Conſtruction and Uſe of the Tables.—We have already explained the conſtruction and uſe of Tables I. and II., which are required to be adapted to the particular teleſcope with which any given micrometer is uſed; and we have alſo explained how the value of a ſingle diviſion, or turn of a ſcrew, is aſcertained by means of the ſun's diameter: but this method gives a derivative rather than an original independent value to the micrometrical ſcale; for if the ſun's diameter be not truly given in the Nautical Almanac (and the late Dr. Maſkelyne had reaſon to alter it in the lateſt years of his life), the error of this meaſure will be introduced into the ſcale derived from it; Table III. is therefore inſerted, as affording the ready means of obtaining an independent ſcale from actual terreſtrial meaſurement. We have already ſhewn how the table of corrections is conſtructed in this table; and the reader will have no difficulty in taking out the proper numbers, as corrections to be added to the true angle, in order to convert it into the apparent or meaſured angle, if he be careful to take the minutes of the given angle from the left-hand vertical column, and the ſeconds from the horizontal line at the top; for in every inſtance, the meeting of the two columns will contain the additive quantity that is to be applied to the true angle, in order to obtain what the teleſcope will give when the value of its ſcale is once duly aſſigned. For inſtance, ſuppoſe the true angle $14' \, 20''$, where $14'$ is taken at the ſide, and $20''$ at the top, the junction of the two columns gives $+ \, 6''.28$, which ſhews that this quantity muſt be added to $14' \, 20''$, the true angle, to make $14' \, 26''.28$, the apparent angle, as meaſured by a teleſcope of 63.5 inches focal length. If now this angle, reduced into ſeconds, be divided by the turns of the ſcrew, or diviſions on any ſcale uſed as a micrometrical ſcale, the quotient will be the value in ſeconds of one turn, or diviſion, as the caſe may be, provided the angle in queſtion be that which a true yard actually ſubtends at a known diſtance. For example, when a yard of 36 exact inches was erected at the diſtance of 190.98 yards, the micrometer of Troughton, attached to Tulley's 63.5 inch teleſcope, meaſured it by 34.78 revolutions of its ſcrew; and by Table V. the true angle, read as in Table III. at the ſide and top, correſponding to this diſtance, is $18' \, 0''$; the additive quantity belonging to this angle, as taken from Table III., is $+ \, 9''.89$; and therefore the apparent angle, if meaſured by the ſaid teleſcope, would be $18' \, 9''.89$; therefore $\frac{18' \, 9''.89}{34.78} = 31''.33$ is the value of one revolution of the ſcrew, which is very nearly the ſame as was determined from the ſun, and before tabulated. This coincidence of the celeſtial and terreſtrial meaſures affords a convincing proof that the ſcale has been duly appreciated.

We have ſaid, that this table of corrections, and alſo the following one, which we ſhall explain preſently, are computed excluſively for a teleſcope of 63.5 inches focus, being that which is repreſented, with a Troughton's micrometer attached, in *fig.* 6. of *Plate* XXIX.; and that each different teleſcope ought to have its own tables of corrections correſponding to its focal length, which limitation is required by the theorem on which we have grounded our calculations. But as the *diſtance*, which is the varying term, is the ſame for all teleſcopes, we find that in practice the corrections of any other teleſcope will be ſo nearly proportionate to their reſpective focal lengths, that they may be taken exactly as ſuch, without any ſenſible error; that is, the error ariſing from the table of corrections will be always as ſmall as the error of obſervation in ordinary teleſcopes, unleſs the diſtance be very ſmall, and its correction conſequently great. On this account, Table III., and alſo Table IV., which, it will be ſeen, is derived from it, like Table V., may be conſidered as *general* tables, admitting of proportional parts of their whole corrections to be taken as ſuitable corrections for teleſcopes of other dimenſions. This conſideration is of great importance, with reſpect to the general utility of our tables of correction; and therefore the reader ſhall not depend ſolely on the authority of our bare aſſertion. We have already computed the correction for a teleſcope of 63.5 inches focal length, to be added when the true angle is $34' \, 59''.4$, or diſtance 100 yards, and found it $37''.68$; let us ſee what it will be with the ſame data, when the teleſcope has juſt one half of the ſaid focal length: here we have $\frac{1.764}{2} = .882$ of a yard for the focal length; then $\frac{.882 \times .882}{100 - 882} = \frac{.77924}{99.118} = .00785 = e$, the elongation of the focus, and $\frac{.882 \times .00785 \times 34'.99}{.882} = 35'.3$, or $35' \, 18''$ for the apparent angle, from which, if we ſubtract $34' \, 59''.4$, the true angle, the difference $18''.6$ will be the correſponding correction, which differs only a quarter of a ſecond from $\frac{37''.68}{2}$, or half the correction of the teleſcope of double dimenſions. Beyond 100 yards diſtance, the error, ſmall as it is, will continue to diminiſh as the diſtance increaſes, and a ſmaller diſtance will ſeldom require to be meaſured in this way. The accuracy of this concluſion has been ſtill farther corroborated by actual experiment: a graduated ſtaff was placed erect at a diſtance, by meaſurement of a Troughton's chain of five-feet links, of 261.9 yards, and the two teleſcopes of 63.5 and 45.75 inches focal length, were tried againſt each other thus; a yard by the firſt was found, with Troughton's micrometer, to be equal to 25.33 turns; and by the ſecond, with the ſame inſtrument, to be 18.19; the true angle belonging to this diſtance by Table V. is $13' \, 7''.54$; and the correction for the larger teleſcope by Table III. $+ \, 5''.25$; therefore, taking $\frac{45.75}{63.5}$ or .72 of $5''.25 = 3''.8$ for the correction of the ſmaller teleſcope, we have the following values of the reſpective ſcales; *viz.* $\frac{13' \, 7''.54 + 5''.25}{25.33} = 31''.2984$, &c. and $\frac{13' \, 7''.54 + 3''.8}{18.19} = 43''.504$, which values accord very nearly with thoſe that had been previouſly determined by a ſeries of ſolar meaſures, and the latter of them exactly, as far as to the third place in the decimal figures.

Table IV. is the table to be uſed with Table V. for finding, firſt the true angle from the apparent one, and then the true diſtance at once from this true angle: its corrections are arranged ſomewhat differently from thoſe in Table III., and have an oppoſite ſign, but are borrowed from Table III. in ſuch way, that by means of a little tranſpoſition, the terms of one may be converted into thoſe of the other; as, for example, at the apparent angle $18' \, 40''$, in Table IV., the correction is $- \, 10''.4$, and the true angle conſequently $18' \, 29''.6$; and at $18' \, 30''$, the neareſt numbers for the true angle in Table III., the correction is $+ \, 10''.44$, which makes its correſponding apparent angle $18' \, 40''.44$. In the former of theſe two tables, the correction is calculated to the hundredth part of a ſecond; it being that from which the ſcale has its value appreciated; but in the latter, it was deemed convenient to leave out the hundredth parts, as being

being beyond the powers of the telescope, or rather of the human eye, when a single observation is taken.

Before Table V. was constructed, it was found by plane trigonometry, that one yard will subtend an angle of one minute at 3437.7 yards distance; and, as the distance decreases in the same ratio in which the angle increases, the table was made by a continual reduction of this number into halves, thirds, fourths, &c. as far as to 30′, and all the intermediate seconds from 1′ to 30′, were inserted with their corresponding distances. For instance, at the true angle of 18′ 30″, the true distance is 185.82 yards; it being always understood, that the measured angle is subtended by an exact yard placed at right angles to the line of sight, in either a vertical or horizontal position, and that the correction taken from Table IV. has been applied to the measured or apparent angle. If two yards should be used as the opposed object at a great distance, then *half* the angle only must be taken; but if half a yard only be used at small distances, then *double* the angle will be proper; and should the distance be within 110.95 yards, the smallest distance contained in the table; in which case the angle will exceed 30′: the distance belonging to *half* the angle will always be *double* the distance required. Suppose the angle 33′; then half of this is 16′ 30″, and the double number 208.34; consequently 104.17 yards will be the corresponding distance; and thus the table will extend to any short distance, by taking a given portion of the measured angle, when reduced to the true one, and by using the same portion of the corresponding distance, provided the angle do not exceed 60′, which is the limit of Table IV., and which is as much as a telescope magnifying only 30 times will usually take into the field of view.

In order to exemplify the use of these new tables, and at the same time to prove their accuracy, we obtained from Mr. Troughton a couple of staves, having each a sliding yard of brass, cut into notches for decimal divisions of a yard, which are capable of being seen at a distance, with an apparatus for placing them perpendicular in any given situation: on the 8th of October 1816, one of these staves was fixed in a perpendicular position at an unknown distance on level ground, and the following measures were taken of the angle subtended by a yard, by Troughton's micrometer successively adapted to each of the four telescopes, thus:

With telescope	30.15 in.	24.59 revol. =	27′ 2″.9	(by Tables I. and II.)	− 10″.4	(by Table IV.)	= 26′ 52″.5
	45.75 in.	37.53 revol. =	27 10.5	- - -	− 15.6	- -	= 26 54.9
	63.5 in.	52.25 revol. =	27 15.43	- - -	− 21.85	- -	= 26 53.58
	118.8 in.	98.52 revol. =	27 35.1	- - -	− 41.0	- -	= 26 54.1
							4)215.08
						Average	= 26 53.77

By Table V. the distance corresponding to this angle is 127.81 yards, and by measurement of a good chain, it was afterwards found to be 5.808 × 22 = 127.776 yards, the difference or error being only .034 of a yard, or something less than an inch and a half. During the observations, the sun was obscured by clouds, and the object viewed had no vibratory motion, which is a circumstance essential to be attended to.

With Dollond's divided object-glass applied to the telescope of 45.75, the measure was 2 in. 11 div. 19 ver., or 1294 of the vernier, which, multiplied by 1″.24, the solar value of unity, gave the measured angle only 26′ 44″.56; but on examining the ratio in which the focus elongates at different distances, we found that the divergence of the rays was lessened so much, in passing through the divided object-glass, before they entered the achromatic object-glass, that the table of corrections would be of no use for this arrangement of two separate object-glasses.

On the 16th of the same month the graduated staff was erected at a greater unknown distance, and the following measures were taken by Troughton's micrometer, as before, *viz.*

With telescope	45.75 in.	27.59 revol. =	20′ 0″.1	− 8″.6 (correction)	= 19′ 51″.5
	63.5 in.	38.48 revol. =	20 4.4	− 12 - -	= 19 52.4
					2)103.9
				Average	= 19 51.95

to which angle the corresponding distance by Table V. is 173.0 yards; and the subsequent measure by the chain accurately repeated was 172.92 yards, in which determination the error was .08 of a yard, or 2.88 inches only.

From these operations we are persuaded that a good telescope, with a Troughton's micrometer, will determine distances, by simple inspection, when within the eighth part of a mile, with more accuracy than is usually done by a surveyor's chain or measuring-wheel; and, consequently, if both a backward and forward view be taken from one station, situated near the middle of a line joining two graduated staves, a *quarter of a mile* may be so determined at *one station* in the space of two or three minutes after the station is taken. But it may be said, why not take a quarter of a mile at one sight, since the power of a good telescope will command a small object at this distance? To which we answer, that the error arising from distance may be considered rather as a geometrical than an optical error: our experiments have convinced us that a small angle may be measured by Troughton's micrometer, when the thickness of the spider's line is allowed for, (*viz.* $\frac{6}{100}$th of a turn of the screw in our micrometer,) so accurately, that the error of observation in favourable weather will seldom exceed *one second;* but the error in distance, corresponding to an error of one second in the measured angle, increases in the duplicate ratio of the distance, and consequently becomes too considerable to be admissible beyond a limited distance; for instance, at the distance of 220 yards, or the eighth of a mile, an error of 1″ in the angle subtended by a yard produces only an error of 0.23 of a yard in distance; but at 440 yards, or a quarter of a mile, the error in distance corresponding to the same error in the angle is 0.92; that is, at twice the distance the geometrical error is four times augmented; which circumstance limits

limits the distance at which micrometrical measurements in longimetry can be usefully employed at one station. What may be called the *optical* error, or that which arises from want of parallelism in the rays of light on entering the object-glass, and is allowed for in our fourth table, on the contrary, decreases with an increase of distance, and very nearly in a sub-duplicate ratio; so that the correction arising out of this optical error becomes insensible at no very great distance in telescopes of ordinary dimensions: for instance, at 220 yards, or its angle 15′ 38″, the correction is — 7″.4 by our Table IV.; but at 440, or its angle 7′ 49″, the correction diminishes to 1″.9, or nearly a fourth of the former at double the distance. Hence there is a peculiar distance at which every separate telescope will have its optical error or correction reduced to 1″, or quantity of probable error of observation, beyond which distance the tabulated corrections may be disregarded in ordinary operations. With the telescope of 63.5 inches focus, the correction will be less than 1″ at 590 yards distance; with that of 45.75 inches, at 537; and with that of 30.15 inches, at 430, the distance continuing to diminish with the diminishing length of the focus of each object-glass, but not in the same ratio; consequently, when the telescope is very short, and its power small, the optical error may be altogether disregarded, wherever such telescope can be of any real use; because, in all probability, this error will be less than the error of observation arising from want of power.

TELESCOPE *Shell*, in *Conchology*, the name of a species of turbo, with plane, striated, and numerous spires.

TELESCOPICAL STARS, such as are not visible to the naked eye, but discoverable only by the help of a telescope. See STAR.

All stars less than that of the sixth magnitude are telescopic to a middling eye.

TELESE, in *Geography*, a town of Naples, in Lavora, the see of a bishop, who resides at Cerreto; 18 miles E.N.E. of Capua. N. lat. 41° 12′. E. long. 14° 32′.

TELESIA, or TELESSIA, in *Ancient Geography*, a town of Italy, in Samnium.

TELESIA, in *Mineralogy*. See CORUNDUM.

TELESIO, BERNARDINO, in *Biography*, a modern philosopher, the descendant of an illustrious family at Cosenza, in Naples, was born in the year 1508 or 1509. Having received the early part of his education under an uncle at Milan, he accompanied him to Rome in 1525, and shared in the calamities which attended the sack and pillage of that city. At Padua, whither he afterwards removed, he applied himself with diligence to the study of mathematics and philosophy. Returning again to Rome, he formed an intimate acquaintance with several persons of distinguished character, and so much ingratiated himself with pope Pius IV. that he was offered the archbishopric of Cosenza, which he declined for himself and obtained for his brother. From Rome he retired to his native country, where he married in advanced age, and for a short time became professor of philosophy in the university of Naples. However, the place of his more constant residence was Cosenza, and here he established an academy called Cosentina. He passed the remainder of his life under the patronage of several persons of distinction, particularly Ferdinand, duke of Nocera; but afflicted by the assassination of one of his sons, and by the calumnies circulated against his school of philosophy, he terminated his life in the year 1588. Telesio distinguished himself by his opposition to the physics of Aristotle, and employed mathematical principles in explaining the laws of nature. These were first divulged in a work printed at Rome in 1565, entitled "De Rerum Natura juxta propria principia, Lib. II." and enlarged to nine books in an edition printed at Naples in 1586. The same system was maintained in other treatises, under the titles of "De his quæ in Aere fiunt, et de Terræ Motibus;" "De Mari;" "De Colorum Genere," &c. His system was in its essence the doctrine of Parmenides, who taught, that the first principles in nature, by means of which all natural phenomena are produced, are cold and heat. (See PARMENIDES and ELEATIC.) Telesio's theory is thus developed: "Matter, which is in itself incapable of action, and admits neither of increase nor diminution, is acted upon by two contrary incorporeal principles, heat and cold. From the perpetual opposition of these, arise the several forms of nature: the prevalence of cold in the lower regions producing the earth and terrestrial bodies, and that of heat in the superior regions, the heavens and celestial bodies. All the changes of natural bodies are owing to this conflict; and according to the degree in which each principle prevails, are the different degrees of density, resistance, capacity, moisture, dryness, &c. which are found in different substances." This system is founded on the fanciful conversion of mere attributes and properties into substantial principles. For lord Bacon observes, that Telesio, no less than Plato and Aristotle, places abstract notions at the basis of his system, and produces his world of real beings from non-entities. This eminent philosopher, however, characterises him as a lover of truth and a benefactor to science; and one who prepared the way for subsequent improvements. After his death, his writings, as containing "innovations," were put into the Index Expurgatorius of the Inquisition. His philosophy, nevertheless, had many advocates, among whom was Campanella; and his works were republished at Venice, in 1590, by Antonio Persio, who wrote a compendium of his philosophy in the vernacular tongue. Telesio's style was more polished than that of other philosophers of his time; and he intermixed some Latin verses of considerable eloquence. Brucker by Enfield.

TELESPHORUS, in *Mythology*, a deity invoked by the Greeks for health, together with Esculapius and Hygeia. The figures of these three divinities occur on several medals; and on some we have Telesphorus with Esculapius alone, and on others with Hygeia.

The figure of Telesphorus is invariably the same, *viz.* that of an infant clothed with a sort of cloak without sleeves, which enfolds its arms, descends below the knees, and has a kind of hood or cowl covering its head.

Montfaucon has given a particular description of this deity, the worship of which is supposed to have passed from Epidaurus to Rome, with that of Esculapius.

TELETÆ, among the *Ancients*, were solemn rites performed in honour of Isis.

TELETZKOI-OZERO, in *Geography*. See ALTIN.

TELETZKOI *Mountain*, deriving its name from the lake Teletzkoi-ozero, one of the greatest eminences of the Altay mountains (see ALTAI), and from which the river Oby issues. It forms, with its lofty summits, the boundary between Siberia and the Soongarey, strikes its powerful ridges down between the lake and the Katunia; and after having turned round the east side and the lake, unites with the Kunetzkoi mountains. This division is one of the greatest, but at the same time the coldest and most inaccessible, of all the Altaian ore-mountains; hence it is, that its quality and contents are little known. This, however, is certain, that very powerful granite and porphyry mountains are in its range, and that the earth near and upon it yields jasper, flint breccia, hornschistus, white (probably saline) chalk-stone, coloured marble, black schistus, marle, sand-stone, and in these thefe there are iron, argentaceous copper, and lead ores, naphtha, afphaltus, &c. The mountains to the right of the Katunia feem to be particularly rich in ores.

TELEUTES, or Telengutes, a tribe of Tartars, who are fuppofed to have derived their name from the lake Telegul in the Altay mountains. They are alfo denominated by the Ruffians the white Kalmucks, becaufe they formerly lived among the Soongarians. Abulgafi reckons them among the Mongolian races; but as their fpeech is manifeftly a corrupt Tartarian, their origin may more confiftently be derived from that nation. In the year 1609 they did homage for the firft time to the Ruffian empire; but it was not till towards the middle of the 17th century, when fome ftems of them removed higher up the Tom, that they became properly fubjects of Ruffia: the greater part of them, however, remained with the Kalmucks. The former dwelt partly in the Tomfkoi diftrict of the Tobolfkian, partly in the Kufnetfkian circle of the government of Kolhyvan; and their number is fo fmall, that they only reckon about 500 males.

TELFS, a town of the county of Tyrol, near the Inn; 15 miles W.S.W. of Infpruck.

TELGEN, a town of Sweden, in Sudermanland, on the lake Mæler; 15 miles S.W. of Stockholm.

TELGET, a town of Germany, in the bifhopric of Munfter; 5 miles E.S.E. of Munfter.

TELGHIOURAN, a town of Afiatic Turkey, in the government of Diarbekir; 30 miles S. of Diarbekir.

TELHEIM, a town of the duchy of Wurzburg; 7 miles S.S.W. of Schweinfurt.

TELHEIRO, a town of Portugal, in the province of Beira; 6 miles S.W. of Pinhel.

TELICA, a volcano of Mexico, near Tecoantepeque.

TELICARDIOS, in *Natural Hiftory*, the name given by fome authors to a ftone found in the fhape of a heart. It owes this figure to its having been found in the fhell of fome large bivalve of the cockle kind; and is more ufually known among authors under the name of bucardites.

TELIGUL, or Telegul, in *Geography*, a lake of Ruffia, in the Altay mountains, about 120 miles in circumference. N. lat. 43° 12′. E. long. 64° 14′.

TELIPHANO, in *Botany*, a name ufed by fome authors for the doronicum, or leopard's bane.

TELL, William, in *Biography*, a celebrated Swifs, was an inhabitant of middle rank of Burgeln, in the canton of Uri, and fon-in-law of Walter Furft. In 1307 he engaged in the confpiracy againft the Auftrian tyranny. Gefler, the German bailiff, fufpecting a plot, artfully contrived a fcheme for afcertaining the extent of fubmiffion to the Auftrian yoke. Accordingly he fet up a hat upon a pole, and commanded that obeyfance fhould be paid to it. Tell refifted the command; and, as tradition reports, the arbitrary bailiff ordered him to fhoot with an arrow at an apple placed on the head of his fon. He cleft the apple without hurting the child; and being obferved to have another arrow, he was interrogated what he intended to do with it. He unhefitatingly replied, that if he had wounded his fon, the other fhaft fhould have been directed to the bailiff's heart. This bold declaration caufed him to be imprifoned. Of this fact there is no doubt; though the incident of the arrow and apple may be fabulous, as it is applied by Saxo Grammaticus to a Dane at an earlier period. The bailiff took Tell with him acrofs the lake of Lucern, defigning to convey him to another canton. In the paffage, a ftorm arofe; and the veffel being in danger, the fetters of Tell who was known to be a fkilful boatman, were taken off, and the helm was committed to his hands. Availing himfelf of this circumftance, he fteered to a rock and made his efcape. Gefler on landing met with his fate from an arrow of Tell, who afterwards retired to Stauffacher in the canton of Schweitz; and on the following new-year's day, all the Auftrian governors were feized and difmiffed from the country; and this circumftance is faid to be the commencement of Swifs freedom. Tell's death is fuppofed to have been occafioned by an inundation at Burgeln in the year 1354. His grateful countrymen erected a rude chapel to his honour on the fpot where he refided, and another upon the rock on which he landed. His pofterity, however, funk into oblivion, without any permanent diftinction; the laft who bore his name died in 1684, and the laft of the female line in 1720. Coxe. Muller. Gen. Biog.

TELLA Pashnum, in *Natural Hiftory*, a name given by the people of the Eaft Indies to a kind of white arfenic, or rat's-bane, found native among them.

It is well known to be a fatal poifon, and ufed to deftroy vermin. It lies in the cliffs of rivers among ftrata of ftone in large white irregular lumps; when held to the fire, it emits copious fumes, fmelling ftrongly of garlic and fulphur, but it does not readily melt or run.

Tella *Sagrum*, a name given by the natives of the Eaft Indies to a kind of earth which they ufe externally to dry up ulcers, and internally in cafes of coughs and colds. It is of the nature of the finer clays, and is found at the bottom of fome of their rivers.

TELLEGROD, in *Geography*, a morafs on the borders of Norway and Lapland, which cannot be croffed without much apprehenfion of danger. During winter it is frozen to the depth of feveral yards, and does not thaw till the fummer is far advanced. The furface may appear dry and folid, but as the heat ftill penetrates downwards, the icy floor which fupports it, foftening and melting, bends and trembles under the fhock of preffure, and at laft gives way, fo that horfes, carriages, and paffengers—all fink into the abyfs. Near the mouth of the Fiord, or firth, a bed of clay-marle is feen diftinctly mixed with fmall fhells. Appearances of a like kind occur along the fouthern fhores of Norway, and the fact is the more remarkable, fince no foffile fhells have been ever found in the interior of the country. This marle, however, is only a local formation, and refts on the fundamental gneifs.

TELLER, an officer in the exchequer, of whom there are four: whofe bufinefs is to receive all monies due to the crown, and thereupon to throw down a bill through a pipe into the tally-court, where it is received by the auditor's clerks, who attend there to write the words of the faid bill upon a tally, and then deliver it to be entered by the clerk of the pells, or his clerk.

The tally is then fplit or cloven by the two deputy chamberlains, who have their feals; and while the fenior deputy reads the one part, the junior examines the other part with the other two clerks.

The tellers' places are in the king's gift, and they have befides their chief clerk or deputy, and other clerks for the difpatch of bufinefs.

Teller, Marcus, in *Biography*, a prieft and mufical compofer in the church of St. Gervais, in Maeftricht, publifhed in 1726, his firft work at Augfburg, under the title of "Mufica facra ftylo plane Italico et Chromatico pro Compofitionis amatoribus, complectens IX Motetta brevia de Tempore, et II Miffas folemnes, &c." His fecond work was pofthumous, and publifhed likewife under the folemn title of "Mufica facra," confifting of four maffes and four motets, for four voices, two violins, tenor, baffoon, and a baffo continuo, or figured bafe.

Teller, Florian, an eminent dramatic compofer of the mufic of grand opera ballets. In 1763 he compofed mufic for the ballet of Orpheus and Euridice, for the duke

duke of Wurtemburg's theatre at Stuttgard; and the year after, for his highness's birth-day, that of Noverre's grand ballet called "The Triumph of Neptune." The ballet music of this composer superseded that of Lulli and Rameau at Paris; and in our opera, the music of the *ballets historiques*, and chaconnes danced by Mad. Heinel and Vestris, was chiefly the production of Teller.

TELLES, in *Geography*, a sea-port of Africa, in the kingdom of Fez, on the coast of the Mediterranean; the harbour is small but safe, and the bottom good; 120 miles E.S.E. of Tangiers.

TELLICHERY, a city of Hindoostan, on the coast of Malabar, belonging to the English, and defended by lines. It was long besieged by the forces of Hyder Ali; but in the year 1782 the troops were defeated, the camp taken, and the general wounded and made prisoner by the British, under the command of major Abingdon. The situation of the town is beautiful and healthy: pepper is the great article of trade, and cardamoms; 48 miles N.N.W. of Calicut. N. lat. 11° 15′. E. long. 75° 20′.

TELLICO, a town of the state of Tennessee, with a block-house; 50 miles S.W. of Knoxville. N. lat. 35° 37′. E. long. 84° 18′.

TELLIER, Michael, in *Biography*, a distinguished Jesuit, was born in 1643, near Pire, in Lower Normandy. He studied at the Jesuits' college at Caen, and entered into the society at eighteen years of age. Having for some time taught the schools, he was directed by his superiors to prepare an edition of Quintus Curtius, "in usum Delphini," which was printed in 1678. He was afterwards selected, with other eminent brethren, to establish at the Jesuits' college at Paris a society of learned men, who might retrieve the honour of the body; but his views were directed to other objects, and he became a zealous controversialist in the subjects of dispute between the Jesuits and other orders. Accordingly, in 1687, he published "Defense des Nouveaux Chretiens et des Missionaires de la Chine, du Japon, et des Indes," which was attacked by Arnauld in his "Morale Pratique," and was announced to the holy office: and sentence of condemnation was averted by a promise that Tellier should come to Rome, and make alterations in his work. This prepared the way for numerous publications; in consequence of which Tellier gained increasing reputation, and was advanced to the offices of revisor, rector, and provincial. Upon the death of F. la Chaise in 1709, he was chosen, in competition with another candidate, and in consequence of an assumed air of modesty, to succeed him as confessor to the king. But whatever modesty he might assume to serve a present purpose, he had little true humility. Ardent, unsympathizing, and despotic, he was hated by his brethren over whom he tyrannized, in the most unwarrantable manner. Fontenelle, who well knew his disposition and character, hearing of his appointment, said, "The Jansenists have sinned." His first act was the demolition of the famous house of Port Royal, which he razed to its foundation; he then forced upon the nation and the magistrates the bull Unigenitus; and he proceeded with such violence, that the Jesuits themselves said, "Father le Tellier drives us at such a rate that he will overturn us." Tellier's conduct brought disgrace on the society, and was ultimately the chief occasion of its abolition. On the death of Louis XIV. he was exiled, first to Amiens, and afterwards to La Flêche, where he died in 1719, at the age of seventy-six. The morals of Tellier were regular; and though some persons suspected him of hypocrisy, others have with greater probability believed, that he was actuated by real zeal for the principles which he had adopted. He was a man of literature, wrote many works, and was a member of the Academy of Belles Lettres. Nouv. Dict. D'Alembert's Hist. of the Jesuits.

TELLIGT, in *Geography*, a town of Germany, in the bishopric of Munster, with a rich abbey, on the Ems; 3 miles from Munster.

TELLIGUO Mountains, or *Iron Mountains*. See Iron *Mountains*.

TELLINA, in the Linnæan system of *Conchology*, a distinct genus of the class of Vermes, and order of Testacea. For the characters of this genus, see Conchology. Gmelin enumerates ninety-one species.

TELLINGANA, in *Geography*, a province of Hindoostan, now called Golconda.

TELLINGSTEDE, a town of the duchy of Holstein; 11 miles S.E. of Lunden.

TELLIPOLI, a town on the N. coast of the island of Ceylon; 9 miles N. of Jaffnapatam.

TELLO, a town on the W. coast of the island of Celebes, and capital of a small kingdom, once united to Macassar. S. lat. 5°. E. long. 120° 2′.—Also, a town on the W. coast of the island of Lombock. S. lat. 8° 24′. E. long. 115° 45′.

Tello *Laugue*, a town on the W. coast of Sumatra. N. lat. 0° 51′. E. long. 98° 21′.

Tello *Point*, a cape on the W. coast of Sumatra. S. lat. 1° 50′. E. long. 100° 31′.

TELLONIUM. See Thelonium.

TELLONUM, in *Ancient Geography*, a place of Gaul, in Aquitania, near the sea-coast, S.E. of Burdigala.

TELLOW, in *Geography*, a town of Brandenburg, in the Middle Mark, famous for its turnips; 10 miles S. of Berlin. N. lat. 52° 23′. E. long. 13° 15′.

TELLUDOPIN, a town of the island of Celebes, in Buggess bay. S. lat. 2° 35′.

TELLURE, in *Agriculture*. See Tiller.

TELLURIUM, in *Mineralogy*, a metal discovered by Klaproth, combined with gold and silver, in the ores from the bannat of Temeswar, and in the Farzebay mountains in Transylvania. The ores of this metal are denominated *native tellurium*, *graphic tellurium*, *yellow tellurium*, and *black tellurium ore*.

Native Tellurium; Gedigen Sylvan, Werner.—The colour is intermediate between tin and silver white, and sometimes inclines to steel-grey. This ore is found massive and disseminated; it is said sometimes to occur crystallized in four-sided prisms; it occurs also in small granular concretions. It yields to the knife, and is rather brittle. The specific gravity, according to Klaproth, is 6.15. Before the blow-pipe, native tellurium melts easily before ignition; it burns with a greenish flame, and is entirely volatilized in a dense white vapour, which has the acrid odour of horse-radish. When exposed to a low heat, it is converted into a yellowish or blackish oxyd: by an increase of temperature it forms a dark brown or black glass, in which gold grains are interspersed: at a still higher heat the oxyd is entirely volatilized. The constituent parts are, according to Klaproth,

Tellurium - - - -	92.55
Iron - - - - -	7.20
Gold - - - - -	.25

The proportion of gold is however variable. In one variety of native tellurium, Klaproth found 9 parts in the 100 of gold. Native tellurium occurs in veins with quartz and lithomarge. It is known, in the older works on mineralogy, by the name of *aurum problematicum*, *aurum paradoxicum*, and *white gold ore*.

