occafioned by the glafs as 5 : 4, before the colours will difappear. The next ftep was to purfue the proportions thus afcertained, in the conftruction of an object-glafs containing water; but after uniting a deep and double convex lens of pure water with a concave one of glafs, the object feen through the telefcope with this compound object-glafs was indeed free from colour, but by no means fo diftinct as was defired, and confequently the fpherical aberration yet remained. This telefcope was made in 1757, and ferved to prove that the feparation of the extreme rays, or what has fince been called the *difperfive power*, in the cafe of an union of glafs with water, is *not proportioned* to the *mean refraction;* as fir Ifaac Newton had afferted it to be, in the fame experiment (fee Newton's Optics, p. 112, 3d edit.): confequently the idea muft now have occurred of trying other diaphanous fubftances with different refractive powers, to fee what the *difperfion* would be in them. After an interval of fome time, during which different kinds of glafs were procured, the ingenious and perfevering artift found, for the firft time in the year 1757, that the *difperfive* power of the cryftal or white *flint*-glafs was *greater* than that of the Englifh *crown*-glafs, and alfo that the power of the latter was very fimilar to that of the Venice ftraw-coloured glafs. He determined, therefore, to try a wedge of flint-glafs, and another of crown-glafs, formed to different angles, as in *fig.* 3, until, when reverfed, their oppofite refractions were equal; which equality took place, when their angles were refpectively 25 degrees and 29 degrees; in which cafe, the fines of half the angles, or the indices of their refractions, were 216 : 250, or nearly as 19 : 22. But though the direction of the pencil of light was

was now unchanged, as was expected, the compound rays had not all the same divergence. The shape of the wedges was then modified, so that the colours disappeared by a due opposition of their respective dispersions; and when this was effected, the refractive powers of the two wedges were found nearly 2 : 3; and, consequently, the sines of half their angles, 19 : 33; which ratio is nearly 4 : 7. In this situation of the wedges, the rays which enter parallel emerge also parallel, while they are equally deflected from the points of emergence. These results may be obtained very strikingly by an union of four wedges, or pair of compound wedges, as represented in *fig*. 4, where the crown receives the rays first, and where the rays, at equal distances from the central line of union, meet always at the same point. This, therefore, pointed out the construction of a double object-glass, such as is represented in *fig*. 5, in which the convex curve of the crown-glass is to the concave curve of the flint of given qualities nearly as 7 : 4, or nearly in the ratio of their respective dispersive powers. But to avoid the too great effect of spherical aberration, arising from the quick curves, the single convex lens of crown-glass was made into a double convex, with double the radius of convexity; and also the single concave might be made double, with a similar increase in its radius of concavity, to answer the same purpose as the combination last described. But, in this case, the convexity of one glass would not fit the concavity of the other, so as to come nearly in contact throughout: it appeared necessary, therefore, that while the internal faces fitted each other, the external concavity of the flint-glass should be eight times less, or of longer radius than before proposed, in order to maintain the balance of opposite dispersions; or otherwise, as in *fig*. 6, if the double concave faces of flint-glass remain as above stated, the front convexity of the crown-glass must be five-sevenths of the due curvature, as proposed above; while the inner surface remains in perfect contact with the concavity of the other. In these combinations, the superior refraction of the convex lens, being diminished one-third part by the opposing refractive power of the concave lens, required this convex to be ground and polished to a focus three times shorter than would be required for the same lens used singly; and the option, that is afforded the artist, of varying the curves at pleasure, provided the combined effect of the compound lens shall produce a proper effect in banishing the colours, admits of a modification that will correct the spherical aberration also, in a great measure. Telescopes on this achromatic principle were first constructed in the year 1758, and when their merit was once acknowledged, the great number that the inventor and his successors have had occasion to make, both for sale among their customers, and for exportation, have afforded them the easy means of trying a variety of concave and convex glasses together in succession, before they were finally paired; so that their success not only originated in, but has been continued by, the aid of experiments, which no one but the Dollonds has had the power of executing to so great an extent. See DOLLOND.

Nor was J. Dollond's success confined to the manipulation of object-glasses alone; he had previously contrived and constructed the improved system of eye-glasses, in which object he was followed by his son-in-law, Ramsden.

This improvement consisted in extending the usual number of eye-glasses to five, so systematically arranged, that by dividing the errors of spherical aberration, they reduced their amount to an inconsiderable quantity.

The value of this arrangement will be best understood from his own words, which we will extract from his letter, published in the Philosophical Transactions of the year 1753. "If any one," says he, "would have the visual angle of a telescope to contain 20 degrees, the extreme pencils of the field must be bent or refracted in an angle of 10 degrees; which, if it be performed by one eye-glass, will cause an aberration from the figure in proportion to the cube of that angle; but if two glasses are so proportioned and situated, as that the refraction may be equally divided between them, they will each of them produce a refraction equal to half the required angle; and, therefore, the aberration being in proportion to the cube of half the angle taken twice over, will be but a fourth part of that, which is in proportion to the cube of the whole angle; because twice the cube of one, is but one-fourth the cube of two; so the aberration from the figure, where two eye-glasses are rightly proportioned, is but a fourth of what must unavoidably be, where the whole is performed by a single eye-glass. By the same way of reasoning, when the refraction is divided between three glasses, the aberration will be found to be but the ninth part of what would be produced from a single glass; because three times the cube of one, is but one-ninth the cube of three. Whence it appears, that by increasing the number of eye-glasses, the indistinctness which is observed near the borders of the field of a telescope, may be very much diminished, though not entirely taken away."

We have given this quotation at full length to shew, that in his adoption of several glasses in an eye-piece, the ingenious mechanic was not entirely indebted to his experiments, unassisted by reasoning and mathematical inferences, and accordingly the Royal Society rewarded his skilful labours with Copley's medal. John Dollond was succeeded in his business by his no less ingenious and industrious son, Peter Dollond, who improved the achromatic object-glass still further, by placing a double concave flint-glass between two convex ones of crown-glass, as in *fig*. 7. and by enlarging the aperture to 3⅗ inches in a 45-inch telescope; of these, a great number has been manufactured, and several of five-feet focal length. His calculations of the radii of convexity and of concavity were never publicly made known; and perhaps constituted a secret, on which the continuance of his celebrity depended, when the time of his father's patent had expired. The business is now successfully conducted by G. Dollond, the nephew, to whom we are indebted for much liberal information; but at no period had any of the Dollonds an agent in Paris, as is said in the new Supplement to the Encyc. Britannica. For several years from the time of the eldest Dollond's death, the foreign Transactions were crowded with dissertations and memoirs on the combinations of achromatic lenses mathematically determined, and the subject afforded ample scope for the geometrical and analytical researches of an Euler, a Clairaut, and a D'Alembert, as well as for Boscovich, Klingenstierna, Kæstner, and Hennert: but in this, as in some other speculative investigations, the labours of the profound mathematician have not much benefited the practical advancement of the art to which these labours have been directed; nay, they have tended to keep at a distance from each other the mathematician and the mechanic.

Boscovich's eye-piece, however, may be considered as constituting an exception to the preceding remark, and deserves here to be particularly noticed. According to one of his theorems, an eye-piece free from colours may be composed of two similar lenses of the same glass, provided they be placed from each other just one-half of the sum of their focal distances; which is very similar to the eye-glass now commonly adopted, in preference to a single lens, in the common astronomical refracting telescope, the only difference being, that in Boſcovich's the lenſes are of equal convexity; whereas, in the common improved aſtronomical eye-piece, the inner lens has a longer focus than the outer one, in the ratio of 3 : 1, and being both plano-convex, they both have their curved faces turned towards the object-glaſs.

From the preceding experiments of the Dollonds, have reſulted all the advantages that the achromatic refracting teleſcopes poſſeſs over the long teleſcopes with ſimple object-glaſſes, and which have put them in competition with the beſt reflectors in the eſſential qualities of power, light, and diſtinctneſs of viſion. There is, however, an imperfection, notwithſtanding Dollond's great ſkill and perſeverance, which remains yet to be overcome, if it is not invincible, which is, that while the colours occaſioned by the extreme rays are corrected with ſufficient accuracy by the compound object-glaſs, yet the intermediate rays are not perfectly corrected; and if any media can be ſo modified as to correct all the rays that fall on every point of the ſurface of the object-glaſs, ſo as to make them unite at the ſame point in the line of the axis; then, and not till then, will the object-glaſs be quite perfect. Peter, the ſon of John Dollond, who, we have ſaid, ſucceeded to his father's buſineſs, purſued this ſubject after his father's death; and in the year 1765, communicated to the Royal Society by letter the reſult of his experiments. He remarks, that when his father had made object-glaſſes of one convex lens of crown-glaſs, and of one concave of flint-glaſs, to be uſed with convex eye-glaſſes, it was found that the exceſs of aberration was in the convex portion of the compound object-glaſs, and that the equality of the counteracting aberrations could not be carried to any great diſtance from the centre of the glaſſes; he therefore attempted, about the year 1758, to make ſhort object-glaſſes of the ſame ſort, to be uſed with concave eye-glaſſes; but it was found, that, as the field of view, in uſing a concave eye-glaſs, depended on the aperture of the object-glaſs, the limits of the aperture were too confined with a double object-glaſs. This trial led the ſenior Dollond to a concluſion, which the ſon took up, and profited by; namely, that the exceſs of ſpherical aberration, occaſioned by one double convex lens of crown-glaſs, might be diminiſhed by ſubſtituting two plano-convex lenſes of ſimilar glaſs and curves, placed one at each ſide of the double concave of flint-glaſs. The ſenior Dollond had ſucceeded with this conſtruction when a concave eye-glaſs was uſed, and when the compound focus was ſhort; but it remained for the ſon to complete a long object-glaſs of this conſtruction, to be uſed with convex eye-glaſſes; which he ſucceeded in doing, firſt with a teleſcope of 5-feet focus, and $3\frac{3}{4}$ inches aperture, and afterwards with a $3\frac{1}{2}$-feet one of the ſame aperture, which he invited the Royal Society to ſee, and which was the prototype of the numerous achromatic teleſcopes of the ſame dimenſions, which have been ſince conſtructed and diſperſed by ſale through all the regions of the globe.

Among the firſt achromatic teleſcopes made by P. Dollond, was one purchaſed by the duc de Chaulnes, who examined very minutely the radii of the reſpective glaſſes, and publiſhed an account of them in French meaſures, which, converted into Engliſh inches, will ſtand thus; 32.4 and 40.8 for the outer convex of crown-glaſs; 22.2 and 30.6 for the double concave of flint; and 30.6 with 35.5 for the inner convex of crown-glaſs; but as the *qualities* of the reſpective glaſſes are not ſpecified, no uſeful inference can be drawn for the conſtruction of another teleſcope, in which the glaſs of each lens may be of another quality. This teleſcope, we learn from the preſent Mr. G. Dollond, had a focal length of 46 inches: and the five-feet teleſcopes ſubſequently made, have each an aperture of four inches: but the largeſt and beſt teleſcope of the achromatic kind ever made by P. Dollond, is that of ten-feet focus, and five inches aperture, lately converted into a ſuperb tranſit inſtrument by Mr. Troughton, and placed in Greenwich Obſervatory. See Transit *Inſtrument.*

Soon after Peter Dollond's teleſcopes began to be in repute, namely, in the year 1759, Benjamin Martin, at the ſame time a mathematician and a mechanic, who had long turned his attention to the conſtruction of teleſcopes, and deſcribed various conſtructions, publiſhed his "New Elements of Optics," a book now, like Edwards's Treatiſe, extremely ſcarce, in which he has entered more minutely into the doctrine of both kinds of aberrations, as they relate to practice, than any other author has done, either before or ſince. He not only followed the ſteps of J. Dollond in determining by glaſs wedges or priſms the relative refractive and diſperſive powers of different ſpecimens of glaſs, but ground ſingle object-glaſſes of ſeveral kinds of glaſs, with tools of the ſame radius, and then compared the geometrical foci of each with the refracted or real foci, by nice meaſurements: by this means he aſcertained the difference between the focus determined theoretically from the known radius, and the real or practical focus of the refracted rays in each glaſs by meaſurement, conſidering at the ſame time the diſtance of the radiant point: and thus he gained, as we ſhall have occaſion to ſhew more particularly hereafter, the ratio between the ſine of the angle of incidence and of the angle of refraction in each ſeparate ſpecimen, which ratio, in a ray paſſing from air into glaſs, had been aſſumed in all former optical theorems as 3 : 2 in all kinds of glaſs, and conſequently the focus for parallel rays had been put equal to radius in double convex lenſes, and alſo equal to the diameter in ſingle convex, without regard to the quality of the glaſs, with reſpect to its refractive power. The *rectification* of the old theorem, founded on the conſtant ratio 3 : 2, formed the baſis of the "New Elements of Optics," in which one half of the difference between the old theoretic and the refracted, or practical foci was called a, and then $\frac{R}{2a} = F$ with parallel rays became the baſis of the rectified theorems, which we propoſe to give preſently in their proper place. According to theſe new elements, and from a meaſurement of the angles of diſperſion, or of the coloured ſpectra contained between the extreme rays, as given by a priſm of flint, and another of crown-glaſs reſpectively, the ratio of which he determined to be as 5 : 3, he calculated that "the radii of the lenſes muſt have the ſame proportion as the differences of the ſines of incidence and refraction in red and violet rays, in priſms of equal refracting angles of white and crown glaſs;" and that, therefore, "the radii [or foci] of the lenſes muſt have the ſame proportion as the angles of diſſipation in refractions by ſuch priſms; and, of courſe, the ſame proportion as the lengths of the coloured ſpectra produced thereby." From theſe conſiderations the author concludes, that "*in all caſes* of a compound lens for producing viſion without colours, the ratio of the radii, r and R, of the concave and convex lenſes (when two only are uſed) muſt be that of 5 : 3; and that then the ratio of their focal diſtances for parallel rays will be that of 3 : 2 nearly. The ratio of the foci of two lenſes being thus determined that ſhall make the colours vaniſh, the longitudinal aberration ariſing from the reſpective curves was next conſidered; and in doing this, care was taken that the comparative foci of the two lenſes was not to be altered by an alteration in the curves now to be rectified. By Huygens's gens's general theorem, the aberration arifing from the curves of any lens may be determined and compared; and it being known from this theorem, that the longitudinal aberration is equal to $\frac{5}{3}$ds of the thicknefs of a double convex lens of equal radii, a double concave was determined from an equation of this aberration fuch, that its contrary aberration might counteract the aberration of the affumed convex lens of equal radii; and the numbers thus produced for the radii of the double convex of crown-glafs, and of the double concave of flint refpectively, were 8.36, 8.36, 10, and 23 inches, in which the focal diftances of the two lenfes are faid to be nearly as 2 : 3. In this combination, the compound focus is ftated to be 23.3 inches, and the radius $r = 23$ is contiguous to the convex glafs. Other calculations were alfo made where the radii of the convex lens were unequal, as well as thofe of the concave, but we do not learn that a good achromatic object-glafs, put together agreeably to Martin's calculations, was ever yet conftructed. In the inftance before us, it is evident that the curve 8.36, coming in contact with the concave 23, muft touch it in the middle, and therefore the proportions are impracticable.

While thefe various improvements in the conftruction of a telefcope were going on, we muft not omit to mention that different kinds of micrometers were applied to it fucceffively, by different ingenious men, for the purpofe of meafuring fmall angles; by which addition, the fcience of aftronomy has been greatly promoted. Among thofe promoters of this noble fcience, may be enumerated Auzout, Gafcoigne, Hooke, Le Fevre, Kirchius, Caffini, Fouchy, Hollman, B. Martin, Savery, J. Dollond, Dr. Mafkelyne, Ramfden, Dr. Herfchel, Smeaton, Rochon, Kæftner, Cavallo, Troughton, and Arago, the prefent aftronomer royal of France.

But it remained for the ingenious optician of Iflington, C. Tulley, to whom we are indebted for much valuable information on the fubject of our prefent inquiries, to calculate and manufacture, from any two given fpecimens of crown and flint glafs, a double object-glafs that fhall, generally fpeaking, be found both achromatic, and alfo as free from the effects of fpherical aberration as art can make it.

After this artift had made himfelf mafter of Martin's propofed plan of compounding an achromatic object-glafs, he found that the curves calculated for this purpofe would not produce their defired effect with any fpecimens of glafs that could be procured; but ftill he thought that a careful repetition of Martin's experiments might lead to refults favourable to his views, when fome modification was made in their application. He therefore, in the year 1800, obtained fix forts of glafs, differing in fpecific gravity, and ground them all to the fame radius by a tool of fpeculum metal, that did not much alter its figure by attrition in grinding, and in giving a partial polifh: thefe lenfes were fitted fucceffively to one cell, that was received by a tube having an eye-piece at the oppofite end, in order that the folar focus of the refracted rays might be the more accurately meafured with each glafs ufed as an object-glafs of a telefcope; and though the polifh was imperfect in thefe lenfes, ground and partially polifhed by the fame tool, yet the image of the fun was clearly defined by them. Thefe focal diftances, limited by the folar image, were in the next place meafured carefully by a nicely divided fcale, and were found to differ from one another confiderably, as we fhall hereafter have occafion to ftate more particularly: the radius of curvature of the tool was alfo afcertained with equal care, and found to exceed in length the longeft of the focal lengths of the refracted rays. The radius of the tool was then divided by each of the refracted focal lengths, and the quotients were called fo many divifors or multipliers, accordingly as the geometrical was to be determined from the refracted focus, or the contrary. Thefe quotients, therefore, bore the fame proportion to unity, that the geometrical focus bore to the refracted focus of each lens, and turned out to be very nearly the fame quantities that Martin had determined with glaffes of fimilar qualities, and that he denoted by the expreffion $2a$ in his rectified theorems. In fact, they were the numbers from which the ratio of the fines of the angles of incidence to the fines of the angles of refraction were accurately determined, as will be explained hereafter. The fpecific gravities of the different lenfes were then taken with a good hydroftatic balance, and were found to increafe with their correfponding divifors, but not in a regular proportion. From thefe experiments a fet of tables was conftructed, containing in parallel columns, both for crown and flint glafs, the fpecific gravities, varying from 3.466 to 2.428, together with the correfponding ratios of the fines of the angles of incidence and of refraction; and alfo the ratios of the two curves, that fhall produce an affigned longitudinal fpherical aberration in any lens; all which calculations are extended from the ratios 1 : 1, 1 : 1.01, 1 : 1.02, &c. in fucceffion, up to 1 : 6, where the aberration is a minimum, as was long ago determined by Huygens: and what is worthy of remark, the French plate-glafs, which had the fpecific gravity loweft, and its divifor only 1.004, and which, confequently, had its refracted focus nearly equal to its geometrical focus, was, in all probability, fimilar to the glafs manufactured at the time when the experiments of fir Ifaac Newton were made, from which the original optical theorems were framed. From thefe tables, our fkilful optician takes his curves by infpection fuitable for glafs of any given fpecific gravity, fuch as will fuit his tools for telefcopes of different lengths; and having as it were the command of the whole range of varying ratios, he can immediately fix on fuitable curves for any glafs, and for any compound focal length, or even affign a fellow that fhall match any practicable lens, convex or concave, that has been previoufly polifhed. Such is the facility which this ingenious and perfevering optician has attained in the higheft branch of his art, whilft, at the fame time, his fkill in grinding, polifhing, and centering his glaffes, is not exceeded by any other artift. The principal deviation from Martin's rules, that Tulley found it neceffary to adopt in his practice, is the application of a *correcting number* to the calculated or tabulated aberration arifing from the figure of the flint-glafs, on account of its difference of refractive power, as compared with that of the crown-glafs: in order to gain which correcting number in all different cafes, he firft reduces the geometrical foci of the two feparate lenfes into the refracted foci by his divifor = Martin's $2a$, and extracts the fquare root of the cubes of thofe refracted foci refpectively; then dividing the root of the flint-glafs by the root of the crown-glafs, he gains the *correcting divifor*, by which the calculated aberration of the flint-glafs is divided, to produce the *corrected aberration* for the concave lens; which lens muft now have its radii determined agreeably to this corrected aberration from the general theorem, or may be taken from the tables to be fubftituted for the radii that would have been requifite, if the proportional aberration had remained uncorrected. And laftly, that the foci of the feparate lenfes may be fo proportioned to each other, and to the compound focus of both the lenfes, which is ufually given when a telefcope is to be made, the ratio between the focus of the crown-glafs and of the compound glafs, having been calculated by an appropriate theorem, as will be explained, is tabulated to fuit different forts of glafs agreeably to their fpecific gravities; fo that Martin's conftant ratio of 5 : 3 is varied according to the variation of the fpecific

cific gravity, which is aſſumed as bearing a due proportion to the diſperſive power. Thus, when a piece of crown and a piece of flint glaſs are produced for an achromatic object-glaſs, the ſpecific gravity is firſt taken, and then the tabulated numbers, correſponding to theſe gravities, are taken from the columns of the tables, and the work is put in hand as ſoon as ſuitable tools are ſelected for producing the curves: or rather, when the relative foci are determined, the curves are fixed on in the tables that will ſuit the aberrations in queſtion, and that can alſo be produced by ſuch tools as are in uſe; for the formation of a new grinding tool is a ſerious undertaking, that the optician will wiſh to avoid. But after all, the chief practical difficulty remains; the ſame curves cannot always be worked to be exactly ſimilar, even in the ſame glaſs, with the ſame tools, and by the beſt workmen; which circumſtance leaves the nice calculator, in ſome meaſure, under the controul of his materials, and renders final adjuſtments indiſpenſable. Theſe obſervations are corroborated both by the candid acknowledgment of Tulley, and by the ſubjoined extracts, which we beg leave to tranſcribe from the letters of our eſtimable correſpondent Mr. G. Dollond.

"The perfection of our object-glaſſes," ſays Mr. Dollond, "is in a great degree promoted by the great pains we take in ſelecting thoſe glaſſes that ſuit each other the beſt; and alſo in adjuſting them very carefully: yet that is not every thing that is neceſſary to produce good object-glaſſes; they muſt be correctly worked, and the glaſſes be of perfect and proper quality.

"With reſpect to the ſurfaces uſed in our various object-glaſſes, it would be almoſt endleſs to enumerate them, as they depend upon, and vary with almoſt every piece of glaſs that is uſed in their formation; and there are ſome nice points in the method of working them, which I ſhould not wiſh at preſent to diſcloſe. Our uſual mode of proceeding is, in the firſt place, to calculate the proportions that are requiſite for the kinds of glaſs that are to be uſed, and then to ſelect from our great number of tools thoſe that come the neareſt to the ſurfaces determined upon; and it frequently happens that we have not any that will anſwer, particularly for the ſpherical aberration. We do not enter into thoſe very nice calculations that would be ſatisfactory to a theoriſt; we only aim at ſomething near to what is required; for to practical men, it is always more eaſy to produce what they wiſh by practical methods. Mr. Short, the celebrated maker of reflecting teleſcopes, uſed to proceed by firſt making his large metal as nearly correct or parabolical as he could, and then, from a number of ſmall metals, to ſelect, by trial, that which corrected the large one in the beſt manner.

"In all matters relating to the practice of optics there is much uncertainty, and it frequently happens that, with the very beſt endeavours, we cannot produce by the ſame means the ſame effect, where extreme correctneſs is required; ſo that you may very readily conceive, that very exact calculations, however requiſite, will not always anſwer. In a rough way of taking the focal lengths and ſurfaces of an achromatic object-glaſs, compoſed of crown and flint glaſs of the uſual denſities, we ſhould ſay crown 1 : 3 and flint 2 : 3; the outer ſurface of the crown ſhorter than that which is next to the flint, and the ſhorteſt radius of the flint next to the crown; and the nearer it can be brought without touching in the middle, the more perfect will be the performance; though this will in a great degree depend on the aberrating powers of the glaſſes uſed; for ſometimes we find it neceſſary to make the crown nearly of equal radii. The French opticians make the radii of the convex lens very unequal, and place the ſhorteſt radius next to the flint; and inſtead of crown they uſe Bohemian plate, which is nearly of the ſame refracting power, but of a different colour, their flint-glaſs being of a much leſs ſpecific gravity than the Engliſh.

"The great barrier to further improvement, particularly in the extenſion of the aperture, is the want of good glaſs, which circumſtance has ever been lamented; and from the exceſſively increaſed duties, which act againſt the improvement of every manufacture, a prohibition is now likely to take place altogether."

In this hiſtorical account of the invention and ſucceſſive improvements of the teleſcope, we have ſaid nothing about the ingenious experiments of Dr. R. Blair, profeſſor of aſtronomy in the univerſity of Edinburgh, which were made, with a view to aſcertain the diſperſive powers of different liquids, about the year 1787, and for this reaſon, that we conſider any teleſcope of which a liquid forms a conſtituent part, to be a temporary rather than a permanent inſtrument. Neither have we given Dr. Herſchel's labours ſo prominent a place in our narrative as they deſerve, becauſe we ſhall have occaſion to deſcribe his reflecting teleſcope, with reference to its appropriate plate, in a ſubſequent ſection of our article.

Beſides the preceding improvers of the teleſcope, ſeveral perſons, chiefly amateurs, have taken out patents, either for alterations in the appendages of this inſtrument, or for peculiar modes of uſing them for particular purpoſes, with a ſhort notice of which we ſhall conclude this ſection of our article. On the 4th of April, 1791, Mr. Robert Blair, a ſurgeon in the navy, took out a patent for ſecuring to himſelf the advantages to be derived from uſing a fluid medium, in conjunction with glaſs, to correct the priſmatic aberration in an object-glaſs of a refracting teleſcope, agreeably to the experiments previouſly made on this ſubject by Dr. Robert Blair, as we have juſt ſtated. On the 26th of January, in the year 1799, Mr. Cater Rand, of Lewes in Suſſex, took out a patent for "an improved military and naval teleſcope, for aſcertaining diſtances, and the ſize and extenſion of objects, at ſight, by means of a new micrometrical adjuſtment." This micrometrical teleſcope, however, was nothing more than the parallel wire micrometer, applied to a common pocket achromatic teleſcope, in which a vernier ſcale projected from the eye-piece, and indicated the quantity of the meaſured angle to the profeſſed accuracy of $6''$; but how the inſtrument was kept ſteady enough without a ſtand for the uſe of ſuch a micrometer, is not explained. Mr. Dudley Adams, of Fleet-ſtreet, optician, took out a patent, on May 30, 1800, for rendering teleſcopes more portable; the object of which was to ſecure the advantage to be derived from uſing tubes, with ſlits made in ſuch a way as to make them move ſmoothly, and yet without ſhake, within one another. Mr. G. H. Brown, ſecretary to the Weſtminſter fire-office, in Bedford-ſtreet, Covent-Garden, has deſcribed, in the 11th volume of the Repertory of Arts and Manufactures, a reflecting teleſcope, that always lies in a horizontal poſition; and, receiving the rays of light on an inclined plain mirror, having a central perforation, and placed near the inſertion of the eye-tube, reflects them to the large concave ſpeculum, which, by a ſecond reflection, forms the image in the eye-tube. Benjamin Martin conſtructed a reflecting teleſcope in this way, which he uſed in a vertical poſition for terreſtrial objects; and the only difference in the two conſtructions ſeems to be, that in Martin's, the main tube was reclined when viewing elevated objects, ſuch as the heavenly bodies, whereas Brown's plain mirror has a vertical motion independently of the main tube. They have neither of them come into common uſe.

Mr. Manton, gun-ſmith, of Davis-ſtreet, Berkley-ſquare, London, took out a patent on the 23d of January, 1810, for

for securing the use of an exhausted tube, on a supposition that there would be more light when the rays were refracted to a focus *in vacuo*. Mr. Cornelius Varley, artist, now of Newman-street, London, took out a patent for a graphic telescope, for the purpose of delineating drawings from nature, on the principle of Dr. Wollaston's camera lucida, the date of which is April 5, 1811. And on the 21st of May of the same year, Dr. Brewster of Edinburgh, and Mr. Harris, optician, of Holborn, London, jointly took out a patent for a micrometrical, double-image, and coming-up glass, &c. which has its scale of measurement running longitudinally along the tube. This telescope, being on a new construction, will be particularly described hereafter.

2. *Theory of dioptric Telescopes.*—Before we can properly describe the various constructions of either the refracting or reflecting telescope, it will be necessary to explain the principles on which those constructions are founded; and for the sake of order, we will confine ourselves, in the first place, to the consideration of the elementary principles of dioptrics, so far as they are connected with the theory of the refracting telescope. Among the various writers who have considered this subject, in both a scientific and practical manner, Benjamin Martin stands first in our estimation; and as his "New Elements of Optics," published in 1759, are but little known, by reason of the scarceness of this work, notwithstanding it contains the result of all his theoretical and practical investigations, we shall make no scruple in availing ourselves of his labours, as often as they contribute to the purpose of either illustration or practical application: our aim being, in this article, as in some former ones connected with it, to bring the mathematician and the mechanic into a state of mutual understanding.

We propose, therefore, to avoid as much as possible all abstruse calculations, that have no tendency to produce practical advantages, but to introduce, in as familiar a manner as possible, those mathematical investigations only, which are essentially explanatory. The first and fundamental principle in dioptrics is this, that in all uniform media, such as air, water, glass, &c. "the sines of incidence are in a constant ratio to the sines of refraction" of any homogeneal ray of light, incident on the surface of such refracting medium; which principle was first discovered by Snell, when Huygens had gone no further than to assert, that in small obliquities of incidence, the angle of refraction was about one-third of the angle of incidence. In the glass which sir Isaac Newton used, the ratio of the sine of incidence to the sine of refraction was found to be 30 : 21, or nearly 3 : 2, in passing out of air into glass: and had all kinds of glass been found equal with respect to their refractive powers, the radius of convexity would, in all cases, have been equal to the focus of a double convex lens of equal radii; which equality may be considered as the basis of all the *geometrical* theorems in optics, that take no account of the difference of the *refractive powers*. But since the difference of the refractive powers of various specimens of glass has become an object of indispensible examination to the optician of modern times, it has become necessary to introduce into each theorem the ratio between the sine of incidence and sine of refraction, whatever it may be found to be by experiment, before the *refracted* focus of any individual lens, depending on the quality of the glass, in some measure, can be determined from the *geometrical* focus depending on the radius of convexity or concavity. As we have demonstrated, under our article REFRACTION, the constancy of the ratio between the sines of the angles of incidence and of refraction of a mean refracted ray; and have also explained how the geometrical focus of any lens may be determined with converging, parallel, and diverging rays, under the term LENS; we will proceed to apply the doctrine arising out of these demonstrations and explanations to our present purpose. "Let D C (*Plate* XXIV. *Astronomical Instruments*, *fig.* 1.) be a ray of light incident out of any medium X, upon the surface, H O, of another medium Y, which we will suppose to be more dense than X; and from the point of incidence C, let it be refracted to F, out of its first direction D C M. This refraction may be considered as arising out of the attracting power at the surface of the medium Y, and as acting upon the ray in a perpendicular direction, by which, on mechanical principles, it will acquire some additional force and velocity of motion through the medium Y. Now upon the centre C describe the circle A O P H, cutting the incident ray in D; and drawing the diameter A C P perpendicular to H O, let D L fall perpendicular thereto, and it will be the *sine of incidence*. Let D C or C E represent the space described in a given time in the medium X; and from E draw E F parallel to A B, to denote the acquired force in C: then the motions in the directions C E and E F, in the same time, being compounded, will produce a motion in the direction found by joining C F; for C F will be the space described in the medium Y, in the same time that D C (= C E) was passed over in the medium X, and consequently will be the *refracted ray*; and G I, perpendicular to A B, will be the *sine* of refraction.

"Through F draw N M parallel to H O, and draw K E perpendicular to A B; then will B F = K E = D L be the *sine* of incidence; and in the similar triangles C I G, C B F, we have C G : C F :: G I : B F. Hence it appears that we have the sines of the angles of incidence and of refraction B F or D L, and G I, as the velocities C F and C D (= C G) in the different media inversely, and on this supposition they are in a *constant ratio;* because the velocities are invariable, being produced by the uniform operation of nature. And on the contrary, if the ray F C be considered as passing out of a dense medium Y, into a rare medium X, it will be deflected by the superior force of the medium Y, into the direction C D; making D L : I G :: C F : C D, as before.

"Let us now conceive A M D, in *fig.* 2, to be the curved surface of a refracting medium Y, and B a radiant point in a more rare medium X, from which two rays proceed, and fall upon the curve in the points M and N indefinitely near to each other: these rays will be so refracted as to cross each other in a certain point F; to determine which from the given equation of the curve, the distance of the radiant, and the refractions of the media, is that problem in dioptrics, on which the various calculations and inferences depend. That we may render the solution of this problem intelligible to our readers, let us make the lines C M and C N the radii of curvature, and consequently perpendicular to the curve at the points M and N; upon M F and N F let fall the perpendiculars C G and C g, cutting F M in S: also upon the incident rays B M, B N, continued, let fall the perpendiculars C E, C e; and on the centres B and F, describe the small arcs R M, M O; and put B M = d, M E = a, M G = b; the arc M R = s, and the arc M O = t; and lastly, the sine of incidence C E to that of refraction C G, as m to n, the radius of curvature being C M = r. Then the triangles M E C, M R N; M G C, M O N; M B R, Q B e, are similar, as is thus evident: if from the right angles R M E, C M N, you subtract the angle E M N, there remains the angle R M N = E M C; and if from the right angles F M O, C M N, you take the angle F M N, there will remain the angle O M N = G M C. These triangles

angles are, therefore, *equiangular*, and conſequently *ſimilar*. Hence we derive the following analogies for determining the refracted ray M F; *viz*. M E : M C :: M R : M N; that is, $a : r :: s : \frac{rs}{a} =$ M N.

“ Again, from the triangles M G C and M O N, we have M G : M C :: M O : M N; that is, $b : r :: t : \frac{rt}{b} = \frac{rs}{a}$ $\therefore sb = at$; and ſo $a : b :: s : t$, or $\frac{bs}{a} =$ M O. And in the triangles B M R, B Q e, we have B M : B e (= B E) :: M R : Q e; that is, $d : d + a :: s : \frac{ds + as}{d} = Qe$. But $Ce : Cg$ (:: C E : C G) :: $m : n$ :: $Ce - CE : Cg - CG$ :: Qe .: Sg :: $\frac{ds + as}{d} : \frac{nas + nds}{md} = Sg$.

“ Laſtly, the ſimilar triangles E M O, F S g, give M O : S g :: M F : S F or G F; therefore, M O − S g : M O :: M F − G F (or M G) : M F; that is, in ſymbols $\frac{bmds - aans - ands}{amd} : \frac{bs}{a} :: b : \frac{mdbb}{mdb - aan - nda}$ = M F, the focal diſtance required.

“ As the right angles at E and G are both ſubtended by the ſame hypothenuſe, or right line M C, it is evident that this line is the diameter of a ſemicircle, M E G C, paſſing through them, as in *fig.* 3; and if the curve A M D be a circle, then C will be its centre; and when the point M is extremely near to the vertex A, there will be M E = M G = M C, or $a = b = r$. In this caſe, the theorem becomes $\frac{rmd}{md - nd - nr} =$ A F $= f$; and the point F, or focus of refracted rays, is then in the axis B C produced.”

From this original theorem for finding the ſimple refraction of a pencil of diverging rays out of a rare into a denſe medium, may be derived other theorems for finding the ſimple refraction out of a denſe into a rare medium, and for the refraction of lenſes of any of the common ſhapes, either at the firſt or ſecond ſurface. We will ſubjoin a ſmall table of ſuch of thoſe theorems as apply to glaſſes of the ordinary conſtruction.

Theorems for one ſimple Refraction.

Out of Air into Glaſs		
Rays.	Convex.	Concave.
Diverging	$\frac{mdr}{md - nd - nr} = f.$	$\frac{-mdr}{md - nd + nr} = f.$
Parallel	$\frac{mr}{m - n} = f.$	$\frac{-mr}{m - n} = f.$
Converging	$\frac{mdr}{md - nd + nr} = f.$	$\frac{-mdr}{md - nd - nr} = f.$
Out of Glaſs into Air.		
Diverging	$\frac{-ndr}{md - nd + mr} = f.$	$\frac{ndr}{md - nd - mr} = f.$
Parallel	$\frac{-nr}{m - n} = f.$	$\frac{nr}{m - n} = f.$
Converging	$\frac{-ndr}{md - nd - mr} = f.$	$\frac{ndr}{md - nd + mr} = f.$

Hitherto we have conſidered the refraction of a ray at only one ſurface of a lens; but as every lens has two ſurfaces, or radii, r and R, it is neceſſary to carry our inveſtigation farther, and ſee what theorems can be obtained for finding the foci of glaſſes of the different ſhapes, when double refraction takes place, which is the caſe in all inſtances of complete tranſmiſſion. By way of diſtinction, we will conſider r as the radius of the firſt ſurface, or that which receives the rays from the radiant; and R as the ſecond ſurface, or that which is ſuppoſed to be turned from the radiant, in all our ſubſequent theorems. We muſt now conſider a ray, as M N, in *fig.* 4, coming out of a denſe medium Y, after proceeding in a direction towards F, into the rare medium X; but meeting with a ſpherical ſurface N D, on quitting the denſe medium, is refracted into the direction N f, to interſect the axis D f, in the focal point f. When two ſpherical refracting ſurfaces are near to each other, as A M, N D, in *fig.* 5, they conſtitute a lens A M N D, of which the radius of the curve A M is r, when the radiant is on that ſide, but that of N D is denominated R; and the line B A D F, paſſing at right angles through the middle of the lens, is called the axis. Now to

find

find the point f, or focal diſtance Df, of the ray BM, coming from the radiant B, after being twice refracted, *viz.* at M and N, the points of ingreſs and egreſs, is the *general problem of dioptrics.*

In ſolving this problem, our original theorem for ſimple refraction gives us $mdf - mdr = nrf + ndf$, (making $MF = \phi$,) from which equation we deduce this expreſſion; *viz.*

$$\frac{m}{n} = \frac{r+d}{\phi - r} \times \frac{\phi}{d} = \frac{BC}{CF} \times \frac{AF}{AB},$$ which gives this univerſal canon: *viz.* "the ratio of the ſine of incidence to the ſine of refraction, is compounded of the ratio of the diſtances of the conjugate foci B and F from the centre C, and of the ratio of their diſtances from the vertex A." This rule being *general*, finds the focus f, after the ſecond refraction at N: for let $Df = f$, the radius $GD = R$, and the thickneſs of the lens $AD = t$; then we have for the refraction out of a denſe medium into a more rare one, $\frac{n}{m} = \frac{FG}{fG} \times \frac{fD}{FD} = \frac{\phi + R - t}{1 + R} \times \frac{f}{\phi - t}$; from whence we get

$$f = \frac{n\phi R - ntR}{m\phi - mt + mR - n\phi + nt} = Df,$$ the focal diſtance required. If we omit the thickneſs of the lens t, as being inconſiderable, we may reduce the equation into a more ſimple form; for we ſhall have $\frac{n\phi}{m\phi + mR - n\phi} = f$; and this will give $\phi = \frac{mfR}{nR + nf - mf} = \frac{mdr}{md - nd - nr}$, which equation reduced gives

$$\frac{ndrR}{mrd - nrd + mdR - ndR - nrR} = f.$$

But to reduce the number of ſymbols, let us put $\frac{m-n}{n} = a$, and conſequently $m - n = a$, when n is unity, and then this equation becomes $\frac{drR}{ard + aRd - rR} = f$, and this may with propriety be called the *univerſal dioptric theorem*, by which the *refracted focus* of a ray may be determined after paſſing through any lens of a given denſity, or refracting power.

The theorems in the ſubjoined Table I. are all derived from the univerſal theorem thus determined, and will be of great uſe to the optician to determine the *refracted* focus of any lens, and for any diſtance of the radiant, which refracted focus, with parallel rays, will be always equal to the true, or nicely meaſured *ſolar focus*, where d is infinite; whereas the focus determined from the old theorems in Table II. where the value of a is omitted, is always the *geometrical* focus, determined on a ſuppoſition that the ſine of incidence is to the ſine of refraction in all glaſſes as 3 : 2, in which caſe $\frac{m}{n} - \frac{n}{n}$, i. e. $\frac{3-2}{2} = \frac{1}{2}$ invariably, and $\frac{1}{2}r$, in a double convex lens of equal radii, of whatever refractive power, $= f$. In order, therefore, to diſtinguiſh the focus determined from the theorems in Table I., from thoſe ariſing from the theorems in Table II., we will always call the firſt the *refracted focus;* which is that from which the *powers* of a teleſcope or of a microſcope are derived; and the ſecond we will denominate the *geometrical* focus, which is that ariſing from the ſimple conſideration of the radii of curvature, without reference to the refractive power of the glaſs, otherwiſe than as we have ſtated; but is notwithſtanding uſeful to opticians in the formation of the curved faces of their grinding and poliſhing tools; for when the curves of a lens of a given refractive power are to be formed, to produce a given refracted focus, as is frequently required in the nicer optical inſtruments, the refracted focus muſt firſt be converted, by means of the value a of its refractive power, into the *geometrical* focus, and then the radii of curvature belonging to this calculated geometrical focus, will be proper for the tools of the lens of a given refractive focus. Hence we conſider it as a matter of great practical importance, to give, in the ſame place, two tables, one for finding the *refracted*, and the other for finding the *geometrical* foci of ſuch lenſes as are uſually applied in either a teleſcope or microſcope of the refracting conſtruction. In all caſes where the glaſs has two radii, the firſt, as we have ſaid, will be denominated by r, and the ſecond by R.

But before we proceed to tabulate our theorems for both *refracted* and *geometrical* foci of ſingle lenſes, we wiſh it to be clearly underſtood by our readers, that the practical application of thoſe theorems, and of others to be derived from them, to the purpoſe of actual conſtruction of achromatic object-glaſſes, and of achromatic eye-pieces, is intended to be the leading feature of our article; for while volumes have been filled with abſtruſe calculations, derived from formulæ of the moſt celebrated mathematicians, the reſults of thoſe calculations have never produced proper data for the uſe of opticians; more particularly with reſpect to achromatic object-glaſſes, which cannot be conſtructed from any calculations but what are grounded upon experimental examination of the identical ſpecimens of glaſs that are intended to be uſed. And we flatter ourſelves, that the information we have to lay before our readers on this intereſting ſubject, will be the *firſt* that has yet been *publiſhed* in ſuch a *practical form* as will facilitate the labours of the working optician.

TABLE I.—Theorems for finding the *refracted* Foci of Lenfes.

Lenfes with unequal Radii.		
Rays.	Convex.	Concave.
Diverging	$\frac{d\mathrm{R}r}{adr + ad\mathrm{R} - r\mathrm{R}} = f.$	$\frac{d\mathrm{R}r}{-adr - ad\mathrm{R}r - \mathrm{R}r} = f.$
Parallel	$\frac{r\mathrm{R}}{ar + a\mathrm{R}} = f.$	$\frac{r\mathrm{R}}{-ar - a\mathrm{R}} = f.$
Converging	$\frac{-dr\mathrm{R}}{-adr - ad\mathrm{R} - r\mathrm{R}} = f.$	$\frac{-dr\mathrm{R}}{adr + ad\mathrm{R} - r\mathrm{R}} = f.$
Lenfes with equal Radii.		
Diverging	$\frac{dr}{2ad - r} = f.$	$\frac{-dr}{2ad + r} = f.$
Parallel	$\frac{r}{2a} = f.$	$\frac{-r}{2a} = f.$
Converging	$\frac{-dr}{-2ad - r} = f.$	$\frac{dr}{-2ad + r} = f.$
Lenfes with one Radius (R) infinite.		
	Plano-convex.	Plano-concave.
Diverging	$\frac{dr}{ad - r} = f.$	$\frac{-dr}{ad + r} = f.$
Parallel	$\frac{r}{a} = f.$	$\frac{-r}{a} = f.$
Converging	$\frac{-dr}{-ad - r} = f.$	$\frac{-dr}{ad - r} = f.$
Lenfes with one Radius (R) negative, or Menifci.		
	Unequal.	Equal.
Diverging	$\frac{-dr\mathrm{R}}{adr - ad\mathrm{R} + r\mathrm{R}} = f.$	$-d = f.$
Parallel	$\frac{-r\mathrm{R}}{ar - a\mathrm{R}} = f.$	$\frac{-r\mathrm{R}}{0} = f.$
Converging	$\frac{dr\mathrm{R}}{ad\mathrm{R} - adr + r\mathrm{R}} = f.$	$d = f.$
Lenfes with both Radii (r and R) negative, or double concave.		
Diverging	$\frac{dr\mathrm{R}}{-adr - ad\mathrm{R} - r\mathrm{R}} = f$, always negative.	
Parallel	$\frac{r\mathrm{R}}{-ar - a\mathrm{R}} = f$, always negative.	
Converging	$\frac{-dr\mathrm{R}}{adr + ad\mathrm{R} - r\mathrm{R}} = f.$	

TABLE II.—Theorems for finding the *geometrical* Foci of Lenses.

Lenses with unequal Radii.		
Rays.	Convex.	Concave.
Diverging	$\frac{2dRr}{dR + dr - 2rR} = f.$	$\frac{2dRr}{-dR - dr - 2Rr} = f.$
Parallel	$\frac{2rR}{R + r} = f.$	$\frac{2Rr}{-R - r} = f.$
Converging	$\frac{2dRr}{dR + dr + 2Rr} = f.$	$\frac{2dRr}{dR - dr - 2Rr} = f.$
Lenses with equal Radii.		
Diverging	$\frac{dr}{d - r} = f.$	$\frac{dr}{-d - r} = f.$
Parallel	$\frac{dr}{d} = r = f.$	$\frac{dr}{-d} = f.$
Converging	$\frac{dr}{d + r} = f.$	$\frac{-dr}{d - r} = f.$
Lenses with one Radius (R) infinite.		
Diverging	$\frac{2dr}{d - 2r} = f.$	$\frac{-2dr}{d + 2r} = f.$
Parallel	$\frac{2dr}{d} = f.$	$\frac{-2dr}{d} = f.$
Converging	$\frac{2dr}{d + 2r} = f.$	$\frac{2dr}{2r - d} = f.$
Lenses with one Radius (R) negative.		
	Unequal.	Equal.
Diverging	$\frac{-2dRr}{dR - dr + 2Rr} = f.$	$\frac{-2dRr}{2Rr} = -d = f.$
Parallel	$\frac{-2Rr}{R - r} = f.$	$\frac{-2Rr}{0} = f.$
Converging	$\frac{2dRr}{dR - dr + 2Rr} = f.$	$\frac{2drR}{2rR} = d = f.$
Lenses with both Radii (r and R) negative, or double concave.		
Diverging	$\frac{2dRr}{-dR - dr - 2Rr} = f.$	$\frac{dR}{-d - R} = f.$
Parallel	$\frac{2Rr}{-R - r} = f.$	$\frac{dR}{-d} = f.$
Converging	$\frac{-2dRr}{dR + dr - 2Rr} = f.$	$\frac{-dR}{d - R} = f.$

As we explained how Table I. is derived from an univerſal dioptric theorem, we ſhall explain how the theorems in Table II. are deduced from one fundamental equation, on a ſuppoſition that the ſines of incidence and refraction in glaſs are always as 3 : 2. Let L N, in *fig.* 6, repreſent a convex lens, O f its axis, O a radiant point therein, O A a ray proceeding from thence to A, a point in the ſurface L B N; then if C is the centre of convexity of that ſurface, C G, drawn through the point A, will be perpendicular to that ſurface in the point A; C A or C B is the radius, A f the refracted ray, and f the point where it meets the axis after the firſt refraction. Let D B $= d$, C A $=$ R, E B $= t$, the thickneſs of the lens; and let the ſine of the angle of incidence O A G be called m, and the ſine of the angle of refraction C A f or G A H be called n. Now, ſince the point A is ſuppoſed to be very near to the vertex B, O A may be conſidered equal to O B $=$ D, and in the triangle C A O, we ſhall have A O to A C as the angle C to the angle O; that is, d : R :: C : O. Alſo O B + B C $=$ D + R will be as the oppoſite angle C A O or O A G, the ſines of both being the ſame. Then as $m : n :: d + r :$ $\frac{\mathrm{D}n + \mathrm{R}n}{m}$, which will be as the angle C A f; this, taken from the angle A C O $= d$, leaves the angle A f O $= \frac{\mathrm{D}m - \mathrm{R}n - \mathrm{D}n}{m}$. Laſtly, as the angle f : O :: A O or O B : A f or B f; that is, as $\frac{\mathrm{D}m - \mathrm{R}n - \mathrm{D}n}{m}$: R :: D : $\frac{\mathrm{RD}m}{\mathrm{D}m - \mathrm{R}n - \mathrm{D}n} =$ B f, the diſtance of the point f in the axis, after the firſt refraction. But ſince there is a ſecond ſurface L E N of the lens, there muſt neceſſarily be a ſecond refraction of the ray A O to ſome other point in the axis, as F, in *fig.* 7. In this caſe, the refraction being out of a denſe into a rare medium, the ſine of incidence will be to that of refraction the *reverſe* of what it was before, *viz.* as n to m; that is, the ſine of I $a f$ is to the ſine of I a F as n to m, which, in the caſe of ſingle refraction, was as m to n. Here let K a be called r, and E $f = d$; then there will be $d : r ::$ K : f, and E f + E K $= d + r$, which will be as the angle f a K, or its complement I a f; therefore $n : m :: d + r : \frac{dm + rm}{n}$, which will expreſs the angle I a F. Then I a F − a K F $= \frac{dm + rm}{n} - d = \frac{dm - rm - dn}{n} =$ a K F. Now, as F : K :: K a or K B : a F or E F; that is, as $\frac{dm + rm - dn}{n} : d :: r :$ $\frac{ndr}{dm + rm - dn} =$ E F. But B f − B E $= \frac{\mathrm{DR}m}{\mathrm{D}m - \mathrm{R}n - \mathrm{D}n}$ $- t = d =$ E f; therefore, putting $m - n = b$, we ſhall have $d = \frac{\mathrm{DR}m}{\mathrm{D}b - \mathrm{R}n} - t = \frac{\mathrm{DR}m - \mathrm{D}bt + rnt}{\mathrm{D}b - \mathrm{R}n}$.