Graphic Tellurium; Tellure natif graphique, Haüy.—This is worked as an ore of gold at Offenbanya, in Transylvania,

where

where it has hitherto only been found. It is so called, from the particular appearance formed by the aggregation of the crystals; it occurs in veins in porphyry. The colour of graphic tellurium is steel-grey, which is sometimes variously tarnished by exposure to the air: it is also found white, yellow, or lead-grey. It has a shining metallic lustre. It occurs massive, disseminated in leaves, and crystallized in small compressed hexahedral prisms, either with or without tetrahedral summits, and generally arranged in rows on the surface of quartz. There are frequently other prisms attached to the extremities of the former, at right angles with them, giving the whole row an appearance of Persepolitan characters. The planes of the crystals are smooth. "The massive variety, which is very rare, occurs in granular distinct concretions." (Jameson's Min.) It is soft, brittle, and frangible, and yields a lead-grey streak. The specific gravity is 5.723. Before the blow-pipe it burns with a green flame, and is volatilized. The constituent parts, according to Klaproth, are

Tellurium - - - - - -	60
Gold - - - - - - -	30
Silver - - - - - - -	10

Yellow Tellurium Ore.—The colour of this ore is silver-white, passing into yellowish or brass-white and grey. It occurs in grains, and in minute compressed four-sided prisms, with a lamellar structure and bright metallic lustre: it also occurs massive and reticulated: it is soft and somewhat sectile: the specific gravity is 10.878. The constituent parts, according to Klaproth, are

Tellurium - - - - -	44.75
Gold - - - - - -	26.75
Lead - - - - - -	19.5
Silver - - - - - -	8.5
Sulphur - - - - - -	5

This ore, which is worked for the gold and silver it contains, has hitherto been found only at Nagyag, in Transylvania. It occurs in small irregular veins in porpbyry. The most frequent vein-stones are brown spar and quartz: it is sometimes associated with red manganese ore, sulphuret of manganese, native arsenic, plumose antimony, and native gold.

Black Tellurium Ore; Nagyagerz, Werner.—The colour of this ore is between iron-black and dark lead-grey. It occurs massive and in leaves, and also crystallized, in the following forms; oblique four-sided tables, rectangular four-sided tables, six and eight-sided tables, and in acute octohedrons acuminated at the summit. It has a splendent metallic lustre, a more or less curved lamellar structure, with joints on cleavage in one direction. It yields easily to the knife, and is sectile: the thin laminæ are flexible: it stains slightly when rubbed in the fingers. The specific gravity is 8.919. This ore melts very easily before the blow-pipe; the sulphur and tellurium are volatilized; a blackish round-coloured globule remains, which, on being melted with borax, yields a globule which consists of gold alloyed with silver; the slag which remains tinges borax violet-blue. Its constituent parts, according to Klaproth, are

Tellurium - - - - - -	32.2
Lead - - - - - - -	54.0
Gold - - - - - - -	9.0
Silver - - - - - - -	0.5
Copper - - - - - - -	1.3
Sulphur - - - - - - -	3.0

This ore is found associated with the preceding ore of tellurium. An ore of tellurium has lately been discovered in Norway by Esmark. An account of the mines where tellurium is obtained, was published by M. Stutz in the new Memoirs of the Society of Naturalists at Berlin, vol. ii. 1799, and by Esmark, entitled "An Account of a Mineralogical Journey through Hungary, Transylvania, and the Bannat," in the Neuen Bergmannischen Journal, vols. i. and ii. Dr. Clarke, in the 4th vol. of his Travels, has also recently given a description of the tellurium mines, from which we shall briefly extract the most interesting particulars at the close of the present article.

Analysis of the Ores of Tellurium.—These ores are worked for the gold and silver they contain; and the tellurium with which they are combined being extremely volatile at a low degree of heat, this metal was lost in the process of extraction, and was for a long time supposed to be antimony. Muller first suspected that it was a new metal. Bergmann made several experiments upon it, but left the question undecided.

Klaproth, in 1798, read an account of the discovery of this new metal in the public sitting of the Royal Academy of Sciences at Berlin.

The process of extracting the metal from native tellurium is as follows. Six parts of muriatic acid are poured on the crude ore, which has been previously separated as much as possible from its matrix, and mechanically divided. Heat is applied, and three parts of nitric acid are added by degrees. A violent effervescence takes place. By this process the metallic portion of the ore is dissolved, leaving the matrix, which is principally quartz, behind. In the next place, the filtered solution is carefully diluted with as much water as it will bear without being rendered turbid. Caustic potash or soda is added, until the precipitate which is first produced disappears, and only a dark-brown slimy residue remains.

Decant the solution, setting the residuum apart for subsequent examination: it consists of iron and gold. To the alkaline solution add muriatic acid, until it be saturated, most accurately observing the point of saturation. A copious white precipitate ensues, which in a raised temperature falls to the bottom of the vessel in the form of a heavy powder. It is then collected, and washed with equal parts of water and spirits of wine, and dried in a gentle warmth. This is the oxyd of tellurium. To reduce it to a metallic form, it should be heated in a small glass retort along with one-twelfth of its weight of charcoal, or it may be previously moistened with oil. Adapt a receiver to the retort, and let heat be applied till the powder be brought to a state of ignition. Small metallic drops will be seen lining the upper part of the retort, which fall down separately, and are succeeded by others. On refrigeration, the reduced metal (excepting some few metallic drops on the shoulder of the retort) is found fused, with a clean splendent surface, which is most frequently crystalline. At the moment the reduction takes place, a quantity of carbonic acid gas is suddenly generated, carrying along with it some particles of the mixture, which it deposits in the receiver. The other ores of tellurium being worked as gold ore; for their analysis, see GOLD.

Tellurium in the pure reguline state was first obtained by Klaproth, who has given the following description of it: it is of a tin-white colour, verging to lead-grey; it has a very high metallic splendour, and a foliated structure; the surfaces of the fragments are very brilliant. When cooling slowly after fusion, it assumes a crystalline surface. It is very brittle, and easily reduced to powder. Among all the known fusible metals, except the metalline alkalies or earths, tellurium possesses the least specific gravity, being only 6.185.

Tellurium melts sooner than antimony, when exposed to the same degree of heat, but later than lead. It inflames upon charcoal before the blowpipe with a violence resembling detonation, and with a vivid light-blue flame, which on the edges has a greenish tinge. By the continued action of the blowpipe, it is entirely dissipated in a greyish-white vapour, and emits a smell like that of scraped radish.

Tellurium amalgamates very imperfectly with mercury, even when heat is applied. It combines with fulphur in equal proportions when fufed in a gentle heat, and forms a lead-coloured ftriated fubftance. With nitric acid, tellurium yields a limpid colourlefs folution, which is not rendered turbid by water. In the concentrated folution, very light, flender, needle-fhaped cryftals are formed, which commonly affume a dendritical arrangement. Muriatic acid, on the addition of a little nitric acid, affords a fimilar clear folution of this metal. This faturated folution is decompofed by the mere addition of water, which throws down a white powder, but this is again diffolved on adding more water.

The powder thrown down is not a pure oxyd of tellurium, as it is combined with a fmall quantity of muriatic acid. If tellurium be expofed to one hundred times its weight of concentrated fulphuric acid, the acid gradually acquires a tinge of a fine deep amethyftine red. This colour is deftroyed by the addition of water, and by heat.

Carbonated and pure alkalies precipitate tellurium in the form of a white oxyd, combined with water or an hydrate. This is rediffolved by an excefs of alkali. Alkaline fulphurets throw down a dark-brown or blackifh precipitate. Tincture of galls produces a flocculent yellow precipitate. The folutions of this metal in acids are not decompofed by pruffiate of potafh, a property which tellurium poffeffes in common with gold, platina, iridium, ofmium, rhodium, and antimony. Zinc and iron precipitate tellurium from its folution in acids, in the metallic ftate, in the fhape of blackifh flocculi, which acquire a metallic luftre by trituration. Phofphorus is gradually coated with metallic laminæ in a muriatic folution of tellurium.

Oxyd of tellurium on charcoal is reduced with brifk effervefcence, and afterwards volatilized; but if heated in a fmall glafs retort it fufes, and on refrigeration exhibits a ftraw-yellow colour and a ftriated texture. Some of thefe properties of pure metallic tellurium are common to native tellurium. Since the firft difcovery of this metal by Klaproth, it has been further afcertained, that it combines with chlorine in the proportion of 100 parts of tellurium with 90.5 of chlorine. Tellurium forms two diftinct compounds with hydrogen, the one of which is folid, and the other gafeous. The firft is formed by making tellurium the negative furface in water in the Galvanic circuit; by this a brown powder is produced, which is a folid hydruret of tellurium. The fecond is formed by acting with dilute fulphuric acid upon the alloy of tellurium and potaffium, by which a peculiar gas is produced, having a fmell refembling that of fulphuretted hydrogen. It is abforbed by water, and a claret-coloured folution refults, which by expofure to the air becomes brown, and depofits tellurium. After being wafhed with a fmall quantity of water, this gas does not affect vegetable blue colours. It burns with a blueifh flame, depofiting oxyd of tellurium, and unites with alkalies. It precipitates moft metallic folutions, and is itfelf inftantly decompofed by chlorine gas. It may be called telluretted hydrogen gas.

Tellurium is one of thofe metals whofe oxyds poffefs the characters of acids, and form diftinct claffes of falts. The falts formed by a combination of a bafe with the oxyd of tellurium, are called by Berzelius *tellurets*.

Tellurium, according to Klaproth, combines with oxygen in the proportion of 100 parts of the metal with 20.5 of oxygen; but Berzelius determines the proportions to be 100 tellurium and 27.83 oxygen.

This metal has not hitherto been applied to any ufeful purpofe in the arts, which may probably be attributed to its fcarcity, and the comparative recentnefs of its difcovery.

Tellurium Mines.—" The mine of Nagyag is diftant about 15 miles from Deva, in the bannat of Temefwar: it is fituated in the heights of the mountains, lying on the north fide of the river Moros. After croffing the river, we began to climb thefe heights. The roads were not bad, but almoft the whole journey to Nagyag was up a fteep afcent. We were five hours, although drawn by four horfes in a light car, before we reached the fmall town where the mine has been opened.

" As Tranfylvania is the only country in the whole world where tellurium has been difcovered, our curiofity was greatly excited to view the Nagyag mine. At laft the profpect opened upon us with great boldnefs of fcenery quite among the fummits of this mountainous region, and in a manner highly picturefque and ftriking. The fituation of the mine was diftinguifhed by an immenfe heap of difcarded minerals thrown out in working it.

" The whole village of Nagyag has been undermined: the works are not only carried on upon a grand and extenfive fcale, but they are conducted with a degree of neatnefs, for which the Germans have long been famous in mining. Some fpecimens of tellurium are fo exceedingly rich in gold, that in the fale of them for the crown, it is neceffary to weigh them, and to eftimate the price according to the quantity of gold they contain. This kind of ore is always kept locked up in private warehoufes. The common ore lies expofed in heaps, at which the workmen are bufily employed in preparing the ore for ftamping.

" When the mine was firft difcovered, the mountains around it were covered with forefts, which have fince been cut down to fupply the mines with timber. The difcovery of the mine is thus related on the refpectable authority of baron Boon, in his letter to profeffor Feber. ' A Wallachian, whofe name was Armenian John, came to my father, then poffeffed of a rich filver mine at Cuertes, telling him, that as he conftantly obferved flames iffuing from and playing upon a fiffure in the Nagyag foreft, he was of opinion that rich ore might be hid under ground. My father was fortunate enough to liften to the poor man's tale; and accordingly he drove a gallery in the ground which the Wallachian had pointed out. The works went on fome years without fuccefs, and my father had refolved to give them up. However, he made a laft drift towards the fiffure, and there he difcovered the black and lamellated gold ores, which were at firft looked upon as iron glimmer, but proved, when affayed, to be, what they really are, rich gold ores." Travels through the Bannat, Lond. 1799.

" Other veins were afterwards difcovered running parallel to each other from north to fouth, and dipping from weft to eaft. When Boon vifited Nagyag, the mine had only been worked to the depth of 60 fathoms. Its depth is now 150 fathoms. The mountains are entirely compofed of porphyry, covered with red clay or red flate and fandftone. The veins break off as foon as they reach the red flate. Thefe veins contain with the ore, felfpar and fat quartz. There is alfo found here a very rich kind of ore, which is finely woven into the texture of a reddifh felfpar. Among the rich ores, native filver occurs mixed with gold. Another variety is called by the miners *cotton* ore; it confifts of little native filvery gold grains in tellurium, adhering to an argillaceous matrix. All the femi-metals at Nagyag are found, when carefully analyfed, to contain gold. According to Boon, the tellurium mines in the courfe of 20 years yielded above 4,000,000 florins in gold and filver. At the time of our arrival it had been worked 60 years, and was equally productive."

TELLUS, Terra, ⊖, in *Aftronomy*. See Earth.

TELMARA, in *Ancient Geography*, a town of Afia Minor, in Caria.

TELMEEN,

TELMEEN, in *Geography*, a town of Africa, in the country of Sahara, anciently called Almæna; 50 miles W. of Gabs.

TELMES, a town of Morocco; 15 miles from Safi.

TELMISSUS, in *Ancient Geography*, a name given to three towns in Afia Minor, one at the diftance of 60 ftadia from Halicarnaffus, in Lycia; fituated at the S.E. part of the gulf of Glaucus, $2\frac{1}{4}$ leagues N.E. of the promontory Telmeffus, and nearly S.W. of the mouth of the river Glaucus. Its inhabitants were famous for their fkill in augury: this town had a very fine theatre:—the fecond was in Caria, and the third in Pifidia.—Alfo, a mountain of Afia Minor, in Lycia.

TELO MARTIUS, a port of Gallia Narbonnenfis. See TOULON.

TELOBIS, a town of Spain, in the Tarragonefe, belonging to the Jaccetani. Ptol.

TELOBO, in *Geography*, a fmall ifland in the Eaft Indian fea, near the weft coaft of Gilolo. S. lat. 1° 6'. E. long. 127° 15'.

TELON, a name given by the chemifts to fire.

TELONÆ, τελωναι, among the Athenians, farmers of the public revenues: for the feverity with which they were handled, in cafe they failed, fee Potter, Archæol. Græc. lib. i. c. 14. tom. i. p. 81.

TELONIUM. See THELONIUM.

TELONIUS, SALTO, in *Ancient Geography*, a river of Italy, in the country of the Sabines. It fprang towards the S. of Carfeoli, and ran N. to difcharge itfelf into the Velinus.

TELOPEA, in *Botany*, from τηλωπος, *confpicuous at a diftance*, a name very fuitable to this magnificent fhrub, with its fine fcarlet flowers.—Brown Tr. of Linn. Soc. v. 10. 197. Prodr. Nov. Holl. v. 1. 388. Ait. Hort. Kew. v. 1. 212.—Our *Embothrium fpeciofiffimum*, with *E. truncatum* of Labill. Nov. Holl. v. 1. 32. t. 44, conftitute this genus. See EMBOTHRIUM, from which we are unwilling to feparate them, for the reafons given under OREOCALLIS. The extremely clofe natural affinity, and great refemblance, of thefe plants to each other, makes us miftruft even the technical character of the lateral *ftigma* (omitted indeed in Hort. Kew.), fuppofing that organ to be really terminal in *Embothrium*, which on a careful infpection we find reafon to doubt. The efficient part of the ftigma in *E. coccineum* is certainly oblique. We wifh to learn, rather than to dictate, but we cannot confide implicitly in the moft able guide.

TELOS, PISCOPIA, in *Ancient Geography*, an ifland of the Archipelago, fituated S.E. of the ifle of Cos, and N.W. of that of Rhodes. Pliny fays that it was celebrated for its perfumes.

TELPAH, in *Geography*, a town of Hindooftan, in Bahar; 40 miles S.S.W. of Patna.

TELPHUSSA, in *Ancient Geography*, a town of the Peloponnefus, in Arcadia, upon an eminence, at fome diftance from the river Ladon, S.E. of Trophæa. A temple of Ceres was fituated near this town, in which fhe was honoured under the name of Lufia.

TELUMNUM, a town of Aquitanic Gaul, on the route from Aquæ Tarbellicæ to Burdigala, between Cæquofa and Salamacum. Anton. Itin. This is the fame with Tellonum.

TELWARAH, in *Geography*, a town of Hindooftan, in Agimere; 25 miles N. of Buddakano.

TEMA, a town of Africa, in the kingdom of Ningo, on the Gold Coaft.

TEMACHIS, in *Natural Hiftory*, the name of a genus of foffils, of the clafs of the gypfums; the characters of which are thefe: it is of a fofter fubftance than many of the other genera, and of a very bright and glittering hue. The name is derived from the Greek τεμαχος, *fruftulum*, a fmall irregular fragment; the bodies of this genus being compofed of an affemblage of multitudes of irregular flaky fragments, as are all the gypfums; but no genus of them fo vifibly as thefe. Hill. See GYPSUM.

TEMALA, NEGRAIS, in *Ancient Geography*, a maritime town of India, on the weftern coaft beyond the Ganges, S. of Berabonna, where the coaft turns towards the E. at the W. mouth of the river Sabaracus.—Alfo, a river of India, the mouth of which was near Berabonna, and the promontory of Temala.

TEMAN, in *Commerce*, the name of a dry meafure at Mocha, in Arabia, containing 40 meemedas or kellas, and weighing in rice 168 lbs. avoirdupois.

TEMANIK, in *Geography*, a town of Perfia, in the province of Kerman; 25 miles S. of Maftih.

TEMAPARA, in *Zoology*, the name of a peculiar fpecies of lizard, called alfo *tejuguacu*.

It approaches much to the nature of the iguana, but is black, fpotted with white.

TEMBA, in *Geography*, a province of the kingdom of Angola.

TEMBARE, a town on the weft coaft of the ifland of Celebes. S. lat. 1° 27'. E. long. 119° 20'.

TEMBASA, in *Ancient Geography*, a celebrated town of Greece, in the Peloponnefus. Pliny.

TEMBEN, in *Geography*, a town of Abyffinia; 100 miles E.S.E. of Siré.

TEMBLEQUE, a town of Spain, in New Caftile; 13 miles E.S.E. of Toledo.

TEMBRIUM, or TYMBRIUM, in *Ancient Geography*, a town of Afia, in Phrygia.

TEMBROGIUS, a river of Afia, in Phrygia, which ran into the Sangarius.

TEMBRUS, a town of the ifland of Cyprus.

TEMBUL, in *Botany*, a name ufed by fome authors for the plant called betel.

TEMDE, in *Geography*, a river of England, which runs into the Severn, 2 miles above Ludlow.

TEMDEGUE KIAMEN, a poft of Chinefe Tartary; 10 miles S.E. of Tcitcicar.

TEME, or TEAM, a river of England, which rifes in the county of Radnor, and runs into the Severn, 2 miles below Worcefter.

TEMEH, a town of Egypt, on the left bank of the Nile; 9 miles N. of Tahta.

TEMEH *Iffebag*, a town of Egypt; 12 miles N. of Fayoum.

TEMELET, a town of Morocco; 70 miles W.S.W. of Morocco.

TEMELO, in *Ichthyology*, a name ufed by fome for the fifh called in Englifh the *grayling*, and in fome places the *umber*.

TEMEN, in *Geography*, a town of Arabia, in the province of Nedsjed; 80 miles S.S.E. of Jamama.

TEMENDEFUST, or METAFUST, a town of Algiers; 10 miles E. of Algiers.

TEMENEH, a town of Afiatic Turkey, in Natolia; 52 miles W.N.W. of Sinob.

TEMENI, a town of the ifland of Candia; 6 miles S. of Candy.

TEMENI *Porta*, in *Ancient Geography*, a fmall town of Afia Minor, in Lydia.

TEMENIA, a town of Afia, in Phrygia, on the confines of Lycaonia.

TEMENIUM, a fortrefs of the Peloponnefus, on the confines of the Argolide. Here were two temples, one dedicated to Neptune, and another to Venus.

TEMERICUS AGER, a fmall country of Gallia Narbonnenfis, towards the fource of the Rhine.

TEMES, in *Geography*, a river of Hungary, which rifes in the fouth-eaft part of the mountains, and runs into the Danube, oppofite Belgrade.

TEMESA, in *Ancient Geography*, a town of Italy, in Brutium, called Tempfa or Temfa in the time of Strabo.

TEMESCAMANG, in *Geography*, the principal of thofe lakes in Lower Canada formed by the Utawas and its contributory ftreams, which lake has always been a trading port, and which may be faid to continue, by a fucceffion of rivers and lakes, upwards of 50 leagues from the Forks, paffing near the waters of the lake Abbitiby, in N. lat. 48° 30′, which is received by the Moofe river, that difcharges itfelf into James bay. Mackenzie's Travels.

TEMESCHU, a town of New Mexico, in the province of Mayo; 160 miles E.N.E. of Santa Cruz.

TEMESVAR, or Temeswar, a town of Hungary. This is an important fortrefs, fituated on the river Beg, which forms a morafs round it, and is ftrongly fortified. It is the capital of a bannat, the refidence of a governor, and the fee of a Greek bifhop. It was taken by prince Eugene in 1716; and by the peace of Paffarowitz was, with the whole bannat, confirmed to the houfe of Auftria; fince which time it has been almoft wholly rebuilt. It is large and populous; the ftreets broad and well paved. The fortrefs is a caftle with walls nine feet thick, and requires a garrifon of 14,000 men. It contains about 443 fquare German miles, with a population of about 450,000 inhabitants; 52 miles E.N.E. of Belgrade. N. lat. 45° 49′. E. long. 21°.

TEMIN, in *Commerce*, a money of account in Algiers, equivalent to 2 carubes, or 29 afpers. See Coin.

TEMISCHBERG, in *Geography*, a fortrefs of Ruffia, in the government of Caucafus; 60 miles W. of Stavropol.

TEMISSAH, or Temmissa, a large town of Africa, in the province of Fezzan, diftant from Mourzouk, its capital, in an E.N.E. direction, about 120 miles. Here the caravan of pilgrims from Bornou and Nigritia, which takes its departure from Mourzouk about the end of October, or beginning of November, and travels by the way of Cairo to Mecca, arrives in the evening of the feventh day, and ufually provides the ftores of corn and dates, and dried meat, that are requifite for its dreary paffage.

TEMISVAR. See Baba.

TEMITZ, a town of Bohemia, in the circle of Chrudim; 18 miles N.W. of Chrudim.

TEMLOWKA, a town of Algiers, anciently called "Sigus;" 24 miles S.E. of Conftantina.

TEMMA, a town of Africa, on the Gold Coaft. N. lat. 5° 45′. W. long. 0° 55′.

TEMMELISSUS, in *Ancient Geography*, a town of Afia, in Syria, on the route from Celecoma to Lariffa, between Chalcida and Apamea. Anton. Itin.

TEMMES, in *Geography*, a town of Sweden, in the government of Ulea; 20 miles S. of Ulea.

TEMNIKOV, a town of Ruffia, in the government of Tambov; 116 miles N.N.E. of Tambov. N. lat. 54° 28′. E. long. 43° 14′.

TEMNOS, in *Ancient Geography*, a town of Afia Minor, in Ionia, at the mouth and north of the river Hermus. It did not fubfift in the time of Pliny.

TEMOEL, in *Geography*, a town on the weft coaft of the ifland of Celebes. S. lat. 0° 5′. E. long. 119° 35′.

TEMORIS, a town of New Mexico, in the province of Culiacan; 70 miles N.N.E. of Culiacan.

TEMOSOSHI, a town of New Mexico, in the province of Hiaqui; 130 miles E. of Riochico.

TEMPATLAHOAC, in *Ornithology*, the name of a broad-billed bird of the Weft Indies, defcribed by Nieremberg; and by him efteemed a fpecies of duck. It is a variety of the *anas clypeata*. See Duck.

It is of the fize of the common duck; is common on the lakes of Mexico, and is a good eatable bird. Ray.

TEMPE′, in *Ancient Geography*, a celebrated valley of Theffaly, between the mountains Offa and Olympus. Ælian, Pliny, and Strabo reprefent it as 40 ftadia in length, along the middle of which lay the courfe of the river Peneus, which feparated Theffaly from Macedonia. Tempé, according to Livy, was the name given to the wood or foreft, which, though not dangerous, was difficult for an army to pafs, becaufe of two defiles five miles in length; and the river Peneus made a terrifying noife in paffing through this deep valley. Tempé, it is faid, is derived from the Greek τεμπη; in the plural, fignifying wood. Tempé, at its entrance, has a large village, which has been long famous for the accomplifhments of its inhabitants, and for the great trade they carry on with Vienna and the interior of Europe.

Tempé, in *Commerce*. See Stampe.

TEMPELBURG, in *Geography*, a town of Hinder Pomerania; 19 miles W. of New Stettin. N. lat. 53° 29′. E. long. 16° 12′.

TEMPER, in a *Phyfical Senfe*. See Man.

Temper *of a Horfe*, the difpofition of the animal, which fhould be carefully attended to while he is young, as well as in the purchafe.

Temper, in a *Mufical Senfe*. See Temperament, in *Mufic*.

Temper, in a *Mechanical Senfe*. See Tempering.

TEMPERAMENT, Temperamentum, *Temperature*, in *Phyfiology*. See Man.

Temperament, *Temperamento*, in *Mufic*, generally denotes a rectifying or amending of the falfe or imperfect concords, by transferring to them part of the beauty of the perfect ones.

The degrees of the octave, which may be called its *elements*, as being the fmalleft intervals into which it is refolvable, are two greater femitones, two lefs tones, and three greater tones.

Now the different fituation of thefe elements, with refpect to each other, occafions that intervals or concords of the fame name, as thirds, fourths, &c. do not confift of the fame degrees or elements, though there be always the fame number of them: but one fourth, for inftance, is agreeable and perfect, and another not.

To mend thefe imperfect concords, the muficians have bethought themfelves to *temper*, *i. e.* give them part of the agreeablenefs of perfect ones. In order to this, they take a medium between the two, and this they call a *temperament*; which neceffarily produces a new divifion of the octave, or, which amounts to the fame, new elements.

For inftance, whereas naturally its elements are the greater femitone, and the greater and lefs tone; they take a middle tone formed of the greater and the lefs: and the only elements now are the greater femitone, and this mean tone, which renders the five intervals that are tones equal, and thofe that are femitones lefs unequal to thefe.

One might alfo divide each of the five tones of the octave into femitones, which, joined to the two it naturally has, would make twelve: in which cafe, the whole octave would be divided into twelve equal parts, which would be mean femitones.

It is eafy to form various other kinds of temperaments: all the difficulty is to find fuch as are free from two great inconveniencies, *i. e.* which do not alter either all the concords too much, or, at leaft, fome of them.

All fuch divifions of the octave are called *tempered* or *temperative fyftem*.

The temperament does, indeed, according to the definition above given, and confidered in one view, correct fome falfe concords,

concords, yet, in other reſpects, it ſpoils and falſifies both perfect and imperfect concords, and renders diſcords more harſh than they would otherwiſe be, if the intervals were juſtly taken. To explain this, we muſt conſider that all the intervals are founded on the primary proportions ariſing from the numbers 2, 3, and 5, that is, if we do not exceed the compaſs of an octave, $\frac{1}{2}$, $\frac{2}{3}$, and $\frac{4}{5}$. See INTERVAL.

The nearer we come in practice to the true intervals, the more perfect the melody and harmony will be; and it is certain, that the human voice, and ſome inſtruments, as violins, &c. which have no ſtops nor frets, will execute muſic to a great degree of exactneſs; but the caſe is not the ſame with fixed or fretted inſtruments, as harpſichords, organs, lutes, viols, &c. Accuracy is here impoſſible, unleſs we would content ourſelves with always playing in the ſame key, without any tranſition or tranſpoſition whatſoever. In this caſe, indeed, the harpſichord or organ might vie with the accuracy of the voice or violin. For inſtance: if we were to compoſe or play in the key of C, then we might make the ſeveral intervals of that key to be in the following true proportions, 1, $\frac{9}{8}$, $\frac{10}{9}$, $\frac{16}{15}$, $\frac{9}{8}$, $\frac{10}{9}$, $\frac{9}{8}$, $\frac{16}{15}$, that is, in whole numbers, $\left\{\begin{matrix} C & D & E & F & G & A & B & C \\ 24 & 27 & 30 & 32 & 36 & 40 & 45 & 48 \end{matrix}\right\}$ and the inſtrument tuned in this manner, would perform any piece of muſic in C, juſtly compoſed, with great beauty and exactneſs; taking for granted, that every key, fundamental note, or ſound, ought to have its true fifth and fourth, and that theſe ought alſo to have their true fifths and thirds.

Now this being premiſed, it will preſently appear, that in making any tranſpoſition or tranſition from C, we ſhall find ſome falſe concord. Thus, for inſtance, if we proceed to G, and conſider it as a key, or fundamental ſound, we ſhall have the following ſeries of numbers for the octave of G, *viz.* $\left\{\begin{matrix} G & A & B & C & D & E & F & g \\ 36 & 40 & 45 & 48 & 54 & 60 & 64 & 72 \end{matrix}\right\}$

But here the interval between 40 and 54 is falſe, being a comma too much, for the ſecond of a key muſt make a true fifth with the fifth of the ſame key. In like manner, if we were to proceed from C to A, as a new key, we ſhould find the following ſeries for the octave of A, $\left\{\begin{matrix} A & B & C & D & E & F & G & a \\ 40 & 45 & 48 & 54 & 60 & 64 & 72 & 80 \end{matrix}\right\}$ where the interval between A 40 and its fourth D 54 is falſe, being too great by a comma. If any other tranſition were examined, we ſhall always find ſome note falſe; as in F, the ſixth would be redundant by a comma; and in D, the fifth would be deficient by a comma. All which ſhews the impoſſibility of truth and exactneſs of muſic on fixed inſtruments. Yet as theſe inſtruments have their uſe and convenience in ſome reſpects, it was proper to endeavour to find out a method of making them tolerable. It has been obſerved under the article INTERVAL, that the tone major exceeds the tone minor by a comma. Their difference is neceſſary for the truth and perfection of muſic; but yet if theſe tones were rendered equal, the ear would not be offended. And this has ſuggeſted the means of tempering fixed inſtruments. If we were to make all tones equal to the tone major, as ſome imagine the ancients did, then we ſhould find the ditonus, or third, exceeding a true third major by one comma, which would be intolerable. In like manner, if all tones were to be minor, we ſhould have thirds major defective by a comma, which would alſo be intolerable, not to mention other falſe intervals that muſt neceſſarily ariſe from ſuch a ſuppoſition.

Suppoſing then one tone increaſed, and the others diminiſhed by half a comma, we ſhould have our thirds major remain perfect. But ſtill it would be neceſſary to examine what fifths this ſuppoſition would give. Now it is evident that a tone major added to an octave, makes juſt two fifths, thus $\frac{3}{2} \times \frac{3}{2} = \frac{9}{4} = \frac{2}{1} \times \frac{9}{8}$. But the tone here added is a tone major, and the tone we have aſſumed is a temperate tone deficient from the tone major by half a comma; hence the ſum of the two fifths, on this ſuppoſition, will fall ſhort of the truth by half a comma, and conſequently one fifth will be deficient a quarter of a comma. Which difference, although it be ſenſible, yet experience ſhews, that fifths ſo diminiſhed are tolerable.

This temperament is what is called the common or vulgar temperament, and conſiſts, as has been ſaid, in diminiſhing the fifth by a quarter of a comma, in preſerving the third major perfect, and dividing it into two equal tones. Which being ſuppoſed, it follows that the fourth muſt exceed the truth by a quarter of a comma; that the third minor will be deficient by the ſame quantity; that the ſixth minor will be perfect, and the ſixth major redundant by a quarter of a comma; and laſtly, that the ſemitone major will exceed the truth by a quarter of a comma. If we introduce chromatic notes, or flats and ſharps, the ſemitone minor will alſo exceed the truth by a quarter of a comma, and conſequently the difference between the two ſemitones, or the dieſis enharmonica, will be preſerved.

If then we had a harpſichord or organ, with each feint or half note divided, we ſhould have the following notes or ſounds, *viz.* C C♯, D♭, D, D♯, E♭, E, F♯, G♭, G, G♯, A♭, A, A♯, B♭, B, c, in the compaſs of an octave. Yet this ſyſtem of notes, numerous as they ſeem, would not be ſufficient for all tranſitions and tranſpoſitions. For though a piece of muſic tranſpoſed to any of the natural keys C, D, E, F, G, A, B, and to the flats, as E♭ and B♭, and ſome others, would do well; yet, in tranſpoſing to ſharps, as to C♯, we ſhould not find a true third major, unleſs we introduced E♯. And even in flats, as A♭ and E♭, we ſhould not find a true third major in deſcending, or a ſixth minor in aſcending, unleſs we introduced F♭ and C♭. And in like manner, tranſpoſitions to G♯ and E♭ would oblige us to introduce B♯ and C♭. Nor would even this ſuffice, for if neceſſity required a tranſpoſition from the key of C to that of D♯, we ſhould not find a true third major without introducing F♯♯ and c. So that at laſt we ſhall come to a temperate ſyſtem, where, in aſcending, the notes C, D, F, G, A, would each have its ſharp and double ſharp, and the notes B and E each a ſingle ſharp. In deſcending, the notes E, D, B, A, G, would each have their flat and double flat, and the notes F and C each a ſingle flat. And thus the octave would be divided into 31 intervals, whoſe deſignations are

C D♭♭ C♯ D♭ C♯♯ D E♭♭ D♯ E♭ D♯♯
1 2 3 4 5 6 7 8 9 10
E F♭ E♯ F G♭♭ F♯ G♭ F♯♯ G
11 12 13 14 15 16 17 18 19
A♭♭ G♯ A♭♭ G♯♯ A B♭♭ A♯ B♭
20 21 22 23 24 25 26 27
A♯♯ B C B♯ C.
28 29 30 31

Where the letters C, D, E, F, G, A, B, ſignify the common diatonic notes: thoſe marked with a ſingle ♯ or ♭ are the chromatic; and thoſe marked with a double ♯♯ or ♭♭ are enharmonic notes: ſo called, becauſe the interval between them and the next diatonic note is an enharmonic dieſis; for which reaſon, the notes E♯, F♭, and B♯, C♭, are alſo enharmonic.

But even in this diviſion of the octave, all the notes would not have a third major in aſcending and deſcending: thus, for inſtance, D♯♯ has no third major; for this would be F♯♯♯, which is not in the ſcale, nor can any number of additional notes ſuffice in all caſes. But this inconvenience is eaſily remedied, and the ſyſtem conſiderably improved, by making all the thirty-one intervals equal. We have already obſerved, that in the

the common temperament, the femitones major and minor exceed the truth by a quarter of a comma, and that the enharmonic diefis is preferved true. Hence it follows, that the hyperoche, or difference between the chromatic and enharmonic diefis; for example, the interval between Fb and E✻, or Dbb and C✻, &c. will alfo exceed the truth by a quarter of a comma. Now the hyperoche, by our table under INTERVAL, is equal to 1.37695, to which adding a quarter of a comma = 0.25000, we have 1.62695, which differs from the enharmonic diefis 1.90917 only by 0.28222, or about $\frac{2}{7}$ of a comma. Neglecting this fmall difference, let us fuppofe all the thirty-one intervals of the octave equal, it will follow that tranfpofitions to all the notes of the fyftem, whether diatonic, chromatic, or enharmonic, will be equally good, and differ only in pitch or tone, as they ought, but not in accuracy, which muft next be examined.

The divifion of the octave into thirty-one parts may be conveniently done by logarithms. Under the article INTERVAL, I find the logarithm of the octave = 55.79763 commas; confequently each diefis, or divifion of the octave, = 1.79992 comma; hence the fifth, being 18 diefes, will be 32.399 commas. Now the true fifths being 32.640, the fifth confequently in this temperament is deficient by 0.241 parts of a comma, which is lefs than a quarter of a comma by $\frac{1}{110}$ part; and therefore this fifth will, ftrictly fpeaking, be better than that of the vulgar temperament by $\frac{1}{110}$ of the comma; but this is infenfible. Next, proceeding to examine the third, we fhall find it equal to 10 diefes or divifions, that is, 17.999 commas; and the true third major being 17.963 commas, the difference is 0.036, that is, about $\frac{1}{28}$ of a comma. Now as the ear can bear a fifth, altered by a quarter of a comma, it will much more eafily bear the alteration of $\frac{1}{28}$ of a comma in a third major. Again, in this temperament the third minor is indeed, ftrictly fpeaking, worfe than in the vulgar, which differs from the truth but a quarter of a comma, whereas here it differs by about $\frac{1}{27}$ of a comma more; but then this difference is infenfible.

Thus we have been led from the confideration of the vulgar temperament, to the invention of the temperament which divides the octave into 31 equal intervals, commonly called Huygens's temperament. This great mathematician was, indeed, the firft who gave a diftinct account of it, and fhewed its ufe and accuracy. But here, as in many other inventions, we find the hint of the thing much older than the true knowledge of it. See Huygenii Opera omnia, vol. i. p. 748, 749, edit. 1. Lugd. Batav. 1724.

The divifion of the octave into 31 parts was invented in Italy about 300 years ago, by Don Nicola Vincentino. The title of his book is "L'Antica Mufica Riddotta alla Moderna Prattica, &c." Roma, 1555. fol.; and an inftrument, called *archicembalo*, was made upon this fcheme, as Salinas informs us, who at the fame time condemns it, as very difagreeable in practice. But this could be owing to nothing but its not being tuned according to the intention of the inventor. For if all the thirds major of this inftrument were made perfect, and the fifths diminifhed by a quarter of a comma, it is evident that the inftrument would be equally exact with any tuned according to the vulgar temperament, and would fuffice for tranfpofitions to any diatonic or chromatic notes, though not to all the enharmonic, as D✻✻, &c. becaufe we fhould not find its third major. And if the inftrument were tuned according to M. Huygens's fcheme, of making all the divifions equal, it would then have all the 31 keys equally good, and very near the truth. See Salinas, lib. iii. The title of his work is "Francifci Salinæ Burgenfis de Mufica Libri Septem," Salmanticæ, 1577, fol. Merfennus's work is intitled "Harmonicorum, Libri XII. authore F. M. Merfenno Minimo, Lutetiæ Parifiorum," 1648, fol. He publifhed another book before this, the title of which is "Harmonie Univerfelle, contenant la Theorie et la Pratique de la Mufique," Paris, 1636, fol. 2 vols.

Hence it is plain, Salinas and Merfennus had not fufficiently examined this matter.

The ufe of this temperament of M. Huygens deferves to be introduced into the practice of mufic, as it will facilitate the execution of all the genera of mufic, whether diatonic, chromatic, or enharmonic; nor does the multiplicity of its parts render it impracticable, the author affuring us that he had a harpfichord made at Paris with fuch divifions, which was approved of and imitated by fome able muficians. Merfennus alfo gives a fcheme for this purpofe; and Salinas fays he faw and played upon fuch an inftrument. See alfo Don Vincentino before cited, lib. v. p. 99, &c.

M. Huygens, to facilitate the tuning of inftruments with fuch divifions, has given us a table of the parts of an octave, according to his fyftem, together with their logarithms. The table is as follows:

The divifion of the octave into 31 equal parts.					The divifion of the octave according to the common temperament.

The fecond column of this table contains the numbers expreffing the length of chords making 31 equal divifions, the longeft, anfwering to C, being fuppofed to be divided into 100,000 parts.

In the third column are the fyllables by which the notes are ufually named in France; and the afterifc * fhews fome enharmonic notes, of which that near *fol* is moft neceffary.

In the fourth column are the letters commonly ufed to denote the found of the octave.

The

The numbers of the second column were found by means of those in the first, which are their respective logarithms; and these were found by dividing 0.30102999566, the logarithm of 2, by 31. The quotient 97106450 is marked N, and being continually added to the logarithm of 50000, that is, to 4.6989700043, gives all the logarithms of the first column to the greatest 4.9999999993, which being extremely near to 5.0000000000, the logarithm of 100000, shews the operation to have been rightly performed.

The fifth column shews the lengths of the chords in the common temperament; and the sixth column contains their respective logarithms. Vide Huygenii Opera, vol. i. p. 752, 753.

The learned author of this temperament has not given the notes answering to all the divisions of the octave; but that may easily be supplied from what has been said above when we derived this temperament from the consideration of the common.

As Huygens has not given the names of all the intervals that occur in his temperate scale, we shall here insert them in the octave, from C to *c*, with their respective measures in the commas, and tenths of a comma

Intervals.		Names.	Measures.
From C to	Dbb	1. Diminished second, extreme flat second, or enharmonic diesis.	1.8
	C※	2. Semitone minor, or chromatic diesis.	3.6
	Db	3. Flat second, or semitone major.	5.4
	C※※	4. Double semitone minor.	7.2
	D	5. Second, or tone.	9.0
	Ebb	6. Diminished third, or extreme flat third.	10.8
	D※	7. Superfluous second.	12.6
	Eb	8. Third minor, or flat third.	14.4
	D※※	9. Extreme superfluous second.	16.2
	E	10. Third major, or sharp third.	18.0
	Fb	11. Diminished fourth.	19.8
	E※	12. Superfluous third.	21.6
	F	13. Fourth.	23.4
	Gbb	14. Extreme diminished fifth.	25.2
	F※	15. False fourth, or tritonus.	27.0
	Gb	16. False fifth, or semidiapente.	28.8
	F※※	17. Extreme superfluous fourth.	30.6
	G	18. Fifth.	32.4
	Abb	19. Diminished sixth, or extreme flat sixth.	34.2
	G※	20. Superfluous fifth.	36.0
	Ab	21. Flat sixth, or sixth minor.	37.8
	G※※	22. Extreme superfluous fifth.	39.6
	A	23. Sharp sixth, or sixth major.	41.4
	Bbb	24. Diminished seventh, or extreme flat seventh.	43.2
	A※	25. Superfluous sixth.	45.0
	Bb	26. Flat seventh, or seventh minor.	46.8
	A※※	27. Extreme superfluous sixth.	48.6
	B	28. Sharp seventh, or seventh major.	50.4
	*c*b	29. Diminished octave.	52.2
	B※	30. Superfluous seventh.	54.0
	c	31. Octave.	55.8

The temperate diesis enharmonica of Huygens being 1.8 comma, nearly, which is easily remembered, the measure of any interval in the octave may be found by multiplying it by the number denoting the place of that interval. Thus the sixth minor, being the twenty-first interval, will be = 1.8 × 21 = 37.8. The octave, being the thirty-first, will be = 31 × 1.8 = 55.8, which does not differ from the truth by more than 0.00237, that is, not by $\frac{1}{100}$ of a comma, and therefore perfectly insensible. See INTERVAL.

All the intervals in the foregoing table, either have received names, or at least might receive them, from a perfect analogy to the names in use among practical musicians; but many of these intervals are as yet unheard of among practitioners. Perhaps, if all the genera of ancient music were restored, every interval here mentioned might be of use, either in melody or harmony, and thereby greatly add to the variety of composition.

We have already mentioned the advantages of M. Huygens's system; but its excellency will better appear by comparing it with the schemes of others. We may distinguish and name the different temperaments by the number of equal parts into which the octave is supposed to be divided. The temperaments that occur in books are temperaments of 12, 19, 31, 43, 50, 53, and 55 parts, of which in order.

The temperament of 12 parts is founded on the supposition that the semitones major and minor may be made equal. Hence the octave will be divided into 12 equal semitones, seven of which will make the 5th, four the 3d, and three the 3d minor.

The temperament of 19 parts goes upon the supposition that the semitone major is the double of the semitone minor. Hence the tone will be 3, and the third major 6. The diesis enharmonica will be 1, and consequently the octave, being three thirds major and a diesis, will be 19. The fifth contains 11 parts. The harpsichord, in this scheme, will have every feint cut in two, one for the sharp of the lower note, and the other for the flat of the higher. Between B and C, and between E and F, will be interposed keys, which must serve for the sharps of B and E, and the flats of C and F respectively.

The temperament of 31 parts is M. Huygens's, already described: here the semitones are as 3 to 2. The third major is 10, and the fifth 18.

The temperament of 43 is M. Sauveur's, and by him very fully described in the Memoirs of the Royal Academy of Sciences, A.D. 1701, 1702. He supposes the proportion of the semitones to be as 4 to 3. Hence his tone is 7, the third major 14, the fifth 25, and the octave 43. What musical foundation this learned gentleman went upon in the investigation of this temperament, is not known: but it seems liable to insuperable difficulties; for here the diesis enharmonica is but the half of the difference between it and the chromatic diesis: whereas, in truth, this difference, instead of being double of, is really less than the enharmonic diesis, as was long ago objected to him by Mr. Hensling, and appears from the table under INTERVAL. Miscel. Berolin. tom. i. p. 285, 286.

Besides, his enharmonic diesis falls greatly short of the truth, being but 1.27 of a comma, which is an error of 0.64, or nearly $\frac{2}{3}$ of a comma. Whereas, in M. Huygens's temperament, the error of the diesis is almost insensible, being but $\frac{1}{10}$ of a comma. Nor are the practical advantages of M. Sauveur's system any ways comparable to Huygens's. His fifth is indeed, strictly speaking, better; but so little, that the difference is not sensible, not being $\frac{1}{7}$ of a comma. On the other hand, his thirds are sensibly worse, the major being $\frac{1}{5}$, and the minor $\frac{2}{5}$ of a comma falſe. Whereas Huygens's third major does not differ ſenſibly from the truth, and the minor has no ſenſible difference from the third minor deficient by $\frac{1}{4}$ of a comma of the common temperament, which ought to be deemed the limit of the diminution of concords. If we add to this, that the much greater number of parts in M. Sauveur's octave, makes it much more intricate than M. Huygens's, and that theſe parts would be falſe or uſeleſs, even ſuppoſing the enharmonic genus reſtored, no muſician will long heſitate which he ought to prefer.

The temperament of 50 parts is propoſed by Mr. Henſling in the Miſcellan. Berolin. above cited: he takes the proportion of the ſemitone as 5 to 3: hence his tone is 8, the third major 16, the fifth 29, and the octave 50. The third major and fifth in this ſyſtem will be worſe than Huygens's, though the third minor be a little better. The third major is here leſs than the true, and the fifth deficient by more than $\frac{1}{4}$ of a comma, which is a fault, not to mention the inconveniency ariſing from dividing the octave into 50 parts; beſides, 5 : 3, the proportion of the ſemitones here aſſumed, although expreſſed in greater numbers, is not ſo near the truth as M. Huygens's of 3 : 2. See RATIO.

The temperament of 53 parts is mentioned by Merſennus. Here the tones will be unequal, 9 being the tone major, and 8 the minor. Hence the third major will be 17, and the fifth 31, which laſt does not differ from the truth by above $\frac{1}{131}$ part of a comma. The third minor is alſo more perfect than in M. Huygens's ſyſtem. But the multiplicity of parts in the octave of this ſyſtem renders it too intricate; and the diſtinction of tones major and minor upon fixed inſtruments is impracticable.

The laſt temperament we have to mention is that of 55 parts, which M. Sauveur calls the temperament of practical muſicians. Its foundation lies in aſſuming the proportion of the ſemitones as 5 to 4; ſo that the tone will be 9, the third 18, and the fifth 32. The fifth in this ſyſtem, as in that which makes the ſemitones equal, is nearer the truth than M. Huygens's, but this advantage is not $\frac{1}{15}$ of a comma; and on the other hand, the thirds, both major and minor, are here greatly miſtuned, as will appear by the annexed table, exhibiting the thirds and fifths of theſe ſeveral temperaments, as alſo the thirds and fifths of the common temperament, and two mentioned by Salinas, marked 1ſt Salin. 2d Salin. The letter V. ſtands for the fifth; III. for the third major; and 3. for the third minor. The fifths are all deficient, but the thirds are ſometimes leſs than the true; the firſt are marked +, the others −.

Temperaments.	V. Com.	Error.	III. Com.	Error.	3 Com.	Error.

Temperaments formed by the diviſion of the octave into equal parts, may be called geometrical temperaments. The common, and the two mentioned by Salinas, do not proceed upon this foundation; the intention of the firſt inventors not having been to make tranſpoſitions to every note of the ſyſtem equally good; but only to make the moſt uſual tranſitions in the courſe of a piece of muſic tolerable. Hence the parts of the octave, in their ſuppoſition, were not all equal.

The common temperament, as we have ſaid, preſerves the third major perfect. The firſt of Salinas preſerves the third minor perfect. In the ſecond of Salinas, the ſemitone minor is perfect. The foundation of his firſt temperament is making the temperate tone equal to the tone minor and $\frac{1}{3}$ of a comma, or the tone major leſs $\frac{2}{3}$ of a comma. Hence his fifth and third major will be deficient by $\frac{1}{3}$ of a comma; and the third minor conſequently will be true. The ground of his ſecond ſcheme is, to add $\frac{2}{7}$ of a comma to the tone minor, or take $\frac{4}{7}$ from the tone major for his temperate tone. Hence the fifth will be deficient by $\frac{1}{7}$ of a comma, and the thirds major and minor each deficient by $\frac{1}{7}$ of a comma. Conſequently, the ſemitone, being their difference, will be preſerved.

As to Mr. Salmon's ſcale in the Philoſophical Tranſactions, there is nothing true in it, but the diatonic ſcale of C. His ſcale for A is falſe, the fourth being erroneous by a comma: moſt of his ſemitones are likewiſe falſe. In ſhort, it can neither be conſidered as a true ſcale, nor as a temperament.

Before we cloſe this article, it may be proper to add a few words about the method of invention of the foregoing geometrical temperaments. M. Huygens having had the hint of a diviſion of the octave into 31 parts, had nothing farther to do but to examine it by logarithms. But ſuppoſing no ſuch hint had been given, he might have inveſtigated it directly, by the method laid down by himſelf, and alſo by Dr. Wallis and Mr. Cotes, for approximating to the value of given ratios in ſmaller numbers. We have given Mr. Cotes's method under RATIO. The application of that method to the preſent purpoſe is thus: the ratio of the octave to the third major is 55.79763 to 17.96282, and the approximating ratios will be,

1. Greater than the true 28 : 9, 87 : 28, &c.
2. Leſs than the true 3 : 1, 31 : 10, 59 : 19, 205 : 66, &c.

The ratios greater than the true muſt all be rejected; becauſe they give the third major leſs than true, and conſequently the tone (its half) deficient by above $\frac{1}{4}$ of a comma; which gives the fifth deficient above $\frac{1}{4}$ of a comma: but this ought not to be. The firſt of the ratios leſs than true is 3 : 1, or 12 : 4, which is the temperament of 12 parts before deſcribed, and too inaccurate. The next is 31 : 10, or M. Huygens's. The reſt divide the octave into too many parts.

The ſame may be alſo found thus: the ratio of the octave to to the common temperate fifth, deficient by $\frac{1}{4}$ of a comma, is 56.79763 to 32.38952. The approximating ratios to which are,

1. Greater than the true 2 : 1, 7 : 4, 19 : 11, 50 : 29, &c.
2. Lefs than the true 1 : 1, 3 : 2, 5 : 3, 12 : 7, 31 : 18, 205 : 119. Where we have the temperaments of 12, 19, 31, and 50 parts, before examined.

And here all ratios greater than the true ought to be rejected, becaufe they give the fifth lefs than true, that is, in this cafe, deficient by more than $\frac{1}{4}$ of a comma.

If we inveftigate the approximating ratios to the ratio of the femitones major and minor, or 5.19529 to 3.28612, we fhall have the ratios 1 : 1, 2 : 1, 2 : 2, 5 : 3, which refpectively give the temperaments of 12, 19, 31, and 50 parts, before defcribed.

Again, inveftigating the approximating ratios of the fifth to the third major, we fhall find 7 : 4, 9 : 5, 11 : 6, 29 : 16, which will alfo give the temperaments 12, 19, 31, 50, as before.

Laftly, the approximated ratios of the octave to the true fifth are 12 : 7 and 53 : 31 greater than the true; the others being of no ufe, fince the fifth muft neceffarily be diminifhed. Here we find the temperament of 53 parts. As to the temperaments of 43 and 55, being deftitute of any mufical foundation, it is no wonder they do not appear by this method of inveftigation.

M. Huygens, in his Cofmotheoros, fays that the tone or pitch of the voice cannot be preferved, unlefs the confonants be tempered, fo as to deviate a little from the higheft perfection. For the proof of this affertion, he brings a melody confifting of the following founds, C, F, D, G, C; where, if the intervals were to be fung perfect, by taking the interval from C to F a true fourth afcending, from F to D a third minor defcending, from D to G a true fourth afcending, and laftly, from G to C a true fifth defcending, we fhould fall a comma below the C from whence we began. Therefore, if we were to repeat this feries of notes nine times, we fhould at laft fall near a tone major below our firft found.

M. Huygens's folution of this difficulty is, that we remember the note from whence we fet out, and return to it by a fecret temperament, thereby finging the intervals a little imperfect; which, he fays, will be found neceffary in almoft all fongs or melodies.

A like difficulty is mentioned in the Memoirs of the Royal Academy of Sciences; and is there urged for the neceffity of a temperament, even for finging in the fame key. And M. Huygens's folution of the difficulty is there approved of. Ann. 1707, p. 264.

But the folution of thefe learned gentlemen is, as yet, far from being decifive. No experiment has yet been brought to fhew that the human voice fings tempered notes; not even when accompanied by tempered inftruments. It feems to us, on the contrary, that an exercifed voice, guided by a good ear, fings true, even though accompanied by a miftuned inftrument, as harpfichords moft frequently are, efpecially in tranfpofed keys. And were thefe inftruments always as well tuned as art could make them, yet their tones would be equal; and it feems evident to the ear, that the human voice finging naturally two tones in fucceffion, as C, D, E, never makes them equal: and cannot, without great difficulty, and by means of a variation of harmony, be brought to make them equal.

Another folution, therefore, of M. Huygens's difficulty, muft be fought for. The truth feems to be, that the fecond of the key muft be the true tone major above the key and therefore the third between the fecond and fourth of the key muft be fung deficient by a comma. Thus in the key of C, from C to D will be a tone major = $\frac{9}{8}$, and from D to F will be a deficient third = $\frac{32}{27}$. See INTERVAL.

M. Huygens's melody, therefore, will ftand as follows:

$$\left\{\begin{matrix} C & & F & & D & & G & & C \\ \frac{4}{3} & \times & \frac{27}{32} & \times & \frac{4}{3} & \times & \frac{2}{3} & = & 1 \end{matrix}\right\}$$

And the voice would fing the interval F, D, juft as if the note E had been interpofed; in which cafe the notes would be

$$\left\{\begin{matrix} C & & F & & E & & D & & G & & C \\ \frac{4}{3} & \times & \frac{15}{16} & \times & \frac{9}{10} & \times & \frac{4}{3} & \times & \frac{2}{3} & = & 1 \end{matrix}\right\}$$

Thefe notes all come within the diatonic fcale of C; and the voice naturally falls upon the note from whence it fet out. The fame anfwer will hold in the example mentioned in the Memoirs of the Academy of Sciences; where the intervals ♭B, G, E, C occur. And here the interval from ♭B to G fhould be taken = $\frac{27}{32} = \frac{15}{16} \times \frac{9}{10}$, as in the former example; and for the fame reafon, the key being F.

There feems, therefore, no repugnancy between the practice and theory of mufic, while the melody is confined to one key; but it muft be owned, that in tranfitions from key to key, efpecially where feveral parts are to make harmony with each other, there ftill remain difficulties, not mentioned by M. Huygens, or any other writer we know of, which might deferve a farther examination.

We muft not omit mentioning, that the learned Dr. Smith, in his Harmonics, has not only carried the theory of temperaments far beyond all the authors that preceded him; but has fhewn how to tune an inftrument according to any propofed temperament, by the ear only, which is certainly a moft ingenious difcovery.

This learned author prefers what he calls the temperament of equal harmony, which differs infenfibly from the divifion of the octave into fifty parts, to all others; and infifts, that it labours under the feweft defects, and is of all others the moft agreeable in practice. In the fyftem of equal harmony, the temperaments of the fifth, third major and third minor, are refpectively $\frac{5}{18}$ and $\frac{7}{18}$ and $\frac{2}{18}$ of a comma lefs than the truth.

It would be impoffible here to do juftice to the learned author's reafonings on this fubject; we fhall only add, that he eftablifhes, contrary to the common opinion, that the lefs fimple confonances, generally fpeaking, will not bear fo great temperaments as the fimpler confonances.

Dr. Smith mentions a temperament communicated to him by the ingenious Mr. Harrifon, which confifts in making the proportion between the octave and third major equal to that of the circumference of a circle to its diameter. In this temperament the third major is diminifhed by $\frac{3}{5}$ of a comma, but the third minor is very near the truth, and extremely beautiful.

A late author feems to think the divifion of the octave into thirty-one parts, not to be of modern invention, but neceffarily implied in the doctrine of the ancients. At firft fight, it would feem as if the ancients made but twenty-four diefes or divifions in the octave, *viz.* ten to each fourth, and four to the tone; which (the octave being equal to two fourths and a tone) gives twenty-four diefes to the octave. But the author juft quoted contends, that this divifion is to be underftood only in one tenfion, that is, either afcending or defcending; but that, accurately fpeaking, if we confider all the diefes, or divifions of the fourth, both afcending and defcending, we fhall find thirteen; five to each tone, and three to the femitone major; and confequently thirty-one divifions in the octave. Thefe, indeed, are not all naturally equal; but if we make them fo, we fhall ſhall have a temperament known by the moderns under the name of Huygens's temperament. Dr. Pepuſch, in Phil. Tranſ. N° 481. p. 273. See the article Diesis.

Such was the hiſtory and theory of temperament about half a century ago. But as our keyed and wind inſtruments have extended their compaſs and powers, and all the ancient laws of relative modulation are diſregarded by modern compoſers, moſt practical muſicians incline to equal harmony, in which all the keys participate of the imperfection of the ſcale when the octave is confined to twelve ſemitones, of which every one occaſionally ſerves for two or three different purpoſes. As the note A natural, for inſtance, is ſometimes B double flat, and ſometimes G double ſharp, E natural is obliged to officiate for D double ſharp, and ſometimes for F flat.

There are, however, theoriſts who calculate, but never liſten, and who think temperament an abomination, a deadly ſin againſt Pythagoras and his *triple progreſſion*. Now as it is generally agreed that the ancients had no ſimultaneous harmony, or muſic in parts, and allowed of no conſonances but the uniſon, octave, 4th, and 5th, they did wiſely to make them as perfect as poſſible; but ſince the invention of counterpoint, and new inſtruments of fixt tones by keys, frets, and additional ventages, which furniſh but twelve ſemitones, whereas thirty-one different ſounds are wanting to ſupply two diſtinct ſounds for ſynonimous notes, ſuch as A ※ and B b, C ※ D b, D ※ E b, &c. temperament, though it a little diminiſhes the perfection of certain notes, the whole inſtrument is bettered by it, and rendered equally fit for all keys. Every concord, except the uniſon and octave, has a latitude, and allows of *bearings* without offending the ear. A perfect 5th makes an intolerable major 3d below it. And as the 3d, though called an imperfect concord, is the moſt grateful and pleaſing of all the concords when perfect; contrapuntiſts do wiſely to allow tuners to rob 4ths and 5ths of a little of that perfection which they can ſpare without injury, for the good of the whole. If the learned harmoniſt, the abbé Rouſſier, is living, this relaxation of Pythagorean diſcipline, and want of due reſpect for the *triple progreſſion*, will, we fear, diſturb and render him ſomewhat intemperate in cenſuring our *abſurdity*.

We have always regarded muſic as an object for the ear, and wiſh to make it as pleaſing to that ſenſe as poſſible; and have been ſo long accuſtomed to tempered ſcales, as to receive more pain than pleaſure from muſic performed on an inſtrument tuned by perfect 5ths throughout, that is, by the *triple progreſſion*. We ſhall, however, preſcribe no excluſive method of tempering the ſcale; as almoſt every man who tunes his own inſtrument has a ſyſtem of his own: we ſhall only obſerve, that the greateſt muſicians in the courſe of their lives have often changed their method. In our cathedrals and pariſh-churches in general, where the natural keys are made as perfect as poſſible, at the expence of A b, D b, F ※, and C ※, keys that have never been admitted within the pale of the church, organiſts that hear little other muſic, are extremely offended by equal participation of the ſcales, when the pure harmony of their favourite keys is deformed by temperament: and thoſe accuſtomed to the levelling ſyſtem of equal harmony, on the contrary, hold the *wolf* in as much abhorrence, as they would the deſtructive wolf in the Gevauden. At preſent, our tuners mitigate the extremes of equal and unequal temperament, by favouring the natural keys, and making the extraneous or tranſpoſed keys ſomewhat leſs perfect; but devoting the *wolf* to total deſtruction.

It is imagined by many, that the character of keys, particularly the minor, depends on the imperfection of the ſcales, occaſioned by unequal temperament: as F minor is plaintive, E b ſolemn, and E ※ brilliant. But though the difference between the pitch of E b and E ※, D ※ and E b, is but half a note, whatever may be the general pitch of the inſtrument, whether half a note too high, or half a note too low, theſe keys ſtill retain their character, it ſhould ſeem not from the tuning or elevation of the general ſyſtem, but from ſomething for which we are unable to account. See Music, and Sound.

TEMPERATE Zone. See Zone.

TEMPERATURE, in general, denotes the degree of free caloric which a body appears to poſſeſs when compared with other bodies; or, in other words, the ſtate of a body in relation to its capability of producing in other bodies the effects ariſing from the preſence of free caloric. Sir Humphrey Davy defines temperature to be "the power bodies poſſeſs of communicating or receiving heat, or the energy of repulſion." But this definition appears to us to be a little ambiguous, for temperature is not a term indicative of a poſitive faculty in bodies, as this definition may be underſtood to mean; but, as before obſerved, is merely a relative term, expreſſive of the degree in which bodies, in conformity to the grand law of the equal diſtribution of free caloric, can affect, or be affected by other bodies of a lower or higher temperature, that is, poſſeſſing more or leſs free caloric than themſelves.