Alſo $dnr = \frac{\mathrm{DR}mnr - \mathrm{D}btnr + rtnnr}{\mathrm{D}b - \mathrm{R}n}$.

Again, $dm + rm - dn = \mathrm{D}b + rm$; if, therefore, we multiply the equation by b, and add thereto rm, we ſhall have $dm + rm - dn$

$$= \frac{\mathrm{DR}mb - \mathrm{D}btb + \mathrm{R}ntb + \mathrm{D}brm - \mathrm{R}nmr}{\mathrm{D}b - \mathrm{R}n}.$$

Then $\frac{dnr}{dm + rm - dn}$

$$= \frac{\mathrm{DR}mnr - \mathrm{D}btnr + \mathrm{R}tnnr}{\mathrm{DR}mb - \mathrm{D}btb + \mathrm{R}ntb + \mathrm{D}brm - \mathrm{R}nmr} = \mathrm{EF}.$$

This laſt equation may be abridged, by ſubſtituting p for $\frac{n}{b}$, that is, for $\frac{n}{m-n}$, then we ſhall have

$$\frac{p\mathrm{DR}mr - p\mathrm{D}btr + \mathrm{R}tnrp}{\mathrm{DR}m - \mathrm{D}bt + \mathrm{R}nt + \mathrm{D}rn - p\mathrm{R}mr} = \mathrm{EF}.$$

Laſtly, if we take $n = pb$ in $p\mathrm{D}btr$; and $m - n = b$ in $\mathrm{D}bt$; this equation will be finally reduced to this fundamental equation, *viz.*

$$\frac{p\mathrm{DR}rm - \mathrm{D}trn + \mathrm{R}trpn}{\mathrm{DR}m - \mathrm{D}tm + \mathrm{D}tn + \mathrm{R}tn + \mathrm{D}rm - p\mathrm{R}rm} = \mathrm{EF} = f.$$

The ratio of m to n being taken in glaſs as 3 : 2, we ſhall have $\frac{n}{m-n} = \frac{2}{3-2} = 2 = p$ for a glaſs lens, and the equation will then ſtand thus; *viz.*

$$\frac{6\mathrm{DR}r - 2\mathrm{D}tr + 4t\mathrm{R}r}{3\mathrm{DR} - 3\mathrm{D}r - \mathrm{D}t + 2\mathrm{R}t - 6\mathrm{R}r} = \mathrm{EF} = f;$$

and when t, the thickneſs, is diſregarded, we have from this fundamental theorem all the various theorems contained in Table II. for finding the geometrical focus under all the various circumſtances that are likely to occur in the poſition of a ſingle lens, where the refractive power is not adverted to.

To illuſtrate the reſpective uſes of the theorems contained in the two preceding tables, we muſt ſuppoſe the ratio between the ſines of the angle of incidence and of refraction known by ſome of the uſual modes of determining it experimentally; and then, when the ratio of $m : n$ is ſo determined, there will be $\frac{m-n}{n} = a$, the ſymbol introduced in the theorems of the firſt table; when d is equal to the diſtance of the radiant, r the radius, and f the proper focus determined by real refraction through the glaſs uſed, the theorem for finding the value of a is $\frac{dr - rf}{2df} = a$.

For inſtance, Martin ground a piece of white flint-glaſs with a tool of 21.5 inches radius, into a double convex lens, and when a lamp was placed at the diſtance of 417.25 inches, the refracted focus was meaſured accurately, and found to be only 18.75 inches; whence, according to the theorem, we have $\frac{\overline{417.25 \times 21.5} + \overline{21.5 \times 18.75}}{2 \times 417.25 \times 18.75} = 0.599 = a$ $= \frac{m-n}{n}$; and if we put $n = 1$, then m will be 1.599, for $\frac{1.599 - 1}{1} = 0.599$. When the ſun is the radiant, then d becomes infinite, and the theorem becomes, as in the firſt table, $\frac{r}{2a}$, which gives, in this caſe, $\frac{21.5}{1.198} = 17.94$ for the refracted

refracted *solar* focus; whereas, by Table II., the geometrical focus is $\frac{dr}{d} = r = 21.5$. If the refractive power of the glass, and consequently the value of a, had been given, and it had been required to determine the radius of the tool that will grind the given glass into such equal radii as will give the refracted solar focus exactly 17.82 inches, then the theorem $\frac{r}{2a} = f$ becomes, by transposition, $2af = r$, and $1.298 \times 17.94 = 21.5$, as before. In a specimen of crown-glass ground to the same radius, where d was 414.75 inches, $\frac{dr + rf}{2df}$ gave $a = 0.5318$, and consequently $m : n$ as $1.5318 : 1$, with which lens the true solar focus was $\frac{21.5}{1.0636} = 20.214$; and if the lens had been a single convex, the true solar focus would have been $\frac{r}{a} = \frac{21.5}{.5318} = 40.428$, or double the length of the former, while the geometrical focus for parallel rays, by Table II., would have been $\frac{2dr}{d} = 2r = 43.0$; so that for many practical purposes, where $m - n$ is known in the particular glass used, the advantage of the theorems in Table I., over those in Table II., must be evident

Again, let us suppose that the ratio of $m : n$ is ascertained by a prism of any specimen of glass, or by Dr. Wollaston's or Dr. Brewster's instruments for this purpose, and that it is known to be $1.599 : 1$; then we know that $.599 = a$, as before; and let it be required to find the refracted focus with diverging rays, when the radiant is as before at the distance of 417.25 inches, and the radius of curvature of each surface 21.5: in this case the theorem is $\frac{dr}{2ad - r} = f$, or, in numbers, $\frac{417.25 \times 21.5}{2 \times 0.599 \times 417.25 - 21.5} = 18.75$, as before; and in this way the terms given may be varied at pleasure, and the theorem made applicable to the case in question. If the rays had been converging in the last calculation, the theorem would have been $\frac{-dr}{-2ad - r} = f$; or, changing all the signs, (which are here negative, because the distance is more than infinite, that is, the rays more than parallel,) the same may be taken $\frac{dr}{2ad + r} = f$, or $\frac{417.25 \times 21.5}{2 \times 0.599 \times 417.25 + 21.5} = 17.204$, which is less than the solar focus by 0.74 of an inch. In this case the rays must have passed through some other glass, in order that they may proceed in a state of convergence before they enter the lens in question, and the focus of that other glass is here considered as the *radiant* point from which the rays proceed in a state of convergence; and this consideration leads us naturally to inquire into the nature of a focus when two glasses are employed jointly to produce it, under the different circumstances of figure and distance.

Suppose the parallel rays A N and B M, in *fig.* 8, to fall on a plano-convex lens M N, with the curved face turned to the radiant, and to be refracted to its focus at F; then if another plano-convex lens be placed in the line of its axis, at any distance less than C F, so as to intercept the converging rays, they will be refracted still more, and will now converge into the shorter focus f, which is therefore called the *compound focus* of both the lenses. The angle subtended at f, where the eye is supposed to be placed, and which is called the optic angle, is now larger than that formed at F by the first lens, and is equal to what would be formed by the imaginary double convex lens E E, the focal distance of which would be Qf. Now let C F be put = F for the focal distance of the lens N M; O P = y for the focal distance of lens G H; and $Qf = x$ for the focal distance of the imaginary double convex lens E E: also let Of, the compound focal distance, be $= f$; and C O, the distance between the lenses N M and G H, be = D. As the rays, which tend to the point F, after leaving the lens N M, fall on the lens G H *converging*, let us call O F = d, and then, by common optics, we shall have $d = \frac{yf}{y - f} = F - D$; from which equation we get $F + y - D : F - D :: y : f$; and from this analogy the compound focal distance Of is easily obtained. In like manner, the parallel rays L G and S H are refracted by the lens G H, now supposed to be the first lens, to the lens N M, as they proceed towards the point i; but are refracted to the nearer point ϕ, which is the compound focus on the other side; and now we have $C\dot{y} = \frac{F\phi}{F - \phi} = \dot{y} - D$; whence $F + y - D : y - D :: F : \phi = C\phi$, which is therefore known again, because of the similar triangles F N C, F G O, and fE Q, fG O; and because E Q = N C, we have C F : O F :: N C (= E Q) : G O :: $Qf : Of$; that is, $F : F - D :: x : f$; and, therefore, $\frac{Ff}{F - D} = x$. But we had above $\frac{\overline{F - D} \times y}{F + y - D} = f$; which being substituted for f, will give $\frac{Fy}{F + y - D} = x$; from which theorem our problem for finding the compound focus of two lenses, or rather the focus of one lens, that shall have the same focal distance and visual angle as two given ones placed at a given distance shall have together, may be thus found: *viz.* "divide the *product* of the two focal lengths of the given lenses by their *sum*, lessened by their *distance*, and the quotient will be the focal length of the single lens, as required." By way of exemplification, let the focus of N M be put = 6 inches, and that of G H = 4; and then, supposing the curved surfaces turned to the radiant, which is called the best position, as will be seen hereafter, and the distance = 2, we shall have, by the theorem for this purpose, $\frac{6 \times 4}{6 + 4 - 2} = \frac{24}{8} = 3$ for the focus in question; but if the distance had been = 3, then the result would have been $\frac{6 \times 4}{6 + 4 - 3} = \frac{24}{7}$, or 3.42 nearly. But if the distance had been made 4, equal to the focal distance of the lens G H, the compound focus would have been 4 also; and if 6, equal to the focal distance of the lens N M, the compound focus would still have been 6, without any gain of magnifying power in either case, over what would have accrued from the respective single lens; also if the lenses are brought into contact, that is, if D = 0, then we shall have the compound focus the shortest possible, *viz.* $\frac{6 \times 4}{6 + 4 - 0} = \frac{24}{10} = 2.4$. But *distinctness* is an object of of as much importance as magnifying power; and it will be feen hereafter, that there is a certain diftance between the lenfes that promotes this quality the moft poffible, whatever be the radii of the two lenfes. This condition is fulfilled when x is $= \frac{1}{2}$ F, that is, when the focus of the imaginary lens E E is juft one half of that of the outer lens N M; in which cafe the compound focus f will be in the middle of the line O F, and the lens G H placed at half the focal diftance of the imaginary lens. But it is not neceffary that the object, or image of an object $u\,v$, fhould be fituated in the exterior compound focus ϕ: this focus may be fuppofed negative, that is, the image may be between the two lenfes M N and G H, as B A in *fig.* 11. which will always be the cafe when D is greater than y; or, in other words, when the diftance between the two lenfes exceeds the focal diftance of the inner lens G H; for let $F = 6, D = 4$, and $y = 2$, and we fhall have $\frac{6 \times 2}{6+2-4} = \frac{12}{4} = 3$, as in the firft inftance. Neither is it neceffary that both the lenfes be convex or plano-convex, nor yet with the fame face outwards; for fuppofe N M concave, when its focus will be *negative*, or virtually on the oppofite fide of it, and muft be expreffed by $-$ F; in this cafe the theorem becomes $\frac{-Fy}{y-F-D} = x$, for the focus of the imaginary lens E E that fhall have its focus equal to the compound focus, which will always be *pofitive* while F + D is greater than y, but when lefs, then negative; and when $y = F + D$, the rays proceed parallel, and the focus is faid to be *infinite*. The compound focal diftance in this cafe is $\frac{-Fx - Dx}{-F} = f$, and muft be affirmative when x is fo; but when $D = o$, then $f = x$. As an example, let the concave N M have a negative focal diftance $-F = 3$, and let $y = 2$, while $D = 1$; then the focal diftance of the imaginary or equal lens will be $\frac{-6}{2-4}$, or $\frac{-6}{-2} = 3 = x$, and the compound focal diftance will be $\frac{-\overline{3 \times 3} - \overline{1 \times 3}}{-3}$, or $\frac{-12}{-3} = 4 = f$. Whence, in this cafe, fo is equal to 2 F O, whereas when N M was convex, we had the reverfe, F O = 2 fo. When $-F = y$, and $D = o$, i. e. when a concave lens and convex one are placed in contact, with their feparate focal diftances equal, then x becomes infinite, or, in other words, the rays emerge, and proceed in a parallel direction; but if the focal lengths are unequal, there will be a pofitive focus and magnifying power, when the convex has the fhorter radius; for fuppofe $-F = 3$, $y = 2$, and $D = o$, then by the theorem $\frac{F \times y}{F-y}$, we fhall have $\frac{-6}{-1} = 6 = x$, and in this cafe $x = f = 6$ likewife. From thefe inftances it will be feen, on examination, that the *compound focal diftance* O f, of the combined lenfes, is nothing more than the focal diftance f, found by the common geometrical theorem of optics, $\frac{dr}{d-r} = f$, adapted to the conftant lens G H, where O F $= r$, and O P $= f$, when the rays are *diverging*; or O $f = -f$ $\left(= \frac{-dr}{-d-r}\right)$ when the rays fall diverging on the faid lens. See Table II.

Our general theorem may be rendered more extenfive in its application, by varying it according to the data; thus, if F, x, and D be given to find y, it will be $\frac{Fx - xD}{F - x} = y$; to find F with the others given, it will be $\frac{xD - xy}{x - y} = F$; and to find D, there will be $F + y - \frac{Fy}{x} = D$. From thefe analogies we may further obferve, that we have alfo the ratio of the two compound focal diftances to each other, O f and C f, thus; as $f : \phi :: \overline{F - D} \times y : \overline{y - D} \times F$; and, therefore, when $f = \phi$, then $F = y$; or the faid focal diftances can never be equal, but when the lenfes are equal. Laftly, we may obferve, that fince the parallel rays L G, S H, refracted through both the combined lenfes, interfect the axis in the fame point, ϕ, as it would do if it were refracted by the fingle lens E E, as is evident by continuing it to R; therefore, fince G O = R Q, it will follow that the diameter I K, of the principal pencil of rays K ϕ I, diverging from the focus ϕ, will be the fame as it would have been, if it had proceeded directly to the fingle lens E E; and, confequently, this combination of lenfes makes no alteration in that refpect.

Having now explained how the focal point of any lens, or pair of lenfes, differently circumftanced, may be afcertained by one or other of the dioptric theorems, derived from the refractive power of glafs agreeably to certain laws of nature, it will be proper to explain the different fenfes in which the word *focus* is applied by optical writers under different circumftances, that our readers may not be at a lofs to know in what fenfe it is to be taken, whenever it occurs in our fubfequent details. The *principal* or *folar* focus of a lens, is that which is produced by parallel rays coming from an infinite diftance, which that of the fun may be confidered, and when the epithet *refracted* is added, it has reference to the particular glafs by which the rays are refracted; but when *geometrical* is expreffed or underftood, then glafs in general is meant: the *virtual*, refracted, or geometrical focus, is that which, in a concave glafs, would be formed by the diverging rays continued to a point backwards through the glafs till they meet, and is imaginary rather than real, and generally called *negative:* the focus arifing from converging rays paffing through a convex lens is fhorter, or nearer the lens, than the folar focus, and the radiant is fuppofed to be at a greater than an infinite diftance, if fuch an expreffion is allowable; but as no fuch diftance is in nature, converging rays can only be produced by their paffage through a firft lens before they fall on a fecond, which is often the cafe in the conftruction of optical inftruments: but the focus from diverging rays is always more remote than the folar focus from the lens that produces it; and, in confequence of the reference it has to the fituation of the radiant or illuminated object, is denominated the *proper* and fometimes the *relative* focus; for as the radiant approaches the lens, the proper focus recedes in the fame line, and *vice verfa*, as we have more fully explained under the article LENS. Becaufe the radiant and correfponding focus may change places at any time, the two points where they are placed, at oppofite fides of the lens, are called the *conjugate* foci, from their being fo clofely allied, that one cannot move without the other. When the radiant is placed therefore in the princi-

 pal

pal or solar focus of a lens, the rays will emerge and continue parallel, on account of the other conjugate focus being at an infinite distance; and for the same reason, when an object, viewed by a single lens, is placed in its principal focus, the rays will enter the eye in a parallel state, and will be converged to a point on the retina by the humours of the eye, and a number of these rays crossing will form a picture behind the eye of the object viewed: for, what is one of the most remarkable properties of refracted rays coming from a luminous object, they bring with them not only the figure, but the *colours* of the object viewed, and form a picture or image of it, in the place where the different pencils of rays cross one another; and, what is equally remarkable, this picture is not visible until all extraneous light is excluded. We will not pretend to explain this wonderful property of a lens, that directs the transmitted rays so as to form a picture of a distant object in its focus, but merely mention here, that, without it, no telescope, microscope, camera obscura, or magic lantern, could be constructed on dioptric principles.

After having shewn, by our foregoing theorems, how any focus, solar, proper, conjugate, or virtual, may be determined of a single lens, or of a combination of two lenses with the intermediate distance given, the same might be done for any number of lenses, by considering the compound focus of the first two lenses, as the focal distance of a single lens, to be combined with the third lens, and so on till all the lenses are included. Dr. Smith has given, in his Optics, chap. v. the application of Cotes's theorem "for determining the apparent distance, magnitude, situation, degree of distinctness and brightness, the greatest angle of vision and visible area of an object seen by rays successively reflected from any number of plane or spherical surfaces; or successively refracted through any number of lenses of any sort, or through any number of different media, the surfaces of which are plane or spherical, with an application to telescopes and microscopes;" which account our readers may consult with advantage: but as the illustrations and demonstrations demand more plates than can be given to this article, in addition to the eight we have had occasion to introduce, we have been obliged merely to refer to them in this place.

We propose, however, to substitute some *practical* theorems, derived from our tables, which we have been favoured with by Mr. Tulley, that will be found extremely useful to the working optician, who must be supposed, generally speaking, unable to transform the theorems which we have given in our tables, for the purpose of finding the focal distance of a lens, or of a combination of lenses already constructed; and which tabulated theorems are principally useful for determining the powers, and for explaining the construction of an instrument to which they are applicable.

Practical Theorems.

1. When r, the radius of one face of a lens, is given, and F, its principal geometrical focus, to find R, the radius of the other face, the theorem is $\frac{r\,F}{2\,r - F} = R$ for a double convex: thus, let $r = 9$, and $F = 10.3$ inches, and the calculation will be $\frac{9 \times 10.3}{9 \times 2 - 10.3} = \frac{92.7}{7.7} = 12$ nearly, the truth of which may be proved by our theorem for parallel rays with a double convex lens, in Table II. *viz.* $\frac{2\,r\,R}{R + r}$, or $\frac{9 \times 12 \times 2}{9 + 12} = \frac{216}{21} = 10.3$, as before very nearly, for the required focus; and when the refractive power or ratio between the sines of incidence and of refraction is given, this geometrical may be converted into the refracted focus by the quantity $2\,a$, used as a divisor; or, on the contrary, the refracted focus may be turned into the geometrical focus by using $2\,a$ as a multiplier.

2. With a meniscus lens, where r, the convex side, is given, together with F, the theorem is $\frac{r\,F}{F - 2\,r}$ for finding R, the concave side.

3. But when the concave side of a meniscus is given with the focus, to find the convex, the theorem becomes $\frac{r\,F}{2\,r + F} = R$.

4. When the focus of a double convex lens, and the ratio between its two radii, are given, to find the actual radii r and R respectively, first our theorem in Table II. $\frac{2\,r\,R}{R + r} = F$, will give the focus, on a supposition that one side is unity, and the other any given quantity that forms the other term of the ratio; suppose as $1 : 4$; thus $\frac{1 \times 4 \times 2}{1 + 4} = 1.6$, the rational focus; then suppose the focus given $= 12$, and there will be this analogy, as $1.6 : 1 :: 12 : 7.5 = r$; and also as $1.6 : 4 :: 12 : 30 = R$, or otherwise $\frac{12}{1.6} = 7.5$, and $7.5 \times 4 = 30$ will be the respective radii r and R, as before.

5. When the compound focus of two convex lenses, and the separate focus of one of them, are given, to find the separate focus of the other, that shall be suitable to form the combination; if we put $f =$ the focus of the lens given, $F =$ the combined focus, and $x =$ the focus of the lens required, the theorem for this useful purpose is $\frac{f\,F}{f - F} = x$; for example, let $f = 36$, and $F = 15$, then $\frac{36 \times 15}{36 - 15} = 25.7$ nearly, for the focus of the lens required, which is a positive focus, because both lenses are double convex, and might be plano-convex, or one double convex and the other plano-convex, or even meniscus, as the ratio of the radii r and R may be disregarded when the focus only is the object of consideration. But whatever be the forms of the curves relatively, F, the compound focus of two lenses, or more, will, in practice, be the refracted focus; and, therefore, in this theorem, f and x will also be the refracted foci of the separate lenses, and, consequently, when the geometrical focus of f is given, it must be converted into the refracted focus by the divisor $2\,a$, before the calculation is entered upon; it being necessary that all the terms be of the same denomination.

6. If F, the compound focus, be longer than f, the focus of the given convex lens, as is the case in the construction of a double achromatic object-glass, then the lens required will be concave, of which the focus x is sought, and the theorem becomes $\frac{f\,F}{F - f} = x$. Let us, in this example,

reverse

reverse the numbers of f and F, as taken above, by making $f = 15$, and $F = 36$; and then, as before, there will be $\frac{15 \times 36}{36 - 15} = 25.7 = x$, the negative focus of the concave lens required, which may also have any ratio of its curves, or be a plano-concave, provided its focus be that which has been here determined.

Likewise it must be recollected, that when a positive focus is required from an union of two lenses, one convex and the other concave, the focus of the convex must be shorter than that of the concave; or, in other words, the refractive power, depending on the thickness of the lens, when the same glass is used for both lenses, must predominate in the convex; for it is the difference of the opposite refractions that brings the rays finally to a focus: consequently, if the foci are alike, the rays, being refracted alike in opposite directions, will become parallel, or have what is called an infinite focus: and also, if the focus of the concave be made the shorter of the two, the rays, after opposite refractions, will absolutely diverge by the difference of these refractions, and have an imaginary focus, called a virtual or negative focus, at the other side of the compound lens.

7. If the lens given be concave, and a convex one be required to produce a given compound focus, which is another case in the formation of an achromatic object-glass, the theorem will be $\frac{fF}{F+f} = x$, where f is the focus of the concave, and might be put $-f$, to denote its being a negative focus, and x the focus of the convex lens. Let us put $f = 25.7$, and $F = 36$, as above, and then there will be $\frac{25.7 \times 36}{36 + 25.7} = \frac{925.2}{61.7} = 15$, very nearly, for the focus x of the convex required; which, as we have said, must be the refracted focus, and also f of a like denomination, in order to make the refracted compound focus suitable for a tube of thirty-six inches.

8. If the compound focus should be required to be *negative*, or to have the refraction of the concave lens to predominate, when the convex lens is given with the compound focus, the concave may be found by this theorem $\frac{fF}{F+f} = x$, as in the last; but then x here is the focus of the concave lens, which therefore will be 15 when that of the convex is 25.7, and the negative focus, as before, 36.

9. But if the given lens be concave, and the compound focus be required negative, the focus of the convex sought will be had by this theorem $\frac{fF}{F-f} = x$, as in the sixth theorem; the focus x is here, however, that of the convex, which in the other was that of the concave; so that when $f = 15$, and $F = 36$, x will be again $= 25.7$, but negative.

In all these cases, the two lenses are supposed to be in contact with each other; but if D, the distance between them, which is a variable quantity, were given, similar theorems might be formed from our general theorem $\frac{fF}{f + F - D}$ above explained, where, in any position of two convex glasses, f is the focus of one lens, F the focus of the other, and D the distance between them, with a positive compound focus; but if one of the two lenses be convex, and the other concave, the general theorem becomes $\frac{fF}{f - F - D}$ or $\frac{fF}{F - f - D}$, accordingly as F, put for the concave, or f, put for the convex, is the larger: the former theorem being the "*product* divided by the *sum* of the foci, lessened by the *distance*," and the latter the "*product* divided by the *difference* of the foci, lessened by the *distance*." Hence, by a transposition of one or other of the forms of this general theorem, the data and postulata may be varied as occasion may require. The first form is applicable in cases where sliding eye-pieces, or a sliding secondary object-glass, are used in a telescope, which plans have been recommended and adopted by Dr. Brewster, as we shall see hereafter.

In considering the theory of a telescope, (of either the refracting or reflecting sort,) our attention must be directed to two essential particulars, the *image* of an external object formed at the focus of the object-glass, or of the large speculum, as the case may be; and the *means* by which this image is rendered visible to the eye of an observer: and accordingly as the dimensions, shape, quality, arrangement, and number of the lenses and specula vary from each other, may the constructions be said to differ, though the effect to be produced be intended to be the same. That telescope, of whatever construction, must be considered the most perfect, which exhibits to the eye an image of distant objects the most distinctly, as to light, colour, shape, and proportion; and which, at the same time, amplifies this image sufficiently to afford a minute examination of it, in a field of view that is proportionably large to contain it. That quality, which apparently amplifies the object, or rather the image of the object, by enlarging the angle subtended at the pupil of the eye, therefore called the visual angle, is denominated the *power* of the telescope; and in all telescopes, whatever their other qualities may be, the *light* is *diminished* as the *power increases*, so that in every telescope there is a limit to its useful power, which depends on the quantity of light emitted or reflected by the object to be viewed; and it would answer no good purpose to increase the power so much, that a corresponding deficiency of light may render the object invisible. Hence different powers may be applied, with advantage, to objects differently illuminated; and hence different eye-pieces are usually appropriated to the same telescope, particularly when it is destined for celestial, as well as for terrestrial observations. But we proposed to explain first the theory of those telescopes which are usually called *refracting* or *dioptric*, and afterwards of *cata-dioptric*, or those that magnify by the aid of *reflection*.

Under our article LENS we have said (in section 5.) that "the images of objects, opposed in any manner to a convex lens, are exhibited invertedly in its focus," and that "they will be represented distinctly, and in their natural colours," on a paper held at the opposite side of the glass, at nearly the distance of its proper focus, especially if the room be darkened; and in section 7. we have said, that "the diameter of the image of an object delineated beyond a convex lens, is to the object itself, in the ratio of the distance of the images to that of the object;" so that the more distant an object is from the lens, the smaller is the image of that object; and also the shorter is the focus of the lens, until the distance is such, that the rays fall on its surface parallel, or nearly so. Likewise (in section 8.) we have shewn, that "if the eye be placed in the focus of a convex lens, an object viewed through it appears erect and enlarged in the ratio of the distance of the object from the eye, to that of the eye from the lens, if it be near; but infinitely, if remote:" and what is said of an object itself, when viewed through a convex

convex glafs, is equally true of the *image* of an object fo viewed. It is eafy, therefore, to conceive, how two lenfes of different focal lengths may be fo arranged as to make a telefcope that will at the fame time invert and amplify, as to fenfe, a diftant object: for, firft, a lens of a long focal diftance will form a large image of the object oppofed to it, which image, by the croffing of the rays at the focal point, will be inverted a little beyond the folar focus: and fecondly, an eye applied to a lens of fhort focal diftance, which is held fo that its focal point may coincide with that of the larger lens, will receive parallel rays, and will fhew the faid image in an amplified or magnified ftate, and in the fame inverted pofition in which it is exhibited; which image, by being enclofed in a darkening tube, appears with all its natural colours. The power of fuch a telefcope, which is the fimpleft that can be made, is afcertained by finding how often the focal length of the fmall or eye-lens is contained in the focal length of the larger or object-lens; the quotient of fuch divifion will reprefent the *power*. But if the eye-lens be made concave, and placed within the focal point of the object-lens, as much as is equal to the virtual focus of the concave lens, then the converging rays will become parallel, and afterwards, on entering the eye, which may be confidered as a lens of fhort focus, will converge, and form a direct image on the retina; and though the total length of the telefcope will be fhortened by this latter arrangement, by twice the focal length of the eye-lens; yet if the virtual focus of the concave eye-glafs be the fame as the focal diftance of the convex lens, the power will be the fame, and may be afcertained by the fame procefs. With a convex eye-glafs, the inftrument arifing out of the firft arrangement is the original *aftronomical* telefcope, and that arifing out of the fecond is the *Galilean*. The field of view in the former conftruction is directly as the effective breadth of the eye-glafs, and inverfely as the interval between the lenfes; but in the latter, the field is directly as the diameter of the pupil of the eye, and inverfely as its diftance from the lens.

In both thefe conftructions, the fmalleft power, or, which is the fame thing, the fhorteft focus of the object-glafs is with parallel rays; and as the diftance of the object, or radiant point, decreafes according to the principles of optics laid down under Lens, the focal diftance of the object-glafs increafes: and thus the power increafes as the rays become more and more diverging, from a gradual decreafe of diftance; fo that, in fact, the fame telefcope magnifies a near object confiderably more than it does a diftant one; for while the focus of the object-glafs increafes after a certain law, inverfely as the diftance decreafes, the focus of the eye-glafs remains unaltered; and, confequently, the power varies inverfely as the diftance, or directly as the variable focus of the object-glafs.

To remedy the inconvenience of inverfion of the object in the aftronomical telefcope, and alfo of the contracted field of view of the Galilean, two more glaffes were added to the eye-tube, as we before ftated, to render the image of the object *erect*, or rather to form a fecond image in a contrary pofition. The primary intention of thefe two additional eye-glaffes was not to alter the power, but merely to give an erect pofition to the apparent object; the original lens therefore remained as before, and was called the *field*-glafs, as being neareft to the field of view of the old arrangement of two glaffes, while the next glafs was called the fecond eye-glafs, and was placed at double its focal diftance from the field-glafs, fo that the rays might be parallel, and that it might form another image in its focus: this being the image of an image, was denominated the fecondary image, and became erect by a fecond croffing of the rays, and was then viewed through the outermoft or firft eye-glafs, in the fame manner as the firft or inverted image was viewed through the original eye-glafs. This telefcope was denominated the *terreftrial* telefcope; and while the foci of all the three eye-glaffes were fimilar, its power and field of view remained the fame as in the aftronomical telefcope.

The theory of thefe three conftructions will be more clearly underftood by a reference to *Plate* XXV. of *Aftronomical Inftruments*, in which *fig.* 1. fhews the arrangement of the glaffes in the aftronomical telefcope; *fig.* 2. that of the glaffes in the Galilean, and alfo in the common opera-glafs, except that in it the object-glafs is ufually achromatic; and *fig.* 3. exhibits the fyftem of glaffes that compofe the original terreftrial telefcope, or perfpective glafs, before the fubfequent improvements took place. In all thefe figures the fame letters denote the fame parts, as far as they extend; and the magnifying power of each may thus be demonftrated to be as we have before ftated it. Let A B reprefent the object-glafs, and C D the eye-glafs of *fig.* 1; and let H F I and G F M be confidered as two pencils of light, proceeding in ftraight lines from the oppofite ends of a diftant arrow, and croffing each other at the centre F of the faid object-glafs; alfo let the dotted line be a pencil coming from the middle of the arrow, and falling perpendicularly on the fame central point, fo as to pafs along the axis of the glaffes F L E. Under thefe circumftances, the angle $GFH = IEM$, the oppofite angle, is that under which the arrow appears to the natural eye at F; but the angle $IEM = CKD$, is that under which the image I M of the diftant arrow is viewed, when magnified by the eye-glafs C D. But the angle I E M is to the angle I F M, as L F to L E, or as the focal diftance of the object-glafs to the focal diftance of the eye-glafs; therefore $\frac{LF}{LE}$ = the power, as before ftated; and as the lenfes C D, N O, and T U, in *fig.* 3. have equal foci, the fecondary direct image P Q is equal to the primary inverted one I M, and appears under the fame angle.

Now if all the rays of light had been, as they were fuppofed to be before fir Ifaac Newton's experiments, homogeneal; and if a double convex lens, of equal curvature on both fides, had been found to refract all thefe homogeneal rays into one focal point, without any aberration, either lateral or longitudinal; then the telefcopes, we have juft noticed, would have been fufficiently perfect for all the purpofes of exhibiting a well-defined picture of the object viewed in a magnified ftate; and the power might have been increafed to almoft any extent, by varying the ratio between F L and E L; that is, by increafing the focal diftance of the object-glafs, or by leffening the focal diftance of the eye-glafs, or by both; but it was foon found that the rays which enter a lens at or near the edges, are refracted to a point nearer to its furface than the rays that are tranfmitted near the centre; and alfo that the rays of different colours are differently refracted, even from the fame point of the lens, fo as to meet in the line of the axis at different diftances from the neareft furface of the lens. The former of thefe deviations, being occafioned by the fpherical figure of the lens, is called the *fpherical aberration*; and the latter, arifing out of the nature of folar light itfelf, is called the *prifmatic*, *chromatic*, or *Newtonian* aberration. The indiftinctnefs in the formation of the image, occafioned by thefe aberrations of the rays of light, became an object of fir Ifaac Newton's attention, and he foon difcovered that, whatever mechanical means might effect in the fhape of the curve that might rectify the fpherical aberration, the prifmatic aberration would

 remain

remain so long as one substance only remained to be the medium of refraction. The ingenious Huygens, however, supposing that the diminution of the spherical aberration would contribute greatly to the improvement of the telescope, instituted some experiments and calculations, which greatly promoted the science of Dioptrics. He found, that the lengthening of the radius of convexity of an object-glass shortened the versed sine of the curvature, or lessened the thickness of the glass, on which, with equal apertures, the spherical aberration seemed to depend; and also that, in a simple eye-glass, the aberration from the figure was greatest in a double convex lens, when the curves of the two faces were from the same radius; and also that it increased as the radius shortened. The ratio 1 : 1 being found to have the greatest aberration, and 1 : 2 to have less, an investigation was instituted, from which it was at length proved, that the aberration in a double convex lens is the smallest possible, when the radii of convexity are to each other as 1 : 6; the face 1 being turned to the radiant or object to be viewed. From these experiments originated the famous Huygenian telescope of 123 feet focal distance, and a table of apertures corresponding to the respective focal lengths of the object and eye glasses, that would exhibit an image equally well defined: which calculations were the basis of all the long or *aerial* telescopes that were in repute for a whole century; but which are now superseded by the short achromatic refractors.

The same ingenious author of *dioptrics* discovered, that the aberration arising from the curved figure of a lens might be still further diminished, by substituting two lenses in the eye-piece of a telescope instead of one; which discovery was the foundation of all the improved eye-pieces that have been since adopted, under different arrangements of intermediate distance, and with different degrees of curvature. But before we can explain how the indistinctness arising from both the spherical and prismatic aberrations of mixed rays, may be in a great measure counteracted, (on which important consideration, the excellence of modern improved telescopes depends,) it is necessary to examine this subject further, and to shew how the circle of aberration of mixed rays arising from their unequal refrangibility, and also the lateral and longitudinal aberrations arising from the spherical figure of refracting and reflecting surfaces, may be mathematically determined. In doing this, we shall avail ourselves of Dr. Smith's propositions, which are at the same time perspicuous and conclusive.

Prop. I.

Aberrations.—"Let the common sine of incidence be to the sine of refraction of the *least* refrangible rays, as I to R, and to the sine of refraction of the *most* refrangible rays, as I to S; and the diameter of the least circular space, into which heterogeneal parallel rays can be collected by a spherical surface, or by a plano-convex lens, will be to the diameter of its aperture in the constant ratio of S — R to S + R — 2 I."

For let an heterogeneal ray P A (*Plate* XXVI. *fig.* 1.) fall upon a spherical surface A C B, and let it be separated by refraction into the rays A F, A *f*, cutting the axis E C, drawn parallel to P A, in F and *f*. Take the arc C B equal to C A, and let another heterogeneal ray P B, coming parallel to P A, be refracted into the lines B F, B *f*, cutting the two former rays in R and S. Join R S, and produce it till it meets the incident rays produced in I and K, and the perpendiculars E A, E B, to the refracting surface at the points A, B, in H and L. And when A B, the breadth of the aperture or of the pencil, is but moderate, and consequently the refractions at A B but small, the angles of incidence and refraction H A I, H A R, H A S, or the arcs that measure them, or their perpendicular subtenses H I, H R, H S, will be to each other very nearly in the same given ratios as those of the sines I, R, S, of those angles. And disjointly, the differences of those subtenses will be proportionable to the differences of those sines; that is, the line R S : R I :: S — R : R — I, and doubling the consequents, R S : 2 R I or I K — R S :: S — R : 2 R — 2 I; and conjointly, R S : I K, or A B :: S — R : S + R — 2 I. From this given ratio of R S to A B, in which they increase or decrease together, it appears that all the intermediate rays which fall upon A B, will pass through R S. And when parallel rays fall perpendicularly upon the plane side of a plano-convex lens, they are refracted only at their emergence from its convex surface; and so the aberrations are the same in both cases. Q. E. D.

Corol. 1.—Hence the diameter R S, of the circle of prismatic aberrations that contains all the incident rays, is a 55th part of the diameter A B of the aperture of a plano-convex glass, whatever be its focal distance. For supposing with Newton the prismatic spectrum divided into seven colours, and A R and A S to be the outermost red and violet rays, their sines of incidence and refractions I, R, S, are to each other as 50, 77, 78. Whence S — R is to S + R — 2 I, as 1 to 55.

Corol. 2.—The diameter of the least circle that can receive the rays of any single colour, or of several contiguous colours, is also determinable from the proportions of their sines. Thus all the orange and yellow is contained in a circle, whose breadth is the 260th part of the breadth of the aperture of the plano-convex glass; the sines of the outermost orange A R, and yellow A S, being to the common sine of incidence, as $77\frac{1}{5}$ and $77\frac{1}{3}$ to 50.

Corol. 3.—In different surfaces, or plano-convex glasses, the angles of prismatic aberration R A S are as the breadths of the apertures A, B, directly, and as the focal distances C, F, inversely; because any angle, as R A S, is as its subtense R S directly, and as its radius A R or C F inversely.

Lemma.—The versed sines A B, A C, of very small arcs B D, C D, (*figs.* 2. and 3.) of unequal circles B D G, C D H, that have the same right sine A D, are reciprocally proportionable to their diameters B G, C H, very nearly; that is, A B : A C :: C H : B G.

For since the rectangles under B A G and C A H are each equal to the square of A D, and consequently to each other, their sides are reciprocally proportionable; that is, A B is to A C as A H to A G, or as C H to B G very nearly, when the versed sines are incomparably less than the diameters themselves. Q. E. D.

Prop. II.

"When homogeneal parallel rays N A, E C, (*fig.* 4.) fall upon a spherical surface A C, whose centre is E, the longitudinal aberration F T, of any refracted ray A T from F, the focus of the pencil, is to the versed sine of the arc A C, intercepted between the point of incidence and the axis E C F, in the given ratio of the square of the sine of refraction, to the rectangle under the sine of incidence, and the difference of the sines very nearly; and the aberration is the same when the rays fall perpendicularly upon the plane side of a plano-convex lens."

For when the refraction is made in the passage of a ray N A from a denser to a rarer medium, then the intersection T, of the refracted ray A T, with the axis E C F, lies between the refracting surface and its focus F. With the centre T and semi-diameter T A, having described the arc A D, cutting the axis in D, draw the sine A P of the arcs A C, A C, AD, and alſo E N and E M, the ſines of incidence and refraction, for which put n and m; then becauſe the triangles E T M, A T P, are ſimilar, it will be as E T : T A or T D :: (E M : A P or E N ::) E F : F C; and disjointly, T F : E F :: (F C − T D or) T F − C D : F C; and alternately, T F : T F − C D :: E F : F C; and disjointly, T F : C D :: (E F : E C ::) $m : m - n$. Again, ſince (P D : P C :: C E : D T or F C and conjointly) C D : C P :: (E F : F C ::) $m : n$; by compounding this and the foregoing proportion, it will be as T F : C P :: $mm : \overline{m-n},\, n$. Q. E. D.

Corol. 1.—The ſegment A C B P A may be conſidered as a plano-convex lens; and when rays fall parallel upon its plane ſide, the longitudinal aberration of the extreme ray falling upon A is equal to $\frac{9}{2}$ of its thickneſs P C, as appears by putting 3 and 2 for m and n reſpectively.

Corol. 2.—Alſo this aberration $FT = \frac{mm}{\overline{m-n},\,n} \times \frac{AP^2}{2EC}$ $= \frac{mm}{\overline{m-n}|^2} \times \frac{AP^2}{2CF}$. For $PC = \frac{AP^2}{2EC}$ very nearly, and $EC = \frac{m-n}{n} \times CF$.

Corol. 3.—Let the refracted ray A T G produced, cut the line F G, perpendicular to the axis, in G, and the lateral aberration $FG = \frac{mm}{nn} \times \frac{AP^3}{2EC^2} = \frac{mm}{\overline{m-n}|^2} \times \frac{AP^3}{2CF^2}$. For $FG : TF :: AP : TP$, or C F or $\frac{n}{m-n} \times CE$.

Corol. 4.—When the ſemi-diameter of the convexity or the focal diſtance is given, the longitudinal aberrations ariſing from the figure are as the ſquares, and the lateral aberrations as the cubes, of the linear apertures of a plano-convex lens.

Prop. III.

"When parallel rays Q A, E C (*fig.* 5.) are *reflected* from a ſpherical concave A C B, whoſe centre is E, and whoſe aperture, A C B, is but ſmall, the longitudinal aberration T F, of the extreme ray A T, from the geometrical focus F, is equal to half the verſed ſine C P of the ſemi-aperture A C very nearly."

In *fig.* 4. imagine E M, the ſine of refraction, to be diminiſhed to nothing, and then to become negative and equal to E N, the ſine of incidence, and the refraction of the ray to be changed to reflection, as in *fig.* 5; and by the former propoſition it will be, as T F : C P :: $mm : -\overline{m-n},\, n :: nn : -2nn :: 1 : -2$.

But the particular proof is this: By the laſt lemma, the verſed ſine C P nearly equals half the verſed ſine P D of the arc A D, whoſe centre is T, and ſemi-diameter T A or T E, or half the ſemi-diameter of the arc A C very nearly. But $2TF = 2TE - 2EF = ED - EC = CD$ exactly, or C P nearly. Therefore $TF = \frac{1}{2}CP$ nearly.

Corol. 1.—We had $2TF = CD$ exactly, which is the exceſs of the ſecant E D of the arc A C above its radius E A. For joining A D, the angle D A E in the ſemi-circle D A E is a right one.

Corol. 2.—The longitudinal aberration $TF = \frac{AP^2}{4CE}$. For $CP = \frac{AP^2}{2CE}$ nearly.

Corol. 3.—The lateral aberration $FG = \frac{AP^3}{2CE^2}$. For F G : F T :: A P : P T, or $\frac{1}{2}$ C E nearly.

Corol. 4.—When the diameter of the concave or its focal diſtance is given, the longitudinal aberrations are as the ſquares, and the lateral ones as the cubes of the diameters of the apertures.

Prop. IV.

"When parallel rays of any one ſort are refracted by a plano-convex object-glaſs, or when rays of all ſorts are reflected by a ſpherical concave, the diameter of each circle of aberration cauſed by the ſphericalneſs of the figures, is equal to half the lateral aberration of the extreme ray in each, and therefore is given by the former propoſitions."

Let a Y τ be any refracted or reflected ray, cutting the axis E C T in τ (*figs.* 6 and 7.), and the extreme ray A T G, that comes from the contrary ſide of the axis, in Y. Draw Y X perpendicular to the axis; and ſuppoſing the line A T G immoveable, as the point of incidence a moves from the vertex C, the perpendicular X Y will firſt increaſe, becauſe the angle C τa continually increaſes, and afterwards will decreaſe, becauſe the line T τ continually decreaſes; and when X Y is the greateſt, it is evident that all the rays, incident upon the ſame ſide of the axis as itſelf, will paſs through it. To find its greateſt quantity, let the incident ray qa cut the chord A P B in β, and ſuppoſing the variable aperture $P\beta = v$, the variable $TX = x$, and the given lines $PA = a$, $PT = f$, $TF = b$; by Cor. 4. Props. II. and III. the aberration F τ is to the aberration F T (b) as ϖa^2 or $P\beta^2$ (vv) to PA^2 (aa).

Wherefore $F\tau = \frac{vv}{aa} b$, and thence $TF - F\tau = T\tau$ $= \frac{b}{aa} \times \overline{aa - vv}$. Again, P T ($f$) : P A ($a$) :: T X ($x$) : $XY = \frac{ax}{f}$; alſo ϖa (v) : $\varpi\tau$ or P T (f) :: X Y $\left(\frac{ax}{f}\right)$: $X\tau = \frac{ax}{v}$. Hence again, $T\tau$, or $X\tau + XT =$ $\frac{ax}{v} + x = \frac{b}{aa} \times \overline{aa - vv}$ found before; or $\frac{x}{v} \times \overline{a+v}$ $= \frac{b}{aa} \times \overline{a+v} \times \overline{a-v}$. Whence $x = \frac{b}{aa} v \times \overline{a-v}$, and therefore x or T X is the greateſt poſſible when the rectangle $v \times \overline{a-v}$, or $P\beta \times \beta B$ is greateſt, that is, when its ſides $P\beta$, βB, are equal, or when $v = \frac{1}{2}a$. Subſtitute this value for v in the laſt equation, and it gives the greateſt value of $x = \frac{1}{4}b$, or the greateſt $TX = \frac{1}{4}TF$; and therefore the greateſt $XY = \frac{1}{4}FG$, becauſe T X : X Y :: T F : F G; and this X Y, turned about the axis P X, deſcribes the circle of aberrations through which all the rays falling upon A B will juſt paſs. Q. E. D.

Prop. V.

"The circle of aberrations cauſed by the ſphericalneſs of the figure of the object-glaſs of a teleſcope, compared with the circle of aberrations cauſed by the unequal refrangibility of rays, is altogether inconſiderable."

For if the object-glaſs be plano-convex, and the plane ſide be turned towards the object, and the diameter of a ſphere, whereof this glaſs is a ſegment, be called D, and the ſemi-diameter of the aperture of the glaſs be called S, and the ſine

ſine of incidence out of glaſs into air be to the ſine of refraction as n to m; the rays which come parallel to the axis of the glaſs ſhall, in the place where the image of the object is moſt diſtinctly made, be ſcattered all over a little circle, whoſe diameter is $\frac{mm}{nn} \times \frac{S^3}{DD}$ very nearly, if they were all equally refrangible. As for inſtance, if the ſine of incidence n be to the ſine of refraction m as 20 to 31, and if D, the diameter of the ſphere to which the convex ſide of the glaſs is ground, be 100 feet, or 1200 inches, and conſequently the teleſcope about 100 feet long, and S, the ſemi-diameter of the aperture, be two inches; the diameter of this circle of aberrations, that is $\frac{mm}{nn} \times \frac{S^3}{DD}$, will be

$$\frac{31 \times 31 \times 8}{20 \times 20 \times 1200 \times 1200} \text{ or } \frac{961}{72000000} \text{ parts of an inch.}$$

But the diameter of the little circle through which theſe rays are ſcattered by unequal refrangibility, will be about the 55th part of the breadth of the aperture of the object-glaſs, which is here four inches. And therefore the aberration ariſing from the ſpherical figure of the glaſs, is to the aberration ariſing from the different refrangibility, as $\frac{961}{72000000}$ to $\frac{4}{55}$, that is as 1 to 5449; and therefore, being in compariſon ſo very little, deſerves not to be conſidered in the theory of teleſcopes. If we ſuppoſe the little circle of aberrations ariſing from unequal refrangibility, to be 250 times narrower than the circular aperture of the object-glaſs, it would contain all the orange and yellow, and would permit the other fainter and darker colours to paſs by it, which perhaps may ſcarcely affect the ſenſe; yet even in this caſe, the aberration cauſed by the ſpherical figure, would be to the aberration cauſed by the unequal refrangibility, in a 100-feet teleſcope, but as $\frac{961}{72000000}$ to $\frac{4}{250}$, or only as 1 to 1200, which ſufficiently proves the propoſition. Q. E. D.

Corol. 1.—If the focal diſtances and apertures of a reflecting concave and a plano-convex glaſs be both the ſame, the diameter of the circle of aberrations, cauſed by their figures, will be above 30 times leſs in the reflector than in the refractor. For theſe diameters are $\frac{AP^3}{16CF^2}$ and $\frac{mm}{\overline{m-n}|^2} \times \frac{AP^3}{4CF^2}$; which are as $\frac{1}{4}$ to $\frac{mm}{\overline{m-n}|^3}$ or $\frac{31 \times 31}{11 \times 11}$.

Hence, if the length of each teleſcope be 100 feet, the lateral aberrations in the reflector would be 30 × 5449, or 163470 times leſs than the lateral aberrations cauſed by unequal refrangibility in the refractor.

Corol. 2.—The number of pencils, ſome of whoſe rays are mixed together in every point of a confuſed picture, is as the area of the circle of aberrations of the rays in any one pencil; and conſequently the mixture of the rays of different pencils, cauſed by the ſphericalneſs of the figure of an object-glaſs, if they were all alike refrangible, would be to their mixture cauſed by their unequal refrangibility, as 1 to 5449 × 5449, or 29691601 in the preſent inſtance. For conceiving any point in the confuſed picture to be a centre of a circle of aberration, it is manifeſt that all other equal circles of aberration, whoſe centres fall upon the firſt-mentioned circle, will cover its centre, that is, ſome rays of as many pencils will be mixed in this centre as there are points in the circle itſelf; or, which is the ſame thing, the number of pencils mixed in this centre is as the area of the circle of aberrations."

Double achromatic Object-glaſſes.—From theſe five *propoſitions*, and the *corollaries* deduced from them, in all of which the ratio of the ſines of the angles of incidence and of refraction out of air into glaſs is taken as 3 : 2, (which anſwers nearly to the French plate-glaſs,) our readers will ſee, that when any ſingle lens is uſed as the object-glaſs of a refracting teleſcope, there will be not only fringes of colour, but indiſtinctneſs in the image formed at its focal point, ariſing reſpectively out of the two kinds of aberration, the priſmatic and the ſpherical. But Dollond has ſhewn, that theſe aberrations are not the ſame in all ſorts of glaſs: the former depends on the diſperſive power of the glaſs uſed, and the latter on the ratio of the radii of curvature of the two ſurfaces of the lens. The diſperſive power of a priſm of any ſpecimen of glaſs will be to that of another like priſm of a different ſpecimen, as the lengths of the priſmatic ſpectra, formed by them, are reſpectively to each other: and if the foci of two lenſes of different diſperſive powers, one convex, of crown-glaſs for inſtance, and the other concave, of flint, be made directly as their diſperſive powers, and be placed contiguous, ſo that the convex lens may receive the rays firſt, and be of the ſhorter focus, or thicker, its diſperſive power will be ſo counteracted by the oppoſite diſperſive power of the other thin lens of longer focus, that the extreme or prevailing colours of the primary ſpectrum, being reverſed, will both diſappear; and a ſecondary ſpectrum, compoſed of the remaining intermediate colours, will be very inconſiderable in a good achromatic object-glaſs thus compoſed. If the refracted focal diſtances of the two lenſes remain unaltered, when duly proportioned, as 2 : 3, or nearly ſo, the proportion of the radii of the ſurfaces may be altered at pleaſure, ſo as to produce their due proportions of ſpherical aberration. To effect the deſirable purpoſe of baniſhing the ſpherical aberration as much as poſſible, the optician is obliged to calculate the aberrations belonging to convex lenſes of different unequal radii, in order to make the contrary aberrations of the concave as equal thereto as may be; and for this purpoſe the general theorem of Huygens is peculiarly adapted, which we ſhall, therefore, introduce and exemplify here, before we proceed to the conſtruction of an achromatic object-glaſs. According to this theorem, if we put r for the radius of the firſt ſurface of any lens, or that which firſt receives the incident rays; R for the ſecond ſurface; and T for the thickneſs of the lens: then the *aberration* ariſing from the figure of any lens, concave or convex, will be $= \frac{27r^2 + 6rR + 7R^2}{6 \times \overline{r+R}|^2} \times$ T univerſally. (See Martin's New Elements of Optics, part vi. chap. iii. and Dr. Smith's Optics, book 2. chap. xiii.) When the centres of the curves are on oppoſite ſides of the lenſes, the ſigns are as here put down; but if theſe centres are on the ſame ſide as in a meniſcus, then the ſign of r, or of R, muſt be negative, as the caſe may require. For inſtance, let us firſt put r and R equal, and each = 1; then, as unity is not altered by multiplication or diviſion, we ſhall have the ſimpleſt caſe, *viz.* $\frac{27+6+7}{6 \times 2 \times 2} = \frac{40}{24} = \frac{5}{3}$, or 1.66 of T, for the longitudinal aberration, and it will make no difference which face of the lens is turned to the radiant. Secondly, let us take $r = 1$, and R = 2, in which caſe we ſhall have $\frac{27+12+28}{6 \times 9} = \frac{67}{54}$, or $\frac{5}{4}$ of T, very nearly. But if we reverſe the ſides in poſition, by making $r = 2$, and

and R = 1, then the refult will be different, *viz.* $\frac{108 + 12 + 7}{6 \times 9} = \frac{127}{54}$, or nearly $\frac{40}{17}$ of T. The aberration here is more than in the former pofition, in the ratio of 127 : 67; and this is, therefore, called the *worft* pofition; that being always called the *beft*, where the firft furface has a fhorter radius than the fecond. If we fuppofe lenfes of unequal radii to have their focal diftances, their breadth, and confequently their thicknefs the fame, it will be found, by a fimilar procefs, that their aberrations will diminifh, as R continues to exceed r, until r is to R as 1 : 6; in which conftruction of a lens, placed in its beft pofition, the aberration will be a *minimum*, *viz.* $\frac{15}{14}$ of T; but in its reverfed or worft pofition, the aberration will be $\frac{115}{32}$ of the fame. A fingle convex lens, in its beft pofition, has its aberration only $\frac{7}{6}$ of T; but with the plane fide turned to the radiant, in which r may be faid to be infinite, the aberration will be $\frac{9}{2}$ of T. Alfo a double convex, when its radii r and R are to each other as 2 : 5, has the fame aberration as a fingle convex in its beft pofition, and has lefs fpherical aberration than any menifcus whatever; but there is no proportion of the radii of any one lens that will do away the fpherical aberration altogether. If the refractive power of any glafs be fuch, that the fines of incidence and of refraction are not exactly in the ratio 3 : 2, the calculated longitudinal aberration will differ a little from the true one, fo as to require a correction. And with refpect to the lateral aberration, if m be the fine of incidence, and n the fine of refraction = 1, where two lenfes have equal apertures and radii, then the errors arifing from obliquity of incidence will refpectively be as m^2 in one, to $'m^2$ in the other.

Likewife, we derive from the foregoing demonftrations of Dr. Smith the following general and important conclufions: firft, that in lenfes of equal apertures, the *longitudinal* aberrations, arifing from figure, are *inverfely* as the focal diftances (fee Cor. 2. of Prop. II. above quoted); and fecondly, that under like circumftances, the *lateral* aberrations are inverfely as the fquares of the faid focal diftances (fee Cor. 3. of the fame Prop.); and, on the contrary, that when the focal diftances are the fame, and the apertures differ, then the *longitudinal* aberrations are as the fquares (fee Cor. 4.), and the *lateral* as the *cubes* of thofe apertures. The utility of thefe proportions will more fully appear in the fequel.

We proceed now to the moft important part of our article, *viz.* to fhew what means have been not only devifed, but practically applied, for remedying the defects arifing out of thefe two different kinds of aberrations, and for rendering the apparent object, as viewed through a refracting telefcope, at the fame time diftinct and colourlefs. Telefcopes of what are called the *achromatic*, (from α, priv., and χρωμα, *colour*,) or colourlefs kind, are compofed, like other telefcopes, of two parts requiring feparate confideration; *viz.* the object-glafs and the eye-tube: the former being that which produces an *image* free from colours and miftinefs; and the latter that which either renders this image vifible, or produces a fecondary one to be viewed, without the reproduction of colours. But our prefent confideration is that of the object-glafs.

Before the working optician can proceed to prepare his tools for making an achromatic object-glafs, he muft know the refractive and difperfive powers of his glafs. Various methods have been propofed for determining thefe qualities with accuracy; but it will be fufficient for our purpofe to explain thofe which have been found moft practicable. As the ratio between the fine of incidence and the fine of refraction is conftant in the fame glafs, though not the fame ratio in different forts of glafs, the moft certain method of determining this ratio in different fpecimens of glafs is, to grind a piece of each of thofe fpecimens by the fame tool, as Martin and Tulley have done, and then to compare their refracted folar foci with the radius of curvature; and thofe which have the fhorteft refracted foci, will have the greateft refractive power; and the contrary. We have already explained, in the firft fection of our article, how this operation was conducted by Tulley in particular; and we will now ftate the refults of his experiments in the fubjoined little table.

Refults of practical Experiments on the refractive Powers of different Specimens of Glafs, by C. Tulley.

Kinds of Glafs.	R Radius of Tool.	F Focus of refracted Rays.	$\frac{R}{F} = 2a$ a Divifor.	Ratio of the Sines of I and R.	Specific Gravity.	Ratio of difperfive Powers.	Kinds of Glafs ufed together.
Flint 1. -	33.7	28.13	1.198	1.599 : 1	3.466	1.757 : 1	ufed with crown.
Flint 2. -	33.7	29.38	1.147	1.5735 : 1	3.192	1.524 : 1	ufed with crown.
Ratcliffe crown	33.7	31.91	1.056	1.528 : 1	2.527	1 : 1.757 1 : 1.524	ufed with flint 1. ufed with flint 2.
Dutch -	33.7	32.12	1.049	1.524 : 1	2.519	not known.	
Plate 1. -	33.7	33.43	1.008	1.504 : 1	2.450	1 : 1.65 1 : 1.623	ufed with flint 1. ufed with flint 2.
Plate 2. -	33.7	33.56	1.004	1.502 : 1	2.428	1.195 1.167	ufed with flint 1. ufed with flint 2.

If we explain how the numbers in the horizontal column of flint 1. were obtained, the reft of the table will require no further explanation. The tool on which the fix fpecimens of glafs were ground at the fame time, was of fpeculum metal, and did not vary its fhape much during the operation of grinding and partial polifhing, which was all that the glaffes required for viewing the fun, and for adjuftment to the folar focus. The firft flint-glafs, after being thus formed to a curvature on both fides of 33.7 inches radius, equal to that of the tool, was put into a tube and made into a temporary

porary

porary telefcope, when the principal or folar focus, from actual refraction of the rays, was found to be 28.13 inches, which is therefore called the *refracted* folar focus, the geometrical focus derived from the radius of curvature being 33.7. This is the fpecimen of glafs of the greateft denfity as well as of the greateft refractive and difperfive powers, its fpecific gravity having been repeatedly afcertained to be 3.466 with different hydroftatic balances of the moft delicate conftruction. Now if the radiant had been at a near diftance, inftead of the fun being ufed, Martin has fhewn that the value of $a = \frac{m - n}{n}$ may be had from this theorem, *viz.* $\frac{dr + rf}{2df} = a$ (where d, r, and f, are as in our Table I. of Theorems), which is demonftrated in his Philofophia Britannica; and from this theorem he determined the focal diftances and quantity a of his fpecimens of glafs; but when the fun is ufed as the radiant, the diftance becomes *infinite;* and then, neglecting rf as infinitely fmall, the left-hand term becomes $\frac{dr}{2df}$, and the theorem, by ejecting d from the numerator and denominator, is reduced into the form $\frac{r}{2a} = f$, as in our Table I. for parallel rays with a double convex of equal radii. Tulley, therefore, very properly preferred taking the folar focus at once, inftead of taking a meafured diftance for the place of the radiant, and of calculating from a long theorem, and from data that might not be perfectly correct; his refults, therefore, muft be confidered as being more fatisfactory than Martin's. The reduced theorem $\frac{r}{2a} = f$, by tranfpofition becomes $\frac{r}{f} = 2a$, and alfo $f \times 2a = r$; hence $2a$ may be either a divifor or multiplier, accordingly as r or f is given to find the other. Tulley has called this quantity a *divifor*, becaufe, having the radius or geometrical focus of a glafs always, from the known radius of his grinding tool, he can get the *refracted* focus by the proper divifor and a fimple calculation at any time; which mode, as we fhall fee prefently, is very ufeful in the calculation of the compound focus of an achromatic object-glafs. Now to get the actual quantity of $2a$ in figures, there will be $\frac{33.7}{28.13}$ taken from the third and fourth vertical columns, which may be called $\frac{R}{F}$ or $\frac{r}{f} = 2a = 1.198$ for the faid divifor, one half of which is $.599 = a$. Put now m, as before, for the fine of incidence, and n for the fine of refraction, and we have feen above that $\frac{m - n}{n} = a$. Let $n = 1$, and then $m = 1.599$; for $\frac{m - 1}{1} = a \therefore m = 1 + a = 1.599$, and $\frac{1.599 - 1}{1} = .599 = a$; therefore the fine of incidence is to the fine of refraction in this firft fpecimen, in the ratio of $1.599 : 1$; and in like manner the horizontal columns for all the other fpecimens are filled up with very little trouble, when $\frac{R}{F}$ is afcertained by fimple divifion of the tabular or experimental numbers.—With refpect to the vertical column of difperfive powers, thefe powers are beft afcertained by making fix equal prifms of the fame fpecimens of glafs, and by meafuring the coloured folar fpectra of each feparately, under exactly the fame circumftances of diftance, inclination, pofition, &c.; and as the angle of difperfion is meafured by the coloured fpectrum as its fubtenfe, the angles of difperfion of the different fpecimens will vary with the refpective lengths of their fpectra; and if the refracting angle of one of the fpecimens, the firft flint for inftance, be diminifhed by grinding and frefh polifhing, until its fpectrum is of precifely the fame length as that of any other, fay the crown, then the ratio of their refracting angles will be inverfely the ratio of their difperfive powers; and a pair of analogous lenfes, one convex and the other concave, (fuch as thofe feen in *Plate* XXVIII. *figs.* 5. and 6.) will have their difperfive powers fo counteracted, that a pencil of rays incident on the thick crown-glafs will emerge from the thin flint *colourlefs*, and will proceed without colour, notwithftanding the greater refractive power of the convex lens, till, by being refracted, they finally crofs the axis in which the focus is formed; and the focal point will be more or lefs diftant with a pair of lenfes fo combined, accordingly as the difference of the two refracting powers is greater or fmaller. To explain this analogy between a pair of prifms and a lens, either convex or concave, we will fhew how a pencil of folar rays paffing through a prifm of glafs is difperfed at the fecond furface, fo as to form the folar fpectrum compofed of the prifmatic colours: Let $a\,b\,c$, in *fig.* 9, be a triangular piece of glafs, called a prifm, and d a pencil of folar light, entering the prifm at e, in the line $d\,e$ B, parallel to the bafe $a\,c$: on entering the glafs it will be refracted towards this bafe, and emerge at the point f, a little nearer to c than e is to a. At this point of emergence, f, the pencil will begin to *difperfe* into rays of different colours, but whether into feven or any other number, is not our prefent object to enquire. Let A B be a fcreen, receiving the difperfed pencil in a darkened room, and $f\,g$ will be the ray of mean refraction, $f\,h$ will be the red ray, or ray of leaft refraction, and $f\,i$ will be the violet ray, or ray of greateft refraction, $h\,i$ being the length of the coloured fpectrum. Let this prifm be of crown-glafs; then fubftitute another of flint-glafs, exactly in the fame fituation, and the extreme rays, h and i, will now be difperfed to H and I, and the diftance between thofe new points will be the length of the fpectrum with flint-glafs. Now the angle $g\,f$ B with both prifms is called the angle of *deviation*, or of mean refraction; the angle $i\,f\,h$ is called the angle of *difperfion* with the crown, and I f H the fame with the flint prifm; but thefe angles of difperfion are fubtended by the lines $i\,h$ and I H refpectively, which are the lengths of their refpective fpectra, which therefore are the *meafures* of the angles of *difperfion* of the two different prifms. Martin found thefe exactly as 3 : 5, and therefore recommended the geometrical foci of the crown and flint glaffes to be *always* in this proportion; but Tulley has found that this ratio will not be accurate with all fpecimens of flint-glafs, and therefore takes a different ratio, for each fpecimen of glafs that differs in this quality, from Martin's. In the fame fpecimen of glafs, the angle of *deviation* always bears the fame proportion to the angle of *difperfion*, or *diffipation* as it is fometimes called; and it was the opinion of fir Ifaac Newton that this is the cafe in *all fpecimens;* but it remained for the fenior Dollond to difcover, which is the bafis of all achromatic conftructions of an object-glafs, that *the angles of deviation may be the fame, when the angles of difperfion are not the fame,* and *vice verfâ*; and we have a ftriking inftance in crown and flint glafs, in which, when the difperfive powers

powers are made to balance each other in opposite directions, there yet remains a balance of refractive power in favour of the crown, arising from its greater thickness, which disposes colourless rays still to deviate or be refracted, but to a more distant focus than would have been if the crown had been used alone. This effect may be seen in *fig.* 10, where a pair of prisms, *a* and *b*, are inscribed in the double convex lens of crown-glass, and the pair *c* and *c* within the double concave of flint: the incident rays *d e* and *d e*, at each side of the axis *g o*, enter the convex at the points *e* and *e*, and are refracted towards the axis, till they meet with the inverted prisms *c* and *c* of flint, when they are refracted in a contrary direction, so as to prevent their meeting at the point *o* of the axis to which they tended, and emerge at the points *f* and *f* colourless, in consequence of the opposite dispersions which take place in the prisms; but after emersion they tend to a new and more distant point O in the axis, and there come to an achromatic focus.

To render this explanation still more intelligible with respect to the *opposition* of two counteracting dispersions, let there be two separate prisms, placed, as in *fig.* 11, at a distance from each other, and inverted with respect to each other; let *a b c* be the prism of crown-glass, and A B C a similar one of flint-glass; and let two pencils of white light enter these lenses in opposite directions, one *d*, and the other D; then *g* and G will be the rays of mean refraction, *h* and H those of least, or red; and *i* and I those of most, or violet. Now as the refractive power of the flint prism A B C is greater than that of the crown *a b c*, the mean ray G in the first will be nearer its prism, than *g*, the mean ray of the second, to its prism; but the angle of dispersion subtended by H I, will be greater than that subtended by *h i*, while the prisms have the same refracting angles C and *c*. Now as the refraction and dispersion in the same prism are proportionate to the refracting angle, these may be both reduced to any assignable quantity by a reduction of the refracting angle; then let the side of the prism of flint C A be ground down till it becomes C K, thereby making the angle B C A, the original refracting angle, equal B C K, the new refracting angle; and let this second angle be to the first as the refractive power of the crown is to the refractive power of the flint; or, in other words, let the refracting angles C and *c* be inversely as the refractive powers of the two specimens of glass formed into prisms; *viz.* as that of *g f* F : G F *f*; and then the mean ray G will be extended to *c*, and F *c* will be parallel to *f* C; that is, the mean refraction of the two lenses will be alike, the angle G F *f* = ∠ *g f* F, by being alternate. In this situation of the refracting angles of the opposite prisms, the rays would both enter and emerge parallel as to *refraction*; but as to *dispersion*, that of the flint would still predominate a little, or the angle H F I would in some measure exceed the angle *h f i*: but these are the angles we want to have equal; therefore, to make the refracting angles C and *c* of the two prisms proportional to the *dispersive* powers, or to the spectra *h i* and H I in *fig.* 9, let the side B C also of the flint prism be ground down a little to *l*, so that the refracting angle *l* C *k* of this flint, shall be to the refracting angle *a c b* of the crown in this ratio of the spectra; and then not only will the dispersive powers of the two prisms become equal, but, what is equally necessary, G will now fall beyond *c*; that is, the refractive power of the flint by this second diminution of its refracting angle, will become less than the refractive power of the crown, and the difference of these powers will refract the transmitted rays, as in *fig.* 10, finally to the distant point O, as has been explained, while at the same time the rays that arrive there will be without colours. If now we conceive that the refracting angle of each of the flint prisms *e* and *c*, in *fig.* 10, inscribed within the concave lens *c c*, is so proportioned to the refracting angle of the prisms *a* and *b*, inscribed in the convex lens of crown *a b*, as the refracting angle *l* C *k* of the flint prism in *fig.* 11. is to the refracting angle *a c b* of the crown prism, then the double object-glass in *fig.* 10. will be achromatic; its lenses being analogous to the correcting prisms. Thus the theory of a double achromatic object-glass is within the comprehension of our ordinary readers; and as the triple object-glass has two thin convex lenses of crown, instead of one thick, to combine with the flint concave one, a farther explanation is unnecessary, particularly if the thick double convex be supposed to be divided longitudinally into two plano-convexes, and to be placed one on each side of the concave: for when these plano-convexes are formed into two curves, giving the same focal distance each as one of the plano-convexes, then the union of the three lenses will be that represented in *fig.* 7.

We may now proceed to exemplify this theory, arising out of Dollond's grand discovery; and to make the construction as familiar as possible, we will avoid all fluxional calculations, and explain such algebraical ones only, as are indispensable, in the first example at full length, as they occur, so that the abridgments in the subsequent examples may be clearly intelligible. Our aim differs from that of our predecessors in this respect. The illustrious mathematicians Euler, d'Alembert, Clairaut, Boscovich, Klugel, and Robison, have given formulæ for the calculation of achromatic object-glasses, that are above the comprehension of ordinary opticians; and Dr. Brewster has calculated tables, according to these formulæ, of the different curves that suit a *certain specimen* only of flint-glass, and that such as is not to be found, at least in England; *viz.* that which has its sines of the ∠ of incidence and of the ∠ of refraction as 1.604 : 1. Besides, the calculations tabulated are not in a practical form in Table II., the radius of the convex being shorter than that of its contiguous concave. On the contrary, we propose to take glass that falls in our way, and to calculate in a familiar manner the radii of curvature that shall suit specimens already within our reach. In short, our predecessors shew how achromatic object-glasses *may be* made, if *proper glass could be obtained;* and we will explain how achromatic object-glasses *are made*, and in the *best* manner, with glass of our own manufacture.

Example 1.—Let it be required to form a double object-glass of thirty inches focal length, from the second flint-glass and crown-glass given in Tulley's table of experimental results? In the crown-glass, the ratio of the sines of the angles of incidence and of refraction ($m : n$) is 1.528 : 1; and in the flint-glass it is 1.5735 : 1; while the ratio of their dispersive powers are .500 : .762, or 1 : 1.524. The first step is to determine the ratio of the geometrical focus of the first or crown-glass, to the compound focus of the proposed pair of glasses, in order that the radii of this lens may be known, before its proper companion, the flint lens, have its focus determined. It will be convenient to call the radius of the convex 1, and as it is proposed to have it a double convex, the geometrical focus will also be 1; but as the compound focus of both lenses is the *refracted* focus always, the geometrical focus 1 must be turned into the refracted focus also, in order to have both of the same denomination: but to do this we want the divisor, which may be taken from the table, or derived from $\frac{m-n}{n} \times 2$; thus $\frac{1.528 - 1.000}{1.000} = .528 \times 2 = 1.056$, the divisor

diviſor of the crown; and $\frac{1.5735 - 1.000}{1.000} = .5735 \times 2 = 1.147$, the diviſor of the flint. In the next place we have $\frac{1.000}{1.056} = .94697$ for the refracted focus of the crown lens; and becauſe the foci of the crown and flint lenſes muſt be in the ſame ratio as their diſperſive powers, which we have ſtated to be $1 : 1.524$, we ſhall have $\frac{1.524}{1.147} = 1.3827$ for the refracted focus of the concave or flint-glaſs. Now, having $.94697 : 1.3827$ as the ratio of the two ſeparate refracted focal diſtances that ſhall baniſh all colours by their equal and oppoſite diſperſive powers; we next find what will be the compound focus correſponding to theſe two when put in contact. Let F be the focus of the convex, and 'F that of the concave; and by our *practical* theorem 5. there will be $\frac{F \times 'F}{'F - F}$ = the compound focus, which in plain numbers will ſtand thus; $\frac{.94697 \times 1.3827}{1.3827 - .94697} = 3.29$, the proportional compound focus required. Now if the priſmatic aberration were the only one neceſſary to be counteracted, we have already obtained numbers that would enable us to conſtruct an *achromatic* or colourleſs compound object-glaſs; for if we multiply F, 'F, and f alike by $\frac{30}{3.29}$, or 9.12, the geometrical focus of the convex lens, we ſhould have the abſolute refracted focus of $F = \overline{.94697 \times 9.12} = 8.636$; that of $'F = \overline{1.3827 \times 9.12} = 12.61$; and the compound focus $= \overline{3.29 \times 9.12} = 30$ very nearly; and it would be immaterial what the curves were, provided the refracted focal diſtances of F and 'F were as above ſtated: but as the tools for forming the curves reſpectively for the ſides of theſe lenſes, muſt have regard to the *radii* of curvature, it would be now neceſſary to uſe the *diviſors* as *multipliers*, to convert the refracted into the geometrical foci, and then the buſineſs might be put in hand. On this ſuppoſition, of there being only one kind of aberration, the conſtruction of a compound achromatic object-glaſs would be no difficult affair; for while the focal diſtances only are required to be to each other in a given ratio, the radii of curvature might be varied almoſt at pleaſure, without affecting the focal diſtance. But there yet remains the ſpherical aberrations of the two ſeparate lenſes to oppoſe to each other in ſuch proportion, that their tendency to produce *indiſtinctneſs* may be completely obviated. Before the time of ſir Iſaac Newton, this was the only kind of aberration that opticians thought they had to contend with; and though it is ſmall in *quantity*, compared to the priſmatic aberration, yet it is more difficult to conquer. It is, however, contrary to the opinion of that great philoſopher and mathematician, in the power of the modern optician to cure this defect of ſpherical glaſſes, by means equally ſimple, when determined, as thoſe by which the priſmatic colours are made very nearly to vaniſh. As in the annihilation of the priſmatic colours, the *ratio* of the *focal diſtances*, made directly as the ratio of the *diſperſive powers*, is a cure for the firſt imperfection; ſo the *ratio* of the *radii*, r : R, of the two lenſes, ſo calculated as to counteract each other's ſpherical aberrations, is the cure for the ſecond imperfection; and this cure we have yet to apply, without interfering with the remedy which we have juſt preſcribed for the other. In order to mark the diſtinction that muſt be made in the ſymbols, as applied reſpectively to the convex and concave lenſes, let it be underſtood, that the ſubjoined notation will be attended to in our inveſtigation of the curves proper for our preſent purpoſe; *viz.*

Convex.	Concave.	
r	$'r$	means the radius of the firſt ſurface.
R	'R	means the radius of the ſecond ſurface.
F	'F	means the focus from ſolar rays, or geometrical, if ſo expreſſed.
T	'T	the thickneſs of the lens.
A	'A	the ſpherical aberration.
m	$'m$	the ſine of incidence.
n	$'n$	the ſine of refraction.
Φ		the compound focus.

It may be alſo neceſſary to premiſe, that whatever ratio of the radii r and R be fixed upon for the convex lens, the ratio $'r$: 'R of the concave may always be found by proper inveſtigation ſuch, that its aberration will counteract that of r : R; but the reverſe is not true; the aberration of $'r$: 'R may be too great for the aberration of any ratio r : R to equal; therefore the ratio r : R is firſt aſſumed, as is moſt convenient for the optician's tools already formed; and $'r$: 'R muſt be ſo calculated, that its aberration ſhall be in due proportion for correcting the aberration of the aſſumed convex lens. We now have to do with the *geometrical* foci of both lenſes, when their *radii* become the ſubject of inveſtigation; and we have ſeen that $9.12 \left(\frac{30}{3.29}\right)$ is the geometrical focus of the convex lens, therefore $1.524 \times 9.12 = 13.9$ is the geometrical focus of the concave, their ratio being ſtill as their diſperſive powers, very nearly. Let us now aſſume $r = 7.5$, or any other quantity at option, and ſee by the proper theorem what R will be, to have a focus of 9.12 inches: to do this we have, by No. 1. of our *practical theorems*, before given, $\frac{rF}{2r - F} = R$, or, in figures, $\frac{7.5 \times 9.12}{2 \times 7.5 - 9.12} = R = 11.63$; hence $r : R :: 7.5 : 11.63$, or as $1 : 1.55$. In the next place, we muſt determine what is the longitudinal aberration ariſing from the figure of a lens, where the ratio r : R is $1 : 1.55$, which is moſt conveniently done by the general theorem of Huygens, which we have before exemplified, and which ſtands thus; $\frac{27r^2 + 6rR + 7R^2}{6 \times \overline{r+R}^2} \times T = A = 1.3614 \times T$.

$$\begin{array}{lrl|lr}
\textit{viz.} & 27r^2 = & 27.0 & \overline{r+R}^2 = \overline{1+1.55}^2 = & 6.5025 \\
& +\ 6rR = & 9.3 & \text{multiplied by} & 6 \\
& +\ 7R^2 = & 16.8175 & & \\
\text{value of numerator} & = & 53.1175 & \text{value of denominator} = & 39.015
\end{array}$$

Then $\frac{53.1175}{39.015} = 1.3614 \times T = A$.

Having now found $1.361 \times T = A$ of the convex lens, the value of T, which is the ſum of the verſed ſines of the two interſecting curves of its ſurfaces, may be calculated by the ſquare root, or by plane trigonometry, and will be found = .252, when the ſemi-diameter of the lens is 1.5, conſequently $1.361 \times .252 = .3429$, is the abſolute quantity of the ſpherical aberration of the convex lens; but 'T of the

concave

concave is by calculation .1653, and $\frac{.3429}{.1653} = 2.074$ is its proportional aberration. But as the thickneſs, breadth, and geometrical focal length of every lens, of whatever form, muſt, from the properties of the circle, be in proportion to each other (ſee Martin's New Syſtem, art. 705.), 'F may be taken at once, inſtead of uſing T and 'T with their calculated values (which require ſome operations), and then the work will be greatly facilitated; thus $1.361 \times T \times 1.524 = 2.074 \times {'T} = {'A}$. Now, as this quantity 2.074 bears the ſame proportion to 1.361, as the focus of the concave does to the focus of the convex, it might be concluded that this would be the proper aberration to correct the aberration 1.361 of the convex lens; but this is not the caſe, for, firſt, the longitudinal aberrations ariſing from the figure are not in the *ſimple* proportion to the foci of the lenſes reſpectively, neither is the *quantity* the ſame with the flint as with the crown glaſs. Martin aſſerts that the ſpherical longitudinal aberrations are to each other, in like lenſes of different focal lengths, *inverſely* as the *ſquares* of the foci reſpectively; conſequently, in our example, theſe aberrations would be inverſely as $F^2 : {'F^2}$; or as $\overline{13.9 \times 13.9} : \overline{9.12 \times 9.12}$; that is, as 193.21 : 83.174, or as $\left\{ \begin{matrix} A & & 'A \\ 1.361 & : & 0.585 \end{matrix} \right\}$; but when Tulley took 0.585 = 'A, this aberration was found much too little; for when he had ground the lenſes with curves to produce this aberration, he found that the eye-tube required to be drawn outwards more than inwards by the ſcrew, from the true focal point, before the image diſappeared, which is a proof that the concave had leſs than its ſhare of aberration; it being conſidered as a teſt of good correction, when the image diſappears at points of the tube equally diſtant from the point of diſtinct viſion, accordingly as the tube is puſhed in or drawn out from its focal point. And here was probably the difficulty that Martin experienced between his theory and practice. Neither was the aberration thus obtained in due proportion, when corrected by the ſimple ratio of the two diviſors $2a : 2{'a}$, or 1.056 : 1.147, for the difference of the refractive powers; for as 1.147 : 1.056 :: 1.161 : 1.253; but $1.253 \times {'T} = {'A}$ was ſtill too little for due correction. Though the teleſcope was achromatic by virtue of the ratio of the foci of the crown and flint lenſes, yet there was a want of perfect *diſtinctneſs*, owing to the deficiency of aberration attaching to the concave lens. After a multiplicity of inveſtigations, calculations, and practical trials, Tulley at length diſcovered a method of balancing the oppoſite aberrations, which he has continued to practiſe with ſucceſs for years, and which is therefore no new project. The method is this: the value of 'A ($2.074 \times {'T}$) being firſt determined from A, in the ratio of F : 'F, as above explained, the *correcting number* is thus obtained; if we call the ſquare root of the cube of the refracted focus of the convex $= x$, the geometrical focus being taken = 1; and put alſo y for the ſquare root of the cube of the refracted focus of the concave, when its geometrical focus is = 1; then $\frac{y}{x} = z$ is the correcting number, by which the proportional aberration, before determined, muſt be *divided*, to gain the proper or *corrected* aberration, now expreſſed by the ſymbols $\frac{'A}{z}$. In the inſtance before us, the calculation will be $.947^3 = .8492781$, and its ſquare root $= .2914 = x$; and $\sqrt{.872^3} = .2575 = y$; then $\frac{.2575}{.2914} = .883 = z$, the correcting diviſor, and alſo $\frac{'A}{z} = \frac{2.074}{.883} = 2.348 = {'A}$ corrected.

Having now aſcertained the aberration $2.348 \times {'T}$ of the concave lens, that will balance the aberration $1.361 \times T$ of the convex, we muſt proceed to determine the ratio $'r : {'R}$ of the concave, that ſhall have exactly this aberration: to be able to do this without a table of aberration, requires an acquaintance with quadratic equations; for the proportion of the radii $'r$ and 'R muſt be inveſtigated from the corrected aberration which we have now aſcertained.

1ſt. We have $\frac{27r^2 + 6rR + 7R^2}{6 \times \overline{r + R}|^2} \times T = A$ (by the general theorem) $= 2.348 \times {'T}$, as before found; but we make no diſtinction between r, R, T, A, and $'r$, 'R, 'T, 'A, that we may ſimplify the ſymbols: this equation, by evolution of $\overline{r + R}|^2$ in the denominator, becomes $\frac{27r^2 + 6rR + 7R^2}{r^2 + 2rR + R^2} \times \frac{T}{6} = 2.348 \times T$: now by putting R = 1, there will be $\frac{27r^2 + 6r + 7}{r^2 + 2r + 1} \times \frac{T}{6} = 2.348 \times T$; or, dividing both ſides by $\frac{T}{6}$, $6 \times 2.348 = 14.088$, or $14.1 = \frac{27r^2 + 6r + 7}{r^2 + 2r + 1}$; and multiplying both by the denominator, $14.1r^2 + 28.2r + 14.1 = 27r^2 + 6r + 7$: then ſubtracting equal quantities from both, there remains $22.2r + 7.1 = 12.9r^2$; and by tranſpoſition, $12.9r^2 - 22.2r = 7.1$ for the *quadratic*. Now to find the *root*, we have firſt $r^2 - \frac{22.2r}{12.9} = \frac{7.1}{12.9}$; and adding the ſquare of half the co-efficient, $r^2 - \frac{22.2}{12.9}r + \overline{\frac{11.1}{12.9}}|^2 = \frac{7.1}{12.9} + \overline{\frac{11.1}{12.9}}|^2$; therefore the root $r - \frac{11.1}{12.9} = \sqrt{\frac{7.1}{12.9} + \overline{\frac{11.1}{12.9}}|^2}$, and $r = \sqrt{\frac{7.1}{12.9} + \overline{\frac{11.1}{12.9}}|^2} + \frac{11.1}{12.9}$.

Laſtly; to collect the aggregate of the values of r, we have $\frac{7.1}{12.9} = .55$, $\overline{\frac{11.1}{12.9}}|^2 = .74$, and $\sqrt{\overline{.55 + .74}} = \sqrt{1.29} = 1.135$; likewiſe $\frac{11.1}{12.9} = .860$; therefore $1.135 + .860 = 1.995 = r$, which was deſired; and the ratio r : R, which we now put again $'r : {'R} = 1.995 : 1$; and which in Tulley's Table ſtands 2 : 1. After having thus determined the ratio of the radii $'r$ and 'R to be 2 : 1 very nearly, we muſt now find the rational geometrical focal diſtance of this concave by the fourth of our *practical theorems* above exemplified; *viz.* from $\frac{2rR}{r + R}$, we firſt have $\frac{2 \times 2 \times 1}{1 + 2} = 1.333$; and as the geometrical focus is known to be 13.9, we have alſo $\frac{13.9}{1.333} = 10.428 = {'R}$, and 10.428

$\times 2 = {}'r$; ſo that the four radii of the faces and the correſponding foci will ſtand thus; *viz.*

$r = 7.50$, $R = 11.63$ } and F = 9.12, the geometrical focus of the convex lens.

$'R = 10.428$, $'r = 20.856$ } and 'F = 13.9, the geometrical focus of the concave lens.

$\Phi = 30.04$ the compound refracted focus of the teleſcope, according to the proper theorem.

We have now brought the calculations of our firſt example to a concluſion, accompanied by ſuch explanations as may render it unneceſſary to dwell ſo minutely on the following examples; and when we have gained theſe radii for a teleſcope of 30 inches focus, we have the means of making a teleſcope equally achromatic and diſtinct of any other length; for the ratios $r : R$ and $'r : 'R$, being once determined for crown and flint glaſs of given refractive and diſperſive powers, require only to be increaſed in equal quantities to ſuit the foci of the propoſed teleſcopes, as in the ſubjoined table; and it may be proper to notice, that though the ſpecific gravity has not been taken into the account in the calculations of this example, yet it is uſeful as an index to point out the ratio of the ſines of incidence and of refraction, and of the diſperſive powers to be uſed, when the ſpecimens of glaſs are ſelected by their ſpecific gravities only, without an experimental trial by grinding.

The ſubjoined table is ſuitable for achromatic double object-glaſſes of various lengths; where $m : n$ in the crown-glaſs is as $1.528 : 1$, and in the flint as $1.5735 : 1$; their diſperſive powers being $1 : 1.524$.

Table I.—Radii of double Object-glaſſes in Inches.

Φ	r	R	'R	'r
6	1.50	2.326	2.086	4.171
12	3.00	4.652	4.171	8.342
18	4.50	6.978	6.256	12.513
24	6.00	9.304	8.342	16.684
30	7.50	11.630	10.428	20.856
36	9.00	13.956	12.512	25.027
42	10.50	16.282	14.598	29.198
48	12.00	18.608	16.684	33.369
54	13.50	20.934	18.770	37.540
60	15.00	23.260	20.856	41.712
72	18.00	27.912	25.025	50.054
84	21.00	32.564	29.196	58.396
96	24.00	37.216	33.368	66.738
108	27.00	41.868	37.540	75.080
120	30.00	46.52	41.712	83.424

In this table, R and 'R are the faces of the two lenſes which come in contact, and r and $'r$ the external faces; and it will be ſeen that R, being a little longer than 'R, the convex face, will approach the concave one very cloſely, but will not touch it, which is a neceſſary practical condition. When the aberration exceeds 1.666, which is that of $r : R$ when they are each $= 1$, or alike; then r exceeds R, and the lens muſt be reverſed, or put in its worſt poſition; which is the caſe in all our tables for double object-glaſſes with the flint-glaſs; otherwiſe the concave would not have had ſufficient aberration for the convex.

In our next example it will not be neceſſary to do the work at full length, but only to give ſuch an abridgment as will be intelligible to the reader who underſtands the proceſs minutely explained in the preceding example. The denſity of different ſorts of crown-glaſs ſeldom varies; but two ſpecimens of flint can ſeldom be found to be alike. The greater the denſity of flint-glaſs, the more ſuitable it is for the purpoſe of making a concave lens of an achromatic object-glaſs, becauſe the radii of both the lenſes may be longer for the ſame compound refracted focus; and, conſequently, the ſpherical aberration will be leſs than in glaſs that requires ſhorter radii to produce the ſame compound focus. If the form of the concave had been given, the convex would have been determined by a reverſed operation, where the multiplier 1.524 would have been a diviſor, and z a multiplier, &c.

Example 2.—Let it be required to form a double object-glaſs of 30 inches focal length, as before, with the ſame crown-glaſs for the convex, but with the denſeſt flint, in which the ratio $m : n$ is as $1.599 : 1$, and their diſperſive powers $1 : 1.757$?

In this example we have $1.056 = 2a$, or the diviſor for the crown, as before, and $\overline{1.599 - 1} \times 2 = 1.198 = 2a$, or diviſor for the flint; then $\frac{1}{1.056} = .94697 =$ F refracted, and $\frac{1.757}{1.198} = 1.466 = {}'F$, alſo refracted; and alſo $\frac{F \times 'F}{'F - F} =$ 2.67, the ratio of the compound focal length, or what we called the *rational* compound focus; conſequently, the ratio between F geometrical and the compound focus is in this example $1 : 2.67$; and the ratio between the refracted foci of the ſeparate lenſes, to correct the colorific rays, is $\left\{\begin{matrix} F & & 'F \\ .94697 & : & 1.466 \end{matrix}\right\}$. With reſpect to the ſpherical aberrations, which are next to be conſidered, we may in the firſt place determine the quantities x and y, and z the *correcting* diviſor, which is derived from them, thus; $\left\{\begin{matrix} F \\ \surd .94697^3 = .2914 = x \end{matrix}\right\}$; and as $\frac{1}{1.198} = .834$, &c. gives the refracted focus of the flint or concave lens, (F geometrical being $= 1$ in this caſe,) $\surd .834^3 = .2408 = y$, and $\frac{y}{x} = \frac{.2408}{.2914} = z = .826$, the *correcting* diviſor required for this refractive power of the flint-glaſs. In the next place, $\frac{30}{2.67} = 11.23 =$ F (geometrical), and $11.23 \times 1.757 = 19.73 = {}'F$ (geometrical alſo). Let us here aſſume $r = 9$ inches, and then by the theorem $\frac{rF}{2r - F} = R$, we get $R = 14.92$, and conſequently the ratio $r : R$ will be $9 : 14.92$, or $1 : 1.66$ in its loweſt terms. A double convex lens

lens ground with its radii in this ratio, will have its ſpherical aberration $= 1.325 \times T$; to counteract which, the concave muſt have its proper aberration determined; and then the ratio of its radii muſt be inveſtigated, that ſhall make a lens with this determined quantity of aberration. We have ſeen already that $A = 1.325 \times T$, therefore $1.325 \times 1.757 = 2.328 \times {}'T = {}'A$, the proportional aberration for $'F$, conſidered as having the ſame refractive power as F; but the *correcting* diviſor muſt now be applied, and $\frac{'A}{z} = \frac{2.328}{.826} = 2.818$ is the corrected aberration, for which the radii $'r$ and $'R$ are now to be inveſtigated. By putting $'R = 1$, as before, and by working out the root of the quadratic ariſing from $\frac{27 r^2 + 6 r R + 7 R^2}{6 \times \overline{r + R}|^2} \times T = 2.818$, we ſhall have the ratio $'R : {}'r = 1 : 3.075$. And, laſtly, for the actual radii of the concave, we get, by our practical theorem $\frac{2 r R}{r + R} = F$, $\frac{2 \times 1 \times 3.075}{1 + 3.075} = 1.51 = {}'F$ rational, and $\frac{19.73}{1.51} = 13.06 = {}'R$; as alſo $13.06 \times 3.075 = 40.15 = {}'r$, the ſecond ſide of the concave. Whence we now have

$$\left.\begin{array}{l} r = 9.00 \\ R = 14.92 \end{array}\right\} \text{ and } F = 11.23 \text{ geometrical.}$$

$$\left.\begin{array}{l} 'R = 13.06 \\ 'r = 40.15 \end{array}\right\} \text{ and } 'F = 19.73 \text{ geometrical.}$$

$$\Phi = 29.81 \quad \text{according to the proper theorem.}$$

It may be ſatisfactory to prove, that the geometrical quantities F and 'F, which we have here determined, will make Φ, the compound focus of the teleſcope, = 30 inches. But it will be requiſite firſt to turn the geometrical foci F and 'F into the refracted foci, by their reſpective diviſors, denominated $2a$ and $2'a$, *viz.* 1.056 and 1.198: thus, $\frac{11.23}{1.056} = 10.634 = F$ refracted, and $\frac{19.73}{1.198} = 16.479 = F'$ refracted; then by our theorem $\frac{F \times {}'F}{'F - F} = \Phi$, we have $\frac{10.634 \times 16.479}{16.479 - 10.634} = \frac{175.237686}{5.845} = 29.81 = \Phi$; and if the decimal had been carried farther in the geometrical foci, the compound focus would have been quite 30, as required. It may be for the benefit of practical men to ſubjoin a table ſimilar to our preceding one, derived from the radii of curvature determined in this ſecond example. And let it be underſtood by our readers, that in all our tables for the radii of curvature, the length of the teleſcope in inches is denoted by the figures in the firſt vertical column; and that the numbers in the ſame horizontal column with any given length, ſhew the proper geometrical radii of curvature for convex and concave lenſes to conſtruct ſuch teleſcope.

The following table is ſuitable for double achromatic object-glaſſes of various focal lengths, where $m : n$ in the crown-glaſs is as 1.528 : 1, and in the flint as 1.599 : 1; and their diſperſive powers as 1 : 1.757.

TABLE II.—Radii of double Object-glaſſes in Inches.

Φ	r	R	'R	$'r$
6	1.80	2.98	2.61	8.03
12	3.60	5.97	5.22	16.06
18	5.40	8.95	7.83	24.09
24	7.20	11.93	10.44	32.12
30	9.00	14.92	13.06	40.15
36	10.80	17.91	15.67	48.18
42	12.60	20.89	18.28	56.21
48	14.40	23.87	20.89	64.24
54	16.20	26.85	23.49	72.27
60	18.00	29.84	26.12	80.30
72	21.60	35.82	31.34	96.36
84	25.20	41.78	36.56	112.42
96	28.80	47.75	41.76	128.48
108	32.40	53.71	46.98	144.54
120	36.00	59.68	52.24	160.60

Example 3.—We ſhall now take the ſame crown-glaſs, with a flint-glaſs between the two extremes, which we have uſed, *viz.* in which $m : n$ is as 1.584 : 1, and their diſperſive powers as 1 : 1.59; and let it be required to calculate a double achromatic object-glaſs of 30 inches focal length, as before?