There are two means of meaſuring the temperature of bodies, namely, by our ſenſations, or by the different degrees of expanſion produced in bodies on being ſubjected to different degrees of free caloric. The firſt of theſe, from various obvious cauſes, is ſo imperfect and limited, that no dependence can be placed upon it as a meaſure of temperature. The ſecond is much more regular and extenſive, and is, therefore, always at preſent employed. "When two bodies produce the ſame increaſe or diminution of volume in a third body, to which they are equally applied, they are ſaid to be of the ſame temperature; and any body is ſaid to be at a higher or lower temperature, as it produces a greater or leſs expanſion in another body with which it is in contact." Inſtruments founded upon the principle of the expanſion of bodies by heat, and deſtined to meaſure degrees of temperature, are called *thermometers*, or, when the temperature is very high, *pyrometers;* which ſee. Under the ſame heads alſo the important queſtion is diſcuſſed, how far the expanſion of bodies by heat is to be conſidered as an indication of their real temperature. See alſo Caloric.

Temperature *of the Atmoſphere*. See Atmosphere.

Temperature *of Climate*. See Climate.

Temperature *of the Earth*, is that degree of ſenſible heat which exiſts on the ſurface, or in the interior of the ſolid part of the globe. The temperature of the atmoſphere is frequently deſcribed as the ſame with the temperature of the earth, from which it is eſſentially diſtinct. The ſenſible heat of the atmoſphere varies with the latitude, the ſeaſon, and the elevation of the place in which the obſervation is made. The ſuperficial temperature of the earth varies alſo with the latitude and the ſeaſon, and in a ſtill greater degree if the land be dry; but the internal temperature of the earth appears to be permanent in each place throughout the whole year. At a certain depth under the ſurface, the thermometer always indicates the ſame degree of heat; and the difference between the permanent internal temperature in different latitudes, is much leſs than that which exiſts at the ſurface. The depth at which the thermometer remains ſtationary about latitude 52°, is 80 feet: nearer to the equator,

equator, or the poles, a greater depth would be neceſſary to obtain the permanent temperature. At ſtill greater depths, probably, the temperature under each degree of latitude is the ſame all over the globe, except in the vicinity of volcanic fires.

M. Volney, in his travels through North America, ſpeaking of the temperature of the earth, endeavours to oppoſe the opinion of its permanent internal temperature. Setting out from lake Superior, he ſays, and proceeding weſt to the Stoney mountains, and travelling north as far as latitude 72°, the country now well known to the Canadian traveller, diſplays a climate that for ſeverity of cold can be compared only to Siberia. From latitude 46°, the earth is frozen during the whole year. At ſeveral trading poſts between latitude 50° and 56°, it was found impoſſible to have wells. Mr. Shaw had attempted to dig one at the poſt of St. Auguſtin, about forty miles from the mountains; but though it was in the month of July, the ground was frozen at the depth of three feet from the ſurface, and as it grew harder he was obliged to give up the attempt. He relates alſo an account of Mr. Robſon, an Engliſh engineer, who attempted to ſink a well at Prince of Wales's fort, latitude 59°, in the month of September. He firſt found thirty-ſix inches of earth thawed by the preceding warm weather, then a ſtratum of eight inches frozen as hard as a ſtone; under this a ſtratum of ſandy friable earth, froſty and very dry, in which his borer could find no water. The celebrated traveller Ledyard, ſays Volney, affirms, that at Yakutſk, not ſo high as latitude 62°, wells of water cannot be obtained, becauſe it is found by experiment that water freezes at the depth of ſixty feet. From theſe circumſtances, M. Volney would infer that the internal part of the earth is in a conſtant ſtate of congelation. Some of the above obſervations, we believe, were inaccurately made; and it has been too haſtily determined, that the earth is frozen during the whole year in North America, even in latitude 46°; for this is not the caſe 11° further north. We have been favoured with the following ſtatement from an intelligent medical gentleman, who was ſome years reſident in Hudſon's Bay. "On digging a well at York fort, Hudſon's Bay, latitude 57° 7′, in the beginning of October, the following circumſtances were remarked. About thirty inches from the ſurface, a bed of frozen earth, about twelve inches thick, was met with: below was a bed of looſe ſandy clay, about half a yard thick, which was ſucceeded by a bed of the ſame clay, rendered perfectly hard and ſolid by froſt. Sinking lower, ſimilar beds of frozen and looſe earth were found, alternating with each other; the frozen beds, however, conſtantly decreaſing in thickneſs, though not regularly, and at a certain depth they ſeemed to diſappear entirely. Theſe frozen ſtrata are conſidered by the inhabitants as indications of the ſeverity of the preceding winters, each ſtratum being ſuppoſed, with much probability, to be formed in different years, and to be travelling downward until they are thawed by the internal temperature of the earth. The proceſs by which they ſink down may be explained, on the ſuppoſition that the upper ſurface is diminiſhing by heat during ſummer, and the under ſurface increaſing by the congelation of moiſture in contact with it. Another circumſtance, which took place in the ſame latitude, may ſerve to elucidate the obſervation of Ledyard, that the water was conſtantly frozen at ſixty feet under the ſurface at Yakutſk." A well had been ſunk which yielded a plentiful ſupply of water during the firſt ſummer; but the water, being expoſed to the air, froze during the next winter, and remained frozen ever after, being too far below the ſurface to be thawed. Hence it appears that water exiſts unfrozen at a moderate depth under the ſurface in the coldeſt climates, when it has no communication with the external air. The effect of the ſummer heat in the ſame latitude extends about ſeventeen inches under the ſurface, where the ground has been ſhaded; but where it has been expoſed to the ſun, the ſurface is thawed to the depth of three feet. From the ſmall depth to which the ſolar heat penetrates, we may infer that the water below is kept in a fluid ſtate by the internal heat of the globe. It has been generally ſuppoſed, that the permanent temperature of each latitude is the ſame nearly as the mean annual temperature of the atmoſphere, and that this is indicated by the temperature of ſprings or deep wells; but the temperature of ſprings will vary with that of the ſtrata near the ſurface through which they run. (See TEMPERATURE *of Springs*.) It is to be regretted that more numerous obſervations have not been made on the temperature of deep mines. From obſervations recently made in Cornwall, it appears that the temperature increaſes with the depth, at leaſt in ſome of the mines, and in the loweſt it was not leſs than 70°. This may, perhaps, be owing to the chemical changes which are taking place; for it appears, from the evidence of the overſeers of the mines, in reply to certain queries propoſed by the Royal Geological Society of Cornwall, that the water is found conſtantly warmer in the vicinity of veins of copper-ore, than it is in the vicinity of tin-ore: the former veins are in general worked to a greater depth than the latter. It remains to be aſcertained whether this increaſe of temperature be owing to chemical cauſes, or is invariable at the ſame diſtance from the ſurface. The decompoſition of pyrites in copper veins would ſeem to point out a cauſe for the increaſed temperature in their vicinity; it is evident, however, that it is not derived from the ſolar rays. It ſeems reaſonable to believe, from what we at preſent know of the internal temperature of the earth, that there exiſts a permanent ſource of heat within the globe, though we are unacquainted with the cauſes by which it is generated. We are equally ignorant of the cauſes by which light is generated on the ſurface of the ſun: one operation is not more ſurpriſing or inexplicable than the other; nor is the difficulty removed, by ſuppoſing the ſun to be ſurrounded with a luminous atmoſphere. Some philoſophers have maintained the opinion, that the earth has been conſtantly growing colder ſince the period when it was firſt inhabited, and that the organic remains of elephants and other animals, (ſuppoſed to be ſimilar to thoſe of tropical climates,) which are found in Siberia, offer a demonſtrative proof, that the arctic regions once enjoyed the temperature of the torrid zone. It has ſince been aſcertained, by the elaborate reſearches of M. Cuvier, that theſe animals were not of the ſame ſpecies as the African or Aſiatic elephant. A moſt convincing proof of this was afforded by the entire body of one of theſe elephants, which was diſcovered imbedded in ice near the mouth of a river in the north of Siberia, by a Tunguſian fiſherman, in the year 1799. It firſt preſented a ſhapeleſs maſs projecting from an ice-bank. Two years afterwards he could diſtinctly ſee that it was the body of an enormous animal; the entire flank and one of its tuſks had become diſengaged from the ice. In 1803, the ice beginning to melt earlier than uſual, the whole body was diſengaged, and fell from the ice-bank on the ſandy ſhore. In 1806, Mr. Adams went to examine this animal, which ſtill remained on the ſand, but its body was much mutilated. The ſkin was extremely thick and heavy, and as much of it remained as required the exertions of ten men to carry away. More than thirty pounds of the hair and briſtles of the animal were collected. Some of this

this hair was presented to the Museum of Natural History in Paris. It consists of three distinct kinds. The one is stiff black bristles, a foot or more in length; another kind is a coarse flexible hair, of a reddish-brown colour; the third kind is a coarse wool, which grew among the roots of the long hair. These afford undeniable proof, that this animal belonged to a race of elephants inhabiting a cold region, and was not fitted to dwell in the torrid zone. This animal was a male, and had a long mane on its neck. The bones were all perfect. As the only proof offered for the refrigeration of the earth was the former existence of tropical animals in northern latitudes, and as this can no longer be maintained, we have reason to believe that the general temperature of the globe is stationary, though the climate of particular countries may vary at different periods, from cultivation, the destruction of large forests, or other local causes.

Though the annual changes in the temperature of the climate affect the surface only to a small comparative depth, yet the continued effect of the annual mean temperature, considered as a permanent cause, may be sufficient to keep the internal temperature of the earth stationary, in each latitude, at a still greater depth. Hence we find that the internal temperature of the earth, and the mean temperature of the atmosphere, are nearly, but not exactly, the same; for in all northern countries, the mean temperature of the earth is higher than that of the air, and the difference, according to the observations of Dr. Wahlenberg, fellow of the Royal Society of Stockholm, appears to increase as we advance northward, or as the cold of the winter becomes more severe. This would also seem to give additional confirmation to the opinion, that there is a permanent source of heat within the globe itself. The following table shews the rate at which the temperature varies according to the latitude.

	Latitude.	Temp. of the Earth.	Mean Temp. of the Atmosphere.
Berlin - - -	52.5°	49.28°	46.4°
Carlstrom - -	56.25	47.3	42.03
Upsala - - -	60.	43.70	33.38
Umen - - -	64.	37.22	
Degeforts - -	64.25	36.68	

The observations were made on springs which threw up a large quantity of water at a permanent degree of temperature in all seasons. It is to be regretted that we have not a series of observations made with equal care in southern latitudes. M. Volney states, in his "Travels in America," that the mean temperature of wells forty-five feet deep was as under:

	Fahr.
Charlestown - - - - -	63°
Virginia - - - - - -	57
Philadelphia - - - -	53
Massachusetts - - - -	49
Vermont - - - - - -	44

This depth is too small, to give the true mean temperature of the earth; and the observations can only be regarded as approximations to the truth. On the same authority it is stated, that the temperature of the earth, to a considerable depth under the torrid zone, is 14° Reaumur, or 63° Fahrenheit.

In the southern parts of England, the mean temperature, taken from permanent springs, is about 48°; at Edinburgh, 45°; in the north of Ireland, 48°; and at Paris, 51°.

For the temperature of the atmosphere, see ATMOSPHERE, where the mean temperature in different latitudes is given. Mr. Humboldt has lately published a botanical account of the new genera and species of plants discovered in the tropical regions of America, with many interesting observations on the temperature, as affecting the growth of plants. The plants of the torrid zone extend farther through the southern temperate zone than through the northern, owing to the greater influence of the ocean in the southern hemisphere, in moderating the rigour of winter; the ocean bearing a much greater proportion to the surface on the south, than on the north side of the equator. In estimating the climate suited for the growth of particular plants, the mean temperature will not afford a correct standard; for though the mean temperature of the year, in the middle latitudes of North America, be the same as it is in Europe, 7° further north, the temperature of different seasons in these same latitudes by no means agrees. The winters are colder, and the summers hotter, in North America than in Europe. In Philadelphia the summer is as hot as at Rome or Montpellier, while the winter corresponds with that at Vienna. At Quebec the summer is warmer than at Paris, but the winter colder than at St. Petersburgh. In the north of China there is a still greater difference between the heat and cold, than in North America.

In North America, as far as latitude 48°, the summers are four centigrade degrees, or about 7° Fahrenheit, hotter than in the corresponding latitude in Europe. Between the tropics, the mean annual temperature is the same as on the old continent, which may be seen in the following table, expressed in degrees of the centigrade thermometer.

Old Continent.		*New Continent.*	
Senegambia	26.5°	Cumana	27.7°
Madras	26.9	Antilles	27.5
Batavia	25.2	Vera Cruz	25.6
Mantilla	25.6	Havannah	25.6

Twenty-five degrees correspond with seventy-seven degrees of Fahrenheit.

Though the plants of the torrid zone extend farther through the southern temperate zone than through the northern, as we have before stated; yet to a certain distance from the line, the temperature appears to be less on the south than on the north side. Rio Janeiro and Havannah are nearly at the same distance from the equator; but the mean temperature of the summer and winter months in each is as under:

Rio Janeiro.		*Havannah.*	
June	20.0°	December	22.1°
July	21.2	January	21.2
January	26.2	July	28.5
February	27.0	August	28.8

On the coast of Peru, the temperature is diminished by the perpetual cloudiness of the sky, and by a strong sea current setting in from Cape Horn. From the tropic to 34° of south latitude, the mean temperature of the southern hemisphere scarcely differs from that of the northern. Between latitude 34° and 57°, there is a greater difference between the temperatures of summer than of winter: the winters in the southern hemisphere are not colder, but the summers are considerably more so than in the northern hemisphere. In south latitude 48°, the summer temperature is the same as the winter temperature of Toulon, Cadiz, and Rome.

The higher we ascend above the level of the sea, and the farther we advance from the equator, the greater is the difference

ference between the temperature of different feafons of the year. The following table exhibits the temperature between the hotteft and coldeft months, in different latitudes.

	Lat.	Cent. Therm.
Cumana - - -	10.27°	2.4°
Vera Cruz - -	19.11	2.6
Havannah - -	23. 8	7.4
Natches - - -	31.28	17.4
Philadelphia - -	39.56	24.6
Quebec - - -	46.47	33
Nain - - -	57.00	35

In the temperate zone, as we advance northwards, the coldnefs of the winter increafes at a much greater rate than the heat of the fummer diminifhes. Thus at Enonlekis, in latitude 68° 30′, the temperature of July is as hot as that of Edinburgh. Between the tropics, the temperature at no feafon of the year equals that of the fea-fhore; but in the temperate zone, the upper currents of air are fometimes warmer than the lower, during the winter months; and the thermometer, on the fummits of hills, is occafionally three or four degrees higher than in the plains. Hence in the temperate zone, we find the fame plants frequently on low and elevated fituations; but this is never the cafe between the tropics. In the temperate zone on the old continent, when the mean heat of the month is as under, the following plants bloffom:

Fahr.
42°, the Amygdalis perfica,
47, the Prunus domeftica,
52, the Betula alba.

The reafon why plants vegetate with greater rapidity in Lapland and Norway than farther fouth, is owing to the increment of temperature being much greater, and to the temperature of the earth in winter being feveral degrees above that of the air.

From obfervations made in different latitudes, it appears that 1000 fathoms of altitude occafion a diminution of temperature equal to 23° of Fahrenheit; 50 fathoms being nearly equal to half a degree. Mountains 1000 fathoms in height, at 46° of latitude, have the mean temperature of Lapland; and mountains of the fame height between the tropics enjoy the temperature of Sicily.

The following table by Humboldt exhibits the moft remarkable circumftances refpecting the temperature in the three zones. The temperature is taken according to the centigrade thermometer. The fathom 6 French feet, or 6.39453 Englifh feet.

	Torrid Zone.		Temperate Zone.			Frigid Zone.

In the feventh volume of the Tranfactions of the Royal Society of Edinburgh, Dr. John Murray has publifhed a paper on the diffufion of heat on the furface of the earth; in which he attempts to prove, from the nature of caloric, that the temperature of the earth is conftantly increafing from the folar rays, and that this temperature is becoming more equal in different parts of the earth. The atmofphere, he contends, conveys no heat into unlimited fpace; our planet, in relation to the difcharge of caloric from it, is bounded as it were by a wall of iron-conducting matter. He admits, however, that a fmall portion of heat may be loft by radiation: thus, at the hotter parts of the earth's furface, there may be fome emiffion of caloric by radiation; but this, he fays, cannot be equal to the quantity communicated by the folar rays: for of the heat derived from the latter fource, a portion is abforbed by the earth, and conveyed to the interior, as is apparent from the decreafing temperature, as we recede from the furface to a certain depth; and another portion is carried off by the afcending current of heated air, and conveyed to colder regions, where it is abforbed. Thus, even from thoſe parts of the ſurface of the earth where the circumſtances are moſt favourable to radiation, the quantity radiated cannot be equal to the quantity received from the ſolar rays. Over the whole earth the diffuſion muſt be ſtill greater; and inſtead of the concluſion, that the planet diſcharges its exceſs of heat by radiation, there is every reaſon to draw the oppoſite concluſion, that part of the heat which it receives from the ſun is retained. He further infers, that the temperature of the globe muſt riſe, from the mode in which heat is communicated to it by the ſun; and at the ſame time, as it advances, muſt become more equal over the whole ſurface. And this riſe has its limits. There cannot be either unlimited increaſe of heat, or unlimited refrigeration; but the final reſult will be a ſtate of permanence and uniformity, the continuance of which is ſecured by the very circumſtance, that if it is deviated from, this deviation muſt correct itſelf by an increaſe of radiation from the hotter parts, or from an increaſed abſorption of caloric by the colder parts of the globe. According to this theory, in proceſs of time, the equatorial and polar parts of the globe will arrive at the ſame degree of temperature, which will remain ſtationary, as there will be no circulation of heated air or water to the poles. To this reaſoning we conceive it may be objected, that it aſſumes, without ſufficient grounds, that caloric cannot paſs from the earth into unlimited ſpace, and that the ſolar heat does not become latent by chemical union with terreſtrial ſubſtances. It aſſumes alſo, that caloric is a diſtinct ſpecific ſubſtance; an opinion which is denied by ſome of the moſt eminent philoſophers. Nor have we, perhaps, any evidence to prove that the temperature of the earth has changed ſince the earlieſt records of hiſtory, if we except the local changes which reſult from drainage and cultivation. It is well known that the climate of Europe is materially changed ſince the periods of ancient hiſtory, when the Danube was annually frozen, and would admit the paſſage of armies over the ice. The climate of the United States of America has alſo undergone a material change during the laſt century. Both theſe local changes have been produced by the ſame cauſe, the deſtruction of extenſive woods, and the progreſs of agriculture; but, independently of local cauſes, we have no data to infer that the temperature of the globe is increaſing or diminiſhing.

TEMPERATURE *of the Sea*. The temperature of the ſea near the ſurface is affected by the changes of temperature of the atmoſphere, and by the currents which traverſe it. The currents which flow from the equatorial to the polar regions, ſerve to equalize the heat of different latitudes. This is remarkably the caſe with the current called the Gulf ſtream, which paſſes by the ſhores of Mexico, Louiſiana, and Florida, and round the point of the peninſula, under the ſhelter and protection of the Bahama iſlands, which break the efforts of the ocean and the current of the trade wind. This ſtream, on entering the ocean, preſerves its water by the velocity of its current, and may be further diſtinguiſhed by its colour and temperature. The temperature is from eleven to twenty-two degrees higher than that of the ocean. From the Floridas to Newfoundland the current continues increaſing in breadth, and diminiſhing in velocity. Some experiments made by Mr. Jonathan Williams, give the difference of temperature between the Atlantic ocean and the Gulf ſtream as under, December, 1789.

	Fahr.
Soundings in ſhoal-water, on the coaſt, - -	47°
A little before entering the ſtream, - -	60
In the ſtream, - - - -	70
Before reaching Newfoundland, in the ſtream, -	66
At Newfoundland, out of the ſtream, - -	54
Beyond the banks, in the open ſea, - -	60
On approaching the coaſt of England, -	48°
Capt. Billings, in 1791, found the temperature of the ſea on the coaſt of America, - -	61
In the water of the Gulf ſtream, - -	77

In winter, Mr. Williams found the variation between the Gulf ſtream and the ocean 23°; the difference, as might be expected, being leſs in ſummer than in winter. Theſe inquiries have aſcertained another fact, from whence navigators may derive ſome advantage; for by examining the temperature of the ſea in different places, it has been found that the water is colder in proportion to its ſhallowneſs; and hence may be derived an indication of the approach to land, or to a ſhoal. Out of the reach of currents, a difference always exiſts between the temperature of the ſurface and the lower parts of the ſea. In northern latitudes, the ſurface is ſometimes warmer and ſometimes colder than the lower parts; but near the equator, the temperature of the ſurface may be expected to be invariably warmer than at great depths. In all probability, the temperature of the ſea is permanent in each degree of latitude, at a certain depth. Capt. Ellis let down a ſea-gage in N. lat. 25° 13′. W. long. 25° 12′. He found the ſea ſalter and colder in proportion to the depth, till the gage had deſcended 3900 feet, when the mercury in the thermometer came up at 53°; but the water did not grow colder, though he let down the gage 1400 feet lower. At the ſurface of the ſea, the thermometer ſtood at 64°.

From the experiments of Capt. Douglas, near the coaſts of Lapland and Norway, of which an account is given in the 60th volume of the Philoſophical Tranſactions, the following differences were obſerved between the temperature of the ſea at the ſurface, and at certain depths.

Temperature at the Surface.		Depth in Fathoms.	Temperature.
May 12, lat. 70° 40′,	36° Fahr.	78 to 87	39°
May 17, nearly the ſame,	37	86 to 90	39
May 22, lat. 70° 32′,	37	80	39
June 29, lat. 70° 54′,	44	98	40
July 7, lat. 70° 45′,	46	70 at the bottom.	44
July 8, lat. 68° 43′, 12 leagues from the iſland of Lofoot, Norland, - -	47	100 260 not at the bottom.	46 52
July 9, lat. 65° 25′, 20 or 25 leagues from the coaſt of Norway, - -	48	100 210 at the bottom.	46 48
July 10, lat. 64° 40′, about 30 leagues from the coaſt, -	52	75 141 at the ground.	45 46

From

From the above obfervations it appears, that though the fea at a moderate depth was cooler than at the furface during the fummer months in northern latitudes, yet at ftill greater depths the temperature increafed, and at the depth of 260 fathoms was 52° in July, when the furface was only 47°. Now this depth being below the immediate effects of the folar rays, the temperature could only be derived from that of the globe itfelf, which appears to be fufficient to preferve the fea many degrees above the freezing point at the depth of 300 fathoms. Indeed, the temperature of the fea near the tropics, in lat. 25° 13′, at the depth of 650 fathoms, appears to be the fame as the temperature of the fea in lat. 68° 43′, at little more than one-third of that depth, as may be feen by comparing the obfervations of Capt. Ellis with that of Capt. Douglas. We have hence alfo ftrong grounds for believing, that at a certain depth, the temperature of the fea is permanent, and is the fame in every degree of latitude from the equator to the pole, though the depth may vary at which this permanent temperature would be found.

The mean annual temperature of the ftandard fituation in every latitude, as deduced by Mr. Kirwan from the Atlantic and Pacific oceans, is given under the article *Temperature of the* ATMOSPHERE. But fome exceptions to this ftandard, not there noticed, deferve to be mentioned here.

That part of the Pacific ocean which lies between N. lat. 52° and 66°, is only about 45 miles broad at its northern extremity, and 1300 miles at its fouthern. It is, therefore, reafonable to conclude with Mr. Kirwan, that its temperature will be confiderably influenced by the furrounding high land, as well as by the many bleak iflands fcattered through it. Mr. K. fuppofes, that from thefe circumftances the temperature is fully four or five degrees below the ftandard. Small feas furrounded by land are ufually rendered, from this circumftance, at leaft in temperate and cold climates, warmer in fummer and colder in winter than the ftandard ocean: the gulf of Bothnia, for inftance, is ftated to be generally frozen in winter, but in fummer to be fometimes heated to 70°. The German ocean is above three degrees colder in winter, and five degrees warmer in fummer, than the Atlantic. The Mediterranean fea is, for the greater part of its extent, warmer both in fummer and winter than the Atlantic, which therefore flows into it. The Black fea is colder than the Mediterranean, and flows into it.

Thefe obfervations apply chiefly to the furface of the ocean: from experiments that have been made it appears, that at confiderable depths the temperature is much lower than at the furface, and that the deeper we go, the lower it becomes; fo that fome fuppofe that, at very great depths, the water always exifts in a ftate of ice. See Kirwan's "Eftimate of the Temperature of different Climates;" alfo his "Effay on the Variation of the Atmofphere."

TEMPERATURE *of Springs.* Thofe common fprings which throw up a confiderable quantity of water during the whole year, have generally a permanent temperature, or nearly fo; and this is fuppofed to reprefent the mean temperature of the earth in each latitude; but there are other fprings which have a much higher permanent temperature, and fome which throw up their waters at a boiling heat. The following is the permanent temperature of fome of the more celebrated warm fprings in Europe.

	Fahr.
Matlock, - - - -	66°
Buxton, - - - -	82
Briftol, - - - -	74
Bath, - - - -	112 / 116
Vichy, - - - -	120
Carlfbad, - - - -	165°
Aix, - - - -	143
Borfet, - - - -	132
Bareges, - - - -	120

The Geyfers or boiling fountains in Iceland, in the Azores, and in various parts of the world, have a conftant temperature of 212°. The fource of heat, in fome of the latter fprings, is evidently fubterranean fire, as all thofe iflands are of volcanic origin, and are the feats of active volcanoes at the prefent day. It is obferved of other warm fprings, that they generally rife in the vicinity of volcanic or bafaltic rocks. This is the cafe with the warm fprings of Matlock and Buxton. Rocks of bafaltic amygdaloid extend through the high peak of Derbyfhire, where thefe fprings are fituated. Rocks of bafaltic amygdaloid, having a ftill more near refemblance to volcanic lava, extend from Worford bridge, in Gloucefterfhire, in a direction fouthward, and, in all probability, are continued under the furface to Bath and Briftol. According to Humboldt, hot fprings rife from granite and rocks denominated primary, in various parts of South America; and, from the permanent high temperature of warm fprings, we may infer that the fource of heat is fituated deep beneath the furface, and far below thofe caufes which can change the temperature. It has been contended by fome perfons, that the high temperature of warm fprings arifes from the decompofition of pyritous ftrata; but if this were the cafe, the waters would be ftrongly impregnated with fulphate of iron and other mineral matters, which is not the fact; the temperature would alfo decreafe as the pyritic matter became exhaufted, of which we have an analogous illuftration in the faline fprings of Cheltenham and Gloucefter. Thefe fprings rife in a deep ftratum of blue clay, called *lias*, (fee STRATA *of England*,) which abounds in pyrites, and in animal remains; and it is found by experience, that the faline impregnation is greateft when the wells are firft opened, and that the ftrength of the waters gradually declines; on which account, the proprietors are under the neceffity of finking frefh wells to obtain water of the requifite faline ftrength. This might be expected; for as the water percolates through fiffures in the clay, the faline matter in its vicinity is gradually wafhed away. But if the whole bed were in a ftate approaching to ignition, from the decompofition of pyrites, the faline impregnation would be conftantly fupplied to the fprings; for we cannot fuppofe any quantity of pyritous matter to exift equal to heat a whole ftratum by decompofition, without, at the fame time, generating fuch an abundance of faline matter as muft faturate the waters which percolate through it. We are hence led to infer that the fource of heat in warm fprings is fubterranean fire, and as thefe fprings have not been obferved to diminifh in temperature for a period of nearly two thoufand years, we may further infer the great depth at which this fource of heat is fituated, an inference which is warranted by the connection which volcanoes in diftant parts of the world appear to have with each other. (See VOLCANO.) It may be afked, if the fource of heat in warm fprings be fubterranean fire, why are they not all of the fame degree of temperature? To this it may be replied, that, in fome inftances, the warm fprings may be intermixed with cold fprings near the furface; and in other inftances, after rifing to a certain height, they may run in an horizontal direction for a confiderable diftance among the upper ftrata, and thus be gradually cooled. The caufe which can raife up water from vaft depths, muft be fought for in the expanfive power of fteam, and elaftic vapours generated by heat, which we know by experience to be fully adequate to the effect.

Temperature *for Plants*, in *Gardening*, the ſtate of heat in which it is neceſſary to keep particular ſorts of them, in order to their ſtriking or taking root, their healthy growth, and their ſucceeding in the beſt and moſt proper manner. The ſtate or degrees of heat, or the temperature, in all ſuch caſes, muſt be regulated and directed by the nature of the plants, their culture, and the ſituations in which they are grown. For thoſe in hot-houſes and ſtoves, the temperature, in thoſe of the dry ſtove kind, ſhould moſtly be from about fifty to ſeventy degrees, according to the natures, habits, and manners of growth of the plants; and in thoſe of the moiſt ſtove kind, from about ſixty to ninety degrees, as the nature of the beds and plants may be. Plants in conſervatories are kept at various temperatures between thoſe of the firſt kind of the above ſtoves and that of the common open air. And in greenhouſes, nearly ſimilar temperatures are conſtantly to be preſerved, in order to the raiſing, and to the growth of ſuch plants, in the moſt ſuitable and beſt manner.

It is always of great utility and importance to keep the temperatures as ſteady as poſſible, whatever its ſtate may be, in the growth of all theſe ſorts of tender plants.

The temperatures, or ſtates of heat for particular plants, are moſtly given under their proper heads, in deſcribing their culture.

Temperature *of Milk for Cheeſe*, in *Rural Economy*, the degree of heat which is the moſt proper in milk for the purpoſe of making cheeſe. From ſome experiments which have been lately made upon the ſubject, this temperature would ſeem to be about the middle point between that of ſummer and blood heat; or, perhaps, ſomewhere about ninety degrees of Fahrenheit's ſcale may give the average degree of warmth which is moſt proper and neceſſary in the buſineſs.

TEMPERING, in the *Mechanic Arts*, the preparing of ſteel and iron, ſo as to render them more compact, hard, and firm; or even more ſoft and pliant; according to their reſpective occaſions.

Theſe metals are tempered by plunging them, while red-hot, into ſome liquor prepared for the occaſion: ſometimes pure water is uſed for that purpoſe: our lockſmiths, &c. ſcarcely uſe any other.

When an inſtrument has been properly hardened, it is neceſſary to give it a certain degree of ſoftneſs, in order to adapt it for the purpoſe to which it is to be applied. With this view, it ſhould be heated again to a certain point, uſually determined by its colour, and then inſtantly plunged into cold water. This is called "letting it down to the proper temper." It has been a queſtion of difficult ſolution, how the water acts in hardening iron and ſteel. It is well known, ſays Mr. Parkes, in his "Chemical Eſſays," (vol. iv.), that the hotter any piece of iron is made, and the more quickly it is cooled, the harder it will become in its texture; and he ſuggeſts that this may be owing to the loſs of its *latent* heat. In confirmation of this conjecture he alleges, that iron and ſteel are generally allowed to owe their malleability to their latent heat.