Having already the diviſor $(2a)$ of the crown equal 1.056, we begin with getting that of the flint thus, $\overline{1.584 - 1} \times 2 = 1.168 = 2'a$, or proper diviſor; then $\frac{1}{1.056} = .94697 = F$ refracted, as before; and $\frac{1.59}{1.168} = 1.3613 = {}'F$ refracted. Alſo $\frac{F \times {}'F}{'F - F} = 3.111$, the rational compound focus; and $1 : 3.111$ is the ratio between F geometrical and Φ. We have $x = .2914$ from our former examples, and to get y, we have $\frac{1}{1.168} = .856 = {}'F$ refracted, when 'F geometrical is = 1; therefore $\sqrt{.856^3} = .2512 = y$; but $\frac{y}{x} = z$; hence $\frac{.2512}{.2914} = .862 = z$, the correcting diviſor. Again, $\frac{30}{3.111} = 9.643 = F$ geometrical, and $9.64 \times 1.59 = 15.327 = {}'F$ in the ſame denomination. In this example we will take $r = 8$ inches; then, by the proper theorem $\frac{r F}{2r - F} = R$, we have $\frac{8 \times 9.64}{2 \times 8 - 9.64} = 12.12 = {}'F$, and $\frac{12.12}{9.64} = 1.515$; conſequently the geometrical ratio $r : R = 1 : 1.515$. Alſo, from

from the general theorem of Huygens, we find $A = 1.374 \times T$, and $1.374 \times 1.59 = 2.184 \times {'T} = {'A}$ rational, which is yet to be corrected; then $\frac{2.184}{.862} = \frac{'A}{z} = 2.535$, the corrected aberration. By getting the root of the quadratic arising from this aberration agreeably to the general theorem, as before, the ratio of the radii $'R : 'r$ comes out $1 : 2.375$. Lastly, by the theorem $\frac{2rR}{r+R}$ we get $\frac{2 \times 1 \times 2.375}{1 \times 2.375}$ $= 1.407 = {'F}$ rational, and $\frac{15.327}{1.407} = 10.89 = {'R}$, and also $10.89 \times 2.375 = 25.864 = {'r}$. We have, therefore,

$$\left.\begin{array}{l} r = 8.00 \\ R = 12.12 \end{array}\right\} \text{ and } F = 9.643.$$
$$\left.\begin{array}{l} 'R = 10.89 \\ 'r = 25.86 \end{array}\right\} \text{ and } 'F = 15.327.$$

Hence the next table is suitable for double achromatic object-glasses of various focal lengths, where $m : n$ in the crown-glass is as $1.528 : 1$, and in the flint as $1.584 : 1$; and their respective dispersive powers as $1 : 1.590$.

Table III.—Radii of double Object-glasses in Inches.

Φ	r	R	'R	'r
6	1.60	2.42	2.18	5.17
12	3.20	4.84	4.36	10.34
18	4.80	7.27	6.53	15.52
24	6.40	9.69	8.71	20.69
30	8.00	12.12	10.89	25.86
36	9.60	14.54	13.06	31.03
42	11.20	16.97	15.24	36.20
48	12.80	19.38	17.42	41.38
54	14.40	21.81	19.60	46.55
60	16.00	24.24	21.78	51.72
72	19.20	29.08	26.14	62.06
84	22.40	33.93	30.49	72.40
96	25.60	38.77	34.85	82.75
108	28.80	43.63	39.20	93.10
120	32.00	48.48	43.56	103.44

Example 4.—Let us next take an example, in which plate-glass is substituted for crown, and let the sines of the angles of incidence and of refraction in it be as $1.504 : 1$, while $m : n$ in the flint is as $1.573 : 1$, and their dispersive powers $1 : 1.623$; and let the length of the telescope be required to be 30 inches, as before? Then $\frac{m-n}{n} \times 2 = 2a = 1.008$, is the divisor for the plate-glass; and $\frac{m-n}{n} \times 2 = 2a = 1.147$, or a divisor for the flint; also $\frac{1}{1.088} = .992 = F$ refracted; and $\frac{1.623}{1.147} = 1.415 = {'F}$ refracted. Again, $\frac{F \times 'F}{'F - F} = 3.318 = \Phi$ rational; also $\sqrt{.992^3} = x = .3124$, and $\left(\frac{1}{1.147} = .872\right) \sqrt{.872^3}$ $= y = .2575$; whence $\frac{y}{x} = \frac{.2575}{.3124} = .824 = z$. Likewise $\frac{30}{3.318} = 9.03 = F$, and $9.03 \times 1.623 = 14.65 = {'F}$. Put $r = 7.5$; then $\frac{rF}{2r - F} = R = 11.34$, and $\frac{R}{r}$ $= 1.51$, or $r : R :: 1 : 1.51$; hence A, by the general theorem of Huygens, $= 1.376 \times T$, and $'A = 1.376 \times 1.623 = 2.233 \times {'T}$ = the aberration of the concave corrected for the difference of refractive power. The root arising from a quadratic equation of this aberration is $'r = 2.78$, when $'R = 1$, consequently $\frac{2rR}{r+R} = 1.471 = {'F}$ rational, and $\frac{14.65}{1.471} = 9.96 = {'F}$ geometrical; also $9.96 \times 2.78 = 27.68 = {'F}$ geometrical. Thus,

$$\left.\begin{array}{l} r = 7.50 \\ R = 11.34 \end{array}\right\} F = 9.03 \text{ geometrical.}$$
$$\left.\begin{array}{l} 'R = 9.96 \\ 'r = 27.68 \end{array}\right\} 'F = 14.65 \text{ geometrical.}$$

Table IV.—Radii of double Object-glasses, with Lenses of Plate and Flint, in Inches.

120	21.28	127.68	50.40	62.00

In the preceding example, where the ratio of the two radii of the convex lens were given, r comes out $= 5.32$ in a thirty-inch telefcope; and in like manner, when the aberration only is given, the ratio of the radii may firft be determined by a quadratic equation, and then the other curves may be determined as they have been here, without any affumption of r in the convex lens. But in all cafes the relative refractive and difperfive powers muft be known previoufly to the calculations fuch as we have exemplified.

Example 6.—In this example let us take the fame crown and flint glafs as we did in the fecond example, and put $r = 7.5$, as in our firft example; and then the radii will be as in the following table.

TABLE VI.—Radii of double Object-glaffes in Inches.

Φ	r	R	'R	$'r$
6	1.50	4.47	2.91	6.12
12	3.00	8.94	5.82	12.24

72	21.60	22.18	21.92	70.32
84	25.20	25.88	25.57	82.04
96	28.80	29.57	29.23	93.76
108	32.40	33.27	32.87	105.48
120	36.00	36.96	36.52	117.20

In this and the six preceding tables, the radii are calculated for an aperture of three inches for a focal distance of thirty inches; and the optician who may use any of them, with *similar glass*, may increase or diminish his aperture accordingly as the focal length is greater or less than thirty inches.

If we examine and compare the respective radii r and R, and also $'r$ and $'R$ of the convex and concave lenses in the preceding tables, which are all calculated by the same process that is used by Tulley, and several of which have been used in practice, we shall perceive that a difference in the quality of the glass, as to *dispersive* and *refractive* powers, makes the curves of the lenses widely different; and that a small alteration in the assumed value of r, the first face of the convex lens, also produces a great alteration in the curves of the three other faces of the compound object-glass. For instance, if we compare the radii in Table I. with those in Table VI., where r is assumed equal, *viz.* 7.5, in both, and where the same crown-glass is used, and the *flint-glass alone* taken different, the former being No. 2. and the latter No. 1; the radii in the former are $r = 7.5$, $R = 11.63$, $'R = 10.43$, and $'r = 20.86$, in a telescope of thirty inches focal length; whereas in Table VI. there is $r = 7.5$, as before, but $R = 22.34$, $'R = 14.56$, and $'r = 30.58$; which curves are very widely different. And if we compare Table II. with Table VII., in both which r is again assumed equal, as well as the crown, while the two flints are *reversed*, *viz.* the former having No. 1. and the latter No. 2, the comparison will stand thus in telescopes of thirty inches focal length: in Table II. there is $r = 9.00$, $R = 14.92$, $'R = 13.06$, and $'r = 40.15$; but in Table VII. $r = 9.00$, as before, while R is $= 9.24$, $'R = 9.13$, and $'r = 29.30$. Hence it is manifest, that it is not only *useless* but *detrimental* to copy the radii of a double object-glass of even the best telescope that ever was made by any artist, unless the *refractive* and *dispersive* powers of *both* sorts of glass be *precisely the same*, in the given and proposed telescopes intended to be equally good: but when different specimens of glass are necessarily used by different artists, it is hardly to be expected that both the requisite qualities of each piece of glass will be found alike, or even sufficiently near a perfect similarity, to authorise the copying of the radii of a standard telescope, even if those radii could be measured by mechanical means with sufficient accuracy; but the measurement from the *solar focus* of a lens, as is usual, does not afford data for obtaining the *geometrical* focus, and from it the radii of curvature, unless the quantity $2a$ be previously known; though the converse operation, we have before seen, is not difficult to a practical optician. We have no hesitation, therefore, in condemning the practice of analysing a telescope for the purpose of copying it; for it is the certain guide to irrational constructions; and seldom will an instrument so made be free from either colours or indistinctness.

Neither is it safe to copy *tables*, such as those published by Dr. Brewster, in his edition of Ferguson's Lectures, of which the *forms* are also given under the article ACHROMATIC *Telescopes*, (in the Edinburgh Encyclopædia,) until the specimens of glass to be used are ascertained to have the same *refractive* and *dispersive* powers, as those from which the tables are calculated. On comparing these tables with the results of professor Robison's calculations, given in the Encyclopædia Britannica under the article TELESCOPE, we find not only that the basis of these tables is derived from this source, but that the calculations themselves are adopted, without further modification than what is necessary for adapting them to given focal lengths of the compound object-glass. As professor Robison's article on our present subject has hitherto been considered to be the only article in our language that has disclosed the steps by which an *achromatic object-glass* may be constructed directly from mathematical calculations; it will be satisfactory to our readers that we should try what curves will result from Tulley's practical mode of proceeding, when the same data are taken that Robison has used in one of his examples. In an example worked according to Boscovich's formula, the ratio of $m : n$ in the crown-glass is taken as $1.526 : 1$, and in the flint, so high as $1.604 : 1$; while the ratio of the dispersive powers, when converted into the proper terms, are only in the ratio $1 : 1.65$, or $1 : \frac{1}{.6054}$; let us see what will be the curves of a thirty-inch telescope, when r is assumed $= 9.7$, and $R = 9.54$, according to Dr. Brewster's Table VI., derived from Robison's numbers $0.32325 \times 30 = 9.6975$, and $0.31798 \times 30 = 9.5394$.

As r is greater than R in this assumption, the convex lens is in its worst position, and the spherical aberration, A, determined by the general theorem of Huygens, will be $1.682 \times T$: and as the geometrical foci of the two lenses must be directly as their dispersive powers, and as T and $'T$ are inversely as those foci, we shall have $1.682 \times 1.65 = 2.775$ for the proportional aberration $'A$ uncorrected; then as the correcting number, for flint of $1.599 : 1$, which is the most dense that Tulley has met with, is .826, we may take this without apparent error for that of $1.604 : 1$; and then $\frac{2.775}{.826} = 3.26 = {'A}$ is the *corrected* aberration of the concave; and according to this aberration, the root of the quadratic will give $'R : 'r$ as $1 : 5.40$; and by theorem $\frac{2\,r\,R}{r + R}$ the rational focus will be $\frac{2 \times 5.40 \times 1}{5.40 \times 1} = 1.688$; then having $r = 9.7$, and $R = 9.54$, by the same theorem we have F of the convex $= 9.618$, and $F \times 1.65 = 15.8697 = {'F}$, or focus of the concave. Also we have $\frac{15.87}{1.688} = 9.401 = {'R}$, or shorter radius of the concave; and $9.401 \times 5.4 = 50.76 = {'r}$, or longer radius of the concave. Lastly, to obtain the compound focus Φ, we must reduce the geometrical focus of each lens into its refracted focus, by the proper divisors 1.052 for the crown, and 1.208 for the flint; then we shall have $\frac{9.618}{1.052} = 9.14$ for the refracted focus of the convex, and $\frac{15.87}{1.208} = 13.04$ for the refracted focus of the concave; and by the theorem $\frac{F \times {'F}}{{'F} - F}$ these numbers will give $\frac{9.14 \times 13.04}{13.04 - 9.14} = 30.53 = \Phi$.

We have now obtained numbers that will enable us to form the desired comparison; thus, according to Robison,

$$r = 9.7,\ R = 9.54,\ {'R} = 9.54,\ {'r} = 47.47;$$

but according to Tulley,

$$r = 9.7,\ R = 9.54,\ {'R} = 9.40,\ {'r} = 50.7.$$

Also, according to Robison we have $F = 9.618$ and $'F = 13.25$ geometrical, and the compound focus $\Phi = 29.1$. But according to Tulley, $F = 9.618$ and $'F = 15.8697$ geometrical, while the compound focus $\Phi = 30.53$.

Now

Now as F : 'F :: 1 : 1.65 (the refpective difperfive powers), let us fee if either of thefe refults will make an *achromatic* telefcope : thus, as $\left\{\begin{matrix} & & F & 'F \\ 1 : 1.65 & :: & 9.618 : & 15.8697 \end{matrix}\right\}$ which fhews that Tulley's foci are *exactly as the difperfive powers*, and therefore would be *achromatic*, if the *difperfive power* had been truly proportioned to the *refractive* power ; but from long experience he knows, that the difperfive power of flint-glafs of the greateft denfity, compared with that of crown, which feldom varies, is not lefs than 1.759 : 1. Hence Robifon's difperfive power is in the firft place taken too low ; and in the next, allowing it to be truly taken, he has not preferved the two feparate focal diftances in fuch ratio, agreeably to that of the difperfive powers, as will make an *achromatic telefcope*. And this is further proved by the circumftance, that the compound focus does not come out exactly 30, which it will always do by Tulley's procefs, if the proportions are all *rational*. If we fubftitute the ratio 1.759 : 1, inftead of 1.65 : 1, for the difperfive power, which Tulley's table of difperfive powers gives, to correfpond with the refractive powers, when $m : n$ as 1.599 : 1 ; and if we take the convex lens of Robifon in the worft pofition, as before, with $r = 9.7$, and $R = 9.54$, the radii of the concave, by Tulley's mode of calculating, will be $'R = 9.65$, and $'r = 68.04$, and the compound focus $\Phi = 25.6$; with which curves and focal length the telefcope would be *achromatic*, and truly *corrected* for fpherical aberration ; but as R comes out a deeper curve than 'R, thefe furfaces would come in contact at the centre, and therefore are not in a practicable form. Hence we infer that the conftruction of an achromatic telefcope with Robifon's convex lens in its *worft* pofition is impracticable, though a concave might be determined to fuit it in its beft pofition ; *viz.* when its faces are reverfed. There is, indeed, no form of a double convex lens, but a concave may be calculated to fuit it, provided the curves come out in a practicable form ; but, on the contrary, a concave may be fixed on that, in its worft pofition, (which is always its pofition in a double object-glafs,) can have no convex that will match it. Martin has fhewn, that if the aberration of a given concave be $\frac{a}{b} \times 'T$, then $\frac{a}{b} \times 'T \times \frac{6}{T} = \frac{4a}{b} = 6.42857$ will be a *minimum* ; whence $a : b$ :: 6.43 : 4 :: 16 : 10 nearly. Therefore, when $\frac{4a}{b}$ is *lefs* than 6.43, the problem will be impoffible. For inftance, in a plano-concave lens, the aberration is $\frac{7}{6}$ of T, and $\frac{7}{6} \times 4 = 4.66$ only, which fhould not be lefs than 6.43 ; and therefore this lens cannot be ufed fingly with a convex of any defcription ; much lefs can a concave in its beft form, where $r : R :: 1 : 6$, be ufed ; for its aberration $\frac{15}{14} \times T$ gives $\frac{4a}{b} = 4.284$ only. But either of thefe may be ufed in their worft pofition, becaufe then either of them will have aberration enough for any convex. And this previous confideration will enable the fkilful optician to fix on a proper ratio of $'r : 'R$, before he proceeds to his calculation. Should it be afked, why we prefer Tulley's difperfive powers to profeffor Robifon's? our anfwer is this ; that Tulley's were not gained fimply by prifmatic meafurement of the fpectrum, like Robifon's, where fome errors are obvioufly unavoidable ; but have been corrected by repeated comparifon of the focal lengths of the convex and concave lenfes in the very beft achromatic telefcopes felected for the purpofe, where, when a high magnifying power was ufed, the leaft difcolouration would have been obfervable ; and as thefe foci are always in the fame ratio as the difperfive powers, no other method of determining thefe powers can have fimilar pretenfions to accuracy.

When the convex and concave lenfes are both ground and polifhed (fee Glass and Grinding), they require fome care in putting them properly into the tube, fo that they may have their common axis coinciding with the axis of the eye-glaffes, in order that every part of the field of view may be equally diftinct and free from colour : and as there will always be fome errors of workmanfhip, and as both lenfes, but particularly the flint, may not be perfectly homogeneal, one of the lenfes muft be turned round in the common cell, till the faults of one lens are obferved to correct thofe of the other as much as poffible ; which will be known when the vifion is moft diftinct, or the object beft defined. Should any colour remain about the edges of the object, the prifmatic aberration is not corrected ; and if indiftinctnefs does not take place foon, and at equal diftances from the point of diftinct vifion, when the eye-tube is moved in and out, the correction for fpherical aberration is not perfect. A double object-glafs is much more eafily adjufted for a good central pofition, and for the counteraction of oppofite errors of workmanfhip and imperfection of glafs, than a triple one, and has moreover more light, in confequence of having but four reflecting furfaces ; but as it does not admit of any change of the faces in the final adjuftment, the lenfes require to be both truly calculated and nicely worked, in order to make the practice correfpond with the theory ; which is probably the reafon why triple object-glaffes, that admit of changes in their pofitions, are moft frequently made, particularly for fhort telefcopes : befides, half a dozen of thefe lenfes may be ground and polifhed at the fame time ; whereas, for a double object-glafs, each lens requires to be ground and polifhed feparately, and with the greateft care.

Triple achromatic Object-glaffes.—After having explained the theory, and exemplified the conftruction of a double achromatic object-glafs with great minutenefs, we come now to treat of triple object-glaffes, that fhall have the achromatic property ; but it will not be neceffary to give fo many examples, nor fuch minute explanation, as feemed requifite in our preceding part of this fubject, feeing that the calculations for a triple object-glafs are grounded on thofe that we have given for a double one, and do not materially differ from them. It will, however, be proper to fhew how the compound focus of three lenfes is determined, before we proceed to find the achromatic proportions of the refpective radii.

Firft, we muft have recourfe to our *fundamental* theorem, (of Table I. of theorems for the refractive foci of lenfes,) *viz.* $f = \frac{p\,d\,r\,R}{d\,R + d\,r - p\,R\,r}$, where p is the reciprocal of the refracting power of the medium employed, or of $\frac{m-n}{n}$, the meafure of that power, r and R the radii, as before, and d the radiant diftance. To apply this theorem to a fyftem of glaffes, as B, C, D, &c. which we propofe doing, it is convenient to fubftitute, for the general expreffion $\frac{1}{p}$, the letters a, b, and c, as peculiar to each medium refpectively. Suppofing now our three lenfes arranged in the order B, C, D, with B next the radiant object (as in *fig.*

fig. 12. *Plate* XXVIII.), we first determine the focus of B, which becomes in this case, if we substitute $\frac{1}{a}$ for p,

$$F = \frac{1}{a} \times \frac{d r R}{d R + d r - \frac{R r}{a}} = \frac{d r R}{a d R + a d r - R r}.$$

Now f, the focal distance of B, thus found, is manifestly the radiant distance of the second or middle lens C; and as the general theorem above referred to involves the radiant distance d, we have only now to apply that theorem again to the second lens C, substituting, as before, b for $\frac{1}{p}$, and for d, the quantity last found as the focus of B. This gives the compound focal distance of these two lenses B and C, which we will call φ; and this again becomes the radiant distance of the lens D: therefore, lastly, the general theorem is again applied to this lens, substituting c for $\frac{1}{p}$, and the last found focus (φ) for d; by which process, we arrive at the compound focus (Φ) of all the three lenses. In the application of these successive steps, it will be proper to attend to the signs of the quantities, where one of them, which in our case is the middle one, has its focus negative with converging rays. To exemplify this process in a triple object-glass for parallel rays, let B represent the outermost lens, which we will consider as a double convex lens with $\frac{m-n}{n} = a = 0.53$, and r and R each $= 10$; let C be the double concave of similar radii $'r$ and $'R$, and with $\frac{m-n}{n} = b = 0.6$; and let D be a plano-convex, and consequently R infinite, but $r = 10$, as before, and $\frac{m-n}{n} = c = a = 0.53$: then for the focus of B, putting $\frac{1}{p} = a$, we have $\frac{1}{a} \times$

$$\frac{d r R}{d R + d r - \frac{R r}{a}} = \frac{d r R}{a d R + a d r - R r} = \frac{d r R}{a d R - r R}$$

($a d r$ being neglected, when R is infinite) $= \frac{d r}{a d - r}$; and since d is also infinite with parallel rays, the expression becomes $\frac{r}{a} = F$, as in our first table of theorems for the refracted foci of lenses, for the first lens B. This expression is now put for d, when we come to consider the theorem as applied to C: here we have $\frac{1}{p} = b$, and the expression becomes $\frac{1}{b} \times \frac{d r R}{d r + d R - \frac{r R}{b}}$, or $\frac{d r R}{b d r + b d R - r R}$; then, as r is taken equal to R, it will be $\frac{d r}{2 b d - r} = {}'F$ of the lens C. Now, if in this expression we substitute $\frac{r}{a}$, the focus of B, for d, we have for $\frac{d r}{2 b d - r}$ $\frac{r}{a} \times$ $\frac{r}{\frac{2 b r}{a} - r} = \frac{r}{2 b r - r a} = \frac{r}{2 b - a}$ for φ, the compound focus of B and C, or rather, as the rays fall converging on C, and $2b$ is more than a, $= \frac{-r}{-2b-a}$. Again, this quantity will become d for the lens D, and putting the same substitution as before, in the general theorem for D, where $\frac{1}{c}$ is put for p, we shall have $\frac{1}{c} \times$

$$\frac{d r R}{d r + d R - \frac{r R}{c}}, \text{ or } \frac{d r R}{c d r + c d R - r R}, \text{ or, when } r = R,$$

$\frac{d r}{2 c d - r}$; hence we obtain $\frac{r}{2 b - a} \times \frac{r}{2 c \times \frac{r}{2 b - a} - r} =$

$$\frac{r^2}{2 c \times r - \overline{2 b - a} \times r} = \frac{r}{2 c - 2 b + a} = \Phi,$$

or compound focus of all the three lenses, B, C, and D. Let us take, by way of example, three lenses as follow; *viz.* B, a double convex lens of crown-glass, with its refractive power by experiment $= 0.53 = a$, and with equal radii, where r and R are each $= 10$; let the second lens C be a double concave of flint-glass, with the same radii, and of a refractive power $= 0.6$; and let the third lens D be a plano-convex of crown-glass, of a refractive power of 0.53 also, with $R = 10$ likewise; then, according to our last expression $\frac{r}{2c - 2b + a}$, we have $\frac{10}{2c - 2b + c}$, or $\frac{10}{3c - 2b}$ $= \frac{10}{1.59 - 1.2} = \frac{10}{0.39} = 25.6 = \Phi$. In this way the compound focus of any number of lenses may be determined, and the course of the rays might be traced in a geometrical figure out of one glass into another, until they come to their ultimate focus.

For instance, let us consider S and s, in *fig.* 12, to be two parallel solar rays incident on the first lens B, at the points b and b: these rays, on entering, are bent towards the axis $\varphi f \Phi$, and then from the points of emersion tend to their principal focus f; but being intercepted by the double convex lens C, they diverge, after entering at c and c, in a direction which points backwards to the virtual focus φ; but in their progress, they again become incident on the plano-convex at the points d and d, and are again refracted towards the axis, and meet in a distant point Φ, which is, therefore, the compound focus of all the three lenses. And if we conceive the parallel rays, S and s, to be pencils of solar rays, that *disperse* on entering the convex lens B, they will disperse in a contrary direction on entering the concave C, and will again, on entering the plano-convex lens D, have the excess of dispersion of C counteracted by a second opposing dispersion of D, and, instead of coming to unite at the distant points P and Q, to which they tended on entering D, they will meet, by virtue of the prevailing refraction of the two lenses B and D taken jointly, over the refraction of C taken separately, at the compound focus Φ, where the image of the sun will be formed; and if both the focal distances and radii of curvature of all the lenses were achromatically adjusted, as we shall presently direct, the image would be free from colours, and well defined.

The same determination of the foci f, φ, and Φ, in any combination, may, however, be obtained more conveniently in in practice, when r and R are unequal, from our former practical theorems, thus: let us determine the compound focus of B and D by the theorem $\frac{F \times F}{F + F}$, as they have each a poſitive focus, and call this focus $= \varphi$ geometrical, and then $\frac{\varphi}{2a}$ will be φ *refracted;* and ſecondly, let $'F$ geometrical be turned into $\frac{'F}{2b}$ for the refracted focus of the concave C; and then, by the theorem $\frac{F \times 'F}{'F - F} = \Phi$, we ſhall have Φ for the compound refracted focus of the triple object-glaſs, or length of the teleſcope: for example, taking the ſame data as before, we ſhall firſt have $\frac{10 \times 20}{10 + 20} = \frac{200}{30} = 6.66 = \varphi$, and $\frac{6.66}{1.06}$, or $\frac{\varphi}{2a} = 6.28 = \varphi$ refracted; and $\frac{10}{1.2}\left(\frac{'F}{2b}\right) = 8.33 = {}'F$ refracted: alſo, by the theorem $\frac{\varphi \times 'F}{'F - \varphi}$, becauſe $'F$ has a negative focus, we get $\frac{6.28 \times 8.33}{8.33 - 6.28} = \frac{52.33}{2.05} = 25.53 = \Phi$, as was required. We ſhall uſe this method of finding the compound focus φ of two lenſes, and alſo Φ, the focus ariſing from all the three lenſes, where it is to be underſtood that a, the ſymbol for the refractive power of both the crown lenſes B and D, is taken the ſame; and that we expreſs the refractive power of C, the concave, by the ſymbol b, as a ſubſtitute for $'a$.

We muſt further premiſe, that when T, the thickneſs of each lens B and D, is not conſidered, we ſhall ſhew preſently that the ſpherical aberration, ariſing from any ſingle lens that receives the rays of light, may be diminiſhed as 4 : 1, by the combination of two lenſes, to be ſubſtituted for that one. Bearing theſe premiſes in mind, we now proceed to the conſideration of a triple object-glaſs, that ſhall have the due corrections for both the priſmatic and ſpherical aberrations. It will greatly facilitate both our explanation and exemplification, if we ſuppoſe the two convex lenſes B and D, having a compound focus $= \varphi$, to be repreſented by a ſingle lens E, with the ſame focus φ, but with a *diminiſhed* aberration; for then we may proceed nearly as in our ſeven preceding examples; but reverſing the proceſs, when the concave has its radii given, to find the convex lens.

Example 8.—Let it be required to conſtruct a triple achromatic object-glaſs of 30 inches focal length, with the ſame refractive and diſperſive powers as in the firſt example; *viz.* with $m : n$ in the crown as $1.528 : 1$, and in the flint as $1.5735 : 1$; and with the diſperſive powers as $1 : 1.524$; and let the two radii of the concave be each 13.9, ſo as to have $'F$, as in the firſt example.

In the firſt place we have $'r : {}'R :: 1 : 1$, and, as we have ſeen above, $'A = 1.666 \times {}'T$, by the general theorem of Huygens; in the next place, becauſe the *concave* C is *given* to find the *convex* E, the correcting number z, found as before, becomes a *multiplier*, in a reverſed operation, and we have $1.666\ ('A) \times {}'T \times .883\ (z) = 1.4715 \times T = {}'A$ *corrected:* we muſt alſo uſe the former multiplier 1.524 (the diſperſive power, or proportional focus) as a *diviſor*, and then we get $\frac{1.4715}{1.524} = .9655 \times T = A$ of the ſubſtituted lens E, with a focus $= \varphi$; but there is no ſuch ſmall quantity of aberration in any one lens. Let us however ſee what the abſolute aberration $'A$ will be, unconnected with the factor $'T$, which factor we have determined, from the verſed ſines to the radii 13.9 and 13.9, to be $= .1653$; therefore $1.4715 \times .1653 = .2432 = {}'A$ *abſolutely*. Now we have ſeen, in the firſt example, that .252 is = T of the proper convex; let us now conſider that $\frac{.252}{2} = .126$ is = T in one of the lenſes B and D, which we propoſe to make in every reſpect ſimilar, in order to have as few different curves, and conſequently as few different tools, as poſſible; then, becauſe .2432 is the *abſolute* aberration of C, the concave, we have $\frac{.24324}{.126} = 1.93 \times T = A$ of either of the convex lenſes; but T is .126; therefore $1.93 \times .126 = .2432$ is the *abſolute* aberration of each convex lens, exactly equal to the abſolute aberration of the concave. But we have aſſerted, and ſhall demonſtrate hereafter, that when the thickneſs of the lenſes is neglected, a proper combination of two lenſes, placed at a certain diſtance from each other, will diminiſh the aberration belonging to one *four times*, and even when the diſtance = 0, this will be nearly the caſe: now we have $.9655 \times T = A$ in the lens E of equal focus, let us leave out A, and multiply by 4, and we have $4 \times .9655 = 3.862$ very nearly, the ſum of the aberrations (without T) of the two convex lenſes B and D, taken together; *viz.* $2 \times 1.93 = 3.86$; but yet the abſolute aberration of each ſeparate convex lens (T being conſidered) is exactly equal to the abſolute aberration ($'T$ conſidered) of the double concave. This relation of the reſpective aberrations being once eſtabliſhed and confirmed by practice, which Tulley affirms to be the caſe, ſimplifies the complex buſineſs of calculating a triple object-glaſs: for the *ſum* of the abſolute aberrations of the two convex lenſes of like glaſs, muſt be always equal to *double* the abſolute *corrected* aberration of the concave alone, in order to have a due correction for ſpherical aberration, and conſequent indiſtinctneſs. Hence, when the focal diſtance, φ, of the two convex lenſes B and D is in the ſame proportion to $'F$, the focal diſtance of the concave, that their ſeparate diſperſive powers are relatively to that of the concave B, the relative radii of either B or D, or of both, may be *varied* at pleaſure, provided that the *ſum* of their *abſolute* aberrations remain equal to *double* the abſolute aberration of the concave C, and provided that φ, their compound focus, be not altered. But we have not yet adjuſted the two focal diſtances ſo as to make the object-glaſs achromatic, and Φ, or the compound focus of the three, to be equal 30 inches. From an equation of the aberration $1.93 \times T$, or from .2432 abſolutely, we find the ratio of $r : R$ in each lens to be as $1.34 : 1$, which is alſo agreeable to Tulley's tables, from which this ratio may be had by inſpection; alſo the rational geometrical focus for theſe numbers is 1.145. Now according to our firſt example, we have ſeen that when $'F = 13.9$ in a teleſcope of 30 inches focal length, F will be 9.12, when there is only one double convex lens; but here we have two lenſes to produce $9.12 = \varphi$, and therefore, as both lenſes are to be alike, we have $9.12 \times 2 = 18.24 = F$ for each ſeparate focus; therefore $\frac{18.24}{1.145} = 15.93 = R$ of each, and $15.93 \times 1.34 = 21.35 = r$;

$= r$; and the refult of our calculation will ftand thus; *viz.*

First convex B $\begin{cases} r = 21.35 \\ R = 15.93 \end{cases}$ $F = 18.24$, and $A = 1.93 \times T = .2432$.

Concave C $\begin{cases} 'r = 13.9 \\ 'R = 13.9 \end{cases}$ $'F = 13.9$, and $'A = 1.4715 \times 'T = .2432$.

Second convex D $\begin{cases} r = 21.35 \\ R = 15.93 \end{cases}$ $F = 18.24$, and $A = 1.93 \times T = .2432$.

Alfo - - - $\left\{ \frac{F \times F}{F + F} = \phi = 9.12 \right.$

And - - - $\left\{ \frac{'F \times \phi}{'F - \phi} = \Phi = 30.0 \right.$

It is hardly neceffary to obferve, that the quantities T and 'T are here given in *numbers*, for the fake of illuftration; but when the quadratic equation is worked, thofe fymbols may be exterminated, and their values involved in the procefs.

A table of radii for triple object-glaffes, in which the two convex lenfes of crown-glafs, and the one of flint, have refpectively the fame refractive and difperfive powers as in Table I. and $'r = 'R$.

TABLE VIII.—Radii of triple achromatic Object-glaffes.

108	76.86	57.34	50.10	50.10	76.86	57.34
120	85.40	63.72	55.60	55.60	85.40	63.72

Example 9.—Let it be required to conftruct another triple object-glafs of 30 inches focal length, with crown and flint-glafs exactly fimilar to what was ufed in the laft example; but let the radii of the concave be unequal; *viz.* $'r : 'R :: 1 : 1.23$, and in the beft pofition?

In this example we propofe to abridge the work thus; firft, $'A = 1.507 \times 'T$ and $z = .883$, and $\frac{'A}{z} = \frac{1.507}{.883} = 1.33 \times 'T = 'A$ corrected; then $\frac{1.33}{1.524} \left(\frac{'A \text{ cor.}}{'F \text{ rat.}} \right) = .873 \times T$ for the proportional aberration of the fubftituted lens E, as before; which is an impoffible quantity. The focus of this fubftituted lens, as in the laft example, is 9.12, and confequently $9.12 \times 2 = 18.24$ is again the focus of one of the two convex lenfes to be ufed, that of the concave being, as before, 13.9 (for $\frac{13.9}{1.524}$ is $= 9.12$); whence $'r$ and $'R$ will be 12.6 and 15.5 refpectively. T, as before, is $= .126$, and $'T = .1653$ (by calculation); hence $'T \times 1.33 = .2198$ is the *abfolute* aberration of the concave lens, as well as that of each of the two convexes of 18.24 focus; therefore $\frac{.2198}{.126} = 1.745 \times T = A$ of one of thofe lenfes, and the root of the quadratic arifing out of this equation of A, gives the ratio of the radii, where R is unity, thus; as $R : r :: 1 : 1.1$; and the rational focus, by the proper theorem, is 1.048; confequently $\frac{18.24}{1.048} = 17.40$ is $= R$ of each convex lens, and $17.40 \times 1.1 = 19.14$ is $= r$; fo that we have now the fubjoined refults; *viz.*

Convex B $\begin{cases} r = 19.14 \\ R = 17.40 \end{cases}$ $F = 18.24$, and $A = 1.747 \times T = .2198$.

Concave C $\begin{cases} 'r = 12.60 \\ 'R = 15.50 \end{cases}$ $'F = 13.9$, and $'A = 1.33 \times 'T = .2198$.

Convex D $\begin{cases} r = 19.14 \\ R = 17.40 \end{cases}$ $F = 18.24$, and $A = 1.747 \times T = .2198$.

Alfo - - - $\{ \phi = 9.12$ for the compound focus of B and D.

And - - - $\{ \Phi = 30.0$ for the compound focus of B, C, and D.

The following is a table of radii for triple object-glaffes, where the refractive and difperfive powers are as in the laft example, but where the radii of the concave are unequal, *viz.* $'r : 'R :: 1 : 1.1$.

Table IX.—Radii of triple achromatic Object-glasses.

	B Convex.		C Concave		D Convex.

In like manner, any number of tables might be computed for the focal lengths of a triple object-glass, where the lenses have given refractive and dispersive powers, and where the radii assumed for one of the lenses are taken at pleasure; but it will be always desireable to fix on a *concave* lens first in a *triple* object-glass, notwithstanding we have shewn that it is better to assume a *convex* one first, where a *double* object-glass is calculated: for by attending to this direction, the optician will find that counteracting aberrations will be within his reach; and though he may fix on radii in the assumed lens that will not be the best in practice, yet, by changing the ratio of the assumed radii, he will find practicable lenses that will answer his purpose. In our tables of triple object-glasses, the numbers come out very convenient for practice; for in each, both sides of the convex lenses have longer radii than either face of the concave has got, so that there will be no point of contact, in the middle of any of the curves, when they are placed contiguous to one another; and in Table IX. there is just difference enough, between the radii of each of the convex glasses, to allow one of them to be reversed, if it is found that the errors of workmanship, or imperfection of the glass, should require such correction, when the object-glass comes to be finally adjusted. Indeed all the surfaces might be calculated to be a little different from one another, and then there would be the option of eight changes in the final adjustment: but if the glass is homogeneal, and the work well performed, it will always be found best to adhere to the positions for which the lenses have had their radii calculated.

Neither is it desireable, in a *good* achromatic object-glass, to use varnish of any description, as has been recommended.

As we have shewn that professor Robison's data, and the calculations founded on them, do not produce curves proper for an achromatic *double* object-glass, we will conclude this part of our subject by examining if his calculations for a *triple* object-glass are any better adapted for practice. In Dr. Brewster's Table V. (Appendix to his edition of Ferguson's Lectures, vol. ii. p. 418.) a thirty-inch triple object-glass is calculated, according to professor Robison's report of the radii used by the London artists, to have $r = 18.84$, (printed by mistake 18.34,) $R = 22.47$, $'r$ and $'R$ each 17.37, and the second convex the same as the first; where, as before, the ratio $m : n$ in the crown is taken as $1.526 : 1$, and in the flint as $1.604 : 1$, and the ratio of the dispersive powers as $1 : 1.65$. If these numbers will make an *achromatic* object-glass, we shall have $1 : 1.65 :: F : 'F$ exactly; *i. e.* the ratio of the dispersive power will also be the ratio of the geometrical focal distances, agreeably both to theory and practice; but we have, by the theorem $\frac{2rR}{r+R}$, $\frac{2 \times 18.84 \times 22.47}{18.84 + 22.47} = \frac{846.6696}{41.43} = 20.495$ for the focus of one convex lens, and therefore $\frac{20.495}{2} =$ 10.247 for the compound focus of the two; also we have the focus of the concave $= 17.37$ in the table, the radii being equal; hence we have as $1 : 1.65 :: 10.247 : 16.90$, instead of 17.37; therefore the object-glass is *not duly corrected* for the *prismatic* aberration. This conclusion, which is intelligible by every common reader, corroborates our former inference respecting the want of achromatism in the double object-glasses made from Robison's calculations; but let us pursue the enquiry a little farther, and see what focal distance will accord with these numbers: the refractive power of the convex being $.604 = a$, we have $\frac{10.247}{2a}$ $= 9.74$ for the *refracted* focus thereof; and the refractive power of the concave being $.526 = b$, we have $\frac{17.37}{2b} =$ 14.38 for its refracted focus, and by our theorem $\frac{'F \times F}{'F - F}$ $= \Phi$, we have $\frac{14.38 \times 9.74}{14.38 - 9.74} = \frac{140.0612}{4.64} = 30.18$, &c. for the focal length of the object-glass; which is much nearer to the proposed length than the focus of the double object-glass was which we before examined. If we calculate this triple object-glass according to our method, as practised by Tulley, we must begin with 16.9 as the proper focus for the concave, of which we disregard the negative sign, as of no importance in our mode of calculating; we shall then have as $1.65 : 1 :: 16.9 : 10.247$, and this ratio must not be compromised, on any consideration, as being the *achromatic* ratio, on a supposition that the refractive and dispersive powers, as above stated, are in natural proportion; then as the radii $'r$ and $'R$ are assumed *equal*, the aberration of the concave will be $1.666 \times T$, and $z = .826$; therefore $\frac{1.666}{.826} = 1.376 = 'A$ corrected; and $\frac{1.376}{1.65} = .834 = A$ of the substituted single lens E, which, as before, is an impossible quantity to be in *one* lens; but this being doubled, will be $1.668 \times T$ for the proper quantity of each lens; or multiplied by 4, will be a proper

proper quantity for the ſum of both the convex lenſes ; then 'T being found $= .136$, and $T = .112$ in each convex, we ſhall have $A = 1.668 \times 2 \times .112 = .1871$ for each convex, and $'A = 1.376 \times .136 = .1871$ alſo, for the concave, and conſequently the ratio of $r : R$ as $1.01 : 1$; then by uſing the proper theorems, as before directed, theſe radii will come out $r = 20.57$, and $R = 20.37$ in each convex, while the concave will have each of its radii $= 16.9$, as originally aſſumed ; and if the diſperſive was great enough for the refractive power, as above ſpecified, not only would the object-glaſs be *achromatic*, but its focal length would be $= 30$. But we find the geometrical $F = 10.24$, and refracted $F = \frac{10.24}{1.056} = 9.696$, and $\frac{'F}{2\,a} = \frac{16.9}{1.198} = 14.107 =$ 'F refracted, and $\frac{'F \times F}{'F - F} = \Phi$, gives $\frac{14.107 \times 9.696}{14.107 - 9.696} = \frac{136.781}{4.451} = 31$ very nearly ; and hence we infer, that the diſperſive and refractive powers are *irrational* in this calculation, and the exceſs in the focal length is double the quantity with theſe two convex lenſes, B and D, to what we found it with one, in a double object-glaſs, in our former examination. We are not however diſpoſed to depreciate the mathematical labours of a man, whoſe memory will always be dear to every lover of ſcience, and whoſe article TELESCOPE in particular has obtained the encomium of an eminent contemporary mathematician ; but we have felt it our duty to point out the ſource of inaccuracy, which, by entering into the data, has affected the reſult of long and tedious calculations, and may have given much trouble to many, as we know it has done to ſome opticians, who have attempted to copy thoſe reſults in practice. The learned profeſſor has indeed ſtated, as he proceeds, that the value of certain appreciable quantities has been neglected, to ſimplify the proceſs ; and if thoſe quantities had affected the focal diſtance more, and the ratio of the radii $r : R$, and alſo that of $F : 'F$ leſs, the reſulting priſmatic and ſpherical corrections might have been more perfect, even with a defect of diſperſive power, than we now find them. We have not room, however, to enter farther into particulars.

From Dr. Brewſter's experiments, made in his "Treatiſe on New Philoſophical Inſtruments," it appears that the *green* ray is not always in the *middle* of the ſolar ſpectrum, and that with rock-cryſtal it is at the oppoſite ſide of the middle from what it is in glaſs ; hence Tulley infers, that if glaſs could be found of the ſame diſperſive power as rock-cryſtal has, the intermediate colours might be corrected as well as the extreme colours ; and that the ſecondary ſpectrum would diſappear. To effect this improvement, the convex lens of rock-cryſtal muſt be at one ſide of the concave of flint, and the convex of crown or other glaſs, with equal diſperſive power to that of the cryſtal, muſt be at the other ſide. This object is worthy of the optician's future conſideration and purſuit.

Celeſtial achromatic Eye-pieces.—We have already explained, in the former part of this ſection, how the focus of two glaſſes, placed at a *given diſtance* from each other, may be aſcertained, and alſo what is the focus of a ſingle imaginary lens that ſhall be equal to them both in *power :* we propoſe therefore preſently to return to the ſame figure, (*fig.* 8. *Plate* XXIV.) in order to ſhew what the advantage will be in point of *diſtinctneſs*, which is as eſſential a quality in an eye-piece as power. But, in the firſt place, let us ſuppoſe in *fig.* 10. the points 1, 2, and 3, ſo many points of an object, of which the image is formed at F, after paſſing through any lens A B ; then as the point 1 has rays iſſuing from it, that fall on every part of the lens, and as theſe rays are differently refracted at different diſtances from the axis, both towards A and towards B, there will be ſeveral images of this point at the focus F, lying contiguous to each other ; but the rays that come to a focus, after paſſing in and near the central part of the glaſs, will form their images very cloſely together, ſo as very nearly to coincide. The ſame will be true of the points 2 and 3 ſeparately conſidered, under the ſame circumſtances, ſo that while the ſingle lens A B continues to produce both priſmatic and ſpherical aberrations, there will be a confuſion or *indiſtinctneſs* in the image, ariſing from a promiſcuous mixture of a number of contiguous and nearly coincident images ariſing out of the ſpherical figure of the lens, as well as fringes of colour ariſing out of the diſperſion of the differently refrangible rays. This indiſtinctneſs is more conſiderable in a lens uſed as an object-glaſs, than as an eye-piece ; becauſe the image formed by it becomes an object to be viewed by means of the eye-piece, and therefore any diſtortion, confuſion, or colouration that exiſts in the image, will be *magnified* by the eye-piece ; and the greater the magnifying power, the greater will be the evil produced thereby. To obviate this conſequence, which will exiſt partially, even when the beſt compound object-glaſs is uſed that art can accompliſh, the ſingle eye-glaſs has been laid aſide, and a ſyſtem of glaſſes ſubſtituted, that will admit of a high power in the eye-piece, without a proportionate increaſe of indiſtinctneſs or of colour in viewing the image. The firſt arrangement of two glaſſes, as a ſubſtitute for one, to be uſed as a celeſtial eye-piece, where inverſion of the object is not material, was calculated and applied by the ingenious Huygens, who, not aware that the priſmatic aberration could be cured by an oppoſition of *diſperſive* powers, according to Dollond's noble diſcovery, deviſed the method of reducing the quantity of ſpherical aberration by *diviſion ;* and the reſult of his inveſtigations was, that two plano-convex lenſes, (which have each but little aberration in their beſt poſitions,) when placed at ſuch a diſtance from each other that their focal points, for parallel rays, might coincide, would have ſuch a compound focus, as would not only greatly increaſe the power, but ſtill more diminiſh the ſpherical aberration. An arrangement of this ſort was put into the hands of W. Molyneux by Mr. Flamſtead in the year 1686, of which Molyneux determined the compound focus, depending on the radii of curvature of the two glaſſes and the diſtance between them, in the manner we have above explained. But the firſt mathematician who gave the *rationale* of the advantage to be derived from a combination of lenſes, as they have reference to the ſpherical aberration, was ſir Iſaac Newton, whoſe method of explaining it Martin has given in his New Elements of Optics, part i. p. 27, thus: "Let N B M (*fig.* 9.) be the ſpherical ſurface of a plano-convex lens N G M B ; C the centre ; C B the radius or ſemi-diameter taken in the axis ; A N an incident ray ; and N K the ſame refracted, cutting the axis produced in the point K. Alſo let F be the focus of parallel rays which paſs through the glaſs infinitely near to the axis : let F D be a perpendicular to the axis in the point F, then will K F be the curve or difference of the focal diſtance of parallel rays which are incident near the axis, and at the diſtance G N, the ſemi-aperture of the lens. This is called the *aberration* of the extreme ray in *longitude*. Again, let any ray (*a n*) be incident on the other ſide the lens, at the diſtance *b* G, the refracted part of this ray, *n d*, will interſect the other refracted ray N D in the point Q, at the perpendicular diſtance Q O from the axis. This

is

is called the *lateral* error, or the *aberration* in *latitude*. It is evident from the figure, that as the ray $(a\,n)$ approaches the extreme ray A M, the point of interſection Q will approach the axis; and when $a\,n$ coincides with A M, the point Q will coincide with the point K in the axis; and it is as obvious that the point Q will coincide with F, when the ray $(a\,n)$, approaching the axis a B, at laſt becomes coincident with it: therefore there is one poſition of the ray $(a\,n)$, in which it will cut the ray N D in a point Q, which will make Q O a *maximum*, or the greateſt of all. If we take the arc $B\,m = B\,n$, and B M = B N, the rays incident on m and M will interſect in the point P on the other ſide, and ſo make P Q = 2 Q O; and it is alſo plain, that all the rays which fall on the lens between N and M are refracted through the ſpace P Q. Now P Q is the diameter of the *leaſt circular ſpace* poſſible, in which *all the rays* can be congregated, becauſe there will be ſome ray $(a\,n)$ that will meet the extreme ray N D, at the diſtance $Q\,O = \frac{1}{2}\,Q\,P$ from the axis. Hence it follows, that the circular ſpace is the *focus*, or place of the *image* of an object, belonging to parallel rays incident on the lens N M. Further, by reaſon of ſimilar triangles K O Q, K F D, and N G K, we have Q O : K O :: D F : K F :: N G : G K. But it is demonſtrable, (ſee Philoſ. Britannica, 3 edit. p. 58. art. 14.) that when Q O is greateſt, then $K\,O = \frac{1}{4}\,K\,F$, and alſo that K F is always $\frac{9}{2}$ of G B, the thickneſs of the lens; ſo then $K\,O = \frac{9}{8}\,G\,B$, and conſequently $G\,K : G\,N :: \frac{9}{8}\,G\,B : Q\,O$, whence $\frac{9\,G\,B \times G\,N}{8\,G\,K} = O\,Q$; whence P Q, the diameter of the circle of aberration, is known for any given lens.

"It has been demonſtrated, that the error P Q will always be proportioned to $\frac{N\,G^3}{B\,C^4}$; ſo that when the radius is given, the error will be as the cube of the aperture directly: and when the aperture is given, the ſaid error will be as the ſquare of the radius inverſely. It has alſo been demonſtrated, that when the convex ſide of the lens N B M is turned towards parallel rays, the error K F will be but $\frac{7}{6}$ of the thickneſs of the lens G B, and therefore near four times leſs than in the other caſe; for $\frac{9}{2}\,G\,B : \frac{7}{6}\,G\,B :: 54 : 14$, which is almoſt as 4 to 1.

"It has been further demonſtrated, that the aberration P Q is as the ſquare of the ſine of refraction (the ſine of incidence being unity) in all media of different refractive powers: thus if a lens of the ſame focal diſtance and aperture were made of glaſs and water, and ſuppoſe thoſe ſines in glaſs to be as $m : n$, and in water as $'m : 'n$; then will P O in the glaſs lens be to the ſame in the water lens as $m^2 : 'm^2$, or the area of the circles of aberration, and of courſe the indiſtinctneſs of the object will be as the refractions m and $'m$ of the media.

"Whatever has been obſerved with regard to convex and plano-convex lenſes, will hold good in concave and plano-concave ones. And in both ſorts, it is ſuppoſed that all of them have the ſame focal diſtances, apertures, and thickneſſes, while we are comparing their reſpective aberrations.

"Hence it is very evident, that if rays proceed from any point, as (a) at an infinite diſtance to a lens N M, (*fig.* 10.) the image of that point will not be a point, but the area of a circle, whoſe diameter is P Q; and, therefore, that point cannot be diſtinctly repreſented, but will be rendered indiſtinct and confuſed in proportion to the area of the ſaid circle of aberration in the lens, as it is the image of this circle (or dilated point) that is impreſſed on the retina, and excites the idea of the point in the mind.

"Hence it appears alſo, that the points in the ſurfaces or ſubſtances of bodies cannot be perfectly and diſtinctly ſeen, as each of them will be dilated into a ſenſible area; and ſuch as are contiguous, as 1, 2, 3, will have their confuſed images all blended together nearly in the ſame ſpace, *viz.* in the circle of aberration, the diameter of which is P Q.

"Therefore the ſtars, which as to ſenſe are only lucid points, will appear to have ſome magnitude (and not as points) in the focus of the beſt ſort of teleſcopes, even ſuppoſing there were no other cauſe of confuſion or indiſtinct viſion, beſides what reſulted from the ſpherical figure of the lens.

"Now, if the error from a ſpherical ſurface, or, which is the ſame thing, the *indiſtinctneſs* of viſion, depending on, and commenſurate with, the ſpherical aberration of a lens, is as the ſquare of radius inverſely; the *diſtinctneſs* of viſion, on the contrary, will be as the *ſquare* of the *radius directly*; and, therefore, if, by means of two glaſſes, we can get the view of an object, where the radii of the glaſſes bear a greater proportion to their reſpective apertures, than the radius of a ſingle glaſs of equal magnifying power does to its aperture; it is evident the diſtinctneſs of that view will be promoted in proportion to the ſquare of that ratio.

"For example, ſuppoſe (*fig.* 8.) $F - D = y$, or O F, to be the focal diſtance of the lens G H, ſo that the focus of each of the lenſes N M and G H falls on the ſame point F; then, by the proper theorem, we have $x = \frac{1}{2}\,F$, or $Q\,f = \frac{1}{2}\,C\,F$: alſo, ſince in this caſe we have $F : y :: x : f$, therefore $f = \frac{1}{2}\,y$, or $O\,f = \frac{1}{2}\,O\,F$. Now, ſince we have the ſame optic angle G F O by both the glaſſes, as by the ſingle one E E, the ratio of the radius O F to the aperture G O, or of the radius C F to the aperture N C, is double the ratio of $O\,f$ to O G, or of the radius $Q\,f$ to the aperture E Q, and therefore the *diſtinctneſs* of viſion by *both* the lenſes is *four times* greater than that by the *ſingle* lens E E.

"The ſame thing may be demonſtrated from the conſideration, that the aberration P Q is, in the ſame glaſs, always proportioned to the cube of the ſemi-aperture E Q, or ſine of half the optic angle $E\,f\,Q$; and that in ſmall angles (as in the glaſſes of teleſcopes, &c.) the ſine E Q is nearly as the angle $E\,f\,Q$. The aberration, therefore, being as the cube of that angle, it is plain, if we make the ſame angle by two refractions inſtead of one, the quantity of the aberration will be greatly leſſened, ſince the ſum of the cubes of the parts will be much leſs than the cube of the whole; and when the parts are equal, the *ſum* of the cubes of *each* will be but a *fourth part* of the cube of the *whole*. Thus, if the whole angle $E\,f\,Q$ be as 1, the cube thereof is 1; but the half is $\frac{1}{2}$, the cube of which is $\frac{1}{8}$, and twice that, $\frac{2}{8} = \frac{1}{4}$, which is as the aberration ariſing from the two halves, and is therefore but a *fourth part* of the whole.

"This is evidently the caſe when the optic angle $G\,f\,O$ $(= E\,f\,Q)$ is made by two refractions, by the two lenſes N M and G H, ſo poſited, that the focus of each may fall on the ſame point F; for then the angle $G\,f\,O = L\,G\,f$, which is compoſed of the two angles L G F = T N F = G F O, (by reaſon of the parallel lines T N, L G, and F C,) which is the part made by the lens N M. Alſo the angle $F\,G\,f$ is the refraction of the ray N G, or ſecond refraction of the ray A N; and ſince, in the preſent caſe, $O\,f = f\,F$, and $O\,f$ in ſmall angles is equal to $G\,f$ nearly; therefore the angle G F O is equal to the angle $F\,G\,f$ very nearly, thoſe angles being in the ſame ratio with the equal lines $G\,f$ and $f\,F$, when they are not large; and the optic angle $G\,f\,O = G\,F\,O + F\,G\,f$; conſequently the aberration P Q is but a fourth part ſo great by the two lenſes N M and G H together, as it is by lens E E alone.

"But to render this theory general for any poſition or form of of the lenses N M and G H, it is evident, since the aberration is lessened by dividing the optic angle, that the *distinctness* of vision will be thereby promoted; and because each of the angles contribute thereto in proportion to its magnitude, the joint effect of both parts, or angles G F f and f G F, will be as the product or rectangle under both, or as the rectangle of the lines O f and f F; but, according to our former notation, $Ff = F - D - f$; and $Of = f$; consequently $Ff - Df - ff$ will be every where as the distinctness of vision by the two lenses, above that of a single lens of the same magnifying power.

"Let the degree of distinctness thus obtained be represented by $G = Ff - Df - ff$; when this is a *maximum*, or the greatest possible, the fluxions thereof will be nothing; *viz.* $Ff - Df - 2ff = 0$, whence $F - D = 2f$; or $FO = 2Of$; that is, $Of = f$F, or the angle G Ff = fG F, in the *best* position of the lenses, as before demonstrated.

"Consequently, since in that position we have shewn the distinctness of vision to be four times as great as by a single lens, this will be the whole effect of a combination of two glasses, and it may be shewn that three glasses will produce nine times the distinctness, and so on in proportion to the *square* of the *number* of *glasses*; but then if we consider the evil to be remedied is but small, and the damage we sustain in *loss* of *light* and irregularity of refraction through so many lenses, we may soon make the remedy worse than the disease; and every thing considered, it appears probable that two lenses are better than a greater number, particularly for a celestial eye-piece."

By similar reasoning we may explain the advantage of any other eye-piece, as Boscovich's, when we know the radii, the position, and the distance of the lenses that compose it. The Huygenian eye-piece, which we have said has the foci of the two plano-convex lenses, as 3 : 1, at the distance of 2, with 1 next the eye, and the curves exterior to the eye, is peculiarly adapted for a reflecting telescope that has only the spherical aberration; but for a refracting telescope, though achromatic, a little deviation from this form was found necessary to correct the remaining prismatic aberration also. On enquiring of the best opticians, we learn that the final adjustment of distance between two lenses, in a celestial achromatic eye-piece, is made from trials in the tube of the telescope it is intended for; because this distance, and indeed the ratio of the radii of the two lenses, will greatly depend on the state of convergence of the rays, when they are incident on the first surface of the interior glass; and this state will depend on the focal length of the telescope, conjointly with the aperture, and achromatism of the object-glass: so that it would not answer any good purpose to give a table of dimensions, which might mislead rather than assist the young optitian in his practice. The form of an achromatic celestial eye-piece, composed of two plano-convex lenses, is represented in *Plate* XXVIII. *fig.* 13, where the distance exceeds the focal length of the lens 1 next the eye, and in which consequently the image is between the lenses; which is the usual construction when the heavenly bodies are viewed without any reference to the measurement of angles; but as the place of the image will vary in some degree with a change of distance, in taking terrestrial measures, there is another form, commonly called Ramsden's, which is more suitable for micrometrical measurements; because the image, being beyond both lenses, (counting from the eye,) keeps its place, as it regards any scale, wire, or spider's line, that may be used in a micrometer: this form is given in *fig.* 14. of the same plate, and has the position of the interior face reversed, so that the plane face may be parallel to the contiguous image to be viewed: these two lenses are sometimes alike, and always nearly so, in focal length; and the distance between them is less than the focal length of either by such a quantity, that the compound focus falls just beyond the flat face of the interior lens 2, where the image and scale, wire, or line coincide in due adjustment for vision. This form has likewise the advantage of reduced aberration, and is sometimes called the *positive* eye-piece, in opposition to the other form, which is therefore by some astronomers called the *negative* eye-piece. This positive eye-piece is also best adjusted to the instrument of which it is destined to form a part; and either lens may exceed the other in focal distance in a small degree, as circumstances may require.

When this eye-piece is used with a transit instrument, zenith sector, equatorial, or circular instrument for taking altitudes, it is convenient to put a diagonal reflector between the lenses, and to have the eye-lens in the *side* of the tube, for the purpose of taking observations in high altitudes, or even in the zenith. This form is seen in *fig.* 15. of the same plate, and is called a prismatic eye-piece.

The *terrestrial eye-tube* is that which gives an *erect* position to the object, as viewed in a telescope of the refracting sort, to which only it is applied, though it might be applied to the Cassegrainian reflector with equal advantage. It has been seen that, originally, this eye-piece was composed of three similar lenses, placed from each other respectively at the sum of their focal distances, as in *fig.* 3. *Plate* XXV. In this arrangement the magnifying power is not increased, unless the lens, T U, nearest to the eye has its focal distance diminished more than the rest: but the aberration that would arise from the figure of the field-lens C D, is diminished about *nine* times, if we disregard their thickness, *viz.* as the square of the number of glasses employed between the image I M, and the eye at K; consequently, the advantages derived from this eye-piece of Rheita are two-fold; for, first, it gives an erect position to the object; and, secondly, it greatly diminishes the quantity of spherical aberration, and consequently produces a corresponding distinctness; but the *power* of this eye-piece is *simply* that of one of the three lenses. To effect an increase of power at the same time that the two preceding advantages are preserved, various arrangements of three, four, and even of five lenses, have been made for the purpose of constructing a good terrestrial achromatic eye-tube; and the ingenuity of a Dollond and of a Ramsden has been exercised successively to accomplish the desired object. These arrangements, so far as the diminution of spherical, and even of prismatic aberration was concerned, have been understood and explained; but the total power arising out of a number of lenses differently shaped, and placed at different *distances* relatively to each other, has not been so clearly explained; and it should seem, from the manner in which such arrangement has been described by different authors, that the result has generally been ascertained practically rather than theoretically; which indeed must in some degree be the case whenever *power*, or, which is the same thing in effect, whenever actual focal distance, simple or compound, is to be accurately determined. We will not proceed upon the intricate plan of tracing the passage of a refracted pencil of rays through various lenses of different refractive qualities, and placed at various intervals, until they arrive at their last focus, or place of the image of a distant radiant body; neither do we propose to follow the more familiar but less instructive method of simply giving in figures the radii and relative distances of three, four, or five lenses, that shall compose an achromatic eye-tube; but, avoiding each extreme, we shall describe the most improved eye-tube for erect position, upon the principles of a *compound microscope*, which instrument this tube

really

really is of itself, and that of the best construction. We have reserved an account of the *theory* of the *compound microscope* until we arrived at this article, on purpose to shew the intimate connection that it has with the refracting telescope, which, it will be seen presently, is also the case with a compound *reflecting* microscope, that composes a portion of both the Gregorian and Cassegrainian telescopes. First, let $a\,b$ (*Plate* XXV. *fig.* 8.) be considered as an object to be magnified for examination by a compound microscope of the simplest construction; let $d\,f$ be the small object-glass, of which i is the solar focus; then as the radiant object $a\,b$ is at a small distance from the lens $d\,f$, beyond its solar or principal focus, the incident rays coming from it will converge slowly after passing through this lens, and consequently the conjugate focus at the other side of the lens will be remote, as at A B, where an inverted image, A B, of the object $a\,b$ will be formed; and if the object is brought nearer to the solar focus i, the image A B will recede with a linear amplification, for it always subtends the same angle at e, the centre of the object-lens, that the object subtends at the same point; it is therefore obvious, that the linear amplification of the image, compared with the length of the object, will be as their respective distances from the object-lens, *viz.* as $\frac{C\,e}{c\,e}$; and, consequently, the farther the image recedes, that is, the nearer the object is brought towards the solar focus i, the more it will enlarge, which principle is the basis of both the magic lantern, and solar as well as lucernal microscope. Let us call the ratio of the object to its image 1 : 5, as in our figure; then if D F be a double convex eye-glass, placed so that this image, A B, may be in its principal focus, the rays of light coming from it, now considered as a *radiant*, will, by passing through this lens, become *parallel*, in which state they will enter the eye at I, and after converging to a new focus on the retina, will there make a picture of the image of the object, but in a reversed position. The principal pencil of rays coming from d and f of the object-lens, will meet at C, the centre of the image, and diverge till they come to the eye-lens D F, where they are made parallel, and where they define the size of the eye-hole in the cap of the eye-piece; while the angle of vision will be G E H = B E A. In this situation, the image A B is magnified by the eye-glass inversely as its focal distance, that is, as many times as F C is contained in e C; for the visual angle B E A, subtended by B A, exceeds the angle B e A, subtended by the same line B A; and, consequently, its opposite angle $b\,e\,a$, subtended by the object, is in the ratio of $C\,e : C\,E$; and also, when $C\,E = c\,e$, in the ratio of $C\,e : c\,e$; and the whole amplification will consequently be by compounding the ratios $= \frac{C\,e^2}{C\,E \times c\,e}$. But in this construction the field of view is small, though the power is great; and the colorific effect of the prismatic aberrations, as well as the indistinctness and distorsion of the figure of the object, are fully experienced. To do away these impediments to a pleasing view of the object, a second lens was introduced into the eye-piece, as M N, in *fig.* 11. *Plate* XXIV., the original intention of which was, principally, to enlarge the *visible area*, or circle of vision, which it did effectually, while, at the same time, it diminished the power, and in some measure the spherical aberration, though the latter advantage does not seem to have been contemplated; and in this state the compound microscope remains in the present ordinary construction, one of the three lenses, $d\,f$, being the *object-lens*; the second being the *amplifier* M N; and the third the eye-glass G H. Now if we compare the compound celestial eye-piece in *fig.* 8, before described, as having the same power with the single imaginary lens E E in the same figure, we shall see that the only difference in the two arrangements is, that the image in *fig.* 11. is between the lenses, but in *fig.* 8. beyond them both. We have demonstrated the advantages of the combination in *fig.* 8, and have shewn that those advantages will continue, if the image be formed between the lenses; and also that making the distance between the glasses to exceed the focal distance of the eye-glass, will bring the image into this intermediate situation, as is actually the case in the best achromatic telescopes, with both the celestial and terrestrial eye-pieces; particularly when the wire, or cobweb micrometer, is not used. If then we consider the object $a\,b$ in *fig.* 11. to be the small or *primary* image of a distant object, formed in the focus of the achromatic object-glass, the image A B will become the image of an image, or *secondary* image, in a contrary position; and this is the one actually viewed in the terrestrial tube of a telescope. Let us in the next place conceive the terrestrial tube to have only the three glasses that compose the arrangement of the compound microscope, and it is obvious that the image $a\,b$ will be rendered as distinct, and as much enlarged in it, as the object $a\,b$, of similar dimensions, would be in the like compound microscope. Thus have we a terrestrial eye-piece with an arrangement of *three* glasses, which magnifies greatly, and, so far as the pair of eye-glasses are concerned, is achromatic; but with respect to the object-lens $d\,f$, (which might indeed have been made achromatic by a balance of contrary *dispersive* powers, on Dollond's plan of an object-glass for a telescope), there remained room for improvement; and this has been effected by the same principle of *division* of the aberrations, that contributed to the improvement of the celestial eye-pieces with two lenses.

Plate XXVIII. *fig.* 15. shews a combination of two plano-convex lenses, that perform the office of one double convex lens in a compound microscope, or terrestrial eye-tube, in which the lens A is placed next the object in a microscope, or image in a telescope, with its plane face outwards, and the lens B is placed at a distance from A, that exceeds the focal length of either of the two lenses, and that is also greater than the distance between the two eye-glasses; but the proportions vary with circumstances. In the patent micrometrical telescope of Harris, in which the eye-tube is $7\frac{1}{4}$ inches long, the focus of the eye-glass is $1\frac{1}{8}$, that of the field-glass, or amplifier, $1\frac{7}{8}$, and the distance $2\frac{1}{4}$; while the lenses of the eye-end are both menisci; the outermost lens having a focus of $1\frac{1}{4}$, and the inner lens one of 1.2 or $1\frac{2}{10}$, at a distance of $2\frac{1}{2}$. This novel form of a terrestrial eye-tube is found very good for a short telescope, and answers equally well for any variable length of focal distance of the patent object-glasses; and when the telescope has its focal length invariable, the difference between each separate pair of lenses may be varied at pleasure, and then the *power* of the whole combination will vary with the variations of this distance. In all other telescopes of the refracting kind, the two eye-glasses, as well as the pair of lenses at the remote end of the terrestrial tube, near the primary image, are all plano-convex, as we have shewn; and that combination which suits a short telescope, will generally suit a long one; but frequently that which is made purposely for a long one, will not suit a short one. A very good 12-inch terrestrial eye-tube, for a day and night telescope of two feet length, that we lately examined, has the proportions in the eye-tube somewhat different from telescopes with larger power; the eye-lens has a focus of 2 inches; the amplifier $3\frac{1}{2}$, at a distance of 3 inches; and the third and fourth lenses are respectively

respectively $3\frac{1}{2}$ and 3, at a distance of $4\frac{1}{4}$; the fourth lens being that next the primary image. The convex portion of all the four lenses is turned to the centre of the tube in all the terrestrial eye-pieces, except when Ramsden's, or the positive eye-piece, is substituted for the common or negative one. Another good day eye-tube, of $9\frac{1}{4}$ inches length, has the first, or eye-lens, $1\frac{1}{3}$; the second, or amplifier, 2, at a distance of $2\frac{1}{4}$; the third 3, reversed as usual; and the fourth $2\frac{1}{3}$, at a distance of $3\frac{3}{8}$. When a *great power* is wanted, the *celestial* eye-piece does very well for the eye-end of the terrestrial tube; and it would be an advantage to every good telescope, if they were fitted for this purpose by an *adapter*, such as we shall have occasion to describe in our fifth section; for then each telescope would have a great variety of powers; and if the celestial eye-pieces were screwed into a separate tube, instead of a simple adapter, the power might be varied at pleasure, in any proportion, by altering the distance between the two separate pairs of lenses, as we shall hereafter shew has been done by the writer hereof, in his micrometrical measurement of distances in the last section of this article.

But to resume the consideration of our compound microscope (*Plate* XXIV. *fig.* 11.), we now see that the lenses C D and *d f combine* in such a way, that the object *a b*, instead of being a little out of the focus of the single lens *d f*, is a little way out of the *compound* focus of the two; and a circular piece of metal, perforated in the centre, called a diaphragm, is fixed in the tube, at the separate focus of the lens *d f*, to exclude the coloured rays arising from the prismatic dispersion of this lens; and then the rays of least dispersion, that pass through this hole, enter the lens C D near its centre, and, therefore, have afterwards but little spherical aberration; on which account it is obvious, that the image in the microscope, or secondary image in the telescope, will be *distinct* and *colourless;* and it is very extraordinary, that while improvements are daily meditated in every mechanic art, the addition of a second lens, to diminish the aberrations, is not yet made to the object-end of the compound microscope, though the same thing has been done in the terrestrial eye-tube of an achromatic telescope, which not only answers precisely the same purpose, but is in fact itself an *achromatic compound* microscope.

After having gone through our explanation of the practical forms of both the double and triple achromatic object-glasses, and also of the various achromatic eye-tubes, which we have endeavoured to render intelligible to young opticians, we shall finish this long section by giving a short account of the different arrangements of the glasses of an achromatic telescope depending on these various forms, as we have already done with respect to the old telescopes, represented by *figs.* 1, 2, and 3. *Plate* XXV. *Fig.* 4. shews the arrangement of a double object-glass in conjunction with a negative eye-piece of two lenses, with the image between them, the power of which is simply the compound focal length of the object-glass A, divided by the compound focal length of the eye-lenses B and C. This arrangement is that of the best achromatic telescope with a celestial eye-piece, and, being shorter than the terrestrial telescope, is more conveniently managed. When the eye-piece has a slip of graduated mother-of-pearl, contrived by Cavallo, and divided by Mr. Barton, at its diaphragm, it makes an useful micrometer for measuring small angles: and when this eye-piece is taken out, the wire or cobweb micrometer may be screwed in, instead thereof; and then, if the telescope is of a good size, an angle within its reach may be measured with great accuracy. With this celestial telescope the object is inverted, and the light will be directly as the area of the aperture, and inversely as the magnifying power. *Fig.* 5. gives the arrangement of the lenses in a terrestrial achromatic telescope with a triple object-glass; in which A is the object-glass, B the eye-lens, and C the amplifier, or field-lens of the eye-piece B C; D is the third lens, that diminishes the aberration of the fourth lens E, which, in a compound microscope, is called the object-lens. This is considered the best construction of a terrestrial telescope. The power is equal to the compound focus of the object-glass, divided by the compound focus of the eye-piece B C, when the quotient is multiplied by the first part of the microscopic power of the lenses E, D, which part will vary with the distance between the two pairs of lenses. The arrangement in *fig.* 6. differs from that in *fig.* 4. only in the eye-piece, which has here the image beyond it. Also the arrangement in *fig.* 7. differs in like manner from that in *fig.* 5; and what we said respecting power and light of those lenses, is equally true of these. The eye-pieces of the telescopes in *figs.* 6. and 7. are those of the wire and cobweb micrometers.

3. *Theory of cata-dioptric Telescopes.*—When the image of a distant object is formed in any telescope entirely by *reflected* rays meeting at a focus, this image is properly *catoptric* (from the Greek word κάτοπτρον, *speculum*); but when it is formed partly by reflection and partly by refraction of the rays, in coming to a focus, it is then *cata-dioptric*, that is, both catoptric and dioptric; and as the image cannot be viewed without an eye-glass, all reflecting telescopes are promiscuously called *cata-dioptric.*

Before we describe any of the different constructions of a telescope where reflection is concerned, we will explain the principles on which the catoptric theorems are founded, and give a small table of those theorems that determine the focus under different circumstances, as we have already done with respect to the dioptric theorems; at the same time referring our readers for farther information on this subject to the articles CATOPTRICS, MIRROR, and SPECULUM. In *Plate* XXVI. *fig.* 8. *Astronomical Instruments*, let the curve G E be considered as a portion of a convex speculum, formed from the centre C, and C A or C E its radius; then suppose D A to be a ray of light proceeding from D, the radiant point, in the axis of the speculum, and falling on the point A, from whence it is reflected in the direction of the line A c, tending in a contrary direction to a point F, its *virtual focus*, in the axis of the speculum behind the vertex E: then put D E = d; C A or C E = r; C F = z; and F E = $f + z = r$ = C E. Now if we suppose the point A to be very near to E, a point in the axis, the angles at D and C will become very small, and will, consequently, have the same proportion to each other as their opposite sides A C and A D have; but A C = A E, and D A may be taken = D E without any sensible error; hence there will be this analogy, A D C : A C D :: C E : D E :: r : d. Produce now C A to I, and I A will be perpendicular to the face of the speculum in A, the point of reflection; and, therefore, the angles D A I and I A ϕ will be equal. But D A I = ∂ A C, and I A ϕ = C A F, as being respectively opposite, therefore ∂ A C is equal C A F: also ∂ A C = A D C + A C D = $r + d$, and consequently the angle C A F = $r + d$. Again, in the triangle C F A, when the point A is near the axis at E, the angles at A and C will be very small, and will have the same proportion to each other as their opposite sides F C and F A, and the angle F A C : F C A :: F C : F A; but in this case F A may be esteemed = F E, and therefore we have F A C : F C A :: F C : F E :: z : f. But we have seen that the angle at C is as D A or D E, that is, as d, and

d, and also the angle F A C as $r + d$; therefore we have as $f : z :: d : d + r$; and by composition of ratios, $f + z : f :: 2d + r : d$; but $f + z = r \because r : f :: 2d + r : d$; then by multiplying the extremes and means together, we have the equation $dr = 2df + fr$, and dividing by $2d + r$, there results the theorem $\frac{dr}{2d + r} = f =$ EF. This may be considered as the *fundamental theorem* in *catoptrics*, from which the focus may be determined in any speculum, concave, convex, or even plain, whether the rays fall on it diverging, parallel, or converging; and from a due variation of the symbols and signs, as the case may require, we have all the variety of theorems for finding the focus contained in the subjoined table.

TABLE for finding the Focus of Rays reflected by any Speculum.

Rays.	Convex.	Concave.
Diverging -	$\frac{dr}{2d + r} = f.$	$\frac{-dr}{2d - r} = f.$
Parallel - -	$\frac{r.}{2} = f.$	$\frac{-r}{2} = f.$
Converging -	$\frac{-dr}{-2d + r} = f.$	$\frac{dr}{-2d - r} = f.$

To illustrate the utility of this little table, let it be required to determine the respective foci of two specula, both ground and polished, on tools of 30 inches radius, when the radiant object is placed at 300 feet distance, one speculum being convex, and the other concave? In the first place, as the distance is less than infinite, the rays will come diverging from a luminous point; and, therefore, with respect to the convex speculum, we must use the theorem $\frac{dr}{2d + r} = f$, which in figures will stand thus, $\frac{300 \times 2.5}{2 \times 300 + 2.5} = \frac{750}{602.5} = 1.245$ feet, or 14.94 inches for the required focus; but for the concave speculum, the theorem $\frac{-dr}{2d - r} = f$ (or $-f$, because the focus and centre of the curve are on the same side of the speculum) will give us these numbers, *viz.* $\frac{300 \times 2.5}{2 \times 300 - 2.5} = \frac{750}{597.5} = 1.255$ feet, or 15.06 inches for its focal distance; and in like manner may the proper focus be determined for any other radius and distance, however the rays may be circumstanced when they fall on the speculum: whenever they come converging or diverging from a first to a second speculum, the focal point, real or virtual, must be considered as the radiant, and its distance reckoned accordingly.

These theorems, however, imply that the speculum is already made, whereas in many practical cases, the focus is first assumed, and the proper radius of convexity or concavity is required, or, which is the same in effect, the radius of the tool is required that shall be proper for forming the requisite curve. For instance, let it be required to form a tool of such a radius, that an image of any very remote object may be formed, by a speculum ground and polished to its dimensions, at the distance from its reflecting surface of just 18 inches? In this case, the rays must be considered as parallel, because the object is remote; and, indeed, it is always for a remote object that the curve of a large speculum is formed; consequently the theorems $\frac{r}{2} = f$, and $\frac{-r}{2} = f$, or $-f$, will be suitable for the required purpose, in both which $2f = r$; therefore $18 \times 2 = 36$ will be the proper radius of either the convexity or concavity of the tools to be used. If the ray had been diverging, and the focus *affirmative*, or behind the speculum, for a convex speculum the theorem arising from transformation would have been $\frac{2df}{d - f} = r$; and for a concave $\frac{2df}{f - d} = r$; but in the case of a negative focus, or focus before the speculum, the former would have been $\frac{-2df}{d + f} = r$, and the latter $\frac{-2df}{-d - f} = r$. In like manner, the distance may be determined from the radius and proper focus being given; for, supposing the focus affirmative, with a convex speculum, the transformed theorem for diverging rays will be $\frac{rf}{r - 2f} = d$, and with a concave $\frac{fr}{2f + r} = d$: but when the focus is negative, the former will be $\frac{-fr}{r + 2f} = d$, and the latter $\frac{fr}{2f - r} = d$. Hence, when any two of the terms f, r, and d are given, the third may be readily determined.

Thus, in the case of a convex speculum with diverging rays, if we put $d = r$, we shall have $\frac{r}{3} = f$; when $d = \frac{1}{2} r$, then $\frac{r}{4} = f$; when $d = \frac{1}{3} r$, then $\frac{r}{5} = f$; and when $d = \frac{1}{4} r$, then $\frac{r}{6} = f$: from which results we see, that the points D and F both approach the speculum in a regular manner, till at last they will coincide at its vertex; and the same will be the case with a concave speculum, when the rays are converging, except that the focus is negative, or on the same side with the centre of convexity. Also, when a convex speculum is used with converging rays, or a concave with diverging, when $2d = r$, f will be infinite; or, which is the same thing, the rays will be reflected parallel, as is the case in reflecting lamps; and, generally speaking, the focus of any concave or convex speculum may be made to fall in a given point, accordingly as the radiant object is made to approach to or recede from its principal focus with parallel rays; and wherever the focus is made to fall, there an *image* is formed of the object by reflection, in the same wonderful manner as we have had occasion to mention before, when speaking of its formation by refraction. Likewise the connection between D, the radiant point, and F, the focus, is so intimate, that they may at any time change places without error; that is, when D is the radiant, F will be the focus; but if F is taken as the radiant, then D will be the proper focus in all cases.

In order to shew what proportion the length of an image, formed in the focus of reflected rays, will bear to the length of of the object which it represents, let D E (*fig.* 9.) be a portion of a convex speculum, C its centre, V the vertex, O B an object, and I its image; and let it be required to find the proportion that the object, or line B O, bears to the image, or line I M. From the centre C, let the perpendicular C A fall on the object or radiant; and from its extreme points O, B, draw O C and B C, to meet the speculum in the points D and E; and do the same in *fig.* 10, where the curve D E represents a concave speculum: then the line A V will be the axis, in some part of which the rays proceeding from the points O and B will meet, and the points of intersection will be the foci respectively. From O, let a ray O V pass to the vertex of the speculum, so as to make the $\angle$ F V A = $\angle$ O V A, then will V F be the reflected ray, which tending to the point I, in the axis C O, shall there form the image of the point O of the radiant. In like manner, the ray B V will be reflected in the direction V G, and intersecting the axis C B in M, will there depict the point B of the said radiant; and thus all the intermediate points lying between O and B will be represented between I and M, and a complete image of O B will be formed at I M. If we suppose the object at a great distance, and consequently small, the arc E D of the speculum will be very minute, and not sensibly different from a right line, and consequently will be parallel to the radiant B O, because C A is perpendicular to both B O and E D. Also, since the distances O D, A V, and B E, are very nearly equal, from their contiguity, it is plain that the focal distances D I, V *a*, and E M, will also be nearly equal; and, therefore, the image I M will be very nearly a right line, and parallel to the radiant O B, as well as perpendicular to C A.

Now from the nature of reflection, we have $\angle BVA = \angle AVG = \angle aVM$; therefore, $\angle OVA + BVA = \angle aVI + aVM$; namely, $\angle OVB = IVM$; so that the radiant, or object B O, and its image I M, are seen under the same angle from the vertex of the speculum. But the triangles A V O and *a* V I are similar, for the $\angle$ O V A = *a* V I, and the angles at A and *a* are both right angles; therefore, $VA : Va :: AO : aI$. For the same reason, $VA : Va :: AB : aM$; and $VA : Va :: OA + AB : Ia + aM :: OB : IM$; or, in words, "the distance of the object is to the distance of its image, from its vertex V, as the length of the object is to the length of the image."

From the analogy here deduced, it is easy to form theorems, that shall determine either *d*, *f*, or the proportion O : I, when O is the length of the object and I of the image, when the two others are given. For we have given $O : I :: d : f$, and consequently $\frac{Id}{O} = f$; but our fundamental theorem was $\frac{dr}{2d + r} = f$, consequently $\frac{Id}{O} = \frac{dr}{2d + r}$, and so $2dI + Ir = rO$; and $2dI = Or - Ir$; consequently for a convex speculum, the theorem will be $\frac{Or - Ir}{2I} = d$; and for a concave, where *r* is negative, it will be $\frac{Ir - Or}{2I} = d$. But if the focus be required to be negative in a convex, the theorem will be $\frac{-Or - Ir}{2I} = d$; and in a concave, where *r* and *f* are both negative, it will be $\frac{Or + Ir}{2I} = d$. If *r* be required in a convex speculum, when *d* and O : I are given, the theorem will be $\frac{2Id}{O - I} = r$, and in a concave $\frac{2Id}{I - O} = r$; but if the focus is required to be negative, the first will be $\frac{-2Id}{O + I} = r$; and the second $\frac{2Id}{O + I} = r$.

Lastly, when *d* and *r* are given, to find O : I, we shall have this analogy for a convex speculum $O : I :: 2d + r : r$; and for a concave, $O : I :: r - 2d : r$. But if the focus be negative, for a convex, it will be $O : I :: -2d - r : r$; and for a concave, $O : I :: 2d - r : r$; so that, as we have said, when any two of the three terms are given, the other may be determined by calculation. By way of exemplification, let it be required to find the radius of a concave speculum, that shall make the image of an object, placed at 100 feet, as 1 : 60, in front of the speculum. Now *f* being in this case negative, we have the theorem, as before specified, $\frac{2Id}{O + I} = r$, or, in figures, $\frac{2 \times 1 \times 100}{60 + 1} = \frac{200}{61} = 3.28 = r$, nearly; or if *r* be given, and *d* required, the theorem $\frac{Or + Ir}{2I} = d$ will give $\frac{\overline{60 \times 3.28} + \overline{1 \times 3.28}}{2 \times 1} = \frac{200.08}{2} = 100.04 = d$; and if 3.28 had been the *exact* radius, the distance would have come out exactly 100. If the image and object had been given equal, they would both have fallen exactly at the centre of concavity of the mirror; which coincidence affords a ready method of determining the radius of concavity of any speculum, by means of a luminous point used as an object, and brought so that its image will exactly coincide with it. It is hardly necessary to add here, that a concave speculum forms an *inverted* and magnified image; and that a convex one makes it erect, and at the same time diminishes it.

We have before shewn how the aberration of the rays of light may be calculated, when reflected to a focus by a speculum of a spherical figure, when the rays are parallel before they suffer reflection; and it has been demonstrated, that for such rays a parabolic curve is the best suited for correcting such aberration, particularly when the image is formed by only one reflecting surface; but when there is a second or small speculum, either concave or convex, employed in forming a secondary image, or in assisting to form the primary one, a parabolic curve will not be the best for correcting the aberration of the rays; because each speculum will have its own aberration; and the practical optician can employ his skill in producing suitable specula for counteracting each other's errors, with respect to the united effect of their separate aberrations, better than the calculating theorist can pretend to direct; for the moment he screws his eye-tube alternately out and in, beyond and short of distinct vision, he knows the nature of the curves of his specula, and whether the indistinctness arising from aberration is the consequence of too much or too little curvature at the vertex of the large speculum, and can make the final alteration accordingly. This practical dexterity, arising out of experience, supersedes the necessity of tedious mathematical calculations, where some part of the data must necessarily be assumed; and it is much to be wished, that practical men, who have excelled

excelled in this particular, and in other practical niceties, would initiate their successors in the secrets that promoted their excellence, that posterity may benefit from their successful labours; which could not have been Mr. Short's wish, when he deliberately provided for the destruction of his best tools, after he no longer wanted them.

The circumstances that led to the construction of a reflecting telescope did not arise out of chance, as is supposed to have been the case with the dioptric, but out of the difficulty of avoiding the *indistinctness* produced by aberrations of both kinds; and the first arrangement that would probably occur, would be that of a speculum opposed to the eye of the observer, whose head in that case would intercept the incident rays, and prevent their falling on the speculum, unless it were made of an unmanageable diameter. To avoid this inconvenience, Gregory, who was the first to undertake the arduous task of a new construction, devised the expedient of opening a hole in the centre of the large speculum, sufficiently large to admit of the rays that came reflected a second time from a smaller speculum without a central perforation: it would naturally occur to him, that if this second speculum was not larger in diameter than the central hole of the large speculum, no incident light would be intercepted by it, when the rays came parallel, but what would have passed through the central hole of the speculum. This consideration brought the eye to the same end of the tube in which the large speculum was placed, and thus freed the aperture from all obstacles to the free admission of light; but whether the small speculum at first tried was a plain one, or concave, is not of importance to ascertain; it is sufficient for our purpose to know, that a concave one was ultimately adopted, and probably from the property which it possesses of varying the magnifying power to a considerable extent.

We have already said that Gregory's construction of the reflecting telescope is the most ancient, and indeed continues to be the most common, even at this time, on account of the convenience attending its use, and therefore we will begin with an explanation of its theory. *Plate* XXVII. *fig.* 1. *Astronomical Instruments*, represents a section of this instrument as it was originally made, and *fig.* 2. is a representation agreeably to its improved modern construction; in both which we shall use the same letters of reference to the corresponding parts. A B C D, in each figure, denote the tube of wood or brass in which two concave specula are contained; the large one, B D, is perforated at the centre, and placed contiguous to the interior end of the tube, but in such a way as to have a little play when pressed by a circular spring behind it; E F is the small speculum, which is of shorter radius than the speculum B D, and has its centre placed exactly in the centre of the tube opposite the central aperture in the large speculum, and is so adjusted by the screws behind it, that the image of the large speculum forms a concentric circle on its reflecting surface, when viewed by an eye situated in the central hole of the large speculum. In this instrument, as in the refracting telescope, it will be most convenient to describe first the formation of the primary image of a distant object in the body of the tube, and then the microscopic means applied for rendering this image visible in an apparently magnified state; for in truth there is actually a *compound reflecting microscope* made use of as a constituent part of this instrument, in like manner as the terrestrial tube of a refracting telescope of the best achromatic construction, is in itself a compound *refracting microscope.* In the first place, agreeably to the laws of catoptrics, which we have explained, if we consider *a b* and *c d* two rays of light coming from the centre of a distant arrow in a state of divergence approaching to parallelism, and impinging on the large speculum at the points *b* and *d* near the remote edges of the speculum, and at equal distances from its axis, they will be reflected inwardly so as to meet at the point *e*, in the common axis of both the specula, and will form the image of the central point of the arrow; and in like manner, any number of rays proceeding from the opposite ends of the said arrow may be conceived to fall on the speculum, and to be reflected to the points *h* and *i*, and to all the intermediate points, so as to form a perfect image *h e i* in an inverted position, because the rays which enter the tube from the right-hand end of the arrow, will after reflection cross the axis, and form the left-hand end of the image, and *vice versa.* When an image is thus formed, if it could be viewed, under sufficiently favourable circumstances, by an eye placed in the vertex or central aperture of the large speculum, it would subtend the same angle as the object itself seen from the same situation, as we have already demonstrated; and therefore the length of the image will bear the same proportion to the length of the object which it represents, as its distance from the eye, or vertex, is to that of the object; so that the longer the radius of the speculum which forms the image, the more distant, and consequently the longer will this image be, as compared with the object; and for the same reason, the nearer the object, the longer will its image be, until the situation is at the centre of concavity of the speculum, where the object and image will coincide, and appear of like magnitude, but in contrary positions.

This formation of the primary image being understood, we must in the next place consider it as a real microscopic object, placed somewhere between the face of the large speculum, and its centre of concavity, which situation will always depend on the distance of the real object itself, or, which is the same thing, on the degree of divergence of the incident rays coming from the object. Now if the small speculum were so placed as to have this primary image, or microscopic object, in its solar focal point, the rays coming from it would be reflected towards the large speculum in a parallel state; and passing through the central opening of the large speculum, would never converge so as to form a secondary image, in which case the conjugate focus would be said to be *infinite:* and if the said primary image were nearer to the small speculum than its solar focus, the reflected rays would diverge so as not to reach the central hole of the large speculum at all; but if the distance of the primary image *h e i* exceeds the solar focus of the small speculum E F, which is at the point *f*, then the reflected rays coming from the primary image will converge to a conjugate focus somewhere in the axis, and form a *secondary* image, the magnitude of which will increase with its distance from the primary image, which we now consider as a real microscopic object. The place where this secondary image will fall, will depend on the distance of the primary image from the solar focus of the small speculum; and a small change of this distance will cause a great corresponding change in the place of the secondary image, or conjugate focus; so that an adjustment for a small forward and backward motion of the small speculum, by means of a screw at the end of a long rod placed parallel to the tube, and reaching to the eye-end, will suffice for regulating the place where the secondary image shall most conveniently fall to be viewed by an eye-glass. The secondary image has its position reversed, as it regards the primary one, and is therefore in the same position as the object itself, or what is usually called *erect*, in opposition to *inverted.* This secondary image was originally made to fall within the tube, as at *k l*, in the focus of the eye-glass G H, through which it may be viewed by a small hole at I, where the visual angle

G I H is now confiderably enlarged. In order to explain the theory of this reflecting compound microfcope, compofed of the fmall fpeculum E F, and eye-glafs G H, more particularly, which we purpofely omitted to do under the term MICROSCOPE, let us fuppofe a ray of light proceeding from the end *h* of the microfcopic object, or primary image *h e i*, and falling on the central part of the fmall fpeculum at *g*, it will return reflected from this point, fo that the angle of reflection on the other fide of the axis or line *g e*, will be equal to the angle of incidence on this fide, and will therefore return in the line *g e l*, to the place of the conjugate focus, where the point *h* will be depicted at *l*: alfo a ray coming from the point *i* of the fame primary image, and falling on the point *g*, will be reflected in a fimilar manner along the line *g h k*, and will form the point *i*, at *k*, in the fecondary image, which we have reprefented by a dotted line. Now as the primary and fecondary images are fubtended by the fame angle *h g i*, or *k g l*, at the vertex *g* of the fmall fpeculum, agreeably to the laws of catoptrics, it is evident that the linear magnitudes of thefe two images will be directly as their refpective diftances from *g*, the vertex of the fmall fpeculum; therefore, as often as the diftance *g h* is contained in the diftance *g k*, or the diftance *g i* in the diftance *g l*; fo often will the length of the fecondary image *k l*, exceed the length of the primary one *h i*. But this fecondary image *k l* is viewed through the eye-glafs G H, under the vifual angle G I H, and is faid to be again magnified thereby: let us next fee what is the amount of this amplification; we have already faid that an eye at the vertex *g* of the fmall fpeculum, would view both the primary and fecondary images under the fame vifual angle *h g i* or *k g l*; but by an eye at I, the vifual angle is G I H = *k* K *l*, becaufe *l* K is parallel to H I, and *k* K to G I; and *k l* is the common fubtenfe of both angles; confequently, as the diftance L K, or focus of the eye-glafs G H, is to the diftance of L *g*, or diftance of the fmall fpeculum from the fecondary image; fo is the apparent magnitude of the fecondary image, or vifual angle to the eye at *g*, to the fame with the eye at I; and if the diftance *g* L be that at which an object may be beft feen by the naked eye, the whole power of magnifying of fuch microfcope will be $= \frac{g\,k}{g\,h} \times \frac{g\,\mathrm{L}}{\mathrm{K\,L}}$, provided that *h i* be confidered as a real object under microfcopic obfervation. But in a telefcope, the fize of *h i* has a reference to the diftance of the object which it reprefents, and this circumftance muft be taken into confideration in eftimating the power of the Gregorian telefcope. When the eye is placed at *o*, the vertex of the large fpeculum, we have faid, that the object and its primary image are feen under the fame vifual angle; therefore, wherever the primary image may fall in the line of the axis, the angle *h o i* will be to the angle G I H, or *k* K *l*, as the object feen by the naked eye is to its fecondary image, as feen through the eye-glafs, and confequently the latter, divided by the former, will give the power. But the vifual angles *h o i* and *k* K L are to each other in the compound ratio of $\frac{o\,e}{e\,g} \times \frac{\mathrm{L}\,g}{\mathrm{L\,K}}$, which formula, expreffed in meafured diftances, will be more convenient for afcertaining the whole power of a Gregorian telefcope, than the ratio of the vifual angles, which would require previous calculation. For inftance, let *o e*, the diftance of the primary image from the great fpeculum, be given = 24 inches; and *e g*, the diftance of the fame from the fmall fpeculum, be = 3.3; alfo let L *g*, the diftance of the fecondary image from the fmall fpeculum, be = 25.5, and L K, the focus of the eye-glafs, be = 2.3; then we fhall have, agreeably to our formula, $\frac{24}{3.3} \times \frac{25.5}{2.3}$, or, which is the fame thing, $\frac{24 \times 25.5}{3.3 \times 2.3} = \frac{612}{7.59} = 80.6$ for the power of fuch a telefcope, when directed to an object at fuch a diftance as fhall make the primary image fall as we have taken it. For objects very near, the focus of the large fpeculum will be long, and confequently the primary image will approach the fmall fpeculum as the diftance decreafes; for which reafon, the magnifying power will increafe with the diminution of diftance, and *vice verfâ*; fo that the power with parallel rays, or when the telefcope is ufed for celeftial purpofes, will be the fmalleft poffible, and yet this is what is ufually called the power of the telefcope, which circumftance fhews the impropriety of taking the power of a large telefcope from a meafure of a near terreftrial diftance, which mode has been practifed by eminent aftronomers, and recommended by men of fcience. If, however, a correction is applied for the want of parallelifm in the incident rays, as we fhall have occafion to do prefently, then the power may be as accurately obtained at a fhort as at a long diftance. In the old conftruction, which our *fig.* 1. reprefents, the piece of bent brafs at *c*, which fupports the fmall fpeculum, is acted on by the long rod *l* C, that has a milled nut at *l*, and a fcrew cut on the end C, that draws the projecting part N, of the piece *c*, along a flit made in the tube, while a contrivance in the cock M prevents the rod M N from advancing or receding as the rod revolves. Hence the eye-glafs G H remains fixed, and the adjuftment for diftinct vifion is made by the rod M N moving the fmall fpeculum to its proper diftance from the primary image *h i*; and in this way the fecondary image may be made to reft in any given fituation beyond or fhort of the point L, fo that various eye-glaffes may be ufed with the fame fpecula in fucceffion; or different fmall fpecula may be ufed with the fame large one, from which changes a variety of powers may be had with fixed eye-glaffes; but if the eye-glaffes be inferted into a fmaller fliding tube, there will be a third method of varying the power, by bringing the fecondary image into the fliding tube out of the body of the large tube, fo as to increafe the diftance L *g*, which is one of the factors of the dividend in our formula. Thus, whatever may be the arrangement of the fpecula, eye-glafs, and diftance of the primary image, when any three out of the four terms of the formula are given, together with the whole power, the fourth may always be had by a fimple calculation, which is a matter of great convenience to the maker. If, for example, we take the power 80.6 = P, and the radius of curvature of the large fpeculum = 48 inches, in which cafe the primary image with parallel incident rays will fall at $\frac{48}{2} = 24$; and let L *g* and *e g* be refpectively 25.5 and 3.3, to find the focus of the eye-glafs that fhall produce fuch power; we fhall have $\frac{24 \times 25.5}{3.3 \times 80.6} = 2.3$ for the focus of the eye-glafs; or for the diftance *e g* of the primary image from the fmall fpeculum, when the eye-glafs is given, we fhould have $\frac{24 \times 25.5}{2.3 \times 80.6} = 3.3$, as before. But it was foon found, that a fingle eye-glafs not only produces fringes of colour near its edges, arifing from the prifmatic aberration of the rays coming from the fecondary

ary

ary image, now confidered as a real object, but that the field of view is thereby circumfcribed into a fmall area. For thefe reafons, the Huygenian eye-piece, already explained, was fubftituted for the fingle eye-glafs, which fubftitution left little more to be done, in the way of the improvement of the Gregorian telefcope, except what related to the conftruction of the fpecula, which have now been brought nearly to a ftate of perfection, as we have explained, at fome length, under our article SPECULUM. We have introduced *fig.* 2. for the purpofe of explaining more clearly, than we could by a mere verbal defcription, the plan of the Gregorian telefcope in its moft improved ftate, in which, we repeat, the fame letters indicate the fame parts as in *fig.* 1. In this figure we have made the pencils of rays *a b* and *c d* to confift each of three lines, for the purpofe of fhewing how the image is formed at the points of convergence after reflection, and alfo how the inverfion of the image is produced by the croffing of the pencils before they converge to a point at each end of the image. It may alfo be feen how the rays pafs through the interior eye-glafs, before they form the fecondary image between the two glaffes, as in the achromatic aftronomical telefcope, thereby conftituting this image a cata-dioptric one, which before was a catoptric one, according to our definition. The Huygenian eye-piece is peculiarly adapted for the Gregorian telefcope; and when the fpecula have their curves fo adapted as to counteract each other's aberrations, as we before recommended, and are alfo well polifhed, as well as of fuitable metal, a very high power may be applied, and the light by reflection will be to that by refraction alone nearly as 5 : 8, where the apertures are equal; but as a reflector is capable of having a much greater aperture than any refractor that can be conftructed, it will have a proportional advantage in the effential quality of illumination combined with power, on which union its excellence depends. It will not be neceffary to repeat here what we have faid above refpecting the manner of determining a fingle eye-glafs, equal in power to the combined eye-glaffes in the Huygenian eye-tube; but it may be proper to mention here, that fuch a glafs, when determined, muft be fubftituted for the compound eye-piece, in computing the power of the telefcope according to our preceding directions. The diaphragm that precludes the ftraggling and extraneous rays from coming to the eye is put where the fecondary image is formed, and the aperture at the eye is obliged to be fmall in this conftruction of a telefcope, to prevent any other light being admitted into the eye than what is reflected from the fmall fpeculum, and is neceffary for the formation of the fecondary image. When the diameter of the fmall fpeculum, and alfo the exact fituation of the primary image, are known, the aperture at the eye, that fhall admit the principal pencil, may be exactly determined by the fubjoined analogy; *viz.* as the diftance of the fmall mirror from the fecondary image, is to the focal length of the neareft eye-glafs; fo is the diameter of the fmall fpeculum, to the neceffary aperture at the eye. And to find the proper diameter of the fmall fpeculum, or central aperture of the large one, the proportion will be, as the diftance of the primary image from the large fpeculum, is to its diftance from the fmall one, with incident parallel rays; fo is the diameter of the large fpeculum, to the diameter of the fmall one, or of its own central aperture; and when this proportion is preferved, all the reflected light will enter the fmall tube that contains the eye-glaffes, and alfo the extraneous light not falling on the large fpeculum, if any, will be excluded. Laftly, fhould the field of view be required to be equal to a given vifual angle, fuch as that fubtended by the diameter of the fun, this will depend on the *power* of the inftrument, which for this purpofe muft be limited, as in the following example: let a reflecting Gregorian telefcope of four inches diameter of the large fpeculum, and 17.5 inches focus, with a hole in the centre 1.1 diameter, (which is confidered in practice a good proportion,) be required to have a field of view juft 32′, when the focus of the eye-glafs is two inches? The thing required is, that the enlarged fecondary image of the fun fhould juft fill the aperture in the centre of the large fpeculum. The fize of the primary image of the fun depends on the focal length of the large mirror, and muft firft be found: it has been afcertained that, in the focus of a fpeculum (or lens) of fix inches focal length, the image of the fun is .05586 diameter, when he meafures 32′; therefore, as it will be proportionably more in a longer focus, fay as 6 : .05586 :: 17.5 : .1629; alfo, as often as this image .1629 is contained in 1.1, the diameter of the hole in the large fpeculum, which quotient is = 6.75; fo much does the fmall fpeculum magnify the primary image, in converting it into a fecondary one of 1.1 diameter. Again, if we divide the focus of the great fpeculum 17.5, by 6.75 − 1, we have 3.04, the diftance of the primary image from the fmall fpeculum, which is fomewhat more than its folar focus; and alfo if we divide 4, the diameter of the large fpeculum, by the fame (6.75 − 1), we fhall have .695 = the diameter of the fun's image on the face of the fmall metal, while the fecondary image will juft cover the hole of the large fpeculum, as required. Now, laftly, to find what is the power of the telefcope under thofe limitations, we have 17.5 × 6.75 = 118 for the firft part of the power; then $\frac{118}{2} = 59 =$ the whole power, when 2 is the focus of the fingle eye-glafs. If the length of the focus of the principal fpeculum were increafed to 30 inches, or even to 30 feet, while the aperture remains as before, no advantage would be gained in this conftruction from fuch length; for in the cafe of 30 inches focus, the primary image would be .2793, and the power of the fmall fpeculum only 3.93 $\left(\frac{1.1}{.2793}\right)$, while the diftance of the primary image from the fmall fpeculum would be 10.24; the diameter of the image on the face of the fmall fpeculum 1.36; and the magnifying power $\frac{30 \times 3.93}{2} = 59$, as before. There would, indeed, be this difadvantage, that, as the fmall fpeculum has an increafed radius here, its diameter will neceffarily be fo much augmented, as to intercept feveral of the beft rays of light, which are thofe that fall near the centre. The opinion, confequently, that a Gregorian telefcope will be improved by having a long focus of the great fpeculum, with the fame aperture, is erroneous. When two reflecting telefcopes perform alike, as to light and diftinctnefs, the fquare fquare roots of the diameters of the fpecula muft be as the cubes of their foci refpectively. There can always be more power got by the fmall fpeculum and eye-glafs, in even a fhort tube, than the aperture will bear.