A compoſition of divers juices, liquors, &c. has ſometimes been uſed; which is various according to the opinion and experience of the workman: as vinegar, mouſe-ear water, nettle or Spaniſh radiſh-water, the water oozing from broken glaſſes, ſuet, ſalt, oil, ſoot, diſtilled wine, ſal ammoniac, urine, &c. But theſe methods are now generally abandoned. Mr. Stodart, a very ingenious and ſcientific cutler in London, ſays, (as Mr. Nicholſon informs us, Journal, vol. iv. 4to.) that one of his workmen makes up his charcoal fire with ſhavings of leather, finding that this is effectual in preventing the tools from cracking in the proceſs of hardening; and he ſays, that he has found no advantage from the uſe of ſalt in the water.

To harden and temper Engliſh, Flemiſh, and Swediſh ſteel, you muſt give them a pretty high heat; then ſuddenly quench them in water to make them hard; but Spaniſh and Venetian ſteel will need only a blood-red heat before they be quenched.

In conſequence of this operation, all the qualities of ſteel are changed; ſo that from being very ductile and ſoft, it becomes ſo hard and ſtiff, that it is no longer capable of being cut by the file, but is itſelf capable of cutting or piercing very hard bodies, and that it does not yield to the hammer, but may be ſooner broken in pieces than extended. It becomes alſo ſonorous, brittle, very elaſtic, and capable of acquiring the moſt beautiful poliſh. This hardneſs and ductility of ſteel may be diverſified by varying the temper. The hotter the ſteel is when tempered, and the colder the water into which it is plunged, the greater hardneſs it acquires, but at the ſame time it becomes ſo much more brittle. The coldneſs of the water may be increaſed by diſſolving ſalts in it: obſerving that water is always colder while the ſalts continue diſſolving; and that the ſteel will cool ſooner by being ſtirred about or placed in a ſtream, ſo as to come in contact with water not already made warm. On the contrary, the leſs hot the ſteel is when tempered, and the hotter the water is in which it is tempered, the leſs hard it becomes, and alſo the greater ductility it retains: and the proper degree of heat is always relative to the uſe for which the tools made of the ſteel are intended.

If the ſteel be too hard or brittle for an edged tool, &c. let it down by rubbing a piece of grindſtone or whetſtone hard upon the work, to take off the black ſcurf: then brighten, or heat it in the fire: and as it grows hotter, you will ſee the colour change by degrees, in the manner and by the gradations ſtated under the article Cutlery.

Saw-makers temper their tools by rubbing them over with ſuet or other greaſe, and then heating them gradually till the temperature of each tool is ſufficiently raiſed to ſet fire to the greaſe of itſelf and occaſion it to blaze. They are thought to acquire in this mode of treatment a temper equal to that which would be obtained by heating them in the uſual way, till they became of a deep blue. This operation, which is practiſed at Sheffield, is called "blazing." For the method of tempering files, in which the great deſideratum is to blend tenacity with hardneſs, ſee File.

In the year 1789, Mr. David Hartley took out a patent for a method of tempering ſteel by the aid of a pyrometer or thermometer applied near to the ſurface of the article, and at the ſame time recommended the uſe of heated oil, in which (he ſays) many dozens of razors or other tools might be tempered at once with the utmoſt facility, and the various degrees of heat neceſſary for different purpoſes might ſpeedily be determined by experiment. (See Nicholſon's Journal, vol. i. 4to.) An improvement of this principle has been ſince ſuggeſted by Mr. Parkes (Chem. Eſſ. vol. iv.) by providing a bath of oil or of ſome kind of fuſible metal for the tempering of every ſpecies of edged tool, which contrivance would, in his opinion, give to this operation a greater degree of certainty, than has ever been experienced by thoſe who have conducted ſuch manufactories. See Tilting.

Steel is uſually ſold tempered, becauſe in many manufactures, the cuſtom is to temper it as ſoon as it is made, probably that the purchaſers of it may be better able to judge of its quality. When this ſteel is to be uſed, it muſt be untempered by heating it more or leſs, and letting it cool

cool ſlowly, that it may be extended, filed, and receive the neceſſary form: after which every workman tempers it again in his own way.

M. Berthoud, in his treatiſe on marine clocks, recommends hardening the ſteel-balance wheel, by daubing it over with ſoot (of wood) moiſtened with urine, putting it into a ſmall box of thin iron-plate, and covering it over with the ſame compoſition. This box with its contents is to be heated to a blood-red, and then the wheel taken out ſuddenly and quenched.

Mr. Harriſon and M. Berthoud ſeem to agree upon the whole, that the balance-ſpring of time-pieces ſhould be hardened and tempered after it has been coiled up in its proper form; and not tempered firſt and coiled up afterwards, as is the practice in making the main-ſpring. Some curious workmen, in order to equally temper ſmall ſteel inſtruments, employ melted lead as an intermedium. A plate of iron floats upon the melted lead, and receives from it, in all its parts, an equal heat: the pieces of ſteel laid upon this plate, acquire all at once the ſame degree of heat, and are at once quenched in water; the blue or other colours, which they ſucceſſively aſſume, affording ſure marks of the proper points of heat at which they are to be quenched, according to the different degrees of hardneſs required in them. Lewis's Com. Phil. Techn. p. 32.

For the method of tempering ſteel bars for artificial magnets, practiſed by Mr. Canton, ſee *Artificial* MAGNET.

The ancients appear to ſome to have had a better method of tempering than any of the moderns are acquainted with; witneſs their works in porphyry; a ſtone ſo hard, that ſcarcely any of our tools make any impreſſion upon it.

TEMPERING *of Land*, in *Agriculture*, a term ſignifying the preparing it for a crop, eſpecially of wheat. It is a term in much uſe in Norfolk. It implies all the various operations that may be undertaken in this intention.

TEMPEST, TEMPESTAS, a ſtorm or violent commotion of the air, with or without rain, hail, ſnow, &c.

TEMPEST, in *Mythology*, a deity among the Romans, concerning whom we merely know, that Marcellus, as an acknowledgment for having eſcaped a ſtorm, with which he was overtaken at ſea, between the iſlands of Corſica and Sardinia, built a temple to her without the Porta Capena.

TEMPESTA, ANTONIO, in *Biography*, was an ingenious deſigner and painter, born at Florence in 1555, and was initiated in the art by Santi di Titi; afterwards he ſtudied under another artiſt, whoſe name was Stradanus. Tempeſta was gifted with a brilliant and powerful imagination, not, however, of the moſt correct or exalted kind. His favourite ſubjects were battles, ſieges, cavalcades, huntings, proceſſions, &c.; all of which he arranged and deſigned in a novel and rich ſtyle, and executed with uncommon ſpirit and energy. He was employed by Gregory XIII. in the Vatican, which he adorned with groteſque inventions, and ſome few hiſtorical productions. He was alſo employed by the marcheſe Juſtiniani in decorating his palace; and in ſeveral of the churches of Rome, Tempeſta's paintings may be found.

He not only exerciſed his genius and time with the pencil, but devoted much of both to the etching needle; having left behind him nearly 1800 plates of different kinds, and of very conſiderable merit. He died in 1630, aged 75.

TEMPIE, in *Geography*, a town of the iſland of Sardinia; 25 miles E. of Caſtello Arragoneſe.—Alſo, a town of Mexico, in the province of Guadalajara; 500 miles N.W. of Mexico.

TEMPLARS, TEMPLERS, or *Knights of the Temple*, a religious military order, firſt eſtabliſhed at Jeruſalem, in favour of pilgrims travelling to the Holy Land.

The original of this order, the firſt military one in the world, is this: in 1118, ſome pious and noble perſons devoted themſelves to the ſervice of God, in the preſence of the patriarch of Jeruſalem; promiſing to live in perpetual chaſtity, obedience, and poverty, after the manner of canons.

The two principal perſons were Hugo de Paganis, and Geoffry of St. Omers. Baldwin II. then king of Jeruſalem, gave them an apartment in his palace, near the temple at Jeruſalem, not far from the ſepulchre of our Saviour; whence their denomination *Templars*.

Soon afterwards, the canons of the temple gave them a piece of ground near the ſaid temple, on which to build regular houſes; and the king, the lords, the patriarch, and the prelates, each gave them ſomewhat out of their revenue for food and cloaths.

Their firſt undertaking, and what they had firſt in view at their inſtitution, was, to guard the highway againſt robbers, &c. chiefly for the ſafety of pilgrims and croiſes.

The principal articles of their rule were: that they ſhould hear the holy office throughout every day; or that, when their military duties ſhould prevent this, they ſhould ſupply it by a certain number of pater noſters: that they ſhould abſtain from fleſh four days in the week, and on Fridays from eggs and milk-meats: that each knight might have three horſes, and one eſquire: and that they ſhould neither hunt nor fowl.

In the year 1228, this order acquired ſtability, by being confirmed in the council of Troyes, and ſubjected to a rule of diſcipline drawn up by St. Bernard.

In every nation they had a particular governor, called *maſter of the temple*, or of the *militia of the temple*. Their grand-maſter had his reſidence at Paris.

The order of Templars flouriſhed for ſome time, and acquired by the valour of its knights immenſe riches, and an eminent degree of military renown: but as their proſperity increaſed, their vices were multiplied, and their arrogance, luxury, and cruelty, roſe at laſt to ſuch a monſtrous height, that their privileges were revoked, and their order ſuppreſſed with the moſt terrible circumſtances of infamy and ſeverity. Their accuſers were two of their own body, and their chief proſecutor Philip the Fair, of France, who addreſſed his complaints to Clement V. The pope, though at firſt unwilling to proceed againſt them, was under the neceſſity of complying with the king's deſire, ſo that, in the year 1307, upon an appointed day, and for ſome time afterwards, all the knights, who were diſperſed throughout Europe, were ſeized and impriſoned. Such of them as refuſed to confeſs the enormities of which they were accuſed, were put to death; and thoſe who, by tortures and promiſes, were induced to acknowledge the truth of what was laid to their charge, obtained their liberty. In 1312, the whole order was ſuppreſſed by the council of Vienne. A part of the rich revenues they poſſeſſed was beſtowed upon other orders, eſpecially on the knights of St. John, now of Malta, and the reſt confiſcated to the reſpective treaſuries of the ſovereign princes in whoſe dominions their poſſeſſions lay.—The knights Templars, in order to juſtify the ſeverity with which they were treated, were charged with apoſtacy to the Saracens, and holding correſpondence with them; with inſulting the majeſty of God; turning into deriſion the Goſpel of Chriſt; and trampling upon the obligation of all laws, human and divine. Candidates, it is ſaid, upon admiſſion to this order, were commanded to ſpit, in token of contempt, upon an image of Chriſt, and after admiſſion, to worſhip either a

cat,

cat, or a wooden head crowned with gold. It is farther affirmed, that, among them, the odious and unnatural act of sodomy was a matter of obligation; and they are charged with other crimes too horrible to be mentioned, or even imagined. However, though there be reason to believe that in this order, as well as others of the same period, there were shocking examples of impiety and profligacy; yet that the whole order was thus enormously corrupt, is so far from being proved, that the contrary may be concluded even from the acts and records, yet extant, of the tribunals before which they were tried and examined. If to this we add, that many of the accusations advanced against them flatly contradict each other, and that many members of this unfortunate order solemnly avowed their innocence, while languishing under the severest tortures, and even with their dying breath; it would seem probable, that king Philip set on foot this bloody tragedy, with a view to gratify his avarice, and glut his resentment against the Templars, and especially against their grand-master, who had highly offended him. The principal cause of this invincible hatred against them was, that in his quarrel with Boniface VIII. the knights espoused the cause of the pope, and furnished him with money to carry on the war. Mosheim's Eccl. Hist. vol. iii. ed. 8vo. Bower's Hist. of the Popes, vol. vi. p. 393.

TEMPLE, Templum, a public building erected in honour of some deity, either true or false; and in which the people meet to pay religious worship to the same.

The word is formed from the Latin *templum*, which some derive from the Greek τεμενος, signifying the same thing; and others from τεμνω, *abscindo*, *I cut off*, *I separate*, because a temple is a place separated from common uses; others, with more probability, derive it from the old Latin word *templare*, *to contemplate*. It is certain the ancient augurs gave the name *templa* to those parts of the heavens which were marked out for the observation of the flight of birds. Their formula was this: *Templa tesqua sunto.*

Temples were originally all open, and hence received their name. See Phil. Trans. N° 471. sect. 5. where we have an account of the ancient temple in Ireland of the same sort as our famous Stonehenge.

The word *templum*, in its primary sense among the old Romans, signified nothing more than a place set apart, and consecrated by the augurs, whether enclosed or open; in the city, or in the fields.

Clemens Alexandrinus and Eusebius refer the origin of temples to the sepulchres built for the dead. This notion has been lately illustrated and confirmed by a variety of testimonies by Mr. Farmer, in his Treatise on the Worship of Human Spirits, p. 373, &c. Herodotus, Lucian, and Strabo, will have the Egyptians to have been the first who built temples to the gods; and from them the custom was propagated to the Assyrians, comprehending under this appellation Phœnicia, Syria, and other countries. From Egypt and Phœnicia it passed to Greece with the colonies, and from Greece to Rome. The first erected in Greece is ascribed to Deucalion by Apollonius (Argonaut. lib. iii.) and the first in Italy to Janus.

In antiquity we meet with many people who would not build any temples to their gods, for fear of confining them to too narrow bounds. They performed their sacrifices in all places indifferently, from a persuasion, that the whole world is the temple of God, and that he required no other. This was the doctrine of the magi, followed by the Persians, the Scythians, the Numidians, and many other nations mentioned by Herodotus, lib. i. Strabo, lib. xv. and Cicero, in his second oration against Verres.

The Persians, who worshipped the sun, believed it would wrong his power, to enclose *him* in the walls of a temple, who had the whole world for his habitation; and hence, when Xerxes ravaged Greece, the magi exhorted him to destroy all the temples he met with.

The Sicyonians would build no temples to their goddess Coronis; nor the Athenians, for the like reason, erect any statue to Clemency, who, they said, was to live in the hearts of men, not within stone walls.

The Bithynians had no temples but the mountains to worship on; nor had the ancient Germans any other but the woods.

Even some philosophers have blamed the use and building of temples, particularly Diogenes, Zeno, and his followers the Stoics. But it may be said, that if God hath no need of temples, men have need of places to meet in for the public offices of religion: accordingly, temples may be traced back even unto the remotest antiquity. See Hospinian, de Origine Templorum.

The Romans had several kinds of temples; of which those built by the kings, &c. consecrated by the augurs, and in which the exercise of religion was regularly performed, were called, by way of eminence, *templa*, temples. Those that were not consecrated were called *ædes*. The little temples, that were covered or roofed, they called *ædiculæ*; those open, *sacella*. Some other edifices, consecrated to particular mysteries of religion, they called *fana* and *delubra*.

All these kinds of temples, Vitruvius tells us, had other particular denominations, according to the form and manner of their construction; as will be hereafter specified. Indeed, the Romans out-did all nations with regard to temples: they not only built temples to their gods, to their virtues, to their diseases, &c. but also to their emperors, and that in their life-time; instances of which we meet with in medals, inscriptions, and other monuments. Horace compliments Augustus hereupon, and sets him above Hercules, and all the heroes of fable; in that those were only admitted into temples after their death, whereas Augustus had his temples and altars while living.

> "Præsenti tibi maturos largimur honores;
> Jurandasque tuum per nomen ponimus aras."
> Epist. ad Aug.

Suetonius, on this occasion, gives an instance of the modesty of that emperor, who would allow of no temples being erected to him in the city; and even in the provinces, where he knew it was usual to raise temples to the very proconsuls, refused any but those erected in the name of Rome as well as his own. Vide Suet. in Octav. cap. 52.

Whenever a temple was to be erected, the aruspices were consulted as to the scite of it, and the time when the construction of it was to commence. The spot assigned to it was carefully purified, and it was encircled with fillets and garlands. The vestals, accompanied with young boys and girls, washed the ground with water, and the priest expiated it by a solemn sacrifice. Then he touched the foundation-stone, and bound it with a fillet; and the people, animated with extraordinary zeal, threw it in thither with some pieces of money, or metal which had not passed through the furnace. When the edifice was finished, it was consecrated with a variety of ceremonies, in which the priest, or, in his absence, some of his college, presided. Some of these temples were not to be built within the precincts of cities, but without the walls, as those of Mars, Vulcan, and Venus, for reasons particularly assigned by Vitruvius. The temples were held in great veneration; and, in some cases, they were a sanctuary for criminals and debtors. Within they were very

very much adorned; particularly with coftly ftatues of their gods and great men, and a great variety of votive offerings.

The moft celebrated of the ancient temples among the Pagans were the following: *viz.* the temple of Belus (fee BELUS and BABYLON); the temple of Vulcan at Memphis, the magnificence and extent of which are highly extolled by Herodotus; the temple of Jupiter at Thebes or Diofpolis; that of Andera at Hermunthis; that of Proteus at Memphis; that of Minerva at Sais; the temple of Diana at Ephefus (fee DIANA); the temple of Apollo in the city of Miletus, which, as well as that of Diana, was of the Ionic order; the temple of Eleufis, built in honour of Ceres and Proferpine, capable of containing 30,000 perfons; the temple of Jupiter Olympius at Athens, of the Corinthian order; and the temple of Apollo at Delphi, fo famous for its oracles, and for the rich prefents with which it was enriched (fee DELPHI); the temple of Jupiter, which contained his admirable ftatue. The architect of the temple was Libo, a native of the country: its height from the area to the roof was 68 feet, its breadth 95, and its length 230. The throne and ftatue of the god, for we cannot enumerate other fplendid ornaments, were the mafter-piece of Phidias; and antiquity produced nothing fo magnificent nor fo finifhed. The ftatue, of an immenfe height, was of gold and ivory, fo artificially blended, that it could not be beheld but with aftonifhment. The god wore upon his head a crown, which refembled the olive-leaf to perfection: in his right hand he held a victory, likewife of gold and ivory; and in his left a fceptre of exquifite tafte, refulgent with all forts of metals, and fupporting an eagle. The fhoes and mantle of the god were of gold; and upon the mantle were all forts of animals and flowers engraved. The throne was all fparkling with gold and precious ftones. The ivory and ebony, the animals there reprefented, and feveral other ornaments, by their affemblage, formed a delightful variety. At the four corners of the throne were as many Victories, that feemed to be joining hands for a dance, befides two others that were at Jupiter's feet. The feet of the throne, on the fore-fide, were adorned with fphinxes, who were plucking the tender infants from the bofom of the Theban mothers; and underneath were to be feen Apollo and Diana, wounding Niobe's children to death with their arrows. Four crofs bars that were at the feet of the throne, and went from one end to the other, were adorned with a great rumber of figures extremely beautiful: upon one were reprefented feven conquerors at the Olympic games; upon another appeared Hercules, ready to engage with the Amazons, and the number of combatants on either fide was twenty-nine. Befides the feet of the throne, there were likewife pillars to fupport it. In fine, a great balluftrade, painted and adorned with figures, railed in the whole work. Panænus, an able painter of that time, had reprefented there, with inimitable art, Atlas bearing the heavens upon his fhoulders, and Hercules in an attitude ftooping to eafe him of the load: Thefeus and Pirithous, the combat of Hercules with the lion of Nemea, Ajax offering violence to Caffandra, Hippodamia with her mother, Prometheus in chains, and a thoufand other fubjects of fabulous hiftory. In the moft elevated place of the throne, above the head of the god, were the Graces and Hours, of each three in number. The pedeftal which fupported this pile, was equally adorned with the reft. There Phidias had engraved upon gold, on the one fide, the Sun guiding his chariot; on the other, Jupiter and Juno, the Graces, Mercury, and Vefta. There Venus appeared rifing out of the bofom of the fea, and Cupid receiving her; while Pitho, or the goddefs of perfuafion, was prefenting her with a crown. There alfo appeared Apollo and Diana, Minerva and Hercules. At the bottom of the pedeftal, you might have feen Amphitrité and Neptune, and Diana or the moon, who appeared mounted on horfeback. In fine, a woollen veil, of a purple dye, and magnificently embroidered, the prefent of king Antiochus, hung from top to bottom. The throne and ftatue reached from the pavement, which was of the fineft marble, to the roof.

Italy abounded with temples as much as Greece; feveral of which were remarkable for their fingularity or magnificence. Rome was full of temples: fome of the moft remarkable for their origin, materials, ftructure, or ufe, were the following: *viz.* the temple of Apollo, built by Auguftus, in honour of his favourite deity Apollo, after his victory at Actium, upon mount Palatine. Its ftructure was very magnificent; it was built of the fineft marble of Claros, and embellifhed, both within and without, with the richeft ornaments. Its gates were of ivory, enriched with baffo-relievos, reprefenting the Gauls, when they were thrown headlong from the top of the Capitol by T. Manlius. In the frontifpiece was a chariot of the fun, of maffy gold, crowned with rays fo refplendent that they dazzled the eyes of beholders. Within the temple was a marble ftatue of Apollo, made by Scopas, and alfo a coloffal one of brafs, 50 feet high; together with a candleftick in the form of a tree, whofe branches were covered with clufters of lamps refembling fruit. Upon thefe branches the poets ufed to hang their poems, which they offered up to Apollo, as Horace informs us, ep. 3. l. 1. To this temple, dedicated to the "god of arts," was very properly annexed a noble library.—The temple of Bacchus, fituated without the walls of Rome, is now the church of St. Conftantia, fupported on the infide by twenty-four noble pillars of granite. Its ancient mofaic ceiling, and the old window by which light was let in from the roof, ftill remain. Behind the prefent altar ftands an antique urn of porphyry, of large dimenfions; and on each fide of the altar, a finely wrought antique candleftick of marble.—Here was the temple of the goddefs Bona, who was Dryas, the wife of Faunus, diftinguifhed by her exemplary chaftity. The Roman ladies facrificed to her in the night, in a little chapel, into which the men were not allowed to enter, nor were they permitted to be prefent at her facrifices. It was for the violation of this rule, that Cicero profecuted the debauched Clodius. (See his article.)—The temple of Diana was feated on mount Aventine. It was built in the reign of Servius Tullius, at the joint expence of the Romans and Latins, for the purpofe of their meeting annually to offer a facrifice, in commemoration of the league made between the two nations.—The firft temple of Faith is faid to have been erected by Numa, who taught the Romans to worfhip this goddefs, and thus to be reminded, that the moft facred oath they could take was to fwear by their *faith* or *veracity*. His intention was to render their promifes, without writings or witneffes, as firm and certain as contracts made and fworn to with the greateft formalities; and in this he fucceeded to his wifh. Polybius bears this honourable teftimony to the Romans, that they inviolably kept their *faith*, that is, their word, without having occafion for witneffes or fecurities; whereas nothing could bind the Greeks to their promifes.—The temple of Honour was built by Mutius, by order of Marius, and might be reckoned among the nobleft buildings in ancient Rome, if the materials, which were ftone, had correfponded to the greatnefs of the defign. It was remarkable for this circumftance, that the entrance of it was dedicated to Virtue, and the reft to Honour; and that it had no pofticum, or back-door, as other temples had; thus intimating, that we muft not only pafs through virtue to attain to honour, but that honour is alſo obliged to repaſs through virtue, that is, to perſevere in it, and acquire more of it.—The temple of Janus. The Romans built, at different times, three temples to Janus; for an account of which, ſee Janus.—The temple of Jupiter the Preſerver was one of the ſixty temples that ſtood upon the Capitoline hill. Jupiter Cuſtos was repreſented in it, holding his thunder with one hand, and a dart with the other, and the figure of the emperor was under his thunder, to ſhew that he was under Jupiter's protection; or elſe engraved, lying upon a globe, and holding an image of victory, with the eagle at his feet, and theſe words, "Jovi Conſervatori Auguſtorum noſtrorum."—The temple of Jupiter Optimus Maximus, or Jupiter Capitolinus, was moſt commonly called the *Capitol;* which ſee.—The temple of Liberty was built upon mount Aventine, on the ſpot where Cicero's houſe once ſtood, enriched with ſeveral braſs pillars, and many fine ſtatues.—The temple of Mars ſtood on the declivity of the Capitoline hill. In this temple were kept the eagles and other military enſigns of the Romans, and alſo the chariot in which Cæſar had triumphed.—The temple of Peace was begun by the emperor Claudius, and finiſhed by Veſpaſian, who embelliſhed it with paintings and ſtatues of the greateſt maſters, and alſo depoſited in it all the ſpoils and riches taken by his ſon Titus in the temple of Jeruſalem. It was burnt in the reign of Commodus.—The temple of Jupiter the Avenger was the *Pantheon;* which ſee. To the temples already enumerated, we might add thoſe of Antoninus and Fauſtina, of Auguſtus, of Auguſtus and Bacchus, of the Muſes, of Ceres, of Claudius Cæſar, of Concord, of Fame, of the Flavian family, of Faunus, of Fever, of Trajan and Neptune, of Happineſs, of Faith and Jupiter the Preſerver, of Flora, of Bad Fortune, of the eldeſt or firſt-born Fortune, of Public Fortune, of Virile or Courageous Fortune, of Hercules, of Juno, of Juno Moneta, of Juno Soſpita, the giver or preſerver of health, of queen Juno, of Jupiter Feretrius, of Jupiter Stator, of Jupiter Tonans or the Thunderer, of Jupiter the Conqueror, of Liber, an epithet of Bacchus, of the Mother of the gods, of Mercury, of Minerva, of the goddeſs Nenia, of Ops and Saturn, of the Penates or Houſehold gods, of Reſt, of Quirinus, of Romulus and Remus, of Saturn, of Serapis, of the Sun, of the Sun and Moon, of the god Sylvanus, of Tellus or the Earth, of Venus, of Venus and Cupid, of Venus Erycina, of Venus Erycina and the Mind, of Venus Verticordiæ, of Vertumnus, of Veſta, and many others, which, great and ſmall, amounted to upwards of one thouſand.

Temple, *Jewiſh*, at *Jeruſalem*, was an edifice erected much after the model of the tabernacle, but in a much more magnificent and expenſive manner. According to the opinion of ſome, there were three different temples: the firſt built by David and Solomon on mount Moriah, which was part of mount Sion; the ſecond, by Zerubbabel and Joſhua the high prieſt; and the third by Herod. This laſt, however, the Jews will not allow to be a new temple, but only the ſecond repaired or rebuilt. The expence of building Solomon's temple was prodigious: the gold and ſilver employed for this purpoſe amounted to upwards of eight hundred millions ſterling (1 Chron. xxii. 14. xxix. 4. 6, 7.), which, ſays Dr. Prideaux, was ſufficient to have built the whole temple with ſolid ſilver. But as the book of Chronicles was written after the return from the Babyloniſh captivity, it is probable that the Jews might compute by the Babyloniſh talent, which was little more than half the Moſaic talent, or perhaps by the Syriac talent, which was but one-fifth of the Babyloniſh; and thus the whole quantity of gold and ſilver would be reduced to a comparatively moderate quantity, and yet ſufficient for the purpoſe.

Joſephus (lib. vii. xiv. ii.) acquaints us, that the two firſt ſums were only one-tenth part of what is expreſſed in the preſent Hebrew; and Dr. Kennicott (State of the Hebrew Text, vol. ii. p. 355.) thinks it probable, that a cipher was added to them both in ſome very ancient Hebrew copy.

This temple was ſurrounded, except at the front or eaſt end, with three ſtories of chambers, each five cubits ſquare, which reached to half the height of the temple; and the front was graced with a magnificent portico, which roſe to the height of a hundred and twenty cubits. It was plundered by Nebuchadnezzar king of Babylon, and at length deſtroyed, after it had ſtood, according to Joſephus, four hundred and ſeventy years, ſix months, and ten days, from its dedication. Others, however, as Calviſius and Scaliger, reduce the number of years to four hundred and twenty-ſeven, or four hundred and twenty-eight; and Uſher, to four hundred and twenty-four years, three months, and eight days.

The ſecond temple was built by the Jews, after their return from the Babyloniſh captivity, under the direction and influence of Zerubbabel their governor, and of Joſhua the high prieſt, with the leave and encouragement of Cyrus the Perſian emperor, to whom Judæa was now become a tributary kingdom. According to the Jews, this temple was deſtitute of five remarkable appendages, which were the chief glory of the firſt temple; *viz.* the ark and mercy-ſeat, the Schechinah, the holy fire on the altar, which had been firſt kindled from heaven, the urim and thummim, and the ſpirit of prophecy. This temple was plundered and profaned by Antiochus Epiphanes, who alſo cauſed the public worſhip in it to ceaſe; and afterwards purified by Judas Maccabæns, who reſtored the divine worſhip: and after having ſtood five hundred years, rebuilt by Herod, with a magnificence approaching to that of Solomon's. Tacitus calls it *immenſæ opulentiæ templum;* and Joſephus ſays, it was the moſt aſtoniſhing ſtructure he had ever ſeen, as well on account of its architecture as its magnitude, and likewiſe the richneſs and magnificence of its various parts, and the reputation of its ſacred appurtenances. This temple, which Herod began to build about ſixteen years before the birth of Chriſt, and ſo far completed in nine years and a half, as to be fit for divine ſervice, was at length deſtroyed by the Romans on the ſame month and day of the month, on which Solomon's temple was deſtroyed by the Babylonians.

The Jewiſh temple itſelf conſiſted of the portico, the ſanctuary, and the holy of holies; and it was ornamented with ſpacious courts, making a ſquare of half a mile in circumference. The firſt court was called the court of the Gentiles, becauſe they were allowed to come into it, but no farther. Within this was a leſs court, into which none but Iſraelites might enter, divided into the court of the women; and the inner court, in which the temple and altar ſtood, and into which the prieſts and all male Iſraelites might enter.

Temple, in *Architecture*. The ancient temples were diſtinguiſhed, with regard to their conſtruction, into various kinds: as,

Temple *in antæ*, *Ædes in antis*. Theſe, according to Vitruvius, were the moſt ſimple of all temples, having only angular pilaſters, called *antæ*, or *paraſtatæ*, at the corners, and two Tuſcan columns, on each ſide of the doors.

Temple, *Tetraſtyle*, or ſimply *tetraſtyle*, was a temple that had four columns in front, and as many behind. Such was the temple of Fortuna Virilis at Rome.

Temple, *Proſtyle*, that which had only columns in its front,

front, or fore-fide. As that of Ceres at Eleufis, in Greece.

Temple, *Amphyproftyle*, or *double proftyle*, that which had columns both before and behind, and which was alfo tetraftyle.

Temple, *Periptere*, that which had four rows of infulated columns around, and was exhaftyle, *i. e.* had fix columns in front; as the temple of Honour at Rome. See Periptere.

Temple, *Diptere*, that which had two wings, and two rows of columns around, and was alfo octoftyle, or had eight columns in front; as that of Diana at Ephefus.

Temple, *Pfeudo-diptere*. See Pseudo-*diptere*.

Temple, *Hypæthros*. See Hypæthros.

Temple, *Monoptere*. See Monoptere.