The theory of Caffegrain's telefcope is very fimilar to that of the Gregorian, the principal difference being that, in Caffegrain's, the fmall fpeculum is convex inftead of concave. When the radii of the two fpecula and the eye-piece are refpectively the fame in each conftruction, the *powers* will be the fame, though the apparent pofition of the laft image, which we have fhewn to be erect in the Gregorian, is inverted in the Caffegrainian conftruction; for on examining *fig.* 3, which explains the courfe of the rays in Caffegrain's telefcope, it will be feen that the incident rays *a b* and *c d*, after being reflected from the large fpeculum, are

are prevented from coming to a point at the *virtual* image $h\,i$, behind the ſmall ſpeculum, in conſequence of its interpoſition, but are again reflected towards the eye in a ſtate of leſs rapid convergence, till, falling on the lens G H, they are refracted to a focus at L, and form the *real* image $K\,l$, which may be conſidered as the primary image, and is, therefore, not in the ſame poſition as the ſecondary image, which is formed in the Gregorian teleſcope after the rays have *croſſed* each other. When the rays fall on the large ſpeculum, they are reflected in a ſtate of convergence towards the ſmall ſpeculum, becauſe coming from a diſtant object; and they enter the tube either parallel or diverging, accordingly as the object is more or leſs diſtant; but they fall on the ſmall ſpeculum converging, ſo as not to become quite parallel after the ſecond reflection, but ſlowly converging; and the quantity of convergence will depend on the diſtance of the *virtual*, or what may be called imaginary focus, or image $h\,i$, from the ſmall ſpeculum E F, which is here between f, the ſolar focus, and the convex ſpeculum; whereas in the Gregorian inſtrument, the ſolar focus f is between the concave ſpeculum and image $h\,i$. In both conſtructions, $\frac{o\,e}{e\,g} \times \frac{L\,g}{L\,K}$ is the meaſure of the power; and it is evident that the part $\frac{L\,g}{L\,K}$ is the ſame in both; but it is not equally clear that $\frac{o\,e}{e\,g}$ is the ſame, or in the ſame ratio in both. The diſtance $o\,g$ between the two ſpecula is leſs in Caſſegrain's inſtrument than in the Gregorian, by twice the ſolar focus of the ſmall ſpeculum, and by ſo much may the principal tube be ſhorter; therefore, it remains to be proved that $g\,e$ is to $g\,o$ in one teleſcope as $g\,e$ is to $g\,o$ in the other, though differently poſited. In order to prove this analogy, let H D (*Plate* XXVI. *fig.* 11.) be a concave ſpeculum, and E C a convex one, both deſcribed with the ſame radius C D, and on the common axis B C D; and let the point N interſect the radius, ſo as to become the ſolar focus of each ſpeculum, one really, and the other virtually. Let F be a radiant point, from which the ray F H is incident on the concave mirror at the point H, or to which the ray K E incident on the convex ſpeculum is tending: then both theſe rays will be reflected from their reſpective ſpecula to the ſame point B in the axis, and will paſs in the ſame line E B. Again, let C F be an object, and the image thereof $a\,b$, formed by the concave, will be equal to the image A B made by the convex. This may be proved from our preceding theorems for convex and concave ſpecula reſpectively, *viz.* $\frac{d\,r}{2\,d + r} = f$, and $\frac{-\,d\,r}{2\,d - r}$, or $\frac{d\,r}{r - 2\,d}$, when all the ſigns are changed. For as $d =$ F C, C B $= f$ in the convex; ſo in the concave, let F D $= \delta$, and D B $= \phi$; and then we have in the former $d : f :: 2\,d + r : r$, and in the latter $\delta : \phi :: r - 2\,\delta : r$. But $\delta = d + r$, therefore $2\,\delta = 2\,d + 2\,r$, whence $r - 2\,\delta = 2\,d + r$; conſequently $d : f :: \delta : \phi$, that is, C F : C B :: D F : D B; alſo the object and image are to each other in the ſame ratio with each ſpeculum; and, therefore, ſince the object is the ſame in both, the image will be the ſame alſo, or A B $= a\,b$, which was to be proved. After having given this demonſtration, it will be unneceſſary to ſhew how the powers may be varied at pleaſure, agreeably to the variation of the radii of the ſpecula and lenſes that compoſe the eye-piece, all which we have juſt explained with regard to the Gregorian arrangement. As the inſtrument which is the ſubject of our preſent conſideration inverts the objects to which it is directed, it is ſeldom uſed but in aſtronomical obſervations, for which it is peculiarly adapted, ſeeing that it is capable of having greater power, with the ſame length of tube, than any other teleſcope that has been yet invented; though with a terreſtrial eye-piece, it might be uſed for the examination of terreſtrial objects. While we are writing our preſent article, we have before us a Caſſegrainian teleſcope by Tulley, of 36 inches of tube, and $6\frac{1}{2}$ aperture, that will ſhew Saturn or Jupiter, with their moons very well defined, with a power of 440; and that will diſtinctly define the words of a page in this Cyclopædia, at the diſtance of 210 yards with a power of 295.

The maker of this inſtrument has conſtructed two pairs of teleſcopes, one of each pair a Gregorian, and the other a Caſſegrainian, ſo as to match each other exactly in dimenſions, powers, and quality of the metals and glaſs, in order to aſcertain if one conſtruction has any advantage over the other in quantity of light, under exactly the ſame circumſtances; and though ſeveral ſcientific gentlemen, beſides the author of this article, have examined and compared different objects as ſeen ſucceſſively by each of the two teleſcopes of both pairs, yet not the leaſt difference can be diſcerned by any obſerver. When the laſt glimmering of day-light remained, the vaniſhing object ceaſed to be viſible with each like teleſcope at the ſame time, as nearly as could be aſcertained, and that with both pairs, though they are conſtructed with dimenſions greatly different the one pair from the other, and vary conſequently in their powers and quantity of light. This experiment originated out of captain Kater's paper on this ſubject, which was publiſhed in the Philoſophical Tranſactions of London, in the year 1813; and we have no heſitation in ſaying that the quantity of illumination is the ſame in both conſtructions, when the dimenſions and qualities of the conſtituent parts are perfectly ſimilar. Whatever may be the diſperſion of light at the point of croſſing of the rays, in the Gregorian conſtruction, when the diſperſed rays are returned from the ſecond ſpeculum, they are collected again, it ſhould ſeem, *without loſs*, certainly without apparent diminution of light. This conviction we put on record, not out of a ſpirit of controverſy, but from a love of truth.

The firſt account that was publiſhed of the French reflecting teleſcope was in the fifth volume of the Philoſophical Tranſactions of London, in the month of May, in the year 1672, almoſt immediately after the account of ſir Iſaac Newton's conſtruction, which was given in the ſame volume; and a claim was ſet up by Caſſegrain as to the priority of his contrivance, which, however, was not ſubſtantiated; nor was the matter of importance to determine, as the conſtructions are diſſimilar, and as Dr. Gregory's inſtrument preceded both. The ſuppoſed advantages of Caſſegrain's teleſcope over Newton's were ſtated to be theſe: *viz.* 1ſt. That the aperture was not limited to a confined number of rays incident on the large concave ſpeculum; 2dly. That the reflection of the rays will be natural, ſince it is made upon the axis itſelf, and will therefore be more vivid; 3dly. That the viſion will be more pleaſing, when the face is ſcreened from too much light by the broad end of the tube; and, 4thly. That there will be leſs difficulty in diſcovering objects with the eye facing them, than when turned from them. If theſe are advantages, they are, however, equally belonging to the Gregorian teleſcope; and we ſhall preſently have occaſion to ſtate what was Newton's opinion on each of theſe points. In this, as in the Gregorian conſtruction, the power can always be increaſed farther than the aperture will bear; and,

and, therefore, an increase of focal distance of the large speculum, without a proportional increase of aperture, will answer no good purpose, but will render the tube unmanageable. When the aperture of a Cassegrainian or of a Gregorian telescope is to that of a Newtonian as 7.5 to 6, it has been proved that they have equal light with the same powers; the Newtonian having the advantage, in consequence of the obliquity of the angle of reflection of the small plain speculum.

Sir Isaac Newton's construction of the reflecting telescope differs from both the Scotch and French in this respect, that the large concave speculum is entire, and that the small one is quite plain, and placed at an angle of 45°, a little short of the focus; so that the converging rays come to a focus between the small speculum and the side of the tube near its superior end, as seen in *fig.* 4. of our last plate. Sir Isaac had discovered, in his experiments on reflected light, that more rays are reflected in an oblique than in a perpendicular direction; and that, consequently, there would be more light returned to the eye by a small speculum set at 45°, than would be if the angle of reflection were greater. In this instrument, the theory is much more simple than in either of the preceding instruments, on account of there being but one image, *h i*, formed by the incident rays *a b* and *c d*, after two reflections, one of which takes place at the large metal B D, and the other when the rays are in a state of convergence, at the small plain speculum E F; so that the whole length of the focal distance of the large metal B D, is B F + F *e*, or D E + E *e*; and this distance, divided by the focal distance of the small eye-glass G H, reaching to *e*, gives the whole power. This calculation is as simple as in the astronomical refracting telescope above explained, and is analogous thereto. In the instrument first completed by sir Isaac, the eye-glass was a plano-convex, with the plain face turned to the eye, and $\frac{1}{6}$th of an inch focus, while the focal distance of the large speculum was $6\frac{1}{3}$ inches, and its aperture $1\frac{1}{3}$; hence its magnifying power was $\frac{6.33}{.166}$, or $\frac{6\frac{1}{3}}{\frac{1}{6}} = 38$. This was at the time considered a good proportion between the power and aperture, and a table was constructed for different focal distances upon this radical proportion; but it would answer no purpose to copy this table at a time when the reflecting telescope, in every construction, is brought to nearly a state of perfection by the successive improvements of different artists. In this way of producing the image, the position is inverted; and the only mode of increasing the power with the same eye-glass, is by lengthening the tube and focus of the large speculum; or with the same large metal, by shortening the focus of the eye-glass. In this telescope, any of the eye-pieces, simple or compound, may be applied at pleasure: and if the large speculum be made of the best metal, of a proper parabolic figure, and with a good polish, the image will be sharp and well defined; and as there are no colorific rays in a separated state, the charge, or power of the eye-piece may be great in proportion to the focal length of the large metal, which is the distinguishing character of this construction, particularly when the small speculum is perfectly flat and well polished. The principal objection to this, as a portable instrument, is its unmanageable length, which was first given it by Hadley, who out of a pigmy made it a giant, and astonished the philosophic world. The length of the tube was made six feet, in which was included a metal of six inches aperture, and $62\frac{5}{8}$ focus; and Newton's power of 38 was increased to 230. See Phil. Transf. vol. xxxii. p. 303, or Abr. vi. p. 165.

In sir Isaac Newton's reply to Cassegrain's claim of superior advantages, he states, first, that there will be more light lost by reflection from a small convex speculum, than from a plain speculum of an oval shape, and placed in an oblique position; secondly, that the convex speculum will not reflect the rays so truly as the plain one, unless it be of an hyperbolic figure, which is difficult to form, and even then will reflect only those rays truly which respect the axis; thirdly, that the errors of the convex surface will be augmented by the distance through which they pass before they reach the eye; fourthly, that the errors of the convex surface will be increased by the deflection or bending of the figure from the points where the incident rays ought to fall; fifthly, that on this account the figure is required to be more perfect than art can make it; sixthly, that the errors of the large metal, which is considered to be spherical, will be so augmented by reflection from the small convex metal, that indistinctness will ensue, such as will not allow either a great aperture, or a high charge; and lastly, that as the small metal contributes to increase the power, an over-charge of power, compared with the aperture and focal length of the large speculum, will be unavoidable, so as to produce very obscure and confused vision; for if the small metal be made with a larger radius, in order to diminish the power, too many of the incident rays will be intercepted; and if the charge of the eye-glass is diminished, the area of the field of view will be so far diminished, as to render a small object only visible, and that difficult to find. These might be objections a century and a half ago; but most of them have yielded to subsequent improvements in the nice art of casting, grinding, and polishing of specula, which we explained under the word Speculum, and in the formation and arrangement of the Huygenian eye-piece, which we have said is peculiarly suited to reflecting telescopes; though single lenses will do very well when the spectator confines the axis of his eye to coincide with the axis of the lens, so as not to produce distorsion in the figure of the image viewed. It may be proper to mention further here, that the small telescope called the *finder*, attached to telescopes of considerable power, was first proposed by sir Isaac Newton, to remedy the difficulty of finding the object with his reflecting telescope; and Descartes hath described it in his "Dioptrics" as answering the same purpose when applied to his best telescopes. Indeed objections well founded and rationally stated have led to various improvements in the mechanical arts, and are never to be disregarded, unless they are obviously futile. Had sir Isaac Newton lived to have a peep at the instrument which next claims our attention, he would no doubt have been highly gratified at the progress which the art of constructing telescopes has made since his six-inch reflector, with its ball and socket, was mounted over a candle-stick, or a small pillar greatly resembling this domestic utensil! And yet, to do justice to his inventive genius, if we may apply figurative language to such a subject, the seeds of all the fruit that has since been matured were contained in his primitive little kernel; and we are proud to claim the Newtonian as the *English* production.

"Though last not least," the Herschelian telescope now offers itself to our consideration, which we might with some propriety call the German telescope, inasmuch as the celebrated contriver of its stupendous mechanism is a native of Hanover: it was however constructed in England, and by English workmen, except so far as the ingenious knight of the Royal Hanoverian Guelphic order lent his powerful

powerful aſſiſtance, partly in the execution, but chiefly in the contrivance of the mechanical appendages. The work was immenſe, but royal means furniſhed the power that overcame every obſtacle. In magnitude, as in power, the forty-feet reflector at Slough exceeds every inſtrument that human induſtry has yet put together, and ſtands as a proof of great mechanical ſkill directed by an enterpriſing mind. We truſt that we cannot be underſtood to derogate from the merit of Dr. (now ſir William) Herſchel, when we ſtate that the idea of giving a ſmall degree of obliquity to the large ſpeculum of a reflecting teleſcope, ſo as to bring the image formed in the focal point out of the body of the tube, at its aperture, originated with Le Maire (ſee Machines Approuvées, par l'Acad. vi. p. 61.) about the year 1728; for as we know not that this ſuggeſtion ever met the eye of this illuſtrious aſtronomer and mechanic, previouſly to his undertaking the Herculean labour of conſtructing a teleſcope with a ſpeculum of forty feet focal diſtance, and four feet diameter, it would be unfair not to allow him the credit of the invention as well as of the conſtruction. We mention the name of Maire in compliance with our ſyſtem of tracing, or attempting to trace, from hiſtorical evidence, the origin of each mechanical invention that has contributed, immediately or remotely, to the promotion of the mechanic arts. The theory of this conſtruction is eaſily explicable, by a reference to *fig.* 5. of our plate of the *Theory of Reflecting Teleſcopes*, in which, as before, A B C D is the tube, and B D the large ſpeculum of the immenſe weight of 2118 lbs.; the incident rays *a b* and *c d*, which would have come back to a focus at the point *c*, in the centre of the aperture, if the axis of the ſpeculum had coincided with the axis of the tube; in conſequence of a ſmall inclination of the ſpeculum, given by ſcrews behind, come to a focus near A, at the edge of the tube, where the image of the object is formed by only *one reflection*, which is the leading feature of the conſtruction. This ſimplicity of principle is very convenient when a large aperture is wanted, becauſe the head of the obſerver may be placed entirely at one edge of the tube, ſo as not to intercept any of the rays at the time of making an obſervation; but as the eye looks down the tube in every ſtate of elevation, not only muſt the back be turned to the object viewed, but the obſerver muſt be mounted nearly as high as the ſuperior end of the tube, in order to make his obſervations: hence various pullies, ladders, ſcaffolds, &c. became neceſſary to enable the obſerver to adjuſt both the inſtrument, and at the ſame time his own poſition, all which will be beſt underſtood from the drawing, when we come to explain the particulars of the *conſtruction* hereafter. The power of the Herſchelian, as that of the Newtonian teleſcope, is obtained from the ratio between the focus of the ſpeculum and the focus of the eye-glaſs, which in this inſtrument is not very ſhort, though the image is formed by ſimple reflection. The mode of varying the power is the ſame, therefore, as in the Newtonian reflector, and requires no further explanation.

4. *The Conſtruction of Teleſcopes.*—As we have now given both the *hiſtory* and *theory* of teleſcopes at conſiderable length, we ſhall not be under the neceſſity of dwelling long on each of the ſeveral conſtructions; particularly as a reference to the drawings which we have given, and which are moſtly original, will exhibit to the eye more preciſe information on this part of our article, than any the minuteſt detail would do, unaccompanied by ſuch viſible repreſentations. Now that the long *aerial* teleſcopes are no longer in uſe, we ſhall not fill our pages by deſcribing the different kinds of mechaniſm that were applied for rendering them uſeful in obſervations, by Huygens, Perrault, Sebaſtian, Mairan, and others; moſt of which are deſcribed in vols. i. v. and vi. of the "Machines Approuvées par l'Academie, &c." to which we beg leave to refer the curious reader who wiſhes to know the particulars. All the ſupports for long teleſcopes had neceſſarily one property, which is deſirable alſo in ſtands that are made for modern teleſcopes, but which is frequently neglected; and that is, that the object-end of the teleſcope was ſteadily ſupported by ſome point of reſt near the remote extremity, where the rays were incident. Indeed various ſtands or mountings, as they are ſometimes called, have been contrived for the convenient ſupport of a teleſcope, when it is too heavy for the pocket, and incapable of ſliding by concentric tubes into a portable form; but in every uſeful ſtand the following properties ought to combine: firſt, the inſtrument held by it ſhould be kept firmly in its place, if of the refracting ſort, ſo that the image may have no vibratory motion unfavourable to diſtinct viſion, occaſioned by an unſteady poſition of the object-glaſs; but if it be of the reflecting kind, then it ſhould be ſo ſuſpended, that tremulous motions ariſing from compactneſs of the materials, ſuch as eaſily tranſmit vibratory impulſes, may be avoided: ſecondly, a motion in azimuth, and another in altitude, are indiſpenſable; and if the inſtrument be bulky, or have great power, in each of theſe reſpects there ſhould be both a quick and a ſlow motion, the former to ſave time, and the latter for the ſake of accuracy: thirdly, when the inſtrument is pointed to the required object, it ſhould not be liable to be eaſily moved by any accidental touch of the obſerver's hand or body; unleſs it is managed in a ſtate of ſuſpenſion, as is the caſe with the larger reflectors: fourthly, the parts of the ſtand ſhould be ſtrong enough to bear the ſuperincumbent weight, and not liable to get out of repair; and fifthly, its poſition ſhould be in a ſituation not eaſily ſhaken, or moved by the obſerver's weight, or that of a byſtander. When theſe properties are attended to, the exact ſhape and external appearance become matters of ſecondary conſideration, and each artiſt may purſue his own ſchemes in the conſtruction; but in this, as in ſeveral other departments of the mechanical arts, that work is beſt and quickeſt performed, which is done from approved patterns.

Refracting.—We will firſt deſcribe the refracting teleſcopes repreſented in *Plate* XXIX., and ſhall then proceed to the reflecting inſtruments contained in *Plates* XXX. and XXXI. of *Aſtronomical Inſtruments*, omitting thoſe portable inſtruments that are in the hands of every reader, ſuch as opera-glaſſes, &c. and that belong more properly to the head of Optics.

One of the beſt ſtands for a thirty-inch refractor, by which we always mean an *achromatic* refractor, is that exhibited in *Plate* XXIX. *fig.* 1.; in which A B is a tube of braſs, mounted on the tripod ſtand of the ſame metal C D, and fixed by means of the ſcrews Q and R. In the common conſtruction, the horizontal motion is at C, at the top of the ſtem or cylinder, and the ſyſtem of tubes F, E, P, is not applied, ſo that there is neither the ſlow adjuſtable motions, nor is the inſtrument ſteady in any given poſition; but here the horizontal motion is at D, at the lower extremity of the cylinder, where there is a long bearing for the pivot, with a tightening ſcrew underneath the junction of the feet, and a clamp S to fix the inſtrument in any given direction. Alſo the handle in *fig.* 5, with a Hooke's joint, taking the ſquared axis of the ſcrew at D, gives the ſlow motion in azimuth, while the ſliding and adjuſtable tubes F, E, P, keep the angle of elevation unaltered. Theſe tubes turn on a joint at P; and when a due elevation is given by the quick motion, occaſioned fioned by the freedom of fliding, one within another, a clamping fcrew at E fixes them, and the flow motion produced by the fcrew F, finifhes the obfervation in altitude, as the handle in *fig.* 5. does in azimuth; and both flow motions can be managed, one with each hand, at the fame time. In the prefent reprefentation, the celeftial eye-piece H is fcrewed into its fmall tube, which bears a concealed rack, that is acted on by a pinion on the axis of the thumb-piece G, which may be made more or lefs tight by a fcrew in the middle of its plane, and which adjufts the eye-pieces for diftinct vifion. There may be any number of various celeftial eye-pieces, but two or three are as many as are ufually delivered with an inftrument of this fize. The object-glafs fcrews into the mouth of the tube at B, and is fo fixed by trial, that the moft diftinct view of an object is had when the fcrew is carried home, in which fituation the receiving focket is fixed by the maker; fo that unfcrewing the object-glafs at any time does not injure the inftrument. The centre of motion in altitude is at a joint above C, and the fteadinefs of the tube A B will depend on the diftance of this joint from the fyftem of concentric tubes F, E, P, which may be more conveniently placed towards the eye-end than towards the object-end of the main tube, and with equal effect. When the cylindrical piece beyond the joint of the loweft tube at P, is withdrawn from its hole in a cock, attached to the vertical cylinder, the tubes will pack into one another, and the cylindrical end-piece will enter the hole of the cock T, under the main tube, and remain out of the way of injury, parallel to this tube. The tube I K, in *fig.* 2, fcrews at the end I, into the fame place that the celeftial eye-piece H now occupies, and is called the terreftrial tube, or terreftrial eye-piece, becaufe objects are feen in their direct pofition through it, which through the celeftial eye-piece are feen inverted. Near the end I, a pair of glaffes, called the *field*-glaffes, are fcrewed, and the end K contains the pair of glaffes which is denominated the eye-piece. We have already fhewn that thefe two pairs of glaffes conftitute an achromatic eye-piece, at the fame time that they erect the inverted image formed by the object-glafs in the fmall tube between H and A; and when this image is confidered as a real object, then the terreftrial tube is a compound microfcope of the beft conftruction. This mode of defcribing the arrangement of glaffes, it is prefumed, will be more eafily underftood by thofe readers who underftand the conftruction of a compound microfcope, than any other explanation that can be given. The tube L, in *fig.* 3, is an open tube, which is fometimes made, by particular defire, to receive at its end L the eye-piece, now fcrewed into the tube I K at K; and then, as the empty tube L flides in the tube I K, the diftance between the pair of field-glaffes and pair of eye-glaffes may be varied at pleafure; and as the magnifying power of the compound microfcope varies directly with this diftance, it is evident that the power of the telefcope thus conftructed will vary in like manner. But we have fhewn above, that the power of the telefcope may be varied alfo by varying either the pair of field-glaffes, or the pair of eye-glaffes; hence, when a great variety of powers is defired for the fame inftrument, different pairs of field and of eye-glaffes may be adapted to the fame terreftrial tube with very little additional expence; and in *fig.* 4. we have given three different pieces of fhort tube, containing male or female fcrews, or both, which are called *adapters*, by means of which the celeftial eye-pieces may be adapted as eye-pieces to the terreftrial tube, fo as to gain a great increafe of power for particular purpofes. When the adapter M, in *fig.* 4, which has both a male and female fcrew, is fcrewed into the end K, of the terreftrial tube in *fig.* 2, the celeftial piece H, *fig.* 1, may be fubftituted for the pair of eye-glaffes belonging to this long tube, whenever occafion may require; or the pair of terreftrial eye-glaffes may be made a celeftial pair, on occafions when a low power and enlarged field are wanted. The adapter O, in *fig.* 4, has two diffimilar female fcrews, the fmaller one of which fcrews upon the long tube at the end I, while the larger end receives the outer end of the celeftial eye-piece H, in *fig.* 1, and converts it into a pair of field-glaffes, for which it may be fubftituted, to get the greateft poffible power, with a high magnifier alfo at the end K, or rather at L, with the fliding eye-tube; and in this way the power may be increafed fo much, that all light will difappear, and the inftrument, confequently, will then become ufelefs: but it is better to have additional pairs of proper field-glaffes, than to fubftitute eye-glaffes for this purpofe, becaufe the arrangement of the focal diftances of the field-glaffes is different from that of the eye-glaffes, when they are arranged in the beft manner, as we have explained under our laft fection. The adapter N has two male fcrews and a female fcrew, one of which male fcrews will fit the tube at H, *fig.* 1, and the other the tube at K, *fig.* 2, or L, *fig.* 3, and the female fcrew will receive Troughton's micrometer in either place, or any eye-piece having a mother-of-pearl micrometer, even though it may belong to another telefcope. Thus the adapters, which are fimple in their conftruction, of little expence, and very portable, afford a variety in the ufe of a telefcope, that is at the fame time both ufeful and entertaining; and we have been the more minute in our defcription of them, becaufe they have never before been brought into public notice. The powers of this telefcope ufually vary from 25 to 100 without the adapters, as they are made by opticians; and opticians are no advocates for adapters that increafe the powers too much; but for certain purpofes the power may be augmented to about 120 with diftinctnefs and tolerable light; but then it muft be recollected, that the field of view will admit of only a fmall object, as well as little light, when the power is augmented out of due proportion.

Fig. 6. is a reprefentation of a five-feet achromatic refractor, mounted in the moft ufeful and convenient manner for making either celeftial or terreftrial obfervations, and has all the appendages which we have juft defcribed as belonging to the thirty-inch refractor, when made in the beft manner. A B, as before, denote the main tube, which has a diameter of $4\frac{1}{2}$ inches; and inftead of one fet of fliding concentric tubes, here are two, inferted into the cocks P and P, of a three-legged ftand of mahogany, of which two legs only are feen in the figure, and thefe fhortened, fo as to fall within the room allotted them in the plate. The conftruction of this ftand has been defcribed under the article Equatorial *Stand*, with a reference to *fig.* 5. *Plate* XIII. of our prefent feries of plates; therefore we fhall fatisfy ourfelves with fuch a fhort defcription of the conftituent parts here, as will fimply enable the reader to underftand their ufes. The milled nuts Q and R, attach the main tube A B to the wooden ftand; and the tubes A P and A P keep it fteady from vibratory motion: the femi-circle of brafs between Q and R, moveable about its centre, is racked at the concave part of its circumference, fo as to fit the fcrew on the axis of the handle U, which we have made fhort, to avoid confufion in the figure; therefore, when the fcrew is preffed clofe into the notches of the rack-work, a revolution of the handle U, in either direction, will produce a correfponding motion, in elevation or depreffion, in the telefcope borne by this femi-circle, while the vernier and divifions on the face of the femi-circle indicate the quantity of elevation, when zero is properly adjufted. The manner in which this mechanifm acts, and alfo the method of

producing

producing horizontal motion, will be beſt underſtood from an examination of *fig.* 7, in which the parts are enlarged, and in which the ſame letters denote the ſame things. The thumb-ſcrew V, concealed in *fig.* 6, when turned round, preſſes on the fixed metal under it, and draws up the frame Y, of which one ſide is ſeen, that holds the axis of the ſcrew U, and that turns on two pivots at its remote end X; and in this manner the ſcrew is brought into contact with the notches of the racked ſemi-circle, or is detached from it by a contrary motion. In the former caſe there is a ſlow motion in altitude, and in the latter a quick one. Again, the axis S, of another horizontal and parallel ſcrew, receives the handle, like *fig.* 5, for giving the motion in azimuth. This ſcrew is alſo preſſed into contact with a horizontal racked wheel, that lies fixed between S and W, and gives the ſlow motion. The ſcrew of preſſure is ſeen above S, and when the axis of the handle has its ſcrew detached from the racked circle, the teleſcope is at liberty to have a quick motion in azimuth. The chamfered plate, on which the racked circle reſts, is graduated, and the vernier at W reads the hours and minutes of time: but in order that this circle may be parallel to the equator in the heavens, ſo as to indicate time truly, it is neceſſary to turn the upper half, C, of the block half round, and to turn the whole ſtand ſo that the plane of the graduated circle may be parallel to the plane of the equator, which it will be when the upper point of the axis of motion is directed exactly to the north pole, in which ſituation the hour-circles will coincide with the horary circles of the heavens, or muſt be made ſo by an adjuſtment, which the graduated circle is capable of receiving, by means of an elongated hole, into which the ſcrew enters that fixes it to the block. This block, we have ſaid before, is called Smeaton's block, and anſwers the purpoſe of giving an equatorial motion to the teleſcope, when following a heavenly body by night, and is uſeful for finding one by day, from a knowledge of its right aſcenſion and declination; for what was altitude in the horizontal poſition, becomes declination in the equatorial elevation. This teleſcope is one of the four of which we propoſe to exemplify the uſes in conjunction with Troughton's micrometer; and therefore we have had the micrometer put into its place at K, when the terreſtrial tube I K is uſed; but it might have been at H in place of the celeſtial eye-piece, where the value of the revolutions of the micrometer ſcrew would have been as we have tabulated it in our laſt ſection. The two terreſtrial eye-pieces in *fig.* 8, and one not given there, are made to ſcrew into the terreſtrial tube at K, in addition to all the four celeſtial eye-pieces, which have an adapter to fit them to the ſame place ſucceſſively; which variety affords the choice of ſeven terreſtrial powers with one pair of field-glaſſes; and as there are three pairs of field-glaſſes, the variety becomes $3 \times 7 = 21$ different powers with a fixed eye-tube; but as the eye-tube alſo ſlides, the powers may be varied in ſmall quantities at pleaſure between the two extremes. In this inſtrument, the end I of the terreſtrial tube does not ſcrew into the celeſtial tube that bears the rack, but into an intermediate ſliding-tube, which is here marked H, the uſe of which is to allow an adjuſtment for viſion at very ſhort diſtances, which adjuſtment requires a great length of tube to be drawn out. For the conſtruction of Troughton's and other micrometers, we muſt refer to our article MICROMETER.

The ſcrew G of adjuſtment for diſtinct viſion, is concealed in our drawing by the *finder* or ſmall teleſcope attached, over A, to the main tube, the uſe of which is to bring the object readily into the field of view of the large teleſcope; which is not an eaſy matter, when the power is great; for as the field of view increaſes with a diminution of the power of the teleſcope, and *vice verſâ*, the ſmall teleſcope ſaves much time in ſearching for any object that is viſible in it. But the micrometer would be of little uſe in the night for meaſuring ſmall angles, except when the moon is the object, unleſs ſome mode of illuminating the wires, or ſpider's lines, uſed in making the meaſurement could be adopted. Formerly this object was effected by a piece of braſs, faced with card paper, attached to the object-end of the teleſcope, as in *fig.* 15, and turning on a pivot, A, to any angle of inclination or reclination that the poſition of a lamp, or candle, might require, of which the light was to be reflected into the tube; and an oval hole, in the middle of the reflecting plate, admitted the incident rays coming from the object to be viewed: this plan, however, is attended by the inconvenience, that either the lamp muſt be ſuſpended by the object-end of the teleſcope, ſo as to riſe and fall with it, or otherwiſe the angle of inclination or reclination of the reflecting piece muſt be altered in every new poſition. The firſt perſon who, we believe, laid aſide this apparatus, and introduced a diagonal reflector into the body of the tube, was the Rev. Dr. Uſher of Dublin, who brought the light within the axis of motion of his tranſit teleſcope, as is now commonly done; which method has the advantage of giving light in the ſame manner at all elevations, while the place, where the lamp is placed, never varies. (See the Tranſactions of the Royal Iriſh Academy, 1788, vol. ii. p. 13.) This method, however, was not conſidered as applicable to an ordinary teleſcope, where the axis of motion is below the tube; but Mr. Troughton has very lately applied this principle with ſucceſs in the teleſcope before us, and in others of the ſame conſtruction. At Z, over the centre of motion, a hole is made in the tube, of about one half the diameter of the tube, into which a covering cap of braſs ſcrews, when extraneous light is not wanted; then an elliptical plate of braſs, rough gilt, with an elliptical hole in the middle, is reclined in an angle of 45°, within the main tube, in ſuch a way as to receive the lateral light of a lamp or candle, which it reflects along the tube to the eye-piece of the micrometer; and the light thus reflected is not only mild and pleaſant to the eye, but may be modified, as to quantity, by the poſition of the lamp, and will remain the ſame in all altitudes, if the lamp be in the ſame horizontal line with the reflector, and ſtand at a proper angle with the plane of the reflector. In uſing the teleſcope before us, we found that ſome of the rays falling on the extreme parts of the object-glaſs were loſt in the tube, and that conſequently either the diaphragm was too ſmall, or that the oval aperture of the inclined reflector was not ſufficiently large; but the diſtinctneſs of the image is no doubt promoted by ſuch excluſion: and, indeed, it is the practice of ſome opticians, when they find the longitudinal aberration ariſing from the ſpherical figure of the convex glaſs not well compenſated by the concave one, to ſhut out the extreme rays on purpoſe, by the uſe of a ſmall diaphragm, for which aſſertion we have Mr. Dollond's authority. In the inſtance before us, we have aſcertained by a dynameter, that the reduction of the aperture is in the ratio 30 : 25.6, namely, from 4.5 to 3.84 inches: but our intention is to have the original aperture reſtored.

When a refracting teleſcope exceeds five or ſix feet in length, it requires to be ſupported at both ends, and then the nearer ſupport muſt have adjuſtments for both altitude and azimuth, while the remote one may be a point of reſt. *Fig.* 8. *Plate* XXX. ſhews a ſupport for the eye-end of a long teleſcope, which we believe was contrived by Smeaton, and which anſwers its purpoſe ſufficiently; A B C D is a mahogany

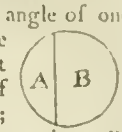
mahogany light frame, four feet fix inches high; the crofs-piece, A B, is fifteen inches long, and the piece C D feventeen, at the diftance of eighteen from the other; another frame, E F G H, with parallel fides, nine inches apart, and more flender than the other frame, paffes through the crofs-bars of the former, in fuch way, as to have an eafy motion; a cylinder or rod of brafs is fcrewed by its head-piece to the crofs-bar E F, and defcends from M to N, through a wooden fcrew L O, which is hollow within, and cut into a fcrew round its circumference: this wooden fcrew terminates above with a brafs focket and thumb-fcrew, which acts as a fcrew of preffure againft the interior brafs rod: the thick wooden piece L has a female fcrew, acting with the male fcrew of the hollow wooden cylinder L O, but is fo made faft to the crofs-bar A B, by a circular plate of brafs above, that though it will turn round, it will neither afcend nor defcend; confequently will produce an afcending or defcending motion in the wooden cylindrical piece L O, and alfo in the brafs rod M N, held by the fcrew K, attached to it. The concave piece of brafs I has two motions in its ftem, one horizontal, and the other vertical, like thofe in the ftem of a fmall telefcope, and receives the eye-end of a long telefcope, to which it is fcrewed, while the remote end is fupported by the branch of a tree, the block of a pulley, an opening in the roof of a houfe, or other elevated part of a building. The adjuftments are thus managed; when the elevated end of the telefcope is made to reft on its bearer, the eye-end adapts itfelf to the inclination by the joint in its ftem under I; then the whole frame is turned to face the object, when the circular motion of the fame fmall ftem yields, and allows the long tube to remain quiet; and if the tube is not exactly pointed in azimuth to the object, the brafs piece P, into which the ftem I is made faft, flides along a groove made in the front face of the crofs-bar E F, until the adjuftment for azimuth is complete. This fliding motion, being manual, may be either quick or flow, as the obferver defires; therefore, when a body in motion is once in the field of view, it may be followed without difficulty, by pufhing the fliding-piece P in a proper direction. The quick and flow motions for adjuftment in altitude are feparate, and are thus produced; firft the thumb-fcrew K is turned back, fo as to let the rod M N afcend freely, till the altitude is nearly right, when it is fixed, and then the piece L is turned, backward or forward, as the cafe may require, with the right hand, while the left flowly flides the piece P, until the object is in the middle of the field; and when diftinct vifion has been properly obtained by the fmall tube at the eye-piece of the telefcope, the pieces L and P, held refpectively in each hand, will always afford the means of keeping the object in the proper part of the field; and though the fupport has but two legs, yet its connection with the fupport at the object-end, through the heavy tube of the telefcope, will always keep it in its place when the adjuftments are fettled. It will not be neceffary to defcribe any more ftands, of which a great variety might be produced, that have been devifed for refracting telefcopes, becaufe we prefume that our readers will be able, after what we have faid on this fubject, to felect fuch as may beft fuit their refpective purpofes.