Temples, among us, denote two inns of court, thus called, becaufe anciently the dwelling-houfe of the knights Templars.

At the fuppreffion of that order they were purchafed by fome profeffors of the common law, and converted into hofpitia, or inns of courts.

They are called the *Inner* and *Middle Temple*, in relation to Effex-houfe, which was alfo a part of the houfe of the Templars, and called the *Outer Temple*, becaufe fituate without Temple-Bar.

In the *Middle Temple*, during the time of the Templars, the king's treafure was kept: as was alfo that of the kings of France in the houfe of the Templars at Paris.

The chief officer was the mafter of the Temple, who was fummoned to parliament in 49 Hen. III. And from him the chief minifter of the Temple church is ftill called *Mafter of the Temple*.

Temple, *Sir* William, in *Biography*, a ftatefman and mifcellaneous writer, was the fon of fir John Temple, mafter of the rolls in Ireland in the reign of Charles I. and II., and author of a Hiftory of the Irifh Rebellion, and born in London in the year 1628. Having finifhed his courfe of claffical education, he was entered, at the age of feventeen, at Emanuel college, in the univerfity of Cambridge, under the tuition of the learned Cudworth. Being defigned for public life, his principal attention at the univerfity was engaged by the ftudy of the modern languages, French and Spanifh; and at the age of twenty, he was fent to finifh his education by travelling on the continent. After fpending fix years in this way, he returned home in 1654, and married the daughter of fir Peter Ofborn, of Chickfand, Bedfordfhire, with whom he became acquainted during his foreign travels. Declining to accept any office under Cromwell, he refided with his father in Ireland, and devoted his time to the ftudy of hiftory and philofophy. At the Reftoration he became a member of the Irifh Convention; and in the Irifh parliament of the year 1661, he was returned as a reprefentative of the county of Carlow, and in 1662 was nominated one of the commiffioners from that parliament to the king. At this time he removed with his family to England; and having faithfully executed a fecret commiffion to the bifhop of Munfter, with which he was entrufted in 1665, he was appointed in the following year refident at the court of Bruffels, and raifed by patent to the rank of a baronet. During the reign of Charles II. he was concerned in a variety of negociations. After the peace of Breda, (July 10, 1667,) fir William went over to Holland, and formed an intimate acquaintance and friendfhip with De Wit, a man frank and open, and of the fame generous and enlarged fentiments with himfelf; and in confequence of the negociations of thefe two able ftatefmen, a defenfive alliance was concluded between Holland and England. Sweden acceded to the confederacy: and thus was formed the triple league, which was generally regarded with equal furprife and approbation. In the conduct of this bufinefs, Temple acquired great honour; but to all the compliments that were paid to him on the occafion, he modeftly replied, that to remove things from their centre, or proper element, required force and labour; but that of themfelves they eafily returned to it. The French monarch and the court of Spain were equally difpleafed; but in the treaty at Aix-la-Chapelle, where Temple appeared as ambaffador extraordinary and mediator, on behalf of England, his addrefs prevailed; the Spanifh minifter complied with the conditions propofed; and the peace between the contending powers was figned in May, 1668. In confequence of this event, fir William was nominated ambaffador to the States-General, and taking up his refidence at the Hague in the month of Auguft of this year, he maintained his intimacy with De Wit, and was alfo on familiar terms with William, prince of Orange, who had then attained the age of eighteen years. But this triple alliance was of fhort duration. The corruption and intrigues of the Englifh court produced a recall of Temple in the year 1669, and when it was propofed to him to return and make way for a breach with Holland, he declined, much to his honour, engaging in hoftility againft a country to which he was attached, and retired from public bufinefs to his feat at Sheen, near Richmond. Here he employed himfelf in the improvement of his manfion, and in the cultivation of his garden; and alfo in writing his "Obfervations on the United Provinces," and a part of his "Mifcellanea." When the war with the Dutch became unpopular through the nation, and the court and its minifters were under a neceffity of bringing it to a termination, fir William Temple was called out of his retirement to negociate with the Spanifh minifter in London: and when the feparate peace with Holland was concluded, he was requefted in the next year, 1674, to undertake the office of ambaffador to the States-General, for the purpofe of negociating a general peace. Before his acceptance of this office, he obtained an audience of the king, with a view of ftating to his majefty the pernicious politics of the Cabal miniftry, and the neceffity of popular meafures for regaining the confidence of the nation. The negociations for peace were commenced at Nimeguen, whither he removed from the Hague in 1676: and during their flow progrefs, he availed himfelf of the opportunity thus afforded him for accomplifhing the popular meafure of the marriage of the prince of Orange to the duke of York's eldeft daughter, which took place in 1677. On another occafion, when the French manifefted their intention of retaining the Spanifh towns, which were to be furrendered by treaty, Temple was difpatched to the Hague to concert effectual meafures with the States for bringing the French to terms; and in fix days he concluded a treaty, July 1678, by which England was bound to declare war againft the French if the towns were not evacuated within the interval of fixteen days; but fo feeble and fluctuating were the Englifh councils, that before the ratification of the projected treaty, peace was figned at Nimeguen, and France was fecured in the poffeffion of a great part of its conquefts.

In 1679 Temple was recalled from the Hague, in order to be appointed one of the fecretaries of ftate; but perceiving the violence of parties, and the prevalence of difcontent, he recommended a council of thirty perfons, which was to be compofed, together with the minifters of the crown, of perfons poffeffing influence and credit in both houfes of parliament. But divifions occurred which prevented the falutary effects of fuch a meafure. Projects of limitation or exclufion were the fubjects of warm difcuffion in parliament.

To

To thele meafures Temple was adverfe; and his laft act in parliament, as member for the univerfity of Cambridge, was to carry from the council the king's final anfwer to the addrefs of the Commons, never to confent to the exclufion of his brother: other members had previoufly declined this difagreeable fervice. When the king, in January 1681, diffolved the parliament without the advice of his privy council, Temple boldly remonftrated againft the meafure; and at length, wearied with the faction and mifgovernment which he had witneffed, he declined the offered return for the univerfity to the new parliament, and retired to Sheen, conveying from thence a meffage to the king, "that he would pafs the reft of his life as good a fubject as any in his kingdom, but would never more meddle with public affairs." The king replied to the meffage, that he bore him no refentment; but his name was expunged from the council. The remainder of his life was fpent in retirement and feclufion from all public bufinefs; and it is faid, that he interfered fo little in political matters, as not to know the defign of the prince of Orange to engage in the expedition that terminated in the revolution, and to be the laft perfon who gave credit to his landing. After James's abdication, however, he waited on the prince at Windfor, and prefented to him his fon. King William urged upon him the acceptance of the office of fecretary of ftate; but he maintained his purpofe of living in retirement. His fon was appointed fecretary at war; but in the week in which he affumed the office, he was feized with melancholy, and threw himfelf into the Thames. His reflection on this afflictive event was that which his Stoic philofophy alone could have dictated: "a wife man might difpofe of himfelf, and render his life as fhort as he pleafed." In his ftate of retirement, he admitted Swift to be his companion, as we have already mentioned under Swift's article. King William occafionally vifited him, and confidentially confulted him on feveral important affairs. In 1694 he loft his wife; and finking gradually under increafing infirmities, occafioned by repeated fits of the gout, his life was terminated at Moor park, in January 1698, in his 70th year. The greateft part of his fortune was bequeathed to the daughters of his unfortunate fon by a French lady, under the exprefs condition that they fhould not marry Frenchmen.

Sir William Temple ranks high as a ftatefman, and alfo as a patriot, who well underftood and zealoufly purfued his country's intereft. His foibles, without giving them a worfe appellation, were impatience with thofe whom he difliked, warmth in difpute, and a fhare of vanity and conceit; but he was fubftantially, fays his biographer, a worthy man in the various relations of life. To outward forms of religion he paid little regard; but his letter to the countefs of Effex is no lefs pious than eloquent: fo that we can fcarcely admit the charge of atheifm with which he is reproached by bifhop Burnet. As a writer, he ranks among the moft eminent and popular of his time. His "Obfervations upon the United Provinces of the Netherlands" were printed in 1672, and deferve the attention of the politician and philofopher: his "Mifcellanea" are lively and entertaining, if not profound. His "Memoirs" elucidate the hiftory of the times. His "Introduction to the Hiftory of England" was publifhed in 1695. His "Letters," in 3 vols., which relate to public tranfactions, were publifhed after his death by Swift. "All fir William Temple's writings," fays one of his biographers, "difplay much acquaintance both with books and men, and are entirely free from the licentioufnefs fo prevalent in that age. Their ftyle is negligent and incorrect, but agreeable, refembling that of eafy and polite converfation." Hume's Hift. vol. vii. 8vo. Biog. Brit. Gen. Biog. Account of his Life, &c. prefixed to the folio edition of his Works, in 2 vols. Lond. 1720.

Sir William Temple did not efcape the lafh of criticifm, and fuch was his vanity or irritability, or perhaps a compofition of both, that his indignation was roufed, and he expreffed himfelf in the following terms: "The criticks are a race of fcholars I am very little acquainted with; having always efteemed them but little brokers, who, having no ftock of their own, fet up and trade with that of other men, buying here and felling there, and commonly abufing both fides, to make out a little paltry gain, either of money or credit, for themfelves, and care not at whofe coft." In another place he fays, "there is, I think, no fort of talent fo defpicable, as that of fuch common criticks, who can at beft pretend to value themfelves by difcovering the defaults of other men, rather than any worth or merit of their own:—a fort of levellers, that will needs equal the beft and richeft of the country, not by improving their own eftates, but reducing thofe of their neighbours, and making them appear as mean and wretched as themfelves."

Temple, in *Geography*, a town of the province of Maine, in the county of Kennebeck, containing 482 inhabitants.—Alfo, a townfhip of New Hampfhire, in the county of Hillfborough, containing 941 inhabitants; 70 miles W. of Portfmouth.

Temple, *Le*, a town of France, in the department of the Lot and Garonne; 7 miles W. of Villeneuve d'Agen.

Temple *Bay*, a bay on the N.E. coaft of New Holland, to the S. of Cape Grenville.—Alfo, a bay on the E. coaft of Labrador. N. lat. 52° 25′. W. long. 55° 50′.

TEMPLEMORE, (*i. e. the Great Church*,) a poft-town of the county of Tipperary, Ireland, where there was formerly held a fair for wool, which lafted feveral days. It is 75 miles S.W. from Dublin.

TEMPLE PATRICK, (*i. e. Patrick's Church*,) a poft-town of the county of Antrim, Ireland, on the river Six-mile-water; $4\frac{1}{2}$ miles E. by S. from Antrim, on the road to Belfaft.

TEMPLERS. See Templars.

TEMPLES, in *Anatomy*. See Tempora.

TEMPLETON, in *Geography*, a town of America, in the ftate of Maffachufetts, and county of Worcefter, containing 1203 inhabitants.

TEMPLETONIA, in *Botany*, is dedicated by Mr. R. Brown, to the honour of John Templeton, efq. of Orange Grove, near Belfaft, a gentleman whofe enquiries have much enriched our knowledge of Irifh plants, and whofe name confequently often appears in the pages of the *Flora Britannica* and *Englifh Botany*.—Brown in Ait. Hort. Kew. v. 4. 269.—Clafs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminofæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, fimple, bell-fhaped, with five rather unequal fegments in the limb, permanent. *Cor.* papilionaceous, of five petals. Standard elliptical, afcending, entire. Wings nearly the length of the ftandard, linear-oblong, obtufe, with a fmall tooth near the bafe at their upper edge. Keel a little fhorter than the wings, oblong, flightly curved, of two half-ovate petals, cohering near the extremity, with fhort claws. *Stam.* Filaments ten, all combined into one tube for more than half their length, feparate above, afcending, five alternate ones rather the fhorteft; anthers uniform, fmall, oblong, incumbent. *Pift.* Germen ftalked, linear-awlfhaped; ftyle awlfhaped, afcending; ftigma capitate. *Peric.* Legume ftalked, linear-oblong, compreffed, obliquely pointed, of one cell and two valves. *Seeds* eight or ten, oval, polifhed, the fcar of each bordered with a prominent creft.

Eff. Ch. Calyx fimple, with five rather unequal teeth. Keel

Keel oblong. Stamens all connected. Anthers uniform. Legume stalked, compressed. Seeds numerous, crested.

1. T. *retusa*. Wedge-leaved Templetonia. Ait. n. 1. (Rafnia retusa; Venten. Malmaif. t. 53.)—Gathered by Mr. Brown, on the south-west coast of New Holland, from whence seeds were sent to England by Mr. Peter Good, in 1803. This is a greenhouse shrub, flowering in spring and summer. *Stem* about a yard high, with straight, angular, smooth, leafy branches. *Leaves* about an inch and half long, alternate, on short stalks, spreading, entire, emarginate, smooth. *Stipulas* in pairs, small, oval, deciduous. *Flowers* lateral, axillary, solitary, on simple stalks, which are rather shorter than the leaves. *Calyx* destitute of the imbricated appendages which make a principal part of the character of the neighbouring genus SCOTTIA. (See that article.) *Petals* near an inch long, of a deep crimson. *Legume* two inches long, and half an inch broad, slightly tumid where each seed is lodged.

TEMPLEUVE *en Pesvele*, in *Geography*, a town of France, in the department of the North; 7 miles S.S.E. of Lille.

TEMPLIN, a town of Germany, in the Ucker Mark of Brandenburg, situated between the Bodensee and Dolgensee. In the year 1735, this place was totally consumed by fire, but has been rebuilt to very great advantage; its streets being now broad and straight, and its houses uniform, exclusive of a spacious market-place in it, which forms a regular quadrangle, insomuch that at present it is one of the most beautiful towns in all the Mark. It carries on a very large trade in timber, which is greatly promoted by means of a canal, newly made. In 1806 it was taken by the French, under the duke of Berg; and the prince of Hohenloe, who had retired hither after the battle of Jena, was made prisoner; 15 miles S.W. of Prenzlow. N. lat. 53° 5'. E. long. 13° 34'.

TEMPLUM SOSTRATI, the name of a kind of surgical bandage described by Galen. He also describes another, under the name of *templum parvum Apollonii Tyrii*.

TEMPO, Ital., time, or measure, in *Music*.

TEMPO *Ordinario*, usual time.

TEMPO *di Gavotta*, gavot time. See GAVOTTA.

TEMPO *di Minuetto*, minuet time.

A TEMPO, or *à tempo primo*, after a pause, or *rallentando*, or *ad libitum*, implies a return to the first time in which a movement is begun; and in recitative, where, in general, no time is kept, *à tempo*, in an accompanied recitative, implies a regular time.

TEMPOAL, in *Geography*, a town of Mexico, in the province of Guasteca; 50 miles S.E. of St. Yago de los Valles.

TEMPORA, in *Anatomy*, the anterior and lateral parts of the head, where the skull is covered by the temporal muscles: the temples in common language. See CRANIUM.

TEMPORAL, TEMPORALIS, a term frequently used for *secular*. In which sense it stands opposed to *ecclesiastical*.

Pope Boniface wrote to Philip the Fair of France, that he was subject to him, both in spirituals and temporals.

At present, all the doctors on this side the Alps own the supremacy of kings in temporals.

TEMPORAL *Action*. See ACTION.

TEMPORAL *Augment*. See AUGMENT.

TEMPORALIS, TEMPORAL, in *Anatomy*, an epithet applied to various parts about the temples; these are a superficial, a middle, and two deep-seated temporal arteries; a temporal bone on each side of the head; a temporal vein; a temporal muscle; and temporal nerves. See the respective articles.

TEMPORALITIES, or TEMPORALTIES, the temporal revenues of an ecclesiastic; particularly such lands, tenements, or lay-fees, tithes, &c. as have been annexed to bishops' sees by our kings, or other persons of high rank in the kingdom. See REVENUE.

The temporalities of a bishop, &c. stand opposed to his spiritualities. See VACATION.

The canonists on the other side of the Alps, anciently gave the pope a power over the temporalities of kings. Yet pope Clement V. owned frankly, that his predecessor Boniface VIII. had exceeded the just bounds of his authority, in meddling with the temporalities of the king of France. Fevret.

TEMPORALIUM CUSTOS. See CUSTOS and VACATION.

TEMPORALIUM *Restitutione*. See RESTITUTIONE.

TEMPORARY FORTIFICATION. See FORTIFICATION.

TEMPORARY *Hours*. See HOUR.

TEMPOREGIATO, in the *Italian Music*, sometimes signifies, that the musicians who accompany the voice, or the person who beats time, should prolong some particular part thereof, to give the actor or singer room to express the passion he is to represent, or to introduce some graces, by way of ornament to the piece.

TEMPOREGIATO is also used in a different sense, for *à tempo*, or *à tempo giusto*.

TEMPORUM OSSA, in *Anatomy*, two bones of the cranium. See CRANIUM.

TEMPSCHE, in *Geography*, a town of France, in the department of the Scheld; 10 miles S.W. of Antwerp.

TEMPTATION, TENTATIO, in *Theology*, an induction or solicitation to evil, whether arising from the world, the flesh, or the devil.

Our Saviour's temptation, previous to the commencement of his public ministry, has been a subject of discussion and controversy among learned divines.

The evangelical account of this transaction may be found in Matt. iv. 1—11. Mark, i. 12, 13. Luke, iv. 1—12. It has generally been supposed, that the evangelical history of our Lord's temptation is to be understood as a narrative of outward transactions: that the devil tempted Christ in person, appeared to him in a visible form, spoke to him with an audible voice, and removed him corporeally from one place to another; and it must be allowed that these suppositions are warranted by the literal interpretation of the history. Nevertheless, this interpretation is liable to a variety of objections. It is unsuitable to the sagacity and policy of the evil spirit. Why, it has been suggested, should the devil assault our blessed Lord at all, and what advantage could he expect to gain over him; more especially when he came to him in person, and appeared before him in a visible form, and under his own proper character, proposing and urging temptations which could proceed only from an evil being? In order to evade this difficulty, some writers, as archbishop Secker and Dr. Chandler, have conjectured that the devil appeared *not as himself*, but under the assumed resemblance of a good angel; and others have supposed that he appeared to Christ in the form of a man. But the history furnishes no ground for these conjectures, and they are equally inconsistent with the temptations themselves, considered in their own nature; nor can it be pretended that Christ was ignorant by whom the several temptations, and particularly the third of them, was proposed; for in his reply, he calls him Satan. Besides, this transaction, according to the literal interpretation of its history, was very ill calculated to promote either the honour of of Chrift, or the inftruction and confolation of his difciples. This objection is ftrengthened, when we confider, that Chrift muft have yielded voluntarily to the mere motion and inftigation of the devil, and have been acceffary to his own difhonour, danger, and temptation. His character muft have been rather degraded than exalted. The temptations prefented to Chrift were fuch in their own nature as could not afford evidence or exercife of his obedience, nor of courfe fuitable confolation or ufeful inftruction to his followers, under real and powerful trials. Moreover, it has been objected to the common opinion, that it afcribes to the devil the performance of the greateft miracles, and of things not only preternatural, but abfurd and impoffible, for fuch we muft regard his fhewing Chrift all the kingdoms of the world from an exceedingly high mountain, and alfo whatever conftitutes the glory and grandeur of its kingdoms. If we are under a neceffity of deviating from a literal, and of adopting a figurative interpretation of the tranfaction recorded in this hiftory, we are warranted in fo doing by other inftances of a fimilar kind, that occur in the facred writings. Thefe writings relate things as actually done, which neverthelefs were only tranfacted in a vifion. Cafes of this kind frequently occur in fcripture; for which we might refer to Genefis, xxxii. 30. Hofea, i. and iii. Jeremiah, xiii. xxv. xxvii. Ezekiel, iii. iv. v. St. Paul calls his "being caught up into the third heaven" and "into Paradife, a vifion and revelation of the Lord." (2 Cor. xii. 1—4.) In conformity to thefe general principles, fome writers of eminene have proceeded in forming their judgment concerning the temptations of Chrift; and conftrained by fuch objections as we have already briefly ftated, they have abandoned the opinion that thefe temptations are to be underftood as outward tranfactions, inafmuch as the things themfelves were improbable, and even impracticable in their own nature; and inafmuch as the real performance could anfwer no valuable purpofe. Calvin allows, in his note on Matt. iv. 5, that feveral circumftances in this hiftory agreed beft to a vifion; and the generality of later writers have admitted, that the devil's fhewing to Chrift all the kingdoms of the world, and all their glory, in a moment of time, was done by fome fictitious fcenery, from a perfuafion, that it could not be done in any other way. Hence it has been argued by others, that if *one* of the temptations were prefented to Chrift in vifion only, why might not the *two others* be prefented to him in the fame manner. Adverting to the hiftory itfelf, it is alleged, that the text, inftead of pofitively and exprefsly afferting that the temptation of Chrift was a real outward tranfaction, contains clear intimations, and even direct affertions of the contrary. Thus, in the paffage relating to the exhibition of the kingdoms of the world, and all their glory, in one view, and in a fingle point of view, the evangelift is not fpeaking of the real fight of all thefe objects; but he muft defign to be underftood of what was inftantaneoufly exhibited to the mind. Other plain intimations occur, that Chrift's temptation is not to be underftood as an outward tranfaction; and it is alleged by the advocates of this opinion, that all the evangelifts who have mentioned this affair, do, in exprefs terms, affirm that it paffed *fpiritually*, and in *vifion*, or that it was merely an ideal or mental reprefentation.

Some of thofe biblical critics, who confider this hiftory as a recital of vifionary reprefentations, maintain that thefe vifions were framed by the devil, and that the temptations are to be afcribed to his immediate agency: thus denying the power of Satan over the body of Chrift, and granting him a nobler empire, a fovereign influence over the mind. Some have indeed fuppofed that Chrift's temptation was nothing more than a bare *meditation* of our Lord upon fuch trials as might poffibly be propofed by the great tempter of mankind. But it is needlefs to make any obfervations on a view of the fubject, which is altogether unfupported by the hiftory.

Another opinion has been propofed by a very able writer, in favour of which he has adduced a variety of arguments, that have given fatisfaction to many perfons who have examined this fubject. Mr. Farmer (in his Inquiry into the Nature and Defign of Chrift's Temptation in the Wildernefs) reprefents our Lord's temptation as befalling him while he was under a prophetic vifion, of which the Spirit of God himfelf was the immediate and fole author. Accordingly he confiders the temptation of Chrift, neither as an outward tranfaction, nor diabolical delufion, but as a divine vifion. At the time when this event occurred, our Saviour was actually in the wildernefs, and therefore when the evangelift fays, that "Jefus was led up of the Spirit into the wildernefs," or as our author more literally renders the words, "then was Jefus brought (or carried) into the wildernefs by the Spirit," he intimates, that into a wildernefs our Lord feemed to himfelf to be carried, or thither he was tranfported in vifion by a prophetic divine afflatus. The expreffions ufed by the other evangelifts, Mark and Luke, are faid to confirm the explication thus given of the language of St. Matthew. Upon the whole, the meaning of the evangelifts will be, "Chrift was brought into a wildernefs (not merely under a divine direction, but) under the full influence of the prophetic Spirit, making fuitable revelations to his mind, and giving him a view particularly of his future trials." And thefe trials are defcribed as "temptations of the devil," on account of the particular mode of their being revealed, being couched under the figure of Satan coming to him, and urging temptations. Our author, proceeding to examine the proper intention of this prophetic vifion, obferves, that the feveral fcenes which it comprehends, though prefented to Chrift in the form, and capable of anfwering the end, of a prefent trial, were directly intended as a fymbolical prediction and reprefentation of the future difficulties of his office and miniftry. The firft fcene in Chrift's vifion was probationary, ferving to difcover the prefent turn and temper of his mind; and alfo prophetical, having a reference to his future miniftry, through the whole courfe of which he was preffed with the fame kind of temptations, and refifted them upon the fame principles. This part of the vifion, therefore, conveyed this general inftruction: "that Chrift, though the fon of God, was to ftruggle with the afflicting hardfhips of hunger and thirft, and all the other evils of humanity, like the loweft of the fons of men; and that he was never to exert his divine power for his own perfonal relief, under the moft preffing difficulties, or for the fupply of his moft urgent occafions; but with refignation and faith to wait for the interpofition of God in his favour." The fecond fcene of this vifion was Jerufalem, the metropolis of Judea and the feat of power; it was the temple of Jerufalem, where the Jews expected the firft appearance of their Meffiah; it was the wing of the temple, the eaftern front of it, which commanded a view of the worfhippers below. From this eminence Chrift is required to throw himfelf down, in a dependence upon the divine protection, that fo his miraculous prefervation might give evidence of his divine miffion, and induce the numerous worfhippers, who were eye-witneffes of it, to acknowledge him immediately as the Meffiah, vifibly defcending from heaven, in a manner agreeable to the expectation of the Jews. Such was the propofal, and the temptation was powerful. The principle upon which he rejected it was, in its fpirit and meaning, this: "the Scripture forbids us

to

to prefcribe to God in what inftances he fhall exert his power; and as we are not to rufh upon danger without a call, in expectation of an extraordinary deliverance; fo neither are we to dictate to divine wifdom what miracles fhall be wrought for men's conviction." As this trial bore reference to his future miniftry, we find that in exemplifying the principle now manifefted, he never needlefsly and unwarrantably expofed himfelf to danger, and then relied on a miraculous interpofition of divine power for his refcue; but he was cautious in declining hazards; avoiding what might exafperate his enemies; and even enjoining filence with regard to his miracles, when the publication of them was likely to excite envy or popular commotion, and to inflame their minds againft him. In difplaying the evidences of his divine miffion, he ftill acted upon the fame maxim, opening his commiffion, not at Jerufalem, but in Galilee. In order to avoid oftentation and offence, he kept himfelf as private as the object of his commiffion would allow; and inftead of courting the favour of the opulent and powerful, he converfed freely with all forts of people. In many other inftances which an attentive perufal of his hiftory will furnifh, his miniftry will correfpond to his prophetic vifion, in which he was tempted to a public and oftentatious difplay of his miraculous powers. In the third fcene, the propofal was inftantaneoufly rejected, and not without a mixture of juft indignation. Befides this trial of his temper, the fcene before us pre-fignified the temptation to which he would be expofed in the courfe of his future miniftry, during which he was called upon to proftitute himfelf, with all his miraculous endowments, to the fervice of Satan, for the fake of worldly honours, or for gratifying the miftaken expectations of the Jewifh people. For a farther illuftration of this fubject, we muft refer to the work already cited. See alfo archbifhop Secker's, Dr. Clarke's, Dr. Chandler's, Mr. Mafon's Sermons, on this fubject. Benfon's Hiftory of the Life of Chrift. Macknight's Truth of the Gofpel Hiftory.

TEMPTATION, *Tentatio*, in our *Ancient Law-books*, is ufed for a trial, proof, or affay. "Tentatio panis fiat bis in anno." Chart. Edw. I. See ASSAY, &c.

TEMROOK, in *Geography*, a famous ftation in the Crimea, fituated at the foot of a fmall mountain, near the northern embouchure of the Kuban. It is now a fingle hut, for the purpofe of fupplying poft-horfes. In Motraye's time, who travelled this way in December 1711, it was a place of greater importance. He defcribes it as confiderable for its commerce in hides, caviare, honey, Circaffian flaves, and horfes. He fuppofed that its caftle ftood where the ancients placed their "Petræus;" and two eminences, he fays, which are named "the point of the ifland," may have been their "Achilleum Promontorium." This, it is fuppofed, was the fituation of Cimmerium. Pallas conjectures, that Temrook may probably have been the "Cimbricus" of Strabo.

TEMS, Fr., *time*, in *Mufic;* as *à contre tems*, againft time.

TEMSENA, in *Geography*, a province of Morocco, fituated on the coaft of the Atlantic, to the S. of Sallee. This province is rich and fertile, and abounds in excellent provifions, of various kinds. Its name feems intended to fignify its falubrity, and the purity of the climate. Temfena appears to be derived from the two Arabic words *Tamam Sana*, *only a year;* as if they fhould fay, that to refide here only a year would be fufficient to infure the fickly the return of their health, and fuch, in fact, is the firm belief of the natives. Corn is very plentiful in this province; it is of a very excellent kind, and the ears frequently bear 70 grains, or more. In the forefts is found a kind of cedar, called *hazar*, of a refinous fmell; it is a hard and incorruptible wood, and the Moors employ it in building their houfes.

This and the neighbouring provinces abound in horfes and horned cattle; their flocks are numerous, and the cavalry of Temfena is the beft appointed of the empire, excepting the Black troops of the emperor, called Abeed Seedy Buharrie. The population of the diftricts of Temfena and Shawia is eftimated at 1,160,000 perfons. The males of Temfena and Shawia are a ftrong, robuft race, of a copper colour; their women poffefs much beauty, and have highly expreffive features; and the animation of the countenance is increafed by the ufe of el kokol filelly, with which they tinge their eye-lafhes and eye-brows. In thefe provinces they are fond of dyeing their hands and feet with a preparation of the herb henna, which gives them a beautiful orange-colour, and, in hot weather, imparts a pleafing coolnefs and foftnefs to the hands, by preventing, in a confiderable degree, the quicknefs of perfpiration.

TEMUS, in *Botany*, a genus which Juffieu has condefcended to adopt, by its barbarous name, from the hardly lefs barbarous information of Molina. Juff. Gen. 435.—Clafs and order, *Polyandria Digynia*. Nat. Ord. uncertain.

Eff. Ch. "Calyx three-cleft. Petals eighteen, linear, very long. Stamens twenty-fix, fhorter than the petals. Anthers globofe. Germens two. Styles two. Berry two-lobed. Seeds tunicated."—Native of Chili, where it is called *Temo*. This it feems is an evergreen *tree*, with alternate *leaves*, and ftalked terminal *flowers*.

TEMUS, in *Geography*, a river of Sardinia, which runs into the fea, 4 miles E. of Caftello Arragonefe.

TENA, a town of South America, in the province of Quito; 15 miles S. of Archidona.

TENABLE, formed from the French *tenir*, and that from the Latin *tenere*, *to hold*, in the *Military Art*, fomething that may be defended, kept, and held, againft affailants.

Tenable is little ufed, but with a negative: when a place is open on all fides, and its defences are all beaten down, it is no longer tenable. When the enemy has gained fuch an eminence, this poft is not tenable.

TENACIOUS BODIES. See TENACITY.

TENACITY, in *Natural Philofophy*, that quality of bodies by which they fuftain a confiderable preffure, or force, without breaking. Mem. Acad. Berlin, 1745, p. 47.

Tenacity is the oppofite quality to fragility, or brittlenefs.

TENACULUM, in *Surgery*, an inftrument ufed in amputation, for pulling out bleeding veffels that are to be tied by ligatures.

TENAGLIA, in *Biography*, a Roman compofer, mentioned by Pietro della Valle, as having fet the opera of "Clearco," for that city, about 1634. This feems to have been one of the firft mufical dramas performed at Rome in a public theatre.

TENAILLE, in *Fortification*, a kind of outwork, confifting of two parallel fides, with a front, in which is a re-entering angle.

In ftrictnefs, that angle, and the faces which compofe it, are the tenaille.

The tenaille is of two kinds; *fimple* and *double*.