We come now to defcribe the portable patent achromatic telefcope, without a ftand, that was invented by Dr. Brewfter, and is fold under the patent by Mr. Harris, optician, in Holborn, London. The conftruction of this telefcope, of which we have already explained the theory, is two-fold, and may be explained by *figs*. 4. and 5. *Plate* XXX. In *fig*. 4. the tubes are fuppofed to be tranfparent, or otherwife fo divided, that the interior parts may be feen in their refpective fituations; A B C D is the outermoft tube, of mahogany, with brafs ends, containing an achromatic object-glafs, A B, at its exterior end; E F G H is the next tube of brafs, fliding fmoothly into the mahogany one, without lateral fhake, and may be called the fecond tube: into this tube the third tube I K fcrews; and in its turn receives the fourth, or terreftrial eye-tube L O, containing the pair of field-glaffes L M, and pair of eye-glaffes N O; all which tubes flide into the fpace of twelve inches, (including the cap,) to fit the pocket. The principal object-glafs, A B, is an inch and feven-eighths in diameter, and has a folar focus of 18.5 inches; and if there were no other glaffes but the four contained in the terreftrial, or fourth tube, this would be nothing more than an ordinary portable or pocket achromatic telefcope: but at I, in the fecond tube, is fcrewed a fecond object-glafs of the achromatic fort, the diameter of which is one inch and three-eighths, and its folar focus 14 inches. When the fecond tube, E F G H, is pufhed into the wooden tube A B C D, the fecond object-glafs, I, approaches the principal object-glafs A B; and when the third tube, I K, is alfo pufhed in, the two object-glaffes come nearly in contact at the end A B of the telefcope: in this fituation, the compound focus of the two object-glaffes, by the theorem $\frac{F \times f}{F + f}$, is about eight inches, which is the fhorteft poffible; and in this ftate of the tubes, when the eye-glaffes are adjufted for diftinct vifion, the power is the fmalleft poffible; but when all the tubes are drawn out, the diftance between the object-glaffes, and confequently the power, will be the greateft poffible, becaufe the converging rays coming from the principal object-glafs A B, will have paffed through one half of the tubes before they fall on the fecond object-glafs, and undergo a fecond refraction, fo as to come to a fhortened focus. In every intermediate pofition of the object-glafs I, the power of the telefcope, that is, the compound focus of the two object-glaffes, will be determined according to their intermediate diftance, by the theorem $\frac{F \times f}{F + f - d}$. Thus in every new pofition of the fecond object-glafs I, the telefcope will have a new power, and thefe powers might be marked by a fcale running lengthwife along the fecond and third tubes which feparate the two object-glaffes; but the inventor has made another ufe of this property, by converting it into an *optical micrometer*: he has fixed two parallel wires in the focus of the eye-piece, and alfo two points of metal, to include a larger angle, in a direction at right angles to the former; fo that when one pair includes a horizontal angle, the other will include a vertical one: an experiment is then made by actual meafurement, of a divided fcale, placed at a meafured diftance, to afcertain what is the angle meafured by the points in the eye-piece, when the object is feen between the parallel wires in each of the extreme pofitions of the fecond object-glafs I, and ftrokes are marked accordingly, as the boundaries of the intended fcale, the end of the next contiguous tube being the index; thus in the inftrument before us, the extreme points or ftrokes of the fcale *a b*, in *fig*. 5, meafure 110′ and 218′ refpectively, at an interval of $15\frac{1}{2}$ inches; and as it has been determined, both from theory and practice, (fee Dr. Brewfter's Treatife on New Philofophical Inftruments,) that the fcale of meafures is a fcale of *equal* parts, thefe $15\frac{1}{2}$ inches are divided into 108 (218 − 110) minute fpaces, while each minute fpace is bifected into fpaces of 30″, which might again be bifected by the eye, if the adjuftment for vifion could be made fo nicely as to admit of fuch eftimation. Hence it is eafy to conceive how this telefcope will meafure any angle fubtended by a diftant object of unknown dimenfions, sions, between 110′ and 218′, within the accuracy of 30″: it is also easy to conceive, that, the angle increasing as we approach an object, the same object may be made to fill the field between the measuring points in a new station, provided the distance between the two object-glasses be so altered, by trial and adjustments, that the exact power is found such as will command this condition, and the new angle at the second station will be indicated, as the old one was at the first; and when the distance between the stations is measured in a right line leading directly to or from the object, the difference of the angles will afford data for determining the distance of the object from either station. For example, supposing the tangents of small angles to be equal to the angles themselves, which they are very nearly, let us call the greater angle *m*, the smaller angle *n*, and the distance between the stations *a*; then, as the distances of the object from each station will always be inversely as the measured angles, we have $n : m$ (of the angles) for the *ratio* of the distances, and the real difference of the same distances by measurement of the interval; therefore, by one of the simplest theorems in algebra, we have $\frac{a\,m}{m - n}$ = the greater distance, and $\frac{a\,n}{m - n}$ = the smaller distance: thus, if we suppose the first, or smaller angle = 46′, and the second, or nearer = 68′, with the interval 120 feet, we shall have $\frac{120 \times 68'}{68' - 46'} = \frac{8106}{22} = 370.9$ for the greater distance, $\frac{120 \times 46'}{68' - 48'} = \frac{5520}{22} = 250.9$ for the smaller, and the difference, as before, 120. But it will be seen in a subsequent section of our article, that to determine distances from small angles with *great accuracy*, the value of a single second ought not to be neglected; and that a correction for want of parallelism, at short distances, is necessary for obtaining the *true* angle, whenever that is wanted. The author, however, has shewn, that the correction in question will vary nearly with the varying length of the telescope, and will not affect the *ratio* of the angles measured, on which the respective distances depend; but this coincidence of the correction with the length or power of the telescope, does not obviate our objections where *real* measures of angles are required, and where extreme accuracy is necessary for the success of the operation. But we have said the construction is twofold: it is extremely difficult, if at all possible, to hold the telescope so steady without a stand, that the angle, contained between the two fixed points in the focus of the piece, can be measured with precision; and this difficulty probably led to the substitution of the divided object-glass, seen in *fig*. 6, and edgewise in *fig*. 7, for the second object-glass I, which we have described. If this divided object-glass, screwed into the second tube at I, had *precisely* the focal distance as the entire one, and had the centres of the semi-lenses brought exactly into contact, the same scale and the same mode of taking the measure of an angle, would apply with it as with the one we before denominated I; likewise the points in the eye-piece would be necessary. But to do away the use of such points, and to render the instrument equally useful without as with a stand, the second object-glass that we have now to describe, as constituting the second construction of the telescope, was divided in the centre diametrically, and had its centres removed from each other, so that each semi-lens forms a separate image of the object viewed. In this construction, two *points* may be fixed on in any object, and when the tubes are so drawn out, that point *a* in one image coincides with point *b* in the other, as in Dollond's object-glass micrometer, then the angle subtended by a line connecting the points *a* and *b* will be indicated on the second scale, or scale *c d*, in *fig*. 5. This scale in our instrument begins with 11′, and ends with 75′; so that the length of $15\frac{1}{2}$ inches, being divided into 64 (75 − 11) spaces, admits of these minute spaces being subdivided into three of 20″ each; and if the adjustment for distinct vision would allow these to be bisected by estimation, the smallest quantity to be measured would be 10″ on this scale, which is indeed as small a quantity as the power of the telescope is capable of distinguishing; and therefore a longer scale would have been of no greater use. The peculiar advantage of this construction is, that, as in Hadley's sextant, a motion in the instrument does not injure the accuracy of the observation, or impede the operation of taking it, but affords the opportunity of re-examining the exactness of the apparent contact. Hence the use of this instrument affords a pleasing exercise, and the necessity of a stand is entirely obviated. We have the authority of Tulley, the only maker, to say, that his grace the duke of Wellington had one of these telescopes, with silver tubes, presented to him by a friend, and there is reason to infer, that his using it as a *coming-up* glass gave him the advantage of ascertaining, better than any of his staff, in what direction the enemy was moving on certain critical occasions. For when it is ascertained by observation, whether the angle subtended by a man in motion is increasing or diminishing, it is easy to infer whether the man is approaching or receding, though the exact measure of the angle be disregarded. And at sea it is equally easy to ascertain whether a ship is gaining or losing ground in a chase, wheu two points in a mast can be distinguished. When this patent telescope has the divided object-glass as the sliding one, the two images appear exactly similar to those in Dollond's divided object-glass micrometer, but the range of scale is much greater: if Dollond's has any advantage over this, it is, that the power of his telescope is usually greater, and that the measures taken at different stations do not depend on two adjustments of the tubes longitudinally, though it is necessary always to have distinct vision, when the edges of the images are brought into contact. We consider that neither of the constructions of the patent telescope, on its present scale, is competent to the measurement of distances from one station with sufficient accuracy; neither has it a range of scale sufficient to make it generally useful for all angles. The writer of this article has had the divided object-glass made to have their centres adjustable to different distances from each other, so as to be capable of measuring all small angles from 1′ up to 75′, and to be estimated by the same scale in the different positions, the value of the first and last positions of the tubes being determined experimentally for each position of the semi lenses, and the marks for the positions being so made, that when the scale runs out in the first position of the semi-lenses, the same value shall begin the scale at their next position; and thus a succession of minutes is continued from unity to the extreme end of the scale at the last position of the glasses; consequently one such instrument is capable of doing as much as several instruments with different pairs of semi-lenses can do, when put in a fixed position according to the patent. But after all, the initial and final values of a scale of a given length must depend on the difference of the focal lengths of the principal and sliding object-glasses; and, therefore, to observe the nice variations in the diameter of the sun or moon, it would be desirable, that the whole scale should measure only about 5′, *viz*. from 28′ to 33′; and then, if the telescope had power enough, the subdivisions of the scale might ascend by single seconds. Indeed it is yet a desidefideratum in aftronomical inftruments to obtain an unobjectionable, and at the fame time an eafy method of meafuring, by a micrometrical telefcope, the diftance between two very fmall ftars, fo near to each other as to be called *double* ftars; for when fo *much* extraneous *light* is admitted into the telefcope as to fhew the fpider's lines, or fcales of a mechanical micrometer, the minute ftars vanifh; and, when optical micrometers with double images are ufed, the light is fo divided between the images, that the ftar alfo vanifhes, in this cafe, from *want* of *light*. Dr. Mafkelyne's prifmatic micrometer is, perhaps, lefs liable to this objection than any other, but is not yet brought into common ufe.

Before we difmifs this part of our article, we beg leave to ftate, that about a hundred years ago, De la Hire contrived a method of giving different values to a pair of wires fixed in the focus of the principal object-glafs of a telefcope, by means of another moveable object-glafs; and alfo that about the year 1771, Mr. James Watt, celebrated for his improvements on the fteam-engine, not only contrived the fame thing, but actually made the meafurement by a longitudinal fcale marked on his tube, nearly as done by Dr. Brewfter. Mr. Watt's claim to *originality*, we believe, is undifputed, and may be proved both by his letter on the fubject to Mr. Smeaton, written near that time, which letter is ftill in exiftence; and alfo from the circumftance of his having about the fame time defcribed his new inftrument to the late Mr. Ramfden. With thefe prior inventions, however, we are well affured Dr. Brewfter was not acquainted at the time of his taking out a patent, in conjunction with Mr. Harris, the prefent vender of the patent telefcope; and therefore he alfo is entitled to the merit of *originality;* and moreover appears to have the fole right to the idea of converting it into a general micrometer, of applying it to the divided object-glafs, and of converting a Gregorian or Caffegrainian telefcope into a micrometer, without any additional lens or mirror. Mr. Watt never made much ufe of *this* micrometrical telefcope, the impreffion on his mind being, that the fcale ought not rigidly to be a fcale of equal parts, which Dr. Brewfter has fince demonftrated to be the cafe, and his line of bufinefs not leading him to finifh all the adjuftments for real ufe.

This ingenious gentleman had previoufly, *viz.* in the year 1770, conftructed a micrometer, with a pair of parallel horizontal wires, croffed by a fingle wire at right angles, in the principal focus of an ordinary telefcope, which acted as a micrometer for determining diftances at one ftation thus; a twelve-feet rod had a circular difc of wood, eight inches in diameter, painted white, that was croffed by a red horizontal line of an inch in width, which difc was made to flide along the rod, while another fimilar difc was fixed faft about a foot above the ground, when the rod ftood in a vertical pofition; then, at any unknown diftance, the fliding difc was lowered till one wire of the telefcope covered its red line, while the other wire covered the red line of the fixed difc; and then a fcale upon the rod, graduated by experimental meafures, indicated the *diftance* by infpection to within $\frac{1}{100}$ part of the whole. This inftrument was ufed with a telefcope of only twelve inches focal length, and an eye-glafs of an inch and a half focus, fo that the magnifying power was only eight times with this inftrument. The furvey of the intended canals of Crinan, Gilp, and Tarbert, was made by Mr. Watt in 1772, as well as the furvey of the canal running from Invernefs to Fort William, called the Caledonian canal, in 1773. This contrivance was fhewn to feveral friends, and amongft them to Mr. Smeaton, though an account of it has never before been publifhed. In the year 1778, a Mr. Green applied to the Society of Arts in the Adelphi for a premium for a fimilar invention; on which occafion, Mr. Smeaton advifed Mr. Watt to attend at the Society's rooms, to ftate the *priority* of *his* claim, which was accordingly done; but as Green's telefcope had more magnifying power than Mr. Watt's, *viz.* 40, and was fuppofed on that account to be more accurate in determining diftances, the claim of priority was ceded in Green's favour, and Mr. Watt's invention was fuffered to go unnoticed by the Society.

A double-image micrometer was alfo invented by Mr. Watt in the year 1771, which, as it has never been defcribed, we fhall make no apology for introducing here, in company with his other ingenious inventions. This inftrument confifted of a circular difc of glafs, whofe plane fides were not ftrictly parallel, but formed with each other an angle of one or two degrees, fay a wedge or prifm of one or two degrees. This difc or prifm was cut by a diamond, at right angles to the flope of the prifm, into two unequal fegments thus;



The leffer piece, A, was fixed, while the larger piece, B, was moveable upon the diamond-cut line, as upon an axis or hinge, as feen in this plan, in which the dotted lines fhew one of the pofitions into which B may be moved.

When the two fegments remain in the fame plane, they refract all the rays, which pafs through them equally; but A remaining fixed, and B moving upon a centre, as drawn in dotted lines, the rays which pafs through B, will be more refracted than thofe which pafs through A, and this will vary with the angle which B makes with A. This divided prifm being fixed in the focus of (or before) the object-glafs of a telefcope, two images are formed of every object by which its diameter may be meafured. An index and divided fector of a circle ferve to meafure the comparative refractions. This inftrument, however, has the fault, that the divifions are not equal parts for equal angles, and moreover the prifms would require to be achromatic, where high magnifying powers are required.

It was not till the year 1777, that the abbé Bofcovich publifhed an account of the prifmatic micrometer of the abbé Rochon made of rock-cryftal, with double refraction, and alfo of his own improvement, or fubftitution of glafs prifms, where one of them revolved round an axis of motion like Mr. Watt's; nor was it till the fame year that Dr. Mafkelyne publifhed his account of a prifmatic micrometer, that meafures a fmall angle by the refracting angle and the diftance of the prifms from the focus of the object-glafs conjointly; where the length of the telefcope was the fcale of meafurement. See Phil. Tranf. 1777.

Reflecting.—We proceed in the next place to defcribe the conftruction of reflecting telefcopes. *Fig.* 1. *Plate* XXX. fhews the figure of a reflecting telefcope of either the Gregorian or Caffegrainian kind, for their external appearance and mode of ufing are the fame, though we have fhewn that their fmall fpecula are differently formed. After the minute defcription that we have given of the ftands for achromatic reflecting telefcopes, we may avoid prolixity, by giving a lefs minute account of thofe that have been appropriated to reflectors, where the ufes of the fame parts are the fame: A B is the main tube of a reflecting telefcope of moderate fize, which may be either with or without a finder, as the power may require, mounted on the tripod G F; at A is the open aperture, and a little fhort of it, within, is the fmall fpeculum, drawn in or out by the fcrew C, which is connected with a longitudinal bar of metal, into which the heel-piece of the ftem of the fmall fpeculum flides, fo as to be taken away or put in at pleafure; within the interior end B of the large tube is the perforated large fpeculum, always concave, and of a proper figure to fuit the face of the

the small speculum. This large speculum is put in with some liberty, as is also the small one in a box containing a spiral spring acting against it to prevent tremors; B is the eye-piece of the Huygenian kind, of which there are usually two or three, according to the size of the instrument. The semi-circle D is racked, and the handle H turns the screw that gives elevation, while the handle I gives the horizontal motion, by its screw driving the racked horizontal plate E: both which are clearly seen in the figure. The vertical motion takes place at the centre of gravity of the tube at the top of the frame between E and D, and the horizontal motion is from an axis in the centre of the racked plate E, which axis has a long bearing down a tube to G, under the junction of the three legs. The three-barred bracing piece F has a joint at each leg, and also at the circular brass plate in the centre, so that a little force applied under this plate will raise it, and allow the legs to come together into contact, as well as the three arms that keep the legs open when the stand is used. This mounting is very portable and steady, particularly when the tube is short, and is every way convenient for use, except that both the vertical and horizontal motions are slow motions, the former of which is tedious when a great change of altitude is wanted in a given time, but the latter is in some measure remedied by the portability of the stand, which may be easily turned altogether, to face any particular object.

When the length of the tube is three feet and upwards, and proportionably wide, *fig.* 2. represents a stand that is greatly to be preferred to that represented by *fig.* 1. We shall put the same letters of reference to the same parts, though there is a difference in the constructions that may require explanation. This stand was contrived and first made by Tulley, who, we understand, claims also the invention of the three-armed brace F, in *fig.* 1, above described. The contriver has evidently contemplated all the requisites for a good construction, and has succeeded in the execution of his plan: A B, as before, is the main tube, B one of the eye-pieces, C the adjusting screw for distinct vision, hid in our drawing behind the tube; but in place of it is seen the finder, attached above the eye-end of the main tube. At D is a sliding-piece of metal with a cylindrical hole, through which the round rod H D passes, and to which it may be fixed, by the pressing screw D, in any given elevation; to this sliding-piece D, two rods D K, D K, are attached by two joints, and two other joints attach them below to the frame E K, so that these rods K, K, are at liberty to rise and fall as the tube is elevated or depressed, but not until the sliding-piece at D has moved along the rod H D. When the piece D is fixed to the rod by the screw of pressure, it forms a point of bearing for the tube at a distance from the centre of motion, which is at the centre of the tube's gravity above the frame of brass work, seen in the figure; thus the telescope is kept steady by two points of bearing in every degree of elevation, though these points will recede from each other gradually as the telescope is depressed towards an horizontal position. When the screw at D is turned back, the motion is sufficiently quick; but when it is fast, the slow motion is produced by the handle at H; for while this handle turns the rod, a screw cut on its interior end works in a fixed cock, near H, that has a female screw within it, and draws the sliding-piece and rod together towards the eye, and thus elevates the tube, while the joints of the rods K, allow a corresponding elevation in them; so that, without undoing the screw at D, a slow motion up or down is produced by merely turning the handle H, which motion, being free from jerks, is very pleasant. Between the brass frame bearing the telescope and the large wooden frame E F, are three circular plates, the uppermost of which is attached to the brass frame, or may be said to form the basis of it, and has an axis of steel fast in its centre; the second circular plate is racked at the concave edge all round, and has a circular hole in the centre, just large enough to receive the steel axis we have mentioned; the third circular plate forms the top of the wooden tripod, and has also a hole in its centre, just sufficient to admit the steel axis above described; but its diameter is somewhat less than the diameter of the racked plate next above it, so that a rim, made fast to the racked plate, surrounds it, in the manner of a box-lid; but there is no other fastening of these three plates together, than the pressure occasioned by the superincumbent weight of the telescope, and of its subjacent frame E K K: the axis, or screw, of the handle I is made fast to the uppermost plate of the said frame, and takes hold of the notches in the racked plate below it, so that when the telescope is turned round in azimuth, by a quick motion, it takes the frame under it, and also the racked circle, round along with it, while the stand or wooden four-footed frame E F stands quiescent; but when the quick motion is finished, the handle I is still in its place at the eye-end of the tube, and turning it round, will give the requisite slow motion; for turning the handle, in connection with the racked plate, turns the superincumbent frame and telescope, without any motion being given to the racked plate itself, which is now kept down to its place by simple pressure of its load above. The stand, or large wooden frame, is braced in all directions, as may be seen in the drawing, and might be advantageously made of cast-iron, as it is not contrived for the convenience of portability.

The best stand for the Newtonian telescope is that which is represented by *fig.* 3, in which A is the elevated mouth of a seven-feet tube, and B the place of the large speculum, that reflects the rays of light back to the small diagonal plane metal near C, which, by a second reflection, brings them to a focus at the eye-piece below C, as seen in the drawing. Above C is the finder, the upper end of which has a small achromatic object-glass, and the lower end the eye-glass. The upper end of the tube rests on a support D, that is capable of being raised or lowered slowly by a pinion on the axis of the handle under D, while the lower end rests on the horizontal bar of the frame E F, that is suspended by a pulley over F; the four pivots *a*, *b*, *c*, and *d*, of the said frame, sliding in the open grooves, seen near those letters, in the main frame, keep the small frame in any given situation, and allow a free motion, first down the vertical, and then down the inclined pieces, that compose the main frame, as low as to G and H; and when the lower end of the tube has been depressed into this situation, the tube may have an elevation approaching towards the zenith: for not only is the upper end elevated by the handles at J for the quick, and at D for the slow motions; but the lower one is depressed by the handle at I, round which the cord is coiled, that goes round a fixed roller at K, and two others at L and M, before it embraces the pulley N, and is hooked to a pin at O, above the frame. The rest of the main frame is so clearly exhibited in the drawing, that no farther description of it is necessary. In some of the instruments of this construction, when the handle J is omitted, and a quicker motion in altitude is required, and also a greater elevation than can be given simply by the handle at D, the second square stem that carries the pinion of the handle is raised by hand, and kept to its elevation by means of a second rack, which is set at liberty by pressing a button at P, connected with the spring-catch of the rack, when this squared stem is lowered again, all which motions will be readily comprehended by any

any perſon tolerably acquainted with the mechaniſm of rack-work. The quick motion in azimuth is given by ſliding the lower end of the tube gently along the bar on which it reſts, or by moving the whole frame, which moves on caſtors; but the ſlow motion is produced by the ſcrew at D. It is ſcarcely neceſſary to add, that the eye of the obſerver is applied to the *ſide* of the tube near its mouth, when the finder has pointed the tube properly to its object. This ſtand was contrived by ſir William Herſchel, whoſe experience in the uſe of various ſtands directed him to prefer one that is not liable to propagate vibratory motion to the large ſpeculum, and that has a point of ſupport near the upper extremity of the tube. We have, however, ſeen a ſix-feet reflector very ſteadily ſupported on a frame ſimilar to that exhibited in *fig.* 2; and the compoſer of the preſent article has a Caſſegrainian teleſcope, with a three-feet tube, fixed between the cheeks of one of the doors of his obſervatory, which turns round with the moveable dome in azimuth, and which elevates in altitude on two pivots reſting in the notches of a pair of braſs plates let into the ſaid cheeks; which mode of mounting is not only convenient for celeſtial obſervations, but is remarkably free from tremors, which advantage may be owing partly to ſteadineſs of poſition, and partly to the mouth of the tube being nearly two feet advanced into the open air. If the dome had not a remarkably eaſy motion on three looſe ebony balls, placed at equal diſtances, this mode of mounting a large teleſcope would not afford a ſlow adjuſtment for motion in azimuth, which it now does with facility.

It is always intereſting to a man of ſcience to know by what progreſſive ſteps a great undertaking is accompliſhed, as well as to learn under what impreſſion the original idea was entertained of forming the plan of operations. When ſir William Herſchel, who was brought up a muſician, reſided as organiſt at Bath, the natural bent of his mind led him to cultivate the pleaſing ſcience of optics, and to ſtudy the theory of mechanics ſo far as to enable him to amuſe himſelf with attempts to conſtruct a reflecting teleſcope: his ſucceſs, in an undertaking of conſiderable difficulty, increaſed with his endeavours to attain ſome degree of excellence; and though at firſt he was ſatisfied to pick a tolerable ſpeculum out of ſome dozens at which he had laboured; yet, feeling that his experience began to give him facilities both in the contrivance and execution of his manipulations, he proceeded by degrees to conſtruct ſpecula of ſeven, ten, and even twenty feet focus of the Newtonian form, to the number of more than 400, beſides ſeveral of the Gregorian kind: but as yet he was unacquainted with any certain practical method of giving a parabolic curve to the face of his metal; on which account he ſelected, by trial, ſuch ſpecula for uſe as he found moſt perfect in figure, and repoliſhed the remainder. In all theſe operations there was much room for experimental obſervation, and the time was not expended in vain. To a mind like Herſchel's, even a failure rouſed a feeling for a new enterpriſe; and it was no ſmall ſtep towards advancement, to have perceived the cauſe of unſucceſsful meaſures: the object being attainable, the means were to be found by ſkilful perſeverance. Nor were the labours of our optician to be confined to the formation of a ſpeculum; his mechanical ſkill was directed to the contrivance and execution of various ſtands for teleſcopes of an unuſual length; and in the year 1778, he produced that which is now uſually applied to the Newtonian teleſcope, and which we have juſt deſcribed as repreſented by *Plate* XXX. *fig.* 3. By the year 1781, Herſchel (beſt known by this title at that period) felt ſuch confidence in his improved methods of proceeding, that he erected a ſtand for a thirty-feet reflecting metal of 36 inches aperture, and ſucceeded in caſting it; but to his mortification the metal cracked in the cooling. The diſappointment attending this accident muſt have been ſevere, but did not damp the ardour of the mechanical adventurer, in which light, no doubt, the enterpriſing contriver was now viewed. A ſecond melting of the ſame metal was immediately determined upon, and a furnace was conſtructed for the purpoſe, which unfortunately gave way, and the liquid metal blew up the pavement. The mortification conſequent on this ſecond accident only plunged our adventurer the deeper, that he might riſe the higher in his next attempt. During an interval of ſome reſpite from optical and mechanical labours, the aſtronomer, however, was not aſleep; and while obſervations were making on the rotations of the planets, with teleſcopes of the Newtonian form, of 7, 10, and 20 feet focal length, the little planet, at firſt ſuppoſed to be a comet, from its having a viſible magnified diſc, was diſcovered. This lucky event rekindled the optician's ardour, and at the ſame time introduced him to the notice of his majeſty; who, by his liberal patronage, promoted the views of this amateur inſtrument-maker, and afforded facility to his future operations.

In the year 1782, a good twenty-feet reflector was finiſhed with a large aperture, and mounted on the Herſchelian ſtand for admitting of *front obſervations*, for which it is found very uſeful. The forty-feet teleſcope, or maſter-piece of mechaniſm, which is more immediately the object of our examination, was begun at Clay-Hall at the latter end of the year 1785, when, through the mediation of the preſident of the Royal Society, the ſupport of regal munificence had been graciouſly promiſed; and, when the various portions of the bulky ſtructure, which employed forty workmen of different denominations, had been removed to Slough, near Windſor, the foundation was begun, which was to be the ſcite for the largeſt teleſcope that had ever been pointed to the heavenly regions. We will not detain our reader by deſcribing the details of maſonry, carpentry, and ſmith's work, which have occupied eighteen large plates, in the ſecond part of vol. lxxxv. of the Philoſophical Tranſactions, for their explanation, but deſcribe ſo much of the inſtrument, and of its appendages, as are uſeful in making actual obſervations.

The beſt view for general repreſentation of the Herſchelian teleſcope, is that which has been given in plate 24. of the volume juſt named, which therefore we have copied into our *Plate* XXXI. of *Aſtronomical Inſtruments*, with ſome ſlight alterations ariſing out of ſubſequent improvements or curtailments of unneceſſary appendages. This view, taken from a ſtation to the ſouth-weſt of the erection, repreſents the teleſcope elevated in the meridian line, and affords the means of ſeeing the front parts of the inſtrument, and of its numerous appendages; but does not allow the mechaniſm that ſupports the inferior end of the tube, and that gives motion in ſome of the adjuſtments, to be explained by a reference to their parts, and therefore muſt be comprehended from a verbal deſcription. The foundation on which the frame-work of the forty-feet teleſcope is erected, conſiſts of two concentric circles of brick-work, one 42, and the other 21 feet in diameter, both ſunk $2\frac{1}{2}$ feet under ground, and tapering from the breadth of 2 ft. 3 in. below, to 1 ft. 2 in. above, where they are capped with paving-ſtones of $12\frac{1}{4}$ inches wide, and 3 thick. In the centre of theſe circles, is fixed faſt into the ground by brick-work, and oppoſite braces of wood, a vertical beam, as a centre of motion, round which the whole ſtructure may

may have a circular motion in azimuth, the plane of the outer circle being made perfectly level. The platform that connects the different parts of the frame-work below, has three principal horizontal beams lying parallel to each other, and three others lying parallel, croſſing the firſt at right angles, beſides various bracing-beams, that tie the whole compactly together, by iron bolts paſſing through the places of croſſing. In our drawing, the outer circle of brick-work and maſonry is denoted by the letters A B, and the circumference of the platform of wood by C D: under each oppoſite end of the ſix main beams is fixed a roller, of ſix inches in diameter, and eight long, having each a ſtrong iron frame bolted into the end of its reſpective beam; ſo that the outer circle has twelve rollers: but theſe were not ſufficient to bear the whole at 21 feet from the centre of motion; therefore eight more rollers, nearly equidiſtant, were fixed to ſtrong parts of the platform, ſo as to be borne by the inner circle of 21 feet diameter; and thus the whole platform, with its ſuperſtructure, is capable of making a revolution, when ſufficient force is applied round the central vertical beam, that enters a hole at the junction of the two central main beams, and that aſcends but a little way out of the ground. Six out of the twelve rollers of the outer circle are ſeen between A B, the brick-work, and C D, the circular edge of the platform, and the reſt may be imagined, not only on the remainder of this circle, but alſo on the inner circle, which is concealed. In theſe rollers, it is of great importance that the axes of motion all point towards the central beam round which they carry the platform, and alſo that their diameters and frames be preciſely of like dimenſions, otherwiſe they will not bear alike on the baſis of maſonry. At twelve feet diſtance from, and all round this moveable platform, are fixed faſt into the ground eight equidiſtant poſts, to an oppoſite pair of which the ends of a long pliable rope are hooked, that give the motion in azimuth; which rope, being conducted over two ſeparate pullies, fixed upon the platform, at oppoſite ſides of the centre, has its ends turned in the direction of tangents, that point in oppoſite directions to their reſpective poſts. The middle part of the rope is made to paſs round one of the ſpokes of a large wheel, carried by the platform, before it winds round the axle, ſo as to coil up both ends of the rope equally; which rope therefore pulls by both tangental ends alike, ſo as to apply an equal force at each oppoſite pulley, while the reſiſtance of the poſts produces the requiſite motion, without a ſtrain on the centre. This mechaniſm gives the operator a great mechanical advantage. That part of the platform C, which connects the extreme ends of the three longitudinal beams, over the rollers at A, is made ſtrong, and is the ſupport for a pair of double ladders, that are ſeen aſcending to the ſummit of the whole frame-work, one on each ſide of the large tube E; and at D is another ſimilar ſupport for two other double ladders, which, aſcending in like manner, meet the former ones, and croſs into them in ſuch a way, as to admit of being bolted together at the points of croſſing. Theſe ladders are propped by other ſhorter ladders, as ſeen in the figure, and ſome upright maſts, of which one is ſeen erected over the roller at B, aſcend in like manner, and afford the means of obtaining horizontal braces at different heights, all round the frame, except where the elevated end E of the teleſcope requires an opening to be left between the front ladders for its different degrees of elevation. The tranſverſe beam F G, which lies horizontally over the croſſings of the double ladders, and is bolted to them, receives the hooks of the different pullies, which we ſhall ſhortly have occaſion to deſcribe, at the ſame time that it connects and braces together all the ladders at their upper extremities. Theſe ladders are each 49 feet 2 inches long, ſo that the height of the tranſverſe beam F G muſt be $\sqrt{49 \times 49 - 20 \times 20} = 45$ nearly, and will therefore admit of the long tube, of 40 feet in length, to be raiſed into a vertical poſition under it. Below the mouth of the large tube, a gallery H I, with its attached brackets K and L, reſts upon the ſlopes of the interior halves of the double ladders, at K and L reſpectively, and may be made to ſlide up or down, into any ſtate of elevation, by two ſyſtems of pullies, and ropes going round the blocks hooked at the junction of each pair of ladders, to the tranſverſe beam F G, as may be ſeen in the figure; and when this gallery is lowered to the landing of the pair of ſteps M, a party may be admitted into it to gratify their curioſity, the floor being 13 feet 6 inches by 6 feet 1½ inch, and paliſaded on the front, as well as partly at both ends. The baſes, or ſliding parts of the brackets, are prevented from ſlipping aſide by lateral rollers of braſs, acting againſt the ſtraight ſides of the middle pole of each double ladder, while other rollers of the ſame metal, acting under them, diminiſh their friction, when drawn up or let down by the pullies. In the framing of theſe brackets, it was neceſſary to introduce contrivances for allowing ſome deviation of the gallery from an exact level, in caſe one of the brackets was elevated by its pulley faſter than the other; which contrivances are not eaſily deſcribed without a reference to the drawings of the ſeparate parts in the original account, or without inſpection of the parts themſelves.

The tube of the teleſcope, which is 39 feet 4 inches in length, and 4 feet 10 inches in diameter, is made entirely of iron; it having been aſcertained that a wooden tube would have exceeded an iron one in weight by at leaſt 3000 lbs. The ſheets were firſt put together by a kind of ſeaming, that requires no rivets; and when the ſides of the iron platform were cut ſtraight, it was lifted by proper tackle into a hollow gutter, and then brought gradually, by various tools, into a cylindrical form. Various hoops are fixed within the tube, and longitudinal bars of iron, connecting ſome of them, were attached to the two ends of the tube, by way of bracing the ſheets, and keeping the ſhape perfect when the pullies are applied to give the neceſſary elevation at the upper end, and that the ſpeculum might be kept ſecure in its bed at the lower end. The hoop by which the upper end of the tube is ſuſpended is eight inches broad, and thicker than the reſt; and the ſyſtem of three pullies, ſeen at N, with each a double block, has a correſponding ſet at O, hooked to the tranſverſe pole G F; and the bars to which the blocks are hooked are ſo bent, that the moving ropes will not come in contact; nor will the elevated tube have its vertical motion diſturbed by the tackle, either in aſcending or deſcending, which was an important precaution. The lower end of the tube is firmly ſupported on rollers, that are capable of being moved forwards or backwards by a double rack, moved by wheels and pinions at R, which we ſhall not attempt to deſcribe minutely; but the uſe of which every mechanic will comprehend without particular explanation. Originally there were ſeveral appendages near the mouth of the tube ſliding by pullies, or fixed to the tube, for the purpoſe of regulating the *ſweeps* taken by this inſtrument; but as the twenty-feet reflector is now uſed for this purpoſe, they are taken off, and have been omitted in our drawing. By an adjuſtment at the lower extremity of the tube, the ſpeculum is turned to a ſmall inclination, ſo that the line of collimation is not coincident with the longitudinal axis of the tube, but croſſes the tube diagonally, and meets the eye in the air, at about two inches from the edge of the tube. Hence no part of the head intercepts the incident rays, and the obſervation

tion is taken with the face looking at the fpeculum, or by what the author has called, by way of diftinction, the *front view*, the back being always turned to the object to be viewed. Befides the pullies of elevation, and of azimuthal motion, there are others for the purpofe of communication, as well as fpeaking-pipes, repeating-bells, and fignals by clock-work, which cannot be clearly comprehended without infpection, or numerous drawings to be referred to; but the dexterity of the obferver has rendered fome of thefe fuperfluous. The large fpeculum is enclofed in a ftrong iron ring, braced acrofs with bars of iron, and an enclofure of iron and tin fheets makes a cafe for it; it is lifted by three handles of iron attached to the fides of the ring, and is put into and taken out of its proper place by the help of a moveable crane, running on a carriage, which operation of courfe requires great care. Three fmall vanes attached to the edge of the tube at the mouth, affift to put the line of collimation right, when they are feen reflected from the fpeculum to the eye-piece. We vifited Slough lately, with a view of examining all the minutiæ of the ftupendous apparatus that is rendered neceffary for the management of this huge telefcope, and that can only be well defcribed on the fpot, and found the fubftance of a letter written by the late Mr. Smeaton on this fubject, immediately after a vifit for the exprefs purpofe of infpecting the apparatus then in exiftence, fo accurate, that we avail ourfelves of this fource of information; and as the letter which is before us is a copy taken from the writer's own manufcript, we have no doubt of its authenticity. It relates however principally to the twenty-feet inftrument.

Gray's Inn, Nov. 4th, 1785.

"My dear friend,

"Since my laft, I have been to pay my vifit to Mr. Herfchel, and according to my promife, proceed to give you fome account of what I have feen; and indeed he has fo much originality about him, as well as natural ingenuity, accompanied with great readinefs and dexterity, that to enter into the detail would be far to exceed the bounds of a letter; I will therefore enter into the great outlines, and fill up as I can. You muft know that, till this vifit, I have held the doctrine about telefcopes that I believe is the common one; that, having fixed upon a proportion that you by experience find to do well in any one fpecies of telefcope, what you are to expect from any other fize of the fame fpecies, is in proportion to the fquare root of the length; fo that increafing the length four times, your telefcope will allow you to take an image of double the diameter; every point of it being illuminated with the fame quantity of light, and painted with an equal degree of diftinctnefs and precifion. This idea and expectation I carried with me to Thornhill, and carried the fame to Clay-Hall; but I did not bring it back with me. Mr. Herfchel's doctrine will illuftrate his purfuits better than minute defcriptions. Whatever his doctrine originally was, experience has taught him that large furfaces of fpeculums are not to be ground and polifhed fo as to preferve fo accurate a figure as thofe of a fmall or moderate fize; he therefore divides the maximum that telefcopes may be expected to bring out, into three diftinct claffes; firft, the greateft poffible degree of magnifying power, where there is a fufficiency of light; fecondly, the greateft degree of diftinctnefs, where there is alfo a fufficiency of light, but where the natural fize of the object does not require the greateft degree of magnifying power; thirdly, the greateft degree of light, where the objects are naturally obfcure, which will afford difcoveries that cannot be brought out either by great degrees of magnifying power, or a capacity of diftinctnefs, where, on thefe accounts, a fufficiency of light is wanting. In conformity with this doctrine, his principal difcoveries have been made upon the ftars, where the greateft degree of magnifying powers have been required, and ufed with his original telefcope of feven feet focal length, which he has pufhed to between fix and feven thoufand times. The greateft difcoveries have alfo been made with thefe, where the greateft diftinctnefs has been required, and a moderate degree of magnifying power; the diameter of the fpeculum of this telefcope being no more than $6\frac{1}{4}$ inches: and alfo, for the fame purpofe, he finds his ten-feet telefcopes applicable, the diameter being 9 inches; but for objects naturally obfcure, he can diftinctly fee an object with his twenty-feet telefcope the diameter 19 inches, (which is feldom charged with a magnifying power of more than 200 times,) which the others will not reach. With this telefcope he is now and has been for fome time paft at work, as he calls it, *fweeping* the heavens. The whole apparatus can upon occafion be turned to any azimuth, but is chiefly ufed with the telefcope turning in the plane of the meridian. The inferior or fpeculum end of the tube is fupported immediately upon the ground; the other end of the tube is raifed and lowered by a tackle, fupported at top upon a double equilateral triangle (or thereabouts); the obferver is alfo hoifted up in a chair, that works on rollers, upon the inclined legs of the triangle next the eye-glafs; and the eye-glafs is brought to anfwer to this ftraight line by fliding the butt of the telefcope near the centre of the whole machine; and by the fame means it can be put into a vertical pofition. The raifing the chair and the fliding of the butt are done by feparate tackles refpectively, touched only occafionally; but the main tackle that raifes the telefcope, when brought to its intended elevation, that is, polar diftance, is worked by a diftinct motion, that caufes it to rife and fall alternately through a fpace of two degrees of the meridian, which being done with fome degree of brifknefs, a plot in the heavens is examined at once of two degrees broad, the motion of the heavens in AR bringing on the objects in fucceffion. By way of regifter, large fheets of paper are prepared, marked and numbered, being ruled into parallel long and crofs lines at a quarter of an inch diftance; a fmall fquare of this kind reprefenting a quarter of a degree in AR and declination: all thofe that are examined being marked with a crofs, and thofe that have been feen, but not fully examined, with a ftroke one way; and when afterwards feen to fatisfaction, the crofs is completed. The place and fpecies of the object are alfo marked upon the paper. In this operation, three perfons are concerned; a labourer works continually the handle backwards and forwards for performing the deftined range; and in this he is prevented from ranging too little or too much, by a fmall piece of machinery, that ftrikes a bell at each end of the range; he alfo ftops on notice: and if any thing comes requiring this notice, and the object to be purfued, the telefcope can by an apparatus, which occafionally heaves it from its meridian bearing, purfue it in right afcenfion for near a quarter of an hour; and that there may be no need for the obferver's eye to be taken from the eye-glafs, an affiftant (Mr. Herfchel's fifter) fits in an adjacent room with the fquared fheet before her, who notes down and in a book writes what is dictated. The time fhe has by the clock facing her, and the polar diftance by a piece of machinery, which continually fhews the degree and minute, and is worked by a ftring actuated by the telefcope in rifing and falling, which comes into the room, and winding round a barrel, performs the requifite motions. The telefcope is fet to its

altitude

altitude by a ſmall quadrant fixed over it, and the correſpondent index is regulated anſwerable to the ſtretching of the cord of communication, by obſerving the firſt known ſtar that paſſes of Flamſtead's catalogue. By this means, what has been done and what is to do is diſtinctly ſeen by the ſheets. In this way, many hundred nebulæ have been diſcovered, not only unknown before, but which no ordinary teleſcopes will reach. The ſpeculum of the great teleſcope of 40 feet is caſt, but was not got home; it is four feet diameter, and about 1050 lbs. weight. Mr. Herſchel tells me there is a warehouſe in Thames-ſtreet, where they keep for ſale metal ready made into ingots, of which they have two ſorts, what they call white metal and bell-metal; I ſuppoſe ſuch as the bells of clocks are made of, but he did not know exactly their compoſition: for his ſpeculum, they put two ingots of bell-metal to one of white metal. He thinks it a lower metal than what he uſed for his former ſpecula of 19 inches, *viz.* $7\frac{3}{4}$ ounces of tin, to 20 ounces of copper. I am not ſure, however, whether I remember right, but you probably will gueſs. He does not propoſe it to magnify more than the preſent one of 19 inches, but to take the whole advantage in light, he makes all his ſpecula flat upon the back ſide. The thickneſs of this laſt great one at the edge was to have been two inches, but by ſome ſhrinking in the mould, and particularly in the middle, I underſtand it is not there above $1\frac{1}{2}$ inch, and alſo leſs at the edge than it was to have been, ſo that it is hollow in the back as well as face; but as it came pretty well upon the face, he promiſes to make uſe of it; and when he has got thus furniſhed, he promiſes to caſt another, having duplicates of all he makes, ſo that while one is in uſe, another can go to the poliſher. They are made to be encloſed in braſs boxes, and their weight lays ſimply upon ſeveral thickneſſes of cloth, and are poliſhed in theſe boxes, and are made to go in and take out ſo conveniently, that they are very frequently put into their tubes and tried with an object while under the operation of poliſhing; and to theſe frequent trials he aſcribes the principal cauſe of his ſucceſs in theſe operations.

* * * * * * *

I remain, dear ſir,
ever your's,
J. Smeaton.

We have only to add farther, on this ſubject, what we learnt in a converſation with ſir William Herſchel, that he prefers ſingle lenſes, before what are called achromatic eye-pieces, from an idea that more *light* is thus had for both his 20 and 40 feet reflectors, and that greater *power* may thus be obtained for his ſmaller inſtruments. We have, however, to regret, that his mode of giving the parabolic curve to the great ſpeculum, by mechanical means, muſt for the preſent remain a *ſecret*, for the diſcloſure of which we feel that we have no right to aſk, while there is an exiſting manufactory that might be injured thereby. The peculiar advantage of the Herſchelian conſtruction is, that there is no light loſt by a *ſecond reflection*, and that the large quantity of poliſhed ſurface reflects more rays than can be collected by any other means. The weight of the metal, which is very brittle when of the beſt mixture, made it neceſſary to have a prevailing portion of copper in the large ſpeculum, which is, therefore, liable to be the ſooner tarniſhed, and to require more frequent poliſhing than would have been requiſite, if the beſt proportion for brightneſs could have been preſerved in the ingredients of the compound metal: but what is defective in quality, is compenſated by the quantity of poliſhed ſurface. It is hardly neceſſary to inform the practical aſtronomer, that when the greateſt powers are uſed, both the light and the field of view, and conſequent time of apparent paſſage through the field, are proportionably diminiſhed. We underſtood the ingenious and dextrous obſerver to ſay, that inſtruction and practice are neceſſary to enable any other perſon to follow a ſtar or planet with the forty-feet reflector; for that a heavenly body ſeen with one of the higheſt powers does not continue in the field more than a few *ſeconds* of time, unleſs the motion of the tube is regulated ſo as to keep pace with the apparent motion of the body; and this is probably the reaſon why few perſons have been in a ſituation to form an eſtimate of the merits of this tranſcendant inſtrument. For the detail of all the parts, ſee vol. lxxxv. of the Philoſ. Tranſ. of London, part ii. 1795.

5. *On the Powers, &c.*—After having deſcribed the moſt convenient conſtructions of a teleſcope, of both the dioptric and cata-dioptric kinds, we propoſed to ſhew how their powers may be practically varied and eſtimated. We have already ſeen, in our ſection on the theory of teleſcopes, how the powers may be calculated, when the focal diſtances of the glaſſes are known. In teleſcopes with one object-glaſs, or concave ſpeculum, and one eye-glaſs, the ſolar foci of which may be called F and f reſpectively, the power P may be always expreſſed by $\frac{F}{f}$; but F varies inverſely with the *diſtance* of an object viewed, while f remains the ſame, therefore the power P will vary alſo inverſely with the diſtance. So long ago as in the year 1740, Benjamin Martin, to whoſe ingenuity the practical opticians of the preſent day are much indebted, propoſed to determine diſtances at one ſtation by this *variation of power* in a long teleſcope; but as the diſtance increaſed, the proportional elongated portion of the ſliding tube containing the eye-glaſſes became ſo ſmall, that the ſcale was too limited to be of any real uſe. We mention this circumſtance, merely to ſhew that the ſame teleſcope with the ſame glaſſes has its powers naturally varying with the diſtance, but in an inverſe ratio, until the incident rays become parallel in conſequence of the great diſtance of the radiant object; hence we may account for the reaſon why the famous Short attributed to his teleſcopes powers which they did not poſſeſs, when directed to very diſtant objects. But, generally ſpeaking, when we ſay that a teleſcope magnifies fifty times, we are underſtood to mean, that it enlarges the diameter of the ſun, or of ſome *diſtant* object, ſo many times; becauſe in this caſe F and f remain both unaltered. (See LENS, 5.) But when the object viewed is at no great diſtance, calling the elongated portion of the ſolar focus e, and the diſtance d, Martin has ſhewn that $e : F :: F + e : d$, or that $\frac{\overline{F+e} \times F}{e} = d$; and he propoſed to determine the quantity of e in all ſituations by mechanical meaſurement. Now ſuppoſing the power to be conſidered as always determined from the ſolar focus of an object-glaſs or ſpeculum, in teleſcopes of the ſimpleſt conſtruction, this power, where the object-glaſs or ſpeculum remains the ſame, can be increaſed only by ſhortening the focus of the eye-glaſs or eye-piece, when it is compoſed of two glaſſes; but there is a limit in the power of dioptric teleſcopes conſtructed with ſingle object-glaſſes, which depends on the priſmatic and ſpherical aberrations, beyond which limit *indiſtinctneſs* takes place; and even in good achromatic and reflecting teleſcopes, the eye-piece may be ſhortened until a deficiency of *light* renders the increaſed power of little uſe, and thus fixes a limit to uſeful power.

After a power is fixed on, in the uſe of a ſimple teleſcope,

scope, such as admits of sufficient light, and allows a field of view large enough to contain the images of the object to be examined, the magnitude of this power may be ascertained by different means, besides $\frac{F}{f}$, which expression is better calculated to explain the theory than to define the practical result; for it is not an easy matter to measure precisely the *exact* compound solar *focus* of an eye-piece composed of two glasses, nor yet that of a single lens, when its focus is short, and consequently its substance considerable in thickness. Neither is it easy to obtain the *exact power* of a terrestrial eye-tube constructed on the principles of a compound microscope. The first practical method of measuring the total power of a telescope, that we shall describe, is extremely simple, and is applicable to telescopes of all constructions, however complex the calculation by theory may be, and gives the result with very little trouble. Whatever be the diameter of the object-glass or speculum of a telescope, in inches and parts, the diameter of its image, or luminous disc, formed in the anterior focus of the eye-piece, by the condensed rays, will bear the same proportion to that diameter, as the focal length of the eye-glass or glasses jointly, bears to the focal length of the object-glass or speculum; these diameters, therefore, may be substituted for the two foci of the respective glasses, or speculum and its eye-glass, in determining the power. Different methods of measuring the luminous disc have been proposed; a nicely divided slip of mother-of-pearl, fixed in a small piece of tube bearing a magnifier at the opposite end, forms a simple instrument, which has been called the pearl *dynameter*, (from δυναμεως, *of power*, and μετρον, *a measure*,) and which answers the purpose very conveniently, when sliding within another short tube for the sake of adjustment, as is seen in *fig.* 9. *Plate* XXIX.

Suppose that the disc of a telescope, with an object-glass of 3.25 inches diameter, measures $\frac{12}{200} = \frac{6}{100}$ of an inch by the pearl dynameter, then $\frac{3.25}{.06} = 54\frac{1}{6}$ is the power required to be measured: and if the same disc had been measured with a reflecting telescope of 7.5 inches diameter of the large speculum, whatever its construction in other respects, the power would have been $\frac{7.5}{.06} = 125$. The correctness of this simple method will depend on the accuracy with which the respective diameters of the disc and object-glass, or speculum, are taken, and the distance to which the telescope is adjusted for distinct vision. The powers of the four achromatic telescopes, for which we have adapted our Tables I. and II. in the next section, were taken in this way, when Troughton's micrometer was applied as a celestial eye-piece, and were determined to be as follow: *viz.*

In.			
30.15	focus	$\left\{ \frac{2.025}{.0663} \right.$	= 30.5 = power.
45.75	ditto	$\left\{ \frac{3.3}{.077} \right.$	= 45.3 = ditto.
63.5	ditto	$\left\{ \frac{3.5}{.0512} \right.$	= 63.5 = ditto.
118.8	ditto	$\left\{ \frac{3.000}{.052} \right.$	= 120.0 = ditto.

These powers, if the data had been taken with perfect accuracy, would have been respectively to each other as the focal lengths of the object-glasses directly, which they are nearly, or inversely as the values of the micrometrical screw, which values have been tabulated, as will be seen in our subsequent section; therefore, when the power of one of the telescopes is obtained accurately by the pearl dynameter, the powers of all the others may be had from the micrometrical values, by reciprocal proportion. Before, however, the dynameter is used, it will be necessary to adjust the eye-piece to distinct vision when viewing a remote object, otherwise the disc will be too small, and the power larger than when celestial observations are taken. Also, to avoid mistaking the anterior glass of the eye-piece for the disc or diminished image of the object-glass, a slip of paper may be stuck on the centre of the exterior face of the object-glass, the image of which will appear on the centre of the disc, and assist the adjustment of the dynameter to its true place of distinct vision, which is essential at the moment of taking the exact measure of the disc. If one of the celestial eye-pieces has got a divided slip of pearl, as recommended by Cavallo, to be used as a micrometer, the interior lens may be taken out, and then the eye-piece will become a dynameter for measuring the powers of all the other eye-pieces, whether celestial or terrestrial, in the way we have here described; but it will be more convenient to use one with a sliding tube of adjustment for distance, as made by T. Jones, of Charing-Cross.