TENAILLE, *Simple*, or *Single*, is a large outwork, confifting of two faces or fides, including a re-entering angle. See *Plate* V. *Fortification*, *fig.* 4. *lit. d.*

TENAILLE, *Double*, or *Flanked*, is a large outwork, confifting of two fimple tenailles, or three faliants, and two re-entering angles. *Fig.* 21. *lit. e.*

The great defects of tenailles are, that they take up too

 much

much room, and on that account are advantageous to the enemy; that the re-entering angle is undefended; the height of the parapet hindering the seeing down into it, so that the enemy can lodge there under covert; and the sides are not sufficiently flanked.

For these reasons, tenailles are now excluded out of fortifications by the best engineers, and never made, but where there wants time to form a horn-work.

Tenaille *of the Place*, is the front of the place, comprehended between the points of two neighbouring bastions; including the curtain, the two flanks raised on the curtain, and the two sides of the bastions which face one another.

So that the tenaille, in this sense, is the same with what is otherwise called the *face of a fortress*.

Tenaille *of the Ditch*, is a low work raised before the curtain, in the middle of the foss or ditch; the parapet of which is only two or three feet higher than the level ground of the ravelin.

There are three different sorts (*Plate* VII. *Fortification*, *fig*. 6. The first are those which are made in the direction of the lines of defence, leaving a passage of three toises between their extremities and the flanks of the bastions, and likewise another of two toises in the middle for a bridge of communication to the ravelin. The second (*fig*. 7.) are those whose faces are in the lines of defence, and sixteen toises long, besides the passage of three toises between them and the flanks of the bastions: their flanks are found by describing arcs from one shoulder of the tenaille as a centre through the other, on which are set off ten toises for the required flanks. The third sort (*fig*. 8.) comprehends those whose faces are sixteen toises, as in the second sort, and the flanks parallel to those of the bastions.

The use of tenailles, in general, is to defend the bottom of the ditch by a grazing fire, and likewise the level ground of the ravelin, and especially the ditch before the redoubt within the ravelin, which cannot be so conveniently defended from any other place. The first sort do not defend the ditch so well as the others, because they are too oblique a defence; but as they are not subject to be enfiladed, M. Vauban has generally preferred them in the fortifying of places. Those of the second sort defend the ditch much better than the first, and add a low flank to those of the bastions; but as these flanks are liable to be enfiladed, they have not been much used. This defect, however, might be remedied, by making them so as to be covered by the extremities of the parapets of the opposite ravelins, or by some other work. Those of the third sort have the same advantage with the second, and are subject to the same inconveniences; and, therefore, they may be used with the same precaution.

Tenailles are esteemed so necessary, that there is hardly any place fortified without them, and it is not without reason; for when the ditch is dry, the part behind the tenailles serves as a place of arms, from which the troops may sally, destroy the works of the enemy in the ditch, oppose their descent, and retire with safety; and the communication from the body of the place to the ravelin becomes easy and secure, which is a great advantage; for by that means the ravelin may make a much better defence, as it can be supplied with troops and necessaries at any time. And if the ditch is wet, they serve as harbours for boats, which may carry out armed men to oppose the passage over the ditch whenever they please; and the communication from the tenailles to the ravelin becomes likewise much easier than it would be without them. Muller's Elem. of Fort. p. 34. See Fortification.

The ram's-horn is a curved tenaille, raised in the foss before the flanks, and presenting its convexity to the covered way. This work seems preferable to either of the other tenailles, both on account of its simplicity, and the defence for which it is constructed.

TENAILLONS, are works constructed on each side of the ravelin, much like the lunettes: they differ, as one of the faces of a tenaillon is in the direction of the ravelin, whereas that of the lunette is perpendicular to it.

Tenaillons are constructed by producing the faces of the ravelin beyond the counterscarp of the ditch, at a distance M N (*Plate* VII. *Fortification*, *fig*. 9.) of thirty toises, and taking on the counterscarp of the great ditch fifteen toises from the re-entering angle p to q, and drawing N q; then q N M p will be the tenaillon required; its ditch is twelve toises, or the same as that of the ravelin. Sometimes there is made a retired battery, in the front of the tenaillons, as at B: this battery is ten toises from the front, to which it is parallel, and fifteen toises long. There are commonly intrenchments made in the tenaillons, such as O; their parapets are parallel to the fronts M N, or rather perpendicular to the side N q, and bisect the side q N; the ditch before this retrenchment is three toises, and there is a banquette before the parapet, next to the ditch, of about eight feet, called *berm*, serving to prevent the earth of the parapet (which seldom has any revetement) from falling into the ditch. The ravelin, before which tenaillons are constructed, must have its saliant angle much greater than the former construction makes them; otherwise the saliant angles of the tenaillons become too acute; for which reason the capital of this ravelin is made forty-five toises, and the faces terminate within three toises of the shoulders. Muller's Elem. Fort. p. 37.

A tenaillon is a work capable of affording great defence to the besiegers; as at the siege of Lisle, in 1708, where the besiegers were twice or thrice drove out of a tenaillon they had taken and retaken.

TENALA, in *Geography*, a town of Sweden, in the province of Nyland; 8 miles N.W. of Eknas.

TENANCY, a habitation, or house to live in, or a tenement or possession held of another.

Tenancy, *Entire*. See Entire.

Tenancy *in Tail*. See Fee-*Tail*.

TENANT, in *Agriculture*, a person holding land or other property of another, either by grant, lease, or otherwise. Tenants are of different kinds, according to the nature of the tenures by which they hold their lands; but, in this last respect, they properly belong to the business of the law. Tenants hold their lands or farms for very different lengths of time, in different districts, as from one year to twenty-one; but in many places they have no leases at all. The most common lengths of time are seven, nine, fourteen, nineteen, and twenty-one. Short leases are now becoming general, as those of seven, nine, and eleven years. Tenants now mostly pay all taxes, except that on property.

The proper choice of tenants is a matter of the greatest importance to the well-doing and continued prosperity and success of all sorts of landed property, of almost any that can be adopted; as where they are improperly provided, there can hardly any thing go on in the manner which it ought to do; nor can there be the best sort of management, that the case will admit of, pursued. Many things will necessarily run into complete neglect, and ruinous states of them be produced as the consequence, which might have been easily and wholly avoided, by more attention in the first selection of the tenants.

The writer of the Middlesex Agricultural Report, after inculcating the necessity and utility of tenants having good and properly regulated leafes of the lands which they hold, remarks, that the letting of farms to tenants at will, or from year to year, is a moft unwife practice, and one which fhould by all means be avoided by the proprietors of landed eftates; as fuch tenants, he contends, from the very nature of their tenures, are precluded from the poffibility of making any improvements; while they have it in their power to ruin the lands they occupy and hold. Rapacious landlords, unfkilful ftewards, and yearly tenancy, it is continued, deftroy the holders' or tenants' confidence, fmother their thoughts of improvements, and, in fhort, make bad tenants, by fetting them to contrive fome mode of occupying the lands, fo as to be able to quit them, on receiving half a year's notice, with the leaft poffible lofs to themfelves; and which can only be done, by keeping the foil continually in a poor ftate, to the evident great loffes of the proprietors, the no lefs ones of the tenants, and the ftill more difadvantages of the community in general. See LEASE, LETTING *of Farms*, and QUALIFICATIONS *of Tenants*.

The writer of the work on "Landed Property" has remarked that, on all large eftates, there are certain eftablifhed cuftoms and ufages to which the proprietors, as well as the tenants or occupiers, confider themfelves mutually amenable, although no legal contracts may fubfift between them; and that, even where imperfect leafes, or other legal agreements, exift, there is ftill, in general, much left for cuftom and ufage to determine. Thefe fixed regulations, though they may be imperfect, it is contended, fhould be ftrictly regarded by fuperintendents, until better ones are fubftituted in their place, not only for the fake of moral juftice, but as fetting an example of integrity and good faith to the tenants. Nothing of this fort fhould ever be broken through by thofe in the management of fuch properties; as tenants on all fuch are conftantly to be met with ready enough to break their ftipulated agreements, without fuch examples; and it muft be extreme folly to induce the others who are well difpofed to do the fame. On the contrary, it is but common prudence to fulfil every covenant, agreement, and promife, which may have been made, with the moft fcrupulous exactnefs, even to the meaneft cottager, in order to infpire proper confidence, and obviate much mifchief.

And befides fetting examples of thefe kinds before the tenants, they ought, it is fuppofed, to be liberalized in their minds, by good offices, and acts of kindnefs, which may be beneficial in various ways. A fpirited improving tenant fhould be refufed few reafonable demands: he fhould have advantages conferred on him, not merely as rewards for his labours in benefiting the lands, but as inducing other tenants to purfue fimilar plans, and to fhew that good managers are noticed and diftinguifhed.

The confequences of an inattention to thefe matters, which is too common in moft parts of the country, are very prejudicial; as the refufing of requefts which would equally benefit the eftate and the tenant, the ftupidly thwarting of the well-meant intentions of the beft tenants upon it, the ignorantly quarrelling with them about mere trifles, and the making no fort of difference between thofe who are improving and thofe who are ruining it, or perhaps the encouraging the latter, and oppofing the former, muft have effects of the worft kind, there can be no doubt. Such tenants as are capable of improving, are alfo capable of impoverifhing; and when difgufted by improper treatment, will be fure to harafs the lands they hold, and take the firft chance they have of removing to farms under more rational management, to the great inconvenience and difadvantage of thofe which they held before.

It is obferved in the Agricultural Survey of Gloucefterfhire, that the leafes of rack-renters there generally commence at Lady-day; and, in this cafe, in the vale, the going-off tenant holds a part of the grafs-lands to old May-day, and has likewife the going-off crop of wheat, with the ufe of the barns for the purpofe of houfing and threfhing it, till the Midfummer following. In this ufage there is, the writer thinks, great inconvenience, efpecially where the new tenant is at variance with the old one, which is not uncommonly the cafe. Each has an opportunity of diftreffing and incommoding the other in various ways. The improved fpirit of agriculture has difcovered, both to landlord and tenant, the abfurdity of this ancient cuftom; and it is gradually falling into difufe. Where an improvement has taken place, the coming-on tenant enters the preceding Michaelmas to plough the land for fpring-crops; the tenant going off at Lady-day ploughs for the wheat-crop, and often fows it. In the cafe of ploughing only, the work is paid for; and when fowed, the crop is valued at Lady-day, and paid by the coming-on tenant. The going-off tenant is alfo frequently paid for his feeds left after the laft year's crop. Under this practice, the new tenant enters on the whole of the eftate at Lady-day. And it is added, that Michaelmas takings are not uncommon; though, in one refpect, they are particularly inconvenient, as the old tenant has no time to fpend the crops of the preceding fummer on the premifes, and the new tenant is either obliged to fell his ftock at a moft unfavourable time, or purchafe fodder for the fupport of it at his new farm; a circumftance he cannot always command, and, when he can, at great lofs. But there are other takings which commence at Candlemas, which have fome inconveniences, particularly that of enabling the new tenant to "hain up" his paftures early, which is a matter of confiderable confequence; for the old tenant, going off at Lady-day, always ftocks as far as he can till the laft moment, thereby leaving the ground as bare as poffible. Nor is the mifchief of this late *haining* always compenfated by the manure left from the cattle, efpecially if the feafon has been wet, and the ground tender. Two years' care will fometimes fcarcely recover the land to a good and even turf, after having been much trodden or *poached*.

But with refpect to agreements between landlord and tenants, it has been fuggefted by fome, that for fmall farms, leafes are lefs neceffary; but a large one cannot well be let without a leafe. Upon a fmall farm, whofe land is good, a man's improvements foon come round; and if the tenant or landlord difagree, either of them is eafily accommodated; but upon a large farm it is quite otherwife. It would not be worth a man's while to fix himfelf upon a large fcale for a year or two; and it would be attended with great expence and lofs, to move from any great diftance, with large quantities of ftock, for a fhort time. Befides, the plans of improvements upon a large farm are more extenfive; and it is longer before the money laid out in them is returned, efpecially upon poor land. But undoubtedly the tenant, upon either a fmall or a large farm, ought to have a fecurity for his property; and there fhould be an agreement to allow him a proportionate recompence for every improvement by which he has raifed the land in its value, as by giving it more manure than could be made from the produce of the farm. When the manure produced upon the farm is the property of the farmer, and, by the terms of his leafe, he is obliged to fell it to the coming tenant at a fair valuation, he often endeavours to make more manure the laft year than any other, and by that means benefits the eftate; but if, on the contrary, he is not paid any thing for it, he will perhaps do every thing in his power to prevent any future improvement upon the farm, as, on fome account or another, he may fancy himfelf himſelf ill uſed upon leaving it. For all under-draining properly done, and for new buildings that were neceſſary for the farm, the tenant ought to be allowed a reward proportionate to the number of years leſs than twenty he may have had the uſe of them. He ſhould likewiſe receive an allowance for quick fences, and the planting of orchards, or of aquatics and other uſeful trees in proper places, on producing fair bills, with receipts to them, of the expences; provided he leaves the eſtate without committing any wilful waſte. The landlord who enters into ſuch a covenant with his tenant, may reaſonably expect to have his farm delivered back to him upon terms equally fair. If the tenant has committed any waſte, he ſhould be obliged to make good all damages. Now ſuch mutual conditions would do away many abſurd reſtrictions that are at preſent laid upon the tenant; as it would then be his intereſt not to injure the farm, becauſe he muſt pay for all damages wantonly done; and the landlord would have no reaſon to check the farmer's experiments and improvements, which would be a great encouragement to both ingenuity and induſtry: for gentlemen's agents are very apt, from too anxious care of the eſtates, to reſtrict tenants in ſuch a manner, that they are little better than a mill-horſe, who can go over only a particular circle of ground. It has been known that an agreement was made to lay a certain quantity of lime on land, where, if the land had been the writer's, he would have given more money than the lime coſt, that it might not be laid on.

And ſometimes, beſides many other injurious modes of culture, which the ignorance or whim of the ſteward obliges the farmer to follow, he is tied down to plough and ſow crops of corn only four years in ſix, and no turnips or clover. But the reſtricting a man from ploughing up graſs-land without leave, is certainly, it is thought, proper, till the landlord ſees what his new tenant makes of the land he does plough; but if he is induſtrious, and tills well, the writer would ſuffer him to plough every inch he choſe: as, on good arable land, it will certainly make in future a difference of from one pound to three pounds an acre in rent to the landlord. The nature and ſituation of the farm are, however, to be well conſidered before this is done.

Alſo where the duration of the term is twenty-one years, it would, it is ſuppoſed, be very proper that, three years before the leaſe expires, he ſhould be reſtricted in the rotation of his crops, ſo as to leave the farm in a proper ſtate to be profitable to the coming tenant. This would likewiſe give time for the tenant to fix himſelf elſewhere, if the landlord and he do not agree again, as well as for the landlord to make proper choice of a new tenant.

It is very common for tenants to live in a very poor way, and obtain little profit, from the want of introducing a proper ſyſtem of huſbandry upon their farms, as it is only this that can afford a full profit; therefore, the beſt methods of management his circumſtances will afford ſhould always be purſued.

There is a great variety of regulations and reſtrictions in regard to tenants, in reſpect to the times and manner of entering upon their farms, the extent and methods of breaking up and cropping the lands, the various improvements in draining, manuring, &c. the making of fences, the ſelling of hay and ſtraw, the diſpoſing of the live-ſtock at the end of leaſes, the occupying of buildings by new tenants, the felling of timber for repairs, and a vaſt number of other matters, many of which are owing to the particular ſituations and circumſtances of the lands that are to be holden by the tenants.

Tenant, or *Tenent*, *Tenens*, in *Law*, one that holds or poſſeſſes lands and tenements of ſome lord or landlord, by any kind of right, either in fee, for life, years, or at will.

The term *tenant* is uſed with divers additions. Thus, *tenant in dower*, is ſhe that poſſeſſes lands by virtue of her dower.

Tenant per Statute-Merchant, he that holds lands forfeited to him by virtue of a ſtatute. See Statute-*Merchant*.

Tenant in Frank-Marriage, is he that holds lands or tenements by virtue of a gift of them, made to him upon marriage, between him and his wife. See Frank-*Marriage*.

Tenant by Courteſy holds for his life, by reaſon of a child begotten by him of his wife, being an inheritrix, and born alive. See Courtesy.

Tenant by Elegit holds by virtue of the writ called an *elegit*.

Tenant in Mortgage holds by means of a mortgage.

Tenant by Verge, in ancient demeſne, is he who is admitted by the rod in court to lands in ancient demeſne. See Verge.

Tenant by Copy of Court-Roll, is one admitted tenant of any lands, &c. within a manor, which, time out of mind, have been demiſed according to the cuſtom of the manor. See Copyhold.

Tenant Paravail. See Paravail.

Tenant by Charter is he that holdeth by feoffment in writing, or other deed. See Charter, and Freehold.

Tenant in Capite, or *Chief*, holdeth of the king in right of his crown. See Capite.

Tenant of the King is he that holdeth of the perſon of the king.

Tenants, *Joint*, thoſe who have equal right in lands or tenements, by virtue of one title. See Joint *Tenants*.

Tenants *in Common*, thoſe who have equal right, but hold by divers titles.

Tenant, *Particular*, he that holds only for his term.

Tenant, *Sole*, is he who has no other joined with him.

Tenant *by Execution*, is he who holds by virtue of an execution upon any ſtatute, recognizance, &c.

Tenants, *Cuſtomary*. See Customary.

Tenant, *Terre*. See Terre-*Tenant*.

Tenant, *Very*. See Very.

Anciently, there were alſo *tenant by knight-ſervice*, *tenant in burgage*, *tenant in ſocage*, *tenant in frank-fee*, *tenant in villenage*. And there are ſtill *tenant in fee-ſimple*, *tenant in fee-tail*, *tenant upon ſufferance*, &c.

Tenant *in Tail after Poſſibility of Iſſue extinct*. See Tail.

Tenant *to the Præcipe*, in *Law*, is he againſt whom the writ of præcipe is to be brought in ſuing out a recovery.

Tenant, or *Tenan*, in *Heraldry*, is uſed for ſomething that ſuſtains, or holds up, the ſhield, or armoury; and is generally ſynonimous with the word *ſupporter*.

The difference which ſome authors make between the two is, that tenants are ſingle, and ſupporters double, one placed on each ſide of the ſhield. But the proper diſtinction ſeems to conſiſt in this, that tenants are human figures, and ſupporters figures of beaſts.

There are various forms of tenants, as well as of ſupporters, *viz.* angels, maids, religious, ſavages, Moors, &c.

The firſt tenants, F. Meneſtrier obſerves, were trunks, or branches of trees; to which the eſcutcheons were faſtened by ſtraps and buckles. Afterwards the knights were repreſented as holding their own eſcutcheons, which were either hung to their neck, or elſe they leaned on them.

The origin of tenants and ſupporters is, by many, referred to the ancient tournaments, in which the cavaliers had their arms borne by ſervants diſguiſed like ſavages, Moors, fabulous deities, bears, lions, &c. See Supporter.

TENA-

TENARIUM, in *Ancient Geography*. See TÆNARIUM.

TENARUS, or TÆNARUS, a mountain of the Peloponneſus, in Laconia.

TENASSERIM, in *Geography*. See SIAM.

TENATARI, in *Ancient Geography*, a people who inhabited that part of Germany which correſponds to the preſent biſhopric of Munſter.

TENBURY, in *Geography*, a market-town in the upper diviſion of the hundred of Doddington, and county of Worceſter, England, is ſituated on the weſtern border of the county, ſeparated from Shropſhire by the river Teme, at the diſtance of 21 miles N.W. by W. from Worceſter, and 134 miles in the ſame bearing from London. The manor of Tenbury, at, or ſoon after the Conqueſt, was held by Robert Fitz-Richard, who was lord of Richard's caſtle; his heir aſſumed the name of Say, in conſequence of a marriage with the heireſs of that family: the property paſt, by a ſucceſſion of heireſſes, through various families, to the Cornwalls, whoſe deſcendants are ſtill the lords of it. The town is not very extenſive, and ſtanding low, is often ſubject to floods from the rapid river Teme. A remarkable inſtance occurred Nov. 17, 1770, when a great part of the church, with its organ and monuments, were deſtroyed. The pariſh of Tenbury is three miles and a half in length, by three and a quarter in breadth; and in the year 1811 contained 308 houſes, and 1562 inhabitants. In the chancel of the church is a curious monument, repreſenting a child in armour, laid in a croſs-legged poſition. Gough, in his Sepulchral Monuments, mentions this figure, and attributes it to the ſon of "John Sturmy, the cruſader, who followed his father to the holy wars when under age."

Over the river, at the north end of the town, is a handſome ſtone bridge of ſix arches. A market is held here on Tueſdays, and there are three annual fairs. Great quantities of hops and apples are cultivated in the vicinity of the town, and conſequently much cyder is made here. The Leominſter canal, coming near the town, affords ready communication for goods, cyder, &c. to diſtant places.

About one mile and a half S.E. of Tenbury is Sutton-park, in the chapel of which are ſome old monuments of the Arundel family. Near this place is Kyre-Wyre, diſtinguiſhed for its "tall and mighty oaks," and for a neat manſion belonging to the Pytts family.—Naſh's Hiſtory, &c. of Worceſterſhire, 2 vols. folio. Beauties of England and Wales; Worceſterſhire.

TENBY, a market and borough town in the hundred of Narbeth, and county of Pembroke, South Wales, is ſituated on the ſhore of Caermarthen bay, 10 miles E. from Pembroke, and 250 miles W. from London. It occupies a rocky promontory of conſiderable elevation, ſtretching over the ſands in a ſoutherly direction, and at high water is nearly incloſed by the ſea. Here is a ſmall but commodious harbour, ſkirted on the land-ſide by a bold amphitheatre of rocks and houſes. Leland ſays, "Tinbigh town ſtondith on a main rokke, but not veri hi, and the Severn Se ſo gulfeth in about hit, that at the ful ſe almoſt the thirde part of the town is incloſid with water. The toune is ſtrongeli waullid and welle gatid, everi gate having his portcolis ex ſolido ferro. But that gate that ledith to Cairmarden ward is moſt ſemelieſt, as circulid without with an embatelid but open roſid towr, after the faſcion of the eaſt gate of Pembroke. Without this gate is a preti ſuburbe. In the middes of the town is a faire paroche chirch. The toun itſelf lakkith freſch water, wherfore utuntur importata." And again, "Ther is a ſinus and a peere made for ſhyppes. The towne is very welthe by marchaundyce; but yt is not very bygge, having but one paroche chyrche. One thing is to be marveled at. There is no welle yn the towne, as yt is ſaide, wherby they be forced to fech theyr water at S. John's without the towne." The wall, which once ſurrounded the town, is yet in ſome places nearly entire. The principal improvement of theſe walls is aſcribed to queen Elizabeth, in whoſe time Tenby was a flouriſhing place. The ſtreets are now in general good, though, on account of the nature of the ground, in ſome inſtances inconveniently narrow and ſteep. They contain a large proportion of very reſpectable houſes, occupied by ſubſtantial tradeſmen and merchants, or by perſons of independent fortunes. The want of water was an inconvenience under which the town long laboured: but by the recommendation and exertions of ſir William Paxton, the town is now furniſhed, at a trifling charge, with an exhauſtleſs ſupply of this neceſſary article. Tenby is one of the contributory boroughs joined with Pembroke in the return of a repreſentative to parliament. The corporation conſiſts of a mayor, aldermen, and common-councilmen, a chamberlain, town-clerk, two ſheriffs or bailiffs, two ſergeants at mace, and twelve conſtables. The town is divided into two diſtricts, which are denominated the In-liberties, and the Out-liberties. The former diviſion is ſubject to the juriſdiction of the magiſtrates of the borough; the latter to that of the county magiſtrates. The preſent extent of the town is not conſiderable, the number of houſes being eſtimated, in the year 1811, at 265, and the population at 1176. It is apparent, however, from the number of ruinated buildings and foundations to be ſeen in the outſkirts, that formerly it muſt have ſpread over a larger ſpace than it now occupies, and contained a much more numerous population. Two weekly markets are held on Wedneſday and Saturday, and five fairs annually. Tenby ſeems to have derived its earlieſt importance from its fiſheries. But when the country fell under the power of the Anglo-Norman invaders, and this diſtrict became inhabited by the Flemiſh ſettlers, its local advantages for commercial objects of greater conſequence were ſeen and appreciated. The harbour was improved for the convenience of ſhipping, and the population of the town and its vicinity was engaged in a woollen manufactory on an extenſive ſcale. The commercial ſpirit thus awakened, procured for the inhabitants numerous privileges and charters from their lords, and from ſucceſſive monarchs. The importance of Tenby, however, has ſunk far below its former rank: its manufactories have diſappeared, and its chief trade at preſent is created by the coal raiſed in its neighbourhood, which is here ſhipped off for other parts of the coaſt, and for the Engliſh markets. The conſequence which the town has loſt in this reſpect ſeems likely to be compenſated by its rapidly advancing reputation as a bathing-place. It poſſeſſes many natural attractions for viſitors; and peculiar advantages in point of convenience have been recently provided. Among theſe, the foremoſt rank muſt be aſſigned to the baths lately erected by ſir William Paxton; in which all accommodations for health and pleaſure are combined. The church of Tenby is ſituated in the middle of the town; it is a ſpacious edifice, compriſing a nave and two ſide aiſles: at the weſt end is a large ſquare tower, ſurmounted by a lofty ſpire. The monaſtic eſtabliſhments of Tenby were an hoſpital, or free chapel of St. John the Baptiſt, a convent of Carmelite friars, founded in 1399, and called St. Mary's college, and an hoſpital or lazar-houſe, dedicated to St. Mary Magdalen. Here was an ancient caſtle, of which there are yet conſiderable remains, though moſtly in a very dilapidated ſtate. The only portions now ſtanding that indicate its former ſtrength are a baſtion and ſquare tower: the reſt of the buildings exhibit the air of a ſplendid manſion rather than

ct

of a military fortrefs. The fituation of this caftle was admirably formed for defence: it occupied the extreme point of the promontory, and was fecured by inacceffible rocks on every fide, except that facing the town, which was ftrengthened by bold fortifications.

On the coaft at Tenby are fome infulated rocks of romantic appearance, which exhibit curious excavations. Some of them are acceffible on foot at low water: this is the cafe with the ifland of St. Catherine, off the Caftle Point, which in one direction has been perforated quite through by the repeated action of the tides. The principal of thefe iflands is *Caldey*, fituated about two miles from the main land. It is about a mile in length, and half a mile wide, and is eftimated to comprife about fix hundred acres of furface, of which nearly a third is in cultivation. Here was a priory, founded, as is fuppofed, by Robert, the fon of Martin de Turribus. The tower of the priory church, furmounted by a ftone fpire, is yet ftanding, and many of the conventual buildings have been converted into offices, and attached to a handfome modern edifice.

Near the coaft, to the eaftward of Tenby, are feveral refpectable gentlemen's refidences, fome of them of ancient date. Among thefe are Cilgetty, formerly inhabited by the Canon family; Hen-Gaftell, (the old caftle,) the property of Thomas Stokes, efq.; Merrixton, the feat of Charles Swan, efq.; Bonville Court, an ancient manfion of the Bonvilles; and Eare Wear, now called Amroth Caftle, the refidence of captain Ackland; and on the road from Narbeth is Begelty Hall, the feat of James Child, efq.—Beauties of England and Wales, vol. xviii. Pembrokefhire, by T. Rees. Hiftorical Tour through Pembrokefhire, 4to. 1810, by R. Fenton, efq. Account of Tenby, illuftrated with etchings, 4to. 1812, by Charles Norris, efq.

TENCE, a town of France, in the department of the Upper Loire; 12 miles S.E. of Moniftrol.

TENCH, in *Ichthyology*, the Englifh name of the *tinca* of the modern authors, the *fullo* and *gnapheus* of the ancients.

It is, according to the Artedian and Linnæan fyftem, a fpecies of the cyprinus, and is diftinguifhed by Artedi by the name of the blackifh, mucous, or flimy *cyprinus* (which fee), with the end of the tail even. See *Tench* Fishing.

Tench's *Ifland*, in *Geography*, an ifland in the Pacific ocean, fo called by Lieut. Ball, commander of the Supply, returning from Norfolk ifland to England in the year 1790. The ifland cannot be more than two miles in circumference: it is low, but entirely covered with trees, many of which are the cocoa-nut; there were likewife others of a large fize. Thefe trees reached to the margin of a very fine fandy beach, which entirely furrounds the ifland. A great number of canoes were lying on the beach; and, it is fuppofed, there cannot be lefs than a thoufand inhabitants on the ifland. The natives who were in the canoes were ftout and healthy-looking men; their fkin was perfectly fmooth, and free from any diforder: they were quite naked, and of a copper colour; their hair refembled that of the New Hollanders. Some of their beards reached as low as the navel, and there was an appearance of much art being ufed in forming them into long ringlets: fo that it fhould feem as if the prevailing fafhion on this ifland was that of keeping the beard well combed, curled, and oiled. Two or three of the men had fomething like a bead or bone fufpended to a ftring, which was faftened round the neck. S. lat. 1° 39′. E. long. 150° 31′.

TENCOA, a town of Mexico, in the province of Honduras; 110 miles W. of Comayagua. N. lat. 14° 48′. W. long. 90° 22′.

TENCZA, a town of Auftrian Poland; 13 miles W. of Cracow.

TEND, in our *Old Writers*, feems to fignify as much as tender, or offer; as to tend or traverfe an averment, &c.

TENDA, in *Geography*, a town of Africa, or rather feveral towns clofe together, the capital of a country of the fame name, on the right bank of the Gambia, fituated to the fouth-weft of Bondou, and fouth-eaft of Woolly. N. lat. 13° 2′. W. long. 11° 55′.—Alfo, a town of France, in the department of the Maritime Alps; late capital of a county to which it gave name, annexed to Piedmont, fituated at the union of the Roia and Brogna. It has only one parifh church, which is a beautiful ftructure, a caftle walled round and flanked with towers, on a rock, which commands the environs of the town. In the 16th century, it came to the duke of Savoy. The foil is not fertile, being on all fides furrounded by the Alps; it yields, however, good pafturage and timber; the rivers alfo furnifh the inhabitants with excellent trout; 22 miles N.E. of Nice.

TENDE, *Col de*, the moft remarkable paffage through the Maritime Alps. See Alps.

TENDEBA, in *Ancient Geography*, a town of Afia Minor, in Caria.

TENDEBAR, in *Geography*, a town of Africa, in the kingdom of Kaen. N. lat. 13° 15′. W. long. 15° 57′.

TENDER, in a *legal fenfe*, fignifies as much as to offer, or endeavour, the performance of any thing, in order to fave the penalty, or forfeiture, incurred by non-performance.

Thus, to tender rent, is to offer it at the time and place when and where it ought to have been paid; which will fave the condition of that time, though the landlord refufe to accept it.

Tender, in *Sea Language*, is a veffel attending on fome other larger and more confiderable one. It is employed in the king's fervice on various occafions; as to receive volunteers and impreffed men, and to convey them to a diftant place; to attend on fhips of war or fquadrons; and to carry intelligence or orders from one place to another, &c.