As this dynameter has lately been constructed in an *improved* manner, by the maker we have just named, and as it has never been described, we will here give our readers a short account of its improved construction. *Fig.* 9. of *Plate* XXIX. represents this neat little instrument of nearly its full size, where *a*, *b*, and *c*, are so many small tubes within one another: the shortest tube, *a*, contains the two plano-convex lenses *f* and *g*, which constitute what we have called the positive, or Ramsden's eye-piece, with the two curved faces opposed to each other; and as this eye-piece screws into the tube *b*, near the end *g*, it may be considered as a part of this tube, when screwed into its place: the tube *b* has a slip of the mother-of-pearl, *d d*, very delicately made, and screwed fast across a diaphragm near its remote end, at such a distance from the lens *g*, that the screw of the eye-piece *a* will adjust the pearl for distinct vision, as an object in the compound focus of the eye-piece, for any eye that may have occasion to use it. The slip of pearl is divided into such minute parts, that 500 of them are equal to an inch, and yet the eye-piece has power enough to give a clear view of them, and to enable the eye to count the dividing strokes, of which every fifth is of double, and every tenth of four times the length of the subdividing strokes. When the scale is rendered clearly visible and legible, by the screw of adjustment, the tube *b* is inserted into the outermost tube *c*, which has a diaphragm and covered hole at *c*, and when this hole is uncovered, tube *c* is brought into contact with the eye-piece of the telescope, centre to centre, so as to receive the pencil of condensed rays, that usually enters the eye of a spectator; then, if the image of the object-glass of the telescope formed at the place of the eye, is not well defined on the slip of pearl, tube *b* must be pushed into tube *c*, till this will be the case, and then the number of divisions and sub-divisions of the pearl scale, that the little luminous circle exactly covers, will give the measure required; and if the number read be *doubled*, because they are 500th parts of an inch, they will then be so many parts out of 1000, and will therefore be decimal parts of an inch; the denominator being considered = 1000.

Another method of ascertaining the powers of a telescope, when a dynameter is not at hand, is by what is called *false vision*, which requires a little practice before it can be applied with success. By this method, one eye views the magnified image of a distant object *in* the telescope; and the

the other eye, being alſo uſed, but *out of* the teleſcope, projects that image upon a horizontal line, bounded by ſome obſervable diſtinct marks, that can be known again: then as often as the angle ſubtended at the place of obſervation by the object, of which the image was obſerved, is contained in the angle ſubtended by the horizontal line into which it was projected, ſo much does the image apparently exceed the object; *i. e.* ſo much does the teleſcope magnify. For inſtance, ſuppoſe that forty bricks in the wall of a diſtant building appeared juſt to occupy the whole field of view of any teleſcope, and that the angle ſubtended by thoſe bricks meaſured 50′, by any other inſtrument, which would be the caſe at the eighth of a mile very nearly; then ſuppoſe that the horizontal line covered by the forty magnified bricks, or by the luminous circle of the field of view, was bounded by two trees, and ſubtended an angle of 41° 40′; on theſe ſuppoſitions, the power would be $\frac{41^\circ\,40'}{50'} = 50$: and in this way, but not ſo well as by the pearl dynameter, a teleſcope compoſed of any number of glaſſes, or ſpecula and glaſſes, may have its power determined, without any regard to the radii of the glaſſes or ſpecula, or to their reſpective poſitions. Should the reſults of the two methods accord, it may be taken for granted, that the determination ariſing from the average is ſufficiently accurate. The powers of the four teleſcopes with the ſame eye-piece, which we have before mentioned, were taken again by this ſecond method, and found to be as in the ſubjoined ſtatement; *viz.*

In.		
30.15 focus -	$\frac{681'}{22'}$	= 30.9
45.75 ditto -	$\frac{681'}{14'.5}$	= 47.0
63.5 ditto -	$\frac{681'}{10'.5}$	= 64.8
118.8 ditto -	$\frac{681'}{5'.6}$	= 121.6

In taking theſe meaſures, it was found convenient to make uſe of the ſpace included between the two ſpider's lines of Troughton's micrometer, inſtead of the whole field of view; which ſubſtitution not only prevented diſtorſion, by confining the objects to the middle of the field of view, but diminiſhed the angle to be projected within the dimenſions of the pupil of the eye, ſo that the head did not require to be turned from its firſt poſition in making the projection. Two painted ſtaves were ſtuck into the ground at about 700 feet from the eye, at ſuch a diſtance from each other, that they could both be ſeen within about one-half of the field of view; the ſpider's lines were then opened till they coincided with the two ſtaves, when projected upon them by falſe viſion, and the value of the revolutions was then found to be as above ſtated. This was done with the teleſcope of 30.15 inches focus; but the ſame projection would have taken place at the ſame opening of the lines, with any of the other three teleſcopes at the ſame diſtance from the ſtaves; therefore it was not neceſſary to repeat this operation with the other teleſcopes, becauſe the reſpective values of the ſame opening, or number of revolutions, are given in our Tables I. and II., as will be ſeen preſently, for all the teleſcopes, as ſo many diviſors for the common dividend. Thus Troughton's micrometer may be uſed with great advantage in determining the power of any teleſcope to which it is adapted; and even Cavallo's may be ſubſtituted for the ſame purpoſe, when that eye-piece is uſed to which it is appropriated. But the moſt convenient, as well as moſt accurate dynameter that we have ſeen, is that which has an eye-glaſs divided, ſo as to form two images of the luminous diſc, when the centres of the ſemi-lenſes are ſeparated by a ſcrew with a divided head. This double-image dynameter was invented by Ramſden, probably ſoon after Dollond's object-glaſs micrometer was invented, and is now made by G. Dollond, and alſo, with ſome variation, by Thomas Jones, of Charing-Croſs, who was a pupil of Ramſden's ſchool. As this elegant and uſeful little inſtrument has not been deſcribed, we ſhall introduce a ſhort account of it in this place. *Fig.* 12. *Plate* XXIX. *of Aſtronomical Inſtruments*, repreſents the exterior appearance of Mr. Dollond's conſtruction, and *fig.* 14. its plan, when the covering plate is taken off; in both which figures the ſame letters refer to the ſame parts. The frame that contains the ſcrew is denoted by *a*, and *b* is the interior or ſliding-tube of braſs, made faſt to the ſaid frame, having the divided lens at the eye-end, near the letter of reference *a* in *fig.* 12; and *c* is the outer tube, which is placed in contact with the outermoſt eye-glaſs of the teleſcope, when the luminous diſc is to be meaſured, and admits of adjuſtment of the tube *b* to diſtinct viſion of the diſc: *d* is a milled head of a concealed ſcrew, which ſeparates the two ſemi-lenſes until the luminous diſc is ſeen double, with the oppoſite edge of each diſc nearly in contact, as in *fig.* 13: *e* is the divided head of the ſcrew, or micrometrical head, with 100 diviſions properly numbered; and *f* is the ſcale for indicating the number of revolutions of the ſcrew, as the divided head *e* does the parts of a revolution. The axis of this ſcrew is made faſt to the frame, ſo as not to move from its ſituation while it revolves, and is of bell-metal; it is made hollow within, and is tapped to a thread of the ſame fineneſs as that of the exterior ſcrew; then a ſmaller ſcrew of ſteel enters the tapped tube, as ſeen in *fig.* 14, and has its other end pinned faſt to the piece of braſs *g b*, at the point *g*, which piece carries one half of the divided lens, while the other half is carried by a ſimilar piece, *b h*, to which the ſcale *f* is alſo ſcrewed faſt. The foot-piece of *b h* is tapped, ſo as to receive the thick ſcrew of the axis; and a bent ſpring of metal, *i h*, bears againſt both pieces, *g b* and *b h*, ſo as to keep the ſcrews connected with them free from ſhake. During this deſcription of the concealed parts of the frame, the mechanical reader will have anticipated, that when the micrometer head, and nut *d*, made faſt to the axis of the thick ſcrew, turn together in the direction that makes the figures increaſe, the thick ſcrew will draw the piece *b h*, and with it the ſcale *f*, and one ſemi-lens, towards the nut; but as the ſmall ſcrew of ſteel is a left-handed ſcrew, *i. e.* has its thread winding in a contrary direction, and is faſt to the piece *g b*, it will recede from the nut, and take the other ſemi-lens in a contrary direction, ſo that the centres of the ſemi-lens will ſeparate with a velocity equal to the ſum of the contrary motions of the two ſemi-lenſes; and as theſe centres recede, the original diſc will become a double diſc, as in *fig.* 13, and may by ſeparation be made two diſcs, when the ſemi-lenſes are removed to their greateſt diſtance. Hence, when the value of one revolution is known, the amount of any given number of revolutions and parts is had, as being multiples of that revolution. In the dynameter before us, there is a diſc of thin horn or ivory, juſt $\frac{1}{10}$th of an inch in diameter, in the ſliding-piece that cloſes the aperture of the exterior end of tube *c*; and five revolutions of the ſcrew juſt divides this diſc into two contiguous ones, ſo that each ſubdiviſion of the micrometer *e* is juſt $\frac{1}{1000}$th of an inch, and when doubled, may be put down in decimal numbers. But there is another uſe of the horn diſc, beſides that of giving a value to the micrometer; it ſo fo much refembles the luminous difc formed by the image of the object-glafs which is to be meafured, that the mode of dividing this difc by the fcrew may be illuftrative of the mode of application to the meafurement of the actual difc formed with diftinct vifion, by the refracted rays that have paffed through the eye-tube of a telefcope.

This inftrument forms, befides, a pleafing microfcope not only for viewing, but for meafuring too, the real dimenfions of any microfcopic object; and when applied to a nicely divided fcale, it may be afcertained whether or not the horn difc is exactly $\frac{1}{10}$th of an inch in diameter; *viz.* whether or not five revolutions of the fcrew will bring the ftrokes that include $\frac{1}{10}$th of an inch into exact apparent coincidence; for if not, a correction depending on the excefs or deficiency muft be applied to all meafures of a luminous difc, that are to determine the total power of any telefcope; or otherwife the two lenfes of the eye-piece muft have their *diftance* between them fo adjufted, that five revolutions will exactly meafure $\frac{1}{10}$th of an inch; for as the two femi-lenfes, when brought to have their centres coincident, conftitute one of the two lenfes of a pofitive eye-piece, as in the pearl dynameter, and as in Troughton's micrometer, we have fhewn that altering the diftance between thefe lenfes, will alter their compound focus, and confequently their magnifying power, on which the apparent magnitude of the luminous difc depends. In ufing this inftrument, the eye is applied above the centre of the tube *b*, over *a* in *fig.* 12, and the tube *c* is ufed, as in the pearl dynameter, for adjuftment for diftinct vifion of the difcs.

When Ramfden firft made the double-image dynameter, as now conftructed by Mr. Dollond, and as we have here defcribed it, he found that there was fome play in the fcrews after they had been in ufe for fome time, fo that they would not immediately obey the direct and retrograde motions of the nut *d*; and that the lofs thus arifing affected the meafure by the femi-lenfes, which did not move contemporaneoufly; but in the inftrument under our examination there is no fault of this kind.

The dynameter which Ramfden confidered as on an improved conftruction, as it regards the imperfection juft noticed, is now made by his pupil Thomas Jones, who, we have faid, has alfo improved the pearl dynameter already defcribed. *Figs.* 10. and 11. reprefent the interior parts of Thomas Jones's dynameter, which we have alfo before us; there is no frame *a* here, but the tube *b* contains the lenfes of the eye-piece, of which that next the eye is divided, as in Dollond's inftrument; and the tube *c* is the fame, except that it carries a lens *k*, with which the divifions on the fcale *f* are read, when the dynameter has its pofition reverfed, after the meafurement is finifhed. The nut *d*, and divided head *e*, are alfo the fame as we have defcribed; but the femi-lenfes are not fixed in fliding-pieces of metal, fuch as we have defcribed; neither is the fcrew fimilar to what we have above noticed. Within the tube *b* is an interior tube of much fmaller diameter, and nearly of equal length, which is divided longitudinally into two fimilar halves, which turn on feparate pivots in a gimbal, or moveable ring, within the remote end of the tube *b*, and each femi-lens is fixed in the nearer end of its own femi-tube. Thefe femi-tubes are marked *m* and *n* refpectively in *fig.* 10, and one of the pivots in the ring is at *o*; the other being at the oppofite end of the diameter of the ring: the extreme ends of the pivots turn in the tube *b*. The fection of the femi-tubes, holding the femi-lenfes, is feen in *fig.* 11, together with the micrometer head and nut. The axis of the fcrew is of bell-metal, and folid: the end neareft to the micrometer head has threads of double finenefs to the end within the tube, and the action is fo ingenioufly contrived, that the femi-lenfes are moved in contrary directions by the fame fcrew, notwithftanding the threads all incline one way. The cylindrical nut *g* is tapped for the finer thread; and as this nut is fcrewed faft to the tube *b*, as feen in *fig.* 11. more plainly, the forward motion of this axis has its velocity guided by this fine part of the fcrew; and the end that enters the tube, preffes againft a ftud *h*, made faft to the femi-tube of the femi-lens 1; and a longitudinal counteracting fpring concealed in tube *b*, and made faft to it at the lower end, allows the femi-tube to recede, but preffes it clofe to the end of the fcrew; then another ftud *l*, made faft to the femi-tube of the femi-lens 2, is tapped for receiving the coarfer thread on the axis of the fame fcrew, which thus gives a double retrograde velocity to this femi-tube, compared with what it receives from the pufh of the finer fcrew; and as there are two threads in the fine fcrew for one in the coarfe one, and as both are cut on the fame axis, the apparent motion of the femi-lens 2, is actually the difference of two contrary, but contemporaneous motions; and thefe motions are fo flow, that five revolutions are equal to $\frac{1}{10}$th of an inch, and confequently the reading is in decimal numbers already. Otherwife, this dynameter is applied exactly as we have above explained.

Befides thefe dynameters, we have examined a double-image one by Dollond, in which the micrometer head was divided into forty parts, and in which the ivory difc was only $\frac{1}{16}$th of an inch, fo that 2.50 revolutions meafured the difc, and a *double* meafure might be obtained by making the contact of the two difcs firft to the left and then to the right, in order to make the error of zero vanifh, in which cafe half the fum of the two meafures was the true meafure corrected for the oppofite errors of zero, and the graduated circle or head of the micrometer turned ftiff on the axis of the fcrew for adjuftment to zero. This inftrument profeffed to have $5 \times 40 = 200$ divifions in $\frac{1}{10}$th of an inch, and confequently only 2000 in an inch; but on examining the value of a revolution with a fine fcale, we found that 198 divifions meafured $\frac{1}{10}$th of an inch: we will therefore exemplify the ufe of this inftrument, by fhewing how the correction for the imperfection of the fcale may be applied in actual practice. In the firft place, the fcrew is turned in a retrograde direction until contact of the two difcs takes place to the left of the original fingle difc; in this fituation the 40 on the divided head muft be put to zero, or the lozenge marked as a pointer to the micrometer head, and the ftroke indicated on the fmall fcale *f*, by another lozenge or index, muft be noted; then turn the fcrew, firft till the two difcs unite in one, where a fingle meafure might be taken, and then till they are again in contact to the right; in which fituation, the whole diameter of one difc will have croffed the whole diameter of the other, and therefore the fcrew and its parts will give a *double* meafure of the real diameter. In an actual trial of a telefcope, this double meafure was found to be two revolutions of the fcrew, and 37 parts of the head, or $\frac{37}{40}$ of another revolution; and on an average of feveral trials, $\frac{1}{10}$th of an inch was found not exactly equal to 200, but to 198 of the divifions of the head, as we have ftated above; then $\frac{117}{198}$ of $\frac{1}{10}$th of an inch was the double meafure of the difc; or $\frac{117}{3960} = .0295$ of an inch was the fingle meafure; and the diameter of the object-glafs being 3.24 inches, we have the power $= \frac{3.24}{.0295} = 110.1$ with great correctnefs, the telefcope having been previoufly adjufted for viewing the folar fpots. This was the determination of the power of our telefcope of 63.5 inches focal diftance, when No. 4. of the celeftial eye-pieces was on; and in the fame way all the other powers, celeftial or terreftrial,

trial,

trial, may as readily be obtained. T. Jones's conſtruction is however more convenient for uſe, and is more accurate, though it meaſures only one diſc, unleſs the power be great, and conſequently the diſc ſmall. The divided head is fixed faſt to the axis of the ſcrew, and is divided into 100 parts, 500 of which meaſure exactly $\frac{1}{20}$th of an inch, ſo that the inch is ſub-divided into 10,000 of theſe parts, and the decimal numbers are read off at once without calculation: thus, when the diſc is adjuſted to appear ſingle and well defined, the index, which is the edge of the ſcale *f*, ſtands at 100, or zero of the micrometer head, and the edge of the circular rim of the head is coincident with the firſt ſtroke of the ſcale; but when one revolution of the ſcrew has taken place, the ſaid edge is found coincident with the ſecond ſtroke of the ſcale, and ſo on, as the divided head revolves; when the two diſcs were brought into contact, the quantity indicated, as ſeen through a lens *k*, was 2.95, *viz.* two revolutions, and $\frac{95}{100}$ on the head of the ſcrew; but in this inſtrument, five revolutions, we have ſaid, are equal to $\frac{1}{20}$th of an inch, and therefore one revolution $= \frac{1}{100}$, conſequently $\frac{295}{10000}$, or .0295 of an inch, is the meaſure, as before; ſo that all that is requiſite to do, in regiſtering the meaſures taken with this inſtrument, is to prefix a cipher to the figures read off by inſpection, and then the decimal quantity, or diviſor, is had, without further calculation, for a teleſcope of any aperture, either dioptric or cata-dioptric, and of any conſtruction.

In both Dollond's and T. Jones's dynameters the diſc is ſeen without diſtorſion and without priſmatic colours, and the inſtrument forms a ſingle microſcope of the moſt uſeful kind; for, by the latter in particular, ſmall objects may have their dimenſions taken to the accuracy of $\frac{1}{10000}$th part of an inch, and at the ſame time the figures may be had by inſpection, from the ſcale and its parts, to form places in decimals when a cipher is prefixed, as we have above explained. The powers of our four teleſcopes, with the eye-piece of Troughton's micrometer, were found by T. Jones's double-image dynameter agreeably to the ſubjoined ſtatement; *viz.*

In.				
30.15 focus	-	$\left\{\frac{1.50}{.049}\right.$	$= 30.6$	= power.
45.75 ditto	-	$\left\{\frac{3.50}{.076}\right.$	$= 46.0$	= ditto.
63.5 ditto	-	$\left\{\frac{3.25}{.0504}\right.$	$= 64.5$	= ditto.
118.8 ditto	-	$\left\{\frac{3.000}{.0252}\right.$	$= 119.0$	= ditto.

In all the three determinations of powers, the adjuſtment for viſion was to a diſtant *terreſtrial* object, and conſequently theſe are ſomewhat too great. From the experience we have had of theſe different modes of aſcertaining the powers of a teleſcope, we have no heſitation in giving the preference to the double-image dynameter, in which the two images may be brought into very nice contact: whereas in the pearl dynameter, which is alſo very good, ſomething is always left to eſtimation in taking the fractional part of a diviſion; and when *falſe viſion* is uſed, the adjuſtment of the eyes to different diſtances, one within the teleſcope and the other without, at the ſame time, leaves conſiderable uncertainty in the ſize of the projected field of view, which will vary according to the ſtate and poſition of the eye in every trial. We mention this laſt circumſtance as worthy of conſideration, becauſe ſeveral micrometrical determinations of the diſtance between double ſtars have been made, particularly by ſir W. Herſchel, where the *power* of the teleſcope determined by *falſe viſion* is made in effect the *ſcale* of the *meaſure*; conſequently if the *power* is not accurately aſſigned, the *meaſure* of the angular diſtance depending on it will be proportionably erroneous. Aſtronomers, we repeat, are yet in want of an unobjectionable mode of meaſuring the angular diſtances of *very ſmall* double ſtars, which cannot be ſeen when extraneous light is admitted into the teleſcope, and which therefore have hitherto been projected on two luminous points, placed at meaſured diſtances from each other, for the purpoſe of aſcertaining the apparent celeſtial interval in its magnified ſtate, from a compariſon with a known terreſtrial interval in its unmagnified ſtate, which method is liable to conſiderable uncertainty, and can only be admiſſible upon the principle of its admitting of an average taken from a ſucceſſion of meaſures under different circumſtances.

We have already explained, in our preceding ſection, how the powers of any teleſcope that has a terreſtrial eye-tube, may be varied by the application of the celeſtial eye-pieces to the eye-end of this, by the help of adapters, and therefore we ſhall only ſay further on this part of our ſubject, that however the power is varied by changes of poſition of the eye-pieces, or by additional field-glaſſes, any of the dynameters will give the total power, under any of the diſpoſitions, by the ſimple meaſurement of the diſc, which we have explained; but ſhould there be any doubt about the *excluſion* of the rays incident on the extreme circular edge of the object-glaſs by the diaphragm, or by Troughton's new illuminator, a meaſured circle, or long ſlip of paper, ſtuck to the face of the object-glaſs, muſt neceſſarily be ſubſtituted for the glaſs itſelf, which we were obliged to do with three out of the four of our teleſcopes, and then its image at the eye muſt be ſubſtituted for the *diſc*, that we have hitherto deſcribed as the true image of the glaſs itſelf, which it will be only when *all* the rays are tranſmitted and refracted to a focus at the place of the ſaid diſc or image.

In all refracting teleſcopes, that are not achromatic, of which indeed very few are now made, the *indiſtinctneſs* of an object is directly as the area of the aperture, and inverſely as the ſquare of the focal diſtance of the eye-glaſs, when this is ſingle, becauſe the aberrations are proportional to theſe data; but in a reflecting teleſcope, the indiſtinctneſs will be, with ſpherical curves, as the ſixth power of the diameter of the large ſpeculum directly, and as the fourth power of its focal diſtance inverſely, and alſo as the ſquare of the focal diſtance of the eye-glaſs inverſely.

The *light* in any teleſcope, refracting or reflecting, if we diſregard what is loſt by reflection, is directly as the ſquares of the linear apertures, and inverſely as the ſquare of their linear amplifications.

In refracting teleſcopes of various lengths, not achromatic, a given object will appear equally bright and diſtinct, when their linear apertures, and the focal diſtances of their ſingle eye-glaſſes, are ſeverally in a ſubduplicate ratio of their lengths, or focal diſtances of their object-glaſſes: and then alſo their linear amplifications will be in a ſubduplicate ratio of their focal lengths. But in reflecting teleſcopes, and in the beſt achromatic refractors, of various lengths, a given object will appear equally bright and equally diſtinct, when their linear apertures, and alſo their linear amplifications, are as the ſquare-ſquare roots of the cubes of their lengths; and conſequently when the focal diſtances of their eye-glaſſes are alſo as the ſquare-ſquare roots of their lengths. See Smith's Optics, p. 140, et ſeq.

6. *Meaſures taken by Micrometrical Teleſcopes.*—Though the primary uſe of a teleſcope is to render a diſtant object viſible,

visible, by amplifying the visual angle, yet its application to the measurement of small angles was an object that engaged the astronomer's attention at no great distance of time from its invention. When the apparent diameters of the planetary bodies had once been increased, so as to subtend an appreciable angle at the eye of the observer, it soon became a matter of interest to measure those angles in their enlarged state. We have already given the description of the different MICROMETERS that have been successively applied to a telescope for the purpose of measuring minute angles, and terrestrial distances corresponding thereto; but we have reserved our account of the means proper to be used in these operations, as constituting a portion of our present article. We propose to illustrate the use of a few of the most accurate and useful micrometers by such examples, as will suffice to render the application of any other micrometer intelligible.

When an object to be viewed is remote, the rays of light which proceed from it may be considered as coming from it in parallel lines, and in this case the focus of the object-glass, or speculum, is the shortest possible; consequently, the power of the instrument depending on this focal distance, is the smallest possible with the same eye-piece; but the rays which proceed from a near object, come to the object-glass or speculum *diverging*, and consequently do not come to a focus so soon as in the former case; so that the *power* is greater than when a distant object is viewed. This variation of power depending on the distance of the object viewed, is accompanied by a new adjustment of the eye-piece for distinct vision in every telescope of considerable magnitude; and the longer the focus of the object-glass is, the greater is the variation of power with the same variation of distance. Hence the angle that is measured by any of the micrometers attached to a telescope, is the true angle only when the object subtending that angle is remote; and a correction, depending both on the distance and focal length of the telescope, becomes necessary for converting the *apparent* measured angle into the *true* one. To a want of attention to this circumstance in the practical application of micrometrical telescopes to the measurement of terrestrial distances, is principally to be attributed the failure of their success; and celestial objects have consequently engrossed their utility almost exclusively. We conceive, therefore, that we shall render our readers an acceptable service by shewing, not only how small celestial angles may be measured by a telescope fitted up with an accurate micrometer, but also how terrestrial angles, subtended by objects at various distances, may be ascertained, and their corresponding distances be obtained with great accuracy; and that by simple vision at one station, when the distance is not very considerable. The composer of the present article has made experiments with different micrometers adapted to telescopes of various lengths, and can therefore illustrate the theory by actual examples in sufficient variety.

Celestial Measures.—When a micrometer of any description, mechanical or optical, is proposed to be used with a telescope, it is necessary that the value of one of its divisions be ascertained with that identical telescope when viewing a remote object, such as a heavenly body; or otherwise, that a correction for distance be applied previously to the determination of such value. We will first suppose the object at a sufficient distance to require no correction for want of parallelism of the rays of light, and will shew how to appreciate the micrometrical scale for such remote distance without correction. The diameter of the sun has been so well ascertained by actual measurement of the best instruments, from month to month, and from year to year, that it may be taken from the Nautical Almanac, or Connoissance des Tems, on any given day, as a standard, from which the value of a corresponding number of divisions on the scale of the micrometer may be assigned with great accuracy, after allowance is made for apparent variation in the sun's diameter by altitude; and when the number of minutes and seconds corresponding to a certain number of divisions on the scale is ascertained, the value of one division is readily obtained by dividing the whole number of minutes and seconds by the whole number of divisions that measure the said quantity: and then whatever may have been the error of the observation, as affecting the whole scale, the quantity of it belonging to one division will be only $\frac{1}{30}$, $\frac{1}{40}$, or $\frac{1}{50}$ of the whole, accordingly as there were 30, 40, or 50 divisions in the scale that corresponded to the correct diameter of the sun. For instance, on the 7th of August 1815, the sun's diameter was measured at noon by a Troughton's micrometer, attached to a five-feet refracting achromatic telescope made by Tulley, and was found to be equal to 60.65 turns of the screw, when taken in a vertical direction, while the sun passed horizontally between the two parallel spider's lines in the focus of the eye-piece. In this situation the altitude of the sun was so great, that the difference between the refractions of the upper and lower limbs was insensible, and therefore may be neglected in the calculation of the value of the scale of notches that indicate the revolutions of the screw. On this day, the semi-diameter of the sun, as given in the Nautical Almanac, was $15' \, 48''.3$, and the notches corresponding to the sun's diameter were 60.65, or 60 entire notches, and $\frac{65}{100}$ taken from the divided head of the screw; then $\frac{15' \, 48''.3 \times 2}{60.65} = 31''.27$ is the value of one notch, or revolution of the screw, according to this observation. Again, on the 15th of October, of the same year, the sun's diameter, at nine o'clock A. M., was found equal to 61.50 revolutions of the same screw, used with the same telescope, when the sun's semi-diameter is given $16' \, 4''.8$, or the diameter $32' \, 9''.6$; but at the low altitude at which this measure was taken, the difference of the two refractions of the upper and lower limbs amounted, by the table of refractions, to $2''.6$, to be subtracted from the real to produce the apparent diameter, because the vertical diameter was contracted by this quantity, the lower limb being more elevated by refraction than the upper one; therefore, according to this observation, the value comes out $\frac{32' \, 7''}{61.5} = 31''.33$ for each revolution; hence the average of the two measures, taken at different times, and at different altitudes, is $\frac{31''.27 + 31''.33}{2} = 31''.3$, which determination accords with measures taken at other periods, and also with terrestrial measures subsequently taken, as will appear hereafter.

When this value of the micrometer's revolutions was ascertained, the solar focus of the object-glass was exactly measured, and found to be 63.5 inches. Three other achromatic telescopes were then procured, and had the same micrometer adapted to them respectively, by as many rings of brass, which had each a male and a female screw: the former to screw into the tube of its telescope, and the latter to receive the coarse thread of the micrometer; which rings we have called *adapters*. The focal lengths of the respective object-glasses were found by accurate measurement to be 30.15, 45.75, and 118.3 inches; and the corresponding values

values of the micrometer's revolution, found as above deſcribed, were 66″.0, 43″.5, and 16″.8; *viz.* exactly in the inverſe proportion of their focal lengths, as the theory requires. Hence, when the value of the micrometer is known with a teleſcope of a known focal length, its value may be had, when applied to any other teleſcope of a determined focal length, by reciprocal proportion; for as 30.15 in. : 63.5 in. :: 31″.3 : 66″.0; and converſely, when the values are known, and the focal length of one of the teleſcopes, the focal lengths of all the others may be determined; which is equally the caſe with the *powers*, depending ſolely on the focal lengths when the ſame eye-piece is uſed with each. When the values of the micrometer ſcrew had been determined, both by meaſurement of the ſun, and by mutual compariſon of the focal lengths of the four achromatic teleſcopes, the two following tables were conſtructed to facilitate the uſe of the micrometer with any or all of the ſaid teleſcopes, which we ſubjoin as a ſpecimen by which other tables may be conſtructed by the ſimple arrangement of the multiples of the value of unity.

Table I.—Values of entire Revolutions of the Micrometer's Screw, with four different Teleſcopes.

.34	22.5	14.8	10.6	5.7	.68	44.9	29.6	21.3	11.4					

The use of these tables will be best understood from a few real examples.

1. The sun's diameter was taken by Troughton's micrometer, applied to the telescope of 45.75 inches focal length, on the 27th of May 1815, when his altitude was so high as to require no correction for the difference of the two refractions of the lower and upper limbs, and was found equal to 43.62 turns of the screw: then by Table I. 43 = 31′ 10″.5, and by Table II. .62 = 26″.9, the sum of which is 31′ 37″.4, the diameter given in the Nautical Almanac being 31′ 37″. In this observation the thickness of the spider's line was allowed for.

2. On the 7th of August 1815, the sun's diameter at noon measured 60.60 turns, when the micrometer was used with the telescope of 63.5 inches focal length; whence we have 60 in Table I. = 31′ 18″, and .60 in Table II. = 18″.8, making together 31′ 36″.8, the diameter in the Nautical Almanac for that day being 15′ 48″.3 × 2 = 31′ 36″.6. When these measures were taken, the telescope was on an equatorial stand, and the parallel lines were so placed, that the sun's body passed along the space contained between them, without any apparent variation of altitude, which position is necessary in every observation taken with Troughton's micrometer, when the object has an apparent motion.

3. On the 14th of August 1815, the moon's diameter was measured about 9 P.M. not far from the meridian, when her altitude was about 18°, with Troughton's micrometer, attached to the telescope of 45.75 inches focus, and was found equal to 41.52 turns of the screw; the horizontal semi-diameter, according to the Nautical Almanac, being at noon 15′ 4″, and at midnight 15′ 0″, consequently at the time 15′ 1″. To the horizontal diameter 30′ 2″, add the augmentation at 18° altitude, (from Table IV. of the *requisite tables*,) *viz.* 5″, and the diameter in altitude will be 30′ 7″. Now from Table I. take the value of 41 turns = 29′ 43″.5, and from Table II. take the value of .52 = 22″.6; the sum of which two values will be 30′ 6″.1, which must be increased by 5″, the difference of refraction at 18°, and 18° 30′ of altitude; so that the diameter, when the reductions are all made, is too great by 4″ nearly, which error may be in the lunar tables, or in the observation, which was made when the moon's age was only eleven days, and therefore under an unfavourable circumstance;

for

for in this ſituation the illuminated portion of the moon is always apparently larger than the dark portion.

4. The ſun's diameter was again taken at nine o'clock A.M. on the 15th of October, with the teleſcope of 63.5 inches, and was found equal to 61.56 turns, when the altitude was ſuch as to require an addition of 2″.6 for the variation of the refraction in half a degree of altitude; and here we have from Table I. 60 + 1 = 31′ 18″ + 31″.3 = 31′ 49″.3, and from Table II. .56 = 17″.5, making, together with + 2″.6 the correction, the ſum 32′ 9″.4, the diameter given in the Nautical Almanac being 16′ 4″.8 × 2 = 32′ 9″.6.

In all theſe examples, as well as in the data from which the preceding tables were computed, Troughton's micrometer was uſed as a celeſtial eye-piece, where the object was conſequently inverted, which is the manner in which this micrometer was intended to be uſed; but according to the conſtruction of the modern terreſtrial eye-tube, this micrometer may be ſubſtituted, by help of an adapter, for the two glaſſes at the eye-end of this tube, in which ſituation the magnifying power is very conſiderably increaſed, and conſequently the ſcale rendered capable of meaſuring ſmaller portions of a ſecond, than in the uſual way, particularly when there is light enough in the field of view, *i. e.* when the object-glaſs has a large diameter. When the micrometer in queſtion is applied to the eye-end of the terreſtrial tube of the teleſcope of 45.75 inches, one turn is equal to only 16″.03, which ſhews the power to be ſomewhat greater than when the 118.8 inches teleſcope was uſed as a celeſtial teleſcope with the ſame micrometer; and with the teleſcope of 63.5 inches, which has three pair of ſeparate field-glaſſes, the terreſtrial powers with the ſaid micrometer gives the reſpective values of one turn of the ſcrew 9″.97, 7″.98, and 5″.15; ſo that this teleſcope has four various values of the micrometrical ſcale, which may be uſed in ſucceſſion for meaſuring the ſame angle, according to circumſtances, and each variety may have a ſeparate table computed for its particular uſe. This application of Troughton's micrometer to the terreſtrial tube, and the additional pairs of field-glaſſes, were contrived by the author of this article, and led to another addition, which in itſelf admits of ſtill greater varieties. On obſerving that the modern terreſtrial eye-tube is in fact a *compound microſcope*, it occurred to him, that there are three modes of increaſing the power of this inſtrument; firſt, by ſhortening the compound focus of the eye-glaſſes; ſecondly, by ſhortening the compound focus of the pair of field-glaſſes; and thirdly, by lengthening the diſtance between the compound eye-glaſs and compound field-glaſs (or object-glaſs of the microſcope). The two former modes had now been tried, and afforded the varieties in the meaſures which we have ſpecified: the laſt one was therefore reſorted to thus; a tube was made to ſlide within the terreſtrial tube, after its own eye-piece was withdrawn, and the micrometer was made to ſcrew into this moveable tube, ſo as to vary the diſtance of the micrometer glaſſes from the field-glaſſes of the teleſcope at pleaſure. The reſult proved as was expected; every new poſition for diſtance gave a new value to the ſcale of the micrometer, and the two extremes of theſe values, with the 63.5 inch teleſcope, were 10″ and 5″ reſpectively *per* revolution of the ſcrew; at leaſt the points were found by experiment on the ſliding tube, where theſe values, and alſo the intermediate ones 9″, 8″, 7″, and 6″ *per* revolution, were marked with a graver. The diſtances of theſe points depended on the field-glaſſes uſed with the ſliding tube; and three ſets of points were inſerted, to correſpond to the three pairs of field-glaſſes, any one of which admitted the ſcale to be ſubdivided into tenths of a ſecond. This mode of applying a ſliding micrometer in the terreſtrial tube is as uſeful as novel; for when the poſition is made for an exact number of ſeconds *per* turn of the ſcrew, the tables are diſpenſed with; the only operation being to multiply the number of turns by the number of ſeconds belonging to the poſition of the ſliding tube, and then to reduce them to minutes by 60 as a diviſor. A few examples will render theſe new methods of uſing the micrometer perfectly intelligible, and will at the ſame time ſhew that they contribute greatly to accuracy, by a ſpecies of repetition of the meaſure, of which they are capable. We will firſt exemplify the method without the ſliding tube.

1. The meaſures of Jupiter's diameter, taken by the 63.5 inch teleſcope on the 19th of April 1816, were as follow:

By Troughton's micrometer uſed as a celeſtial eye-piece -	1.43	× 31.3 ″	=	44.8 ″
By N° 1. of the field-glaſſes with the terreſtrial tube -	4.23	× 9.97	=	42.2
By N° 2. of ditto - -	5.53	× 7.98	=	44.13
By N° 3. of ditto - -	8.32	× 5.15	=	42.85
			4)	173.98
Average of the four meaſures - -			=	43.495

The values of the three field-glaſſes had been taken by terreſtrial meaſurement at 700 feet, on the 31ſt of March 1816, and may require farther correction.

2. On the 30th of April 1816, Jupiter being very nearly in oppoſition, his diameter was meaſured with the 45.75 inch teleſcope, which has only two varieties, a celeſtial and a terreſtrial application of the micrometer, and the reſult was thus: *viz.*

By the celeſtial meaſure, taken to the right of zero - - -	1.04 turns.	
By the ſame, taken to the left of zero -	1.05 ditto.	
	2)2.09	
	1.045	= 43.52 ″
By the terreſtrial meaſure 2.72 × 16″.03		= 43.50
		2)87.02
The average of the celeſtial and terreſtrial meaſures		= 43.51

3. On the 25th of October 1815, the following meaſures were taken of the diameter of Mars with Troughton's micrometer attached to the ſliding tube of the teleſcope 63.5 inches; *viz.*

	Turns.		″		″
Firſt poſition at the dot of 7″ with third field-glaſs -	3.43	×	7	=	24.01
Second poſition with ditto -	2.96	×	8	=	23.68
Third poſition with ditto -	2.68	×	9	=	24.12
Fourth poſition with ditto -	2.40	×	10	=	24.00
With N° 1. field-glaſs and its dot 4″ - - -	6.0	×	4	=	24.00
With N° 2. field-glaſs and its dot 8″ - - -	3.0	×	8	=	24.00
With the micrometer uſed as a celeſtial eye-piece -	0.77	×	31.3	=	24.10
				7)	167.91
					23.987

Theſe

Thefe obfervations of Mars were made near the meridian, when he was a little paft oppofition, and confequently when his diameter was near a maximum, which circumftance we mention, becaufe aftronomers have given very difcordant accounts of the apparent diameter of this planet; and perhaps no determination has been more accurate than we have here given.

4. The fun's diameter was meafured at noon on the 24th of September 1816, by Troughton's micrometer adapted to the 30.15 inch telefcope, in the following manner; *viz.*

By the celeftial power -	$29.21 \times 65''.7$	$= 31'\ 59''.1$
By the terreftrial, with the eye-tube flided to dot 30″	63.92×30	$= 31\ 57.6$
By the terreftrial, at dot 28″	68.50×28	$= 31\ 58.0$
By the terreftrial, at dot 25″	76.74×25	$= 31\ 58.5$
		4)127 53.2
Average meafure - - - - -		$= 31\ 58.3$
By the Nautical Almanac $15'\ 59''.1 \times 2$		$= 31\ 58.2$

On the fliding tube of this telefcope, the dots on the fcale run from 31″ to 19″, at which dots the powers are to each other inverfely as thefe numbers; but the whole diameter of the fun cannot be taken on the fcale of the micrometer when a greater power is ufed, than when the pofition is at dot 25″, or middle dot of the fliding tube, where the power is about 82.

In thefe four examples, the diameters meafured were the vertical diameters, for taking which Troughton's micrometer is peculiarly adapted; but the horizontal diameter of a body in motion cannot be taken with the fame accuracy with this inftrument, on account of the difficulty of keeping the extreme edges of the object in contact with the fpider's lines, while the final adjuftment of the meafure is making. For this purpofe, Dollond's divided object-glafs micrometer is more convenient, and may have its fcale appreciated, and the values thereof tabulated in the way we have already explained. For inftance, we obtained a divided object-glafs, with the requifite adjuftments both for circular motion and for the feparation of the centre of the femi-lenfes, of three inches and a half diameter, and fitted it over the object-end of the 45.75 inch achromatic of Tulley, while the original object-glafs, of the fame dimenfions, remained in its place. The focus of this divided object-glafs was fo long, that it fhortened the original focus only to 40.3 inches. The fcale of the object-glafs is divided into inches and twentieth parts of an inch, one of which parts or fubdivifions is again reduced by a vernier into twenty-five fubordinate parts, fo that $\frac{1}{25}$ of $\frac{1}{20}$, or $\frac{1}{500}$th of an inch, is the fmalleft quantity appreciable by the vernier. On the 9th of Auguft 1816, when the fun's diameter was 31′ 37″, or 1897″, the oppofite limbs of the two apparent images of the fun coincided when the fcale indicated three inches, one-twentieth part, and eleven towards 25 on the vernier, after an allowance was made for the index error by a croffed obfervation of a very fmall angle. Now thefe numbers reduced into the loweft denomination, give 1536 parts of the vernier, and $\frac{1897''}{1536} = 1''.235$ is the value of one of thofe parts; but by a terreftrial meafurement, to be explained hereafter, the value taken at 700 feet diftance, with a correction for want of parallelifm of the rays at this diftance, the value came out $\frac{888''}{713} = 1''.245$; the average of which two determinations, unconnected with each other, is 1″.24 for each unit read on the vernier, and this determination was afterwards confirmed by an obfervation of the fun taken on the 25th September 1816, *viz.* $\frac{1919''}{1549} = 1''.24$ very nearly. After having given a value to Dollond's micrometer thus fitted up, on the 21ft of Auguft 1816, the diameter of Saturn's ring was meafured when its longer diameter was very nearly horizontal, both to the right and left of zero, and was found equal to one fubdivifion and 7.7 on the vernier, or $25 + 7.7 = 32.7$ parts of the vernier; then $32.7 \times 1''.24 = 40''.548$ is the meafure of the greateft length of Saturn's ring taken near the meridian, when the paffage was at nearly 28 minutes paft eleven P.M.; and, confequently, when the planet was at no greater diftance than eight days from oppofition. On the 4th of Auguft 1815, the greateft diameter of Saturn's ring however, meafured with Troughton's micrometer attached to the 63.5 inch telefcope, had been found by careful meafurement $= 1.50 \times 31''.3 = 46''.95$, the planet being then only three days from oppofition. By the fame apparatus the ring had been made 48″.2 on the 10th of September 1815, and on the 25th of the fame month only 43″. Thefe difcrepancies fhew that no dependence can be placed in horizontal meafures made with Troughton's micrometer when the object is *in apparent motion*, but for all other meafures of fmall angles, it is no doubt the beft that has been yet invented.

Dr. Brewfter's micrometer has the fame advantage as Dollond's, when the divided lens is ufed as the fliding lens within the tube; but the power of the patent telefcopes hitherto conftructed is fo fmall, that an angle can feldom be meafured with it nearer than to 10″, and frequently not fo near. The principle, however, is applicable to telefcopes of larger dimenfions.

When Dollond's and Troughton's micrometers are both applied to the telefcope of 45.75 inches, the value of the fcale of Troughton's becomes altered from 43″.5 to 49″.4, namely, in the inverfe ratio of the diminifhed focus; and they may both be ufed with great convenience at the fame time, in which cafe, one may meafure the angular length and the other the angular breadth of the fame body; or, if the body be celeftial, one may give the horizontal and the other the vertical dimenfions at the fame inftant. This mode of applying two micrometers, one optical and the other mechanical, at the fame time, affords a mutual check on the meafures of each, when the body is round, like one of the heavenly bodies, and gives a very fatisfactory refult, when it can be adopted. When Troughton's micrometer is ufed as a celeftial eye-piece, along with Dollond's micrometer attached to the telefcope 45.75, fhortened to 40.3, the double images are formed beyond both eye-glaffes, reckoning from the eye, and gives there 1″.24 as the value of one ftroke on the vernier; whereas when a common celeftial eye-piece is ufed with Dollond's, the fecond glafs of the compound piece fhortens the focus of the object-glafs a little, and the images are feen between the two glaffes of the eye-piece; confequently the value of Dollond's micrometer varies a trifle with every different eye-piece, which is not the cafe with Troughton's, where the image is always in the unaltered focus of the object-glafs. On the 26th of September 1816, a careful feries of obfervations was made of the fun's diameter with both Troughton's and Dollond's micrometers ufed at the fame time, when the former gave $38.85 \times 49''.4 = 31'\ 59''.2$, and the other 15.47 (3 in. 1 div. 22 on vern.) $\times 1''.21 = 31'\ 58''.28$, the diameter of the fun by the Nautical Almanac being

being $31' \, 59''.2$ horizontally, and $31' \, 57''.9$ vertically, at the altitude of $38°$.

Terreſtrial Meaſures.—In the examples which we have given of celeſtial angular meaſures taken by a micrometrical teleſcope, no correction of the meaſured angle was neceſſary, becauſe the rays of light coming from theſe objects may be conſidered as parallel on entering the object-glaſs, and as always converging to the ſame focal point, where the image is formed; hence the magnifying power of the celeſtial teleſcope does not vary. But when terreſtrial objects are viewed at different diſtances, there is a deviation from parallelism in the courſe of the rays, which increaſes in the inverſe ratio of the diſtance, and which lengthens the focus of the object-glaſs, and conſequently increaſes the power of the inſtrument, even with the ſame glaſſes. This alteration in the effective length of a teleſcope is practically diſcovered by the adjuſtment of the eye-piece for diſtinct viſion, which is neceſſarily different at different diſtances from the object viewed. But we have ſhewn, that the ſcales of Troughton's and of Dollond's micrometers will vary with the variable powers of even the ſame teleſcope, and therefore will require a correction for each variety of power, or, in other words, for each variety of terreſtrial diſtance. The determination of theſe varying corrections, therefore, is eſſential to the accuracy of the meaſures taken by a micrometer in all caſes, where the incident rays of light come diverging from objects placed at moderate diſtances. If we put f for the ſolar or principal focus of the object-glaſs of any teleſcope, and d for the diſtance of an object from the ſaid object-glaſs when uſed, the addition to the length of the ſolar focus, which we will call e, according to the laws of *dioptrics*, may be found by this theorem, $\frac{f^2}{d-f} = e$; that is, the ſquare of the ſolar focus, divided by the diſtance in the ſame meaſure, when diminiſhed by one focal diſtance, will be the elongation, or exceſs of the lengthened focus over the ſolar focus; then as the powers are to each other reſpectively as the focal lengths, with the ſame eye-piece, we ſhall have $f : f + e ::$ true angle : meaſured or apparent angle; and converſely, as $f + e : f ::$ apparent angle : true angle. For inſtance, let it be required to aſcertain what is the neceſſary correction for an angle, meaſured by a teleſcope of 63.5 inches focus, that is ſubtended by one yard at a hundred yards diſtance from the object-glaſs. By a ſimple caſe in plain trigonometry, the true angle ſubtended by a yard, at a hundred yards diſtance, is $34' \, 59''.4$, or $34'.99$; and 63.5 inches are 1.764, when reduced into the denomination of yards and decimal parts; then $\frac{1.764 \times 1.764}{100 - 1.764} = \frac{3.111696}{98.236} = 0.03167 = e$, the increaſed length of the focus; and $\frac{1.764 + 0.03167 \times 34'.99}{1.704} =$ $35'.618$, or $35' \, 37''.08$ will be the meaſured angle, therefore $35' \, 37''.08 - 34' \, 59''.4 = 37''.68$ is the correction to be added to the true angle, in order to obtain the apparent angle, that would have been the true angle alſo, if the focus of the object-glaſs had remained unaltered at the diſtance of 100 yards. But it is the correction anſwering to the apparent or meaſured angle that we want, and the determination of this requires a tranſpoſition which is operoſe, and therefore objectionable in practice; on which account we recommend each ſurveyor, military tactician, and leveller, who is diſpoſed to avail himſelf of the uſe of a micrometrical teleſcope, for ſhortening his labours, to uſe tables adapted to the focal length of his own teleſcope, which may give by inſpection the correction proper in all caſes for reducing the apparent angle into the true one, and *vice verſâ*. Tables III. and IV. which are ſubjoined, were computed for this purpoſe, from the theorem juſt exemplified, and are adapted for a teleſcope of 63.5 inches focal length, to which we have added Table V., as a general table for finding the diſtance, in yards and decimal parts, correſponding to any angle, from $1'$ to $30' \, 59''$ incluſively; even to the accuracy of a ſingle ſecond, when that angle is ſubtended by an exact yard. The labour of conſtructing theſe tables has been conſiderable, but the facility and accuracy with which they give the deſired reſults, has amply repaid the computer, and, it is preſumed, will be a recommendation to the notice of our ſcientific readers, to whom their application may in many caſes be found uſeful.