Tender *Plants*, in *Gardening* and *Agriculture*, all fuch as are too delicate and tender in their nature and habits to ftand, or be raifed, grown, or produced in the climate of this country, without artificial protection or affiftance, until they have been fufficiently inured to, and hardened, and habituated againft the effects of it. It has indeed been obferved by fir Jofeph Banks, in a paper containing fome hints concerning the proper mode of inuring plants of this kind to this climate, inferted in the firft volume of the "Tranfactions of the Horticultural Society" of London, that, refpectable and ufeful as every branch of the horticultural art certainly is, no one is more interefting to the public, or more likely to prove advantageous to thofe who may be fo fortunate as to fucceed in it, than that of inuring plants, natives of warmer climates, to bear, without covering, the ungenial fprings, the chilly fummers, and the rigorous winters, by which, efpecially for fome years paft, we have been perpetually vifited. Many attempts have, it is faid, been made in this line, and feveral valuable fhrubs, that ufed to be kept in our ftoves, are now to be feen in the open gardens; there is, however, fome reafon, it is thought, to believe, that every one of thefe was originally the native of a cold climate, though introduced to us through the medium of a warm one; as the gold-tree, aucuba japonica, the montan, pæonia frutefcens, and feveral others, have been in our times.

In the cafe of annuals, however, it is thought probable that much has been done by our anceftors, and fomething by the prefent generation; but it muft be remembered, it is faid, that all that is required in the cafe of an annual, is to enable it to ripen its fruit in a comparatively cold fummer, after which, we know that the hardeft froft has no power to injure

injure the ſeed, though expoſed in the open air to its ſevereſt influence; but a perennial has to encounter froſts with its buds and annual ſhoots, that have ſometimes been ſo ſevere with us, as to rend aſunder the trunks of our indigenous foreſt-trees, as ſtated by Miller.

It is ſuggeſted as probable, that wheat, our principal food corn at preſent, did not bring its ſeed to perfection in this climate, until hardened to it by repeated ſowings. A few years ago, ſome ſpring-wheat from Guzerat was, it is ſaid, ſown with barley in a ſmall cultivated field: it roſe, eared, and bloſſomed, with a healthy appearance, but many ears were, when ripe, wholly without corn, and few brought more than three or four grains to perfection.

In the year 1791, ſome ſeeds of zizania aquatica were, it is ſaid, procured from Canada, and ſown in a pond at Spring-Grove, near Hounſlow; they grew, and produced ſtrong plants, which ripened their ſeeds; and thoſe ſeeds vegetated in the ſucceeding ſpring, but the plants they produced were weak, ſlender, not half ſo tall as thoſe of the firſt generation, and grew in the ſhalloweſt water only; but the ſeeds of theſe plants produced others the next year ſenſibly ſtronger than their parents of the ſecond year. In this manner the plants proceeded, ſpringing up every year from the ſeeds of the preceding one, every year becoming viſibly ſtronger and larger, and riſing from deeper parts of the pond, until the year 1804, when ſeveral of the plants were, it is ſaid, ſix feet in height, and the whole pond was in every part covered with them, as thick as wheat grows on a well-managed field.

Here, it is thought, we have an experiment which proves that an annual plant, ſcarcely able to endure the ungenial ſummer of this country, has become, in fourteen generations, as ſtrong and as vigorous as our indigenous plants are, and as perfect in all its parts as in its native climate and ſituation.

It is ſuggeſted too in the above paper, that the ſettlement lately made at New Holland gives a large ſcope for experiments of this kind: many plants have been brought from thence which endure our climate with very little protection, and ſome of theſe arrive at puberty at an early period: we have already three, it is ſaid, from the ſouth point of Van Diemen's iſland, where the climate cannot be wholly without froſt; mimoſa verticillata, encalyptus hirſuta and obliqua.

In contributing ſtill further to the elucidation and accompliſhment of this new, very uſeful, and important object of the above arts, the account which has been given by Dr. Macculloch, of ſome delicate plants which are cultivated in the open air in the iſland of Guernſey, with the hints on the means of naturalizing tender exotics, inſerted in the firſt volume of the "Memoirs of the Caledonian Horticultural Society," may alſo be found highly uſeful and intereſting.

It is certain, it is conceived, that neither the thermometric ſtate of a given country, nor any meteorological condition which we have yet been able to obſerve, is competent to explain the peculiar affection of plants for particular regions of the earth. The obſervations of M. Ramond, in the "Annales du Muſeum," which have been tranſlated by Mr. Saliſbury, ſhew this, it is ſaid, in a ſtriking point of view. From theſe we ſee the perſevering regularity with which certain plants affect peculiar elevations, apparently unconnected with the nature of the ſoil, but bearing a relation alone to particular ſtates of the atmoſphere, which we have no means of appreciating. Similar facts are familiar to botaniſts in our own country, in the very limited zones of elevation affected by our alpine plants.

It is ſtated farther, that an economical object which depends on this property of plants remains yet to be noticed. This, which is ſtill more in our power, is probably of more conſequence than either of thoſe mentioned above; what is meant is the perfect naturalization of the vine. It is well known, that from many of the ordinary varieties cultivated in this country, we can always inſure a crop of grapes, but not always a crop of ripe ones. From two or three of theſe, the chance of ripening out of doors is conſiderable; from many others, it is hopeleſs. It is not improbable, that by ſucceſſive ſowings of ſeeds, other varieties might be produced, ſtill more certain of ripening than thoſe which ſucceed beſt with us, *viz.* the miller and the ſweetwater. We ſhould thus acquire poſſeſſion of an article of cultivation of great importance, by which a uſeful addition would be made to the agricultural proceeds of land in particular ſituations, and by which we ſhould be enabled to fabricate wines of a quality ſufficiently good to compete with thoſe of foreign growth.

A ſtill more important object is, it is thought, the perfect naturalization of the potatoe, an effect as yet but very partially obtained, notwithſtanding the length of time during which this valuable root has been a ſubject of cultivation. It is certain that this imperfect naturalization has been the reſult of the common practice of propagating by the tubers, to the almoſt total neglect of the ſeeds. It is true that ſeeds have been occaſionally ſown, and new varieties thus produced; but the experiment has ſtopped in the firſt ſtage, having been always undertaken for the mere purpoſe of producing theſe varieties, without any regard to that much more important object, the production of a plant ſufficiently hardy to bear at leaſt the firſt froſts of winter. In the ſouthern parts of our iſland, it is not a deſideratum of much importance, it is ſaid, as the tubers are in general fully formed before the plant is killed by the froſt; but in the northern parts it is an object of great conſequence, the plant being frequently killed long before the roots have attained maturity. In the Highlands of Scotland, in particular, where a froſt will frequently occur early in September, the crop is often prematurely deſtroyed, and the uſes of this vegetable are in conſequence materially limited. It is plain, that it would be neceſſary to ſow the ſeeds of ſucceſſive generations many times before the requiſite degree of hardineſs could be expected, and that the proceſs would demand both patience and time. Yet if it ſhould require more of theſe than we can expect from the ordinary cultivator, it is an experiment which we may at leaſt recommend to thoſe public bodies, which ſo laudably exert themſelves in ameliorating the agriculture and horticulture of this country. The difficulty of procuring ſeeds from ſeedling plants, could doubtleſs, it is thought, be obviated, in ſome meaſure, by depriving the young plant of its tubers, and thus compelling it to direct its energies to the other and more common mode of propagation, with which nature has provided all plants.

The writer cannot, however, conclude the ſuggeſtions in reſpect to this object or ſpeculation, without noticing a formidable objection which ſtands in the way of our attempts to naturalize particular plants. In every caſe where the uſeful varieties have been the reſult of cultivation in a warmer climate from a baſe and uſeleſs parent, it is to be feared, it is ſaid, that the proceſs followed in naturalization, would again throw the plant back to its original ſtate. This objection applies, it is ſuppoſed, chiefly to thoſe fruits, ſuch as the peach, the apple, and the grape, which, in their preſent cultivated ſtate, are almoſt entirely the produce of art. For this reaſon, it is not improbable, that all attempts to naturalıze the grape to a cold climate may fail; yet the trial deſerves, it is ſaid, to be made. The caſe does not apply equally to the potatoe. The original plant appears to be valuable, independent of any artificial character, and would conſequently admit of a change, tending even to ſome degree of deterioration, before it was materially injured in its properties.

TENDERING, a name given to the ſoft tops of deer's horns, when they begin to ſhoot forth.

TENDING, in *Sea Language*, denotes the movement by which a ſhip turns or ſwings round her anchor in a tideway at the beginning of the flood or ebb. Thus, if the flood ſets northerly, it is evident that the ſhip, unleſs when moored head and ſtern, will fall into the line of the current, turning her head to the ſouthward, and *vice verſâ*. This tranſition from one ſituation to the other is called tending or ſwinging. Falconer.

TENDINOSUM CENTRUM. See CENTRUM.

TENDON, TENDO, in *Anatomy*, the hard, inſenſible cords, by means of which muſcular fibres are attached to bones. See MUSCLE, after the deſcription of the muſcular ſyſtem of animal life; and FIBROUS *Syſtem*.

TENDO *Achillis*, the powerful tendon belonging to the muſcles of the calf of the leg, placed juſt above the heel; ſo named in alluſion to the fable, in which Thetis is ſaid to have held her ſon, Achilles, by this part, when ſhe dipped him in the Styx. See GASTROCNEMIUS.

TENDON *of Achilles*, *Ruptured*. When the tendo Achillis is unfortunately cut, or ruptured, as it may be in conſequence of a violent exertion, or ſpaſm of the muſcles, of which it is a continuation, the uſe of the leg is immediately loſt; and unleſs the part be afterwards ſucceſsfully united, the patient muſt remain a cripple for life.

The ancient ſurgeons ſeem not to have been well acquainted with the rupture of the tendo Achillis, which they probably might miſtake for a ſprain, or ſome other complaint. In caſes in which this part had been cut, they recommended approximating the ſeparated portions, and maintaining them in contact by means of a ſuture.

When the ruptured tendo Achillis was afterwards better underſtood, the plan which we have juſt now mentioned was ſtill continued, the integuments being divided for the purpoſe of bringing the tendon into view. But that ſuch a painful mode is altogether uſeleſs and wrong, it is ſcarcely neceſſary for us at the preſent day to obſerve.

The ſuperficial ſituation of the tendo Achillis always makes the nature of the accident eaſy of diſcovery, and it is only when there is a conſiderable degree of ſwelling (which is very rare), that the caſe can be at all difficult to underſtand. When the tendon has been cut through, which is not an ordinary thing, the diviſion of the ſkin brings the ends of the ſinew into view. When the tendon has been ruptured, the patient hears a ſound, like that of the ſmack of a whip, at the moment of the occurrence. In whatſoever way the part has been divided, there is a ſudden incapacity, or, at leaſt, an extreme difficulty of ſtanding and walking. Hence the patient falls down, and cannot get up again. Beſides theſe ſymptoms, there is a very palpable depreſſion between the ends of the tendon, which depreſſion is increaſed when the foot is bent, and diminiſhed, or even quite removed, when the foot is extended. The patient can ſpontaneouſly bend his foot, none of the flexor muſcles being intereſted. The power of extending the foot is ſtill poſſible, as the peronei muſcles, the tibialis poſticus, and long flexors, remain perfect, and may perform this motion. Œuvres Chirurgicales de Deſault par Bichat, tom. i.

The indications are to bring the ends of the divided part together, and to keep them ſo, until they have become firmly united. The firſt object is eaſily fulfilled by putting the foot in a ſtate of complete extenſion; the ſecond, namely, that of keeping the ends of the tendon in contact, is more difficult.

In order to have a right comprehenſion of the indications, we ſhould conſider what keeps the ends of the tendon from being in contact. The flexion of the foot has this effect on the lower portion; the contraction of the gaſtrocnemius and ſoleus on the upper one. The indications then are to put the foot in an unalterable ſtate of extenſion, and to counteract the action of the above muſcles.

The action of the muſcles may be oppoſed: 1. By keeping theſe powers in a continual ſtate of relaxation. For this purpoſe, the leg muſt be kept half bent upon the thigh. 2. By applying methodical preſſure to the muſcles; methodical, becauſe it is to operate on the fleſhy portion of the muſcles, and not on the tendon, the ends of which being depreſſed by it, would be ſeparated from each other, and, inſtead of growing together, would unite to the adjacent parts. The preſſure ſhould alſo operate ſo as to prevent the ends of the tendon from inclining either to the right or left.

This kind of preſſure, which the bandage ought to make, ſeems to have eſcaped the attention of all authors. Who cannot ſee, however, that the action of the muſcles being by this means reſiſted, the upper end of the tendon will not have ſuch a tendency to be drawn upward, and ſeparated from the lower one? Œuvres Chirurgicales de Deſault par Bichat, tom. i.

The famous Petit ſeems entitled to the honour of having firſt deviſed the plan of treating the ruptured, or divided tendo Achillis, by keeping the leg and foot in a particular poſture, with the aid of an apparatus. Seeing that the extenſion of the foot brought the ends of the tendon into contact, it occurred to him that ſuch extenſion ſhould be maintained during the whole of the treatment, in order to bring about a permanent union. This happy idea, the ſimplicity of which ſhould have rendered it obvious to all practitioners, once having originated, became the common baſis, on which have been founded all the numerous methods of cure, which have been ſince recommended. Deſault par Bichat.

The celebrated Dr. Alexander Monro, profeſſor of anatomy at Edinburgh, happened to rupture his tendo Achillis. When the accident took place, he heard a loud crack, as if he had ſuddenly broke a nut with his heel, and he experienced a ſenſation, as if the heel of his ſhoe had made a hole in the floor. This ſenſation, he ſays, has alſo been obſerved by others, though ſome have complained of a ſmart ſtroke, like what would be produced by a ſtone or cane. Immediately ſuſpecting what had happened, the doctor extended his left foot, in which the occurrence had taken place, as ſtrongly as he could with his right hand, while with the left he preſſed the muſcles of the calf downward, ſo as to bring the ends of the broken tendon as near together as poſſible. In this poſition he ſat, until two ſurgeons came to his aſſiſtance. They applied compreſſes, and a bent board to the upper part of the foot, and fore part of the leg, both which they kept, as nearly as poſſible, in a ſtraight line, by a tight bandage, made with a long roller. But as this mode of dreſſing ſoon became very uneaſy, it was changed for the following one. A foot-ſock or ſlipper was made of double quilted ticking, from the heel of which a belt or ſtrap projected, of ſufficient length to come up over the calf of the leg. A ſtrong piece of the ſame materials was prepared, of ſufficient breadth to ſurround the calf, and this was faſtened with lacings. On the back part of this was a buckle, through which the ſtrap of the foot-ſock was paſſed, ſo that the foot could be extended, and the calf brought down at pleaſure. The leg and foot were wrapt up in ſoft flannel, fumigated with benzoin, and the bandage was kept on day and night, the belt being made tighter when the doctor was about to go to ſleep, and looſened when he was awake, and on his guard. For a fortnight he did not move his foot and leg at all, but was conveyed in a chair on caſtors from one part of the room to another. After this he began to move the ankle-joint, but in ſuch a gentle manner, as not to give any pain. The degree of motion was gradually increaſed, as the tendon became capable of bearing it, care being taken to ſtop, when the motion began to create uneaſineſs. The affected limb was moved in this way, for half an hour at a time. In a few days, the hollow between the ſeparated ends of the tendon became imperceptible, though the part continued ſoft much longer. It became, however, gradually thicker and harder, until a knot was at laſt formed in it, apparently of a cartilaginous nature. Though this was at firſt as large as a middling plum, and gradually became ſofter and ſmaller, yet it did not diſappear entirely. Having occaſion to go out ſix weeks after the accident, the doctor put on a pair of ſhoes, with heels two inches high, and contrived a ſteel machine to keep his foot in the proper poſition. This machine, however, he afterwards changed for another, made of the ſame materials as the former. It was not till five months after the accident, that he thought proper to lay aſide all aſſiſtance, and to put the ſtrength of the tendon to a trial. See Monro's Works, p. 661.

It ſeems unneceſſary to enumerate the various plans deviſed ſince the time of Petit. Suffice it to ſtate, that both in a wound and rupture of the tendo Achillis, the ancient method of uſing a ſuture, for keeping the ends of the tendon in contact, is at preſent quite exploded, and poſition of the limb is the grand agent by which the cure is now univerſally accompliſhed. The following was Default's method, which, though it was expreſsly deſigned to fulfil all the above-mentioned indications, may not after all be a more valuable practical plan, than the one adopted by Dr. Monro. After the ends of the tendon had been brought into contact, by moderate flexion of the knee, and complete extenſion of the foot, Default uſed to fill up the hollows on each ſide of the tendon with ſoft lint and compreſſes. The roller applied to the limb made as much preſſure on theſe compreſſes as on the tendon, and hence this part could not be depreſſed too much againſt the ſubjacent parts. Default next took a compreſs, about two inches broad, and long enough to reach from the toes to the middle of the thigh, and placed it under the foot, over the back of the leg, and the lower part of the thigh. He then began to apply a few circles of a roller round the end of the foot, ſo as to fix the lower extremity of the longitudinal compreſs. After covering the whole foot with the roller, he uſed to make the bandage deſcribe the figure of 8, paſſing it under the foot, and acroſs the place where the tendon was ruptured, and the method was finiſhed by encircling the limb upward with the roller, as far as the upper end of the longitudinal compreſs. Default par Bichat.

Certainly this plan ſeems to anſwer every object, and may be worthy of being adopted in this country. The continued preſſure on the muſcles of the calf, by which their action is materially reſiſted, is too much diſregarded by the generality of Engliſh ſurgeons. Conſult Monro's Works Encyclopédie Méthodique, article *Achille, tendon d'*; and Mémoire ſur la Diviſion du Tendon d'Achille, in Œuvres Chirurgicales de Default par Bichat, tom. i. p. 306. Cooper's Dict. of Practical Surgery.

Tendons, *Shooting of the*, *Subſultus tendinum*, in *Medicine*, a ſlight and repeated convulſive twitching of the muſcles, which occurs in the latter ſtages of low fevers; and, as it indicates great debility, and a very morbid condition of the brain or common ſenſorium, it is uſually reckoned among the dangerous ſymptoms of fever. See Fever, and Typhus.

Tendon, in the *Manege*, a ſort of griſtle that ſurrounds one part of the horſe's foot, and is ſeated between the hoof and the coffin-bone, near the coronet. When a horſe has a quitter-bone, the matter that gathers between the coffin-bone and the hoof ſpoils the tendon, and makes it black; and the cure of ſuch a quitter-bone conſiſts in cutting and extirpating the tendon.

TENDREMENT, Fr. in *Muſic*, tenderly, equal to *con tenerezza*, Ital. See Con *Affetto*, and Affettuoso.

TENDRIL, in *Botany* and *Vegetable Phyſiology*. See Cirrus.

TENDUCCI, Ferdinando, in *Biography*, an opera-ſinger in ſoprano, born at Sienna, whence he at firſt aſſumed the name of Seneſino, on account of the celebrity of a ſinger of that city, in the early part of the laſt century; though neither his voice nor ſtyle of ſinging at all reſembled that of the great ſinger and actor, Franciſco Bernardo detto Seneſino, whoſe voice was a rich and full contralto, and in whoſe ſinging and acting there were more of grandeur and dignity than tenderneſs and expreſſion, which characterized Tenducci's ſtyle; and whoſe voice was a high ſoprano of a clear ſilvery tone, which by great pains he had rendered very flexible; but he had formed himſelf more on Caffarelli's ſtyle than on that of Seneſino.

He arrived in England, as ſecond man, in 1758, when Potenza was principal. The firſt notice he obtained was in a cantabile air, ſet by Caffarelli for himſelf, in a fine ſtyle of grand pathetic, ſuch as ſix years after, Manzoli's fine adagio in Ezio, "Caro mio bene addio," was compoſed in by Peſcetti.

It was in 1759, during the reign of Cocchi's "Ciro riconoſciuto," that he became a favourite of the public; for though a young performer, and only ſecond in rank under Potenza, he had a much better voice and manner of ſinging than the performer to whom he gave precedence.

In 1760 he went to Scotland, and we hear no more of him till 1763, when he returned to London, and performed the principal man's part in Dr. Arne's Artaxerxes, of which the ſucceſs was greatly owing to his talents.

At this period, Bach and Abel eſtabliſhed a weekly ſubſcription concert in Hanover-ſquare, which was better patronized and longer ſupported than perhaps any one had ever been in this country, having continued full twenty years with uninterrupted proſperity, at which, during the chief part of the time, Tenducci was the principal ſinger.

In 1770 he ſucceeded Guadagni as firſt man at the great opera, performing that year with the Graſſi in "Corroe," and the next year in "Semiramide riconoſciuta."

In 1764 he went to Ireland, where he and Miſs Brent performed together in Artaxerxes.

In 1765 an Italian opera was performed in Dublin, in which he and the Cremonini ſung principal parts in Mithridates, in the principal cities of that country.

Some time after he returned to London, and was engaged at the opera, where, in 1785, he revived Gluck's Orfeo.

Such is the outline of his profeſſional career in public. The events of his private life are ſtill more varied.

He had not been long in England before he was thrown into

into the king's bench for debt, where he embelliſhed that reſidence by his talents, and amuſed its inhabitants. He was, however, allowed to attend evening concerts elſewhere, attended by a *garde du corps*. But on theſe occaſions, a Jewiſh lady, his patroneſs, carried him in her carriage to the performance, and conducted him ſafe back with his attendant to his limited reſidence; where, during a part of the time, he had the honour of Dr. Smollet for his neighbour.

In Scotland he ſung at the Edinburgh concerts, and gave leſſons in ſinging; by which occupation he improved his own talents ſo much, that he returned to London a much better ſinger than when he left it. So true is the obſervation of Ariſtotle, that no art or ſcience is well learned but by *teaching*, when it is neceſſary to give reaſons for what in private practice is done mechanically.

In Ireland he married a lady of conſiderable fortune, who was enchanted by his talents.

In Italy, whither he carried this lady, he was unmarried, the laws of that country forbidding conjugal union to caſtrati. And on his application to the pope for a diſpenſation, it was refuſed; though the petitioner ſaid that his reaſon for marrying was, the operation in his youth not having been completely performed: "why then," ſays his holineſs, "let it be done more effectually;" and he was obliged to ſeparate himſelf from his tender ſpouſe, and ſhe to conſole herſelf with a more efficient huſband.

When he quitted the ſtage, he employed his whole time in teaching to ſing; had many ſcholars, and a good method of inſtruction; giving to his pupils, in Engliſh, a ſet of axioms or rules of ſtudy and practice tranſlated from the Italian, drawn up, as he ſaid, by himſelf; but which, after his deceaſe, were found in the Solfeggi of Aprile.

Notwithſtanding the great number of his ſcholars, his income was inſufficient to keep him out of debt, or even the king's bench, without the ingenious expedient of becoming a bankrupt, by which he defrauded all his creditors, and died inſolvent, being, as has been reported, buried at the expence of his countrymen, who made a collection for that purpoſe at the Orange coffee-houſe. But from better authority, we have been informed that he died at Genoa.

Tenducci had much profeſſional merit; but as to probity, honour, and ideas of right and wrong, they never ſeem to have extended further than convenience and perſonal ſafety.

TENDUNCULO, in *Geography*, a river of Africa, which runs into the Indian ſea, S. lat. 19° 20′.

TENEA, in *Ancient Geography*, a town of Corinth, on the frontiers of Sicyonia, S. of Epicria. It pretended to derive its foundation from the Trojans made priſoners in the iſle of Tenedos, and brought into this country by Agamemnon. Apollo was much honoured here.

TENEBRÆ, DARKNESS, in the *Romiſh Church*, a ſervice performed on the Wedneſday, Thurſday, and Friday before Eaſter, in commemoration of the agony of our Saviour in the garden; and the darkneſs that overſpread the earth at the time of his crucifixion.

TENEBRIO, in *Entomology*, a genus of the Coleoptera order of inſects, the generic character of which is, that the antennæ are moniliform, with the laſt joint rounded; the thorax plano-convex, margined; the head exſerted, and wing-ſheaths ſtiffiſh.

In the inſects of this genus the body is oblong-oval, and in moſt ſpecies ſomewhat pointed at the extremity. Several ſpecies are alſo deſtitute of wings. This is a numerous genus, and is divided by Fabricius and others into ſeveral diſtinct genera, under the appellations of Pimelia, Bleps, Aturnus, &c. In Gmelin's edition of Linnæus it comprehends 63 ſpecies. The European ſpecies are denoted by an aſteriſc.

A. *Six filiform Feelers; anterior Legs formed for digging, palmate-dentated; including the* Scaritæ *of Fabricius and Pallas.*

Species.

COMPLANATUS. Black, with a ſubquadrate thorax, and ſmooth ſhells or wing-ſheaths; of a large ſize. Found at Cayenne.

MARGINATUS. Black, with a ſubquadrate thorax; ſulcated ſhells; blue margin. Found at Cayenne.

GIGANTEUS. Black, with ſulcated mandibles, and ſmooth ſhells. Found in Africa; nearly allied to the next ſpecies, but thrice as large.

SUBTERRANEUS. Black, with the fore-part of the head ſulcated, and ſtriated ſhells.

CYANEUS. Blue, very ſmooth; antennæ and feet black. Found in New Holland.

* FOSSOR. Pitchy. Found in ſand-hills, which it perforates.

* CURSOR. Brown; oblong thorax; five angles denticulated. Found as the former.

ARABS. Black; ſerrated thorax; antennæ and feet teſtaceous. Found in the Eaſt.

MINUTUS. Black; thorax margined; antennæ clavated, and feet pitchy. Found in Sweden; and twice as large in Saxony.

COLLARIS. Black, with ſhells punctate-ſtriated, and head brown; antennæ and feet pitchy; the anterior ſpinous. Found at Berlin.

BUCEPHALUS. Wholly brown, punctated; eyes black. Found in India.

B. *With unequal filiform Feelers.*

ATRATUS. Wholly black, ſmooth. Found in Egypt.

C. *With four Feelers; the anterior ſubclavate; the poſterior filiform; the* Tenebriones *of Fabricius, and* Mylarides *of Pallas.*

LAMINATUS. Black; thorax ſubquadrate, ſmooth; ſhells ſulcated; anterior legs incurvated at the apex, and ferruginous lamina acute. Found in India; the largeſt of the genus.

GIGAS. Black; ſhell ſtriated; thorax ſmooth. Found in Surinam.

PUNCTATULUS. Black; thorax quadrate; margin ſubdenticulate; ſhells ſtriate-punctated. Found in India; of a large ſize.

SERRATUS. Black, ſmooth; ſhells ſtriated; poſterior legs ſtriated. Found in Sierra Leone.

* MOLITOR. Wholly black; thighs anterior thicker:—an inſect often ſeen in houſes, one of the ſmaller kinds, proceeding from a larva commonly known by the name of meal-worm, from its being ſo frequently found in flour, &c.; it is of a yellowiſh-white colour, about an inch long, ſlender-bodied, and of a highly poliſhed ſurface, and is conſidered as the favourite food of the nightingale, in its captive ſtate, and ſaid to remain two years before it changes into a chryſalis.

LURIDUS. Black, with brown feet. Found in Braſil.

CHALYBEUS. Violet, with feet and antennæ pitchy. Found in Guinea.

MAURITANICUS. Black, beneath pitchy; margins of the

the thorax anterior and poſterior angulated. Found in Algiers.

Variegatus. Oblong, with varied brown and cinereous. Found in Africa.

Abbreviatus. Ovate, black, with ſhell ſtriated, and head tuberculated. Found in India.

Capensis. Ovate, black; ſhell ſtriated; anterior legs dentated-ſpinous. Found at the Cape of Good Hope.

Cornutus. The margins of the double-horned thorax crenated, and the angles projecting. Found in Smyrna.

Sanguinipes. Black, with antennæ and feet ſanguineous. Found in New Holland.

Buprestoides. Black; oval, thorax margined; the connate ſhells ſmooth. Found at the Cape of Good Hope.

Dermestoides. Black; thorax oval, margined; ſhells ſtriated. Found in Saxony.

Culinaris. Ferruginous; ſhells ſtriated; ſhield emarginated. Found in Spain and Sweden.

Barbarus. Black, very ſmooth; thorax orbiculated; the ſhield of the head on the fore-part, with the margin elevated. Found in Mauritania.

* Erraticus. Black; the antennæ, ſuborbiculate thorax, and ſhells ferruginous; brown at the apex.

Pallens. Palely teſtaceous; thorax tranſverſe. Found of a ſmall ſize at the Cape of Good Hope.

Ferrugineus. Ferruginous, with ſhells ſtriated teſtaceous. Found in Africa.

* Villosus. Brown, cinereous-villoſe, ſhells ſmooth and ferruginous.

* Caraboides. Black; thorax oval, margined; ſhells ſtriated.

Brunnipes. Black, ſmooth; ſhells ſtriated; antennæ and feet ferruginous. Found at Dreſden.

Lævigatus. Oblong, black, with ſmoothiſh ſhells. Found in Africa, of a leſs ſize than the molitor.

Gibbosus. Subovate; wholly braſſy, ſhells gibbous-convex; the very fine ſtriæ crenulated. Found in Braſil.

Spinimanus. Thorax margined, ſmooth, ſhells very ſmooth; poſterior obtuſe; fore-legs produced with a very ſtrong arched ſpine. Found in Southern Ruſſia.

Uncinus. Apterous, black; thorax margined, ſubequal; ſhells ſtriated-punctated and angulate; thighs anterior, clavated, very large, biuncinate. Found in Spain.

Piceus. Depreſſed, black; beneath pitchy; ſhells ſtriated. Found in Saxony.

Cylindricus. Very black; thorax with elevated points; antennæ brown; the tarſi beneath yellow-haired. Found at Berlin.

Montanus. Wholly black; ſhells opaque. Found in Hungary.

Tristis. Black, ſub-opaque, varied with excavated points. Found in Carniola.

Pomonæ. Above pitchy, beneath black; ſhells with five elevated ſtriæ. Found in Carniola.

Capreæ. Black; points impreſſed on the thorax and ſhells teſtaceous. Found in Carniola and Switzerland.

Flavus. Yellow, with black eyes. Found in Carniola.

Æstivus. Black; feelers and feet yellow. Found in Denmark.

Striatus. Black; the abdomen beneath denſely ſtriated. Found in Denmark.

Festinans. Wholly black, ſmooth; thorax ferruginous.

Globosus. Black; thorax globoſe; two rough lines elevated. Found in Siberia.

Incurvatus. Wholly pitchy; ſhells ſtriated acroſs the middle. As the laſt.

Ovatus. Ovate, blackiſh-brown; ſhells with eight ſtriæ, ſmooth.

Rotundatus. Black, wholly ſmooth: the coleoptra rotundata.

Subvillosus. Wholly ferruginous, ſubvilloſe.

Glaber. Wholly ferruginous, ſmooth. The four laſt found in France.

* Lignarius. Thorax with two cavities; ſhells violet or red; antennæ and feet ferruginous.

Lardarius. Oblong, yellow-fulvous; eyes black; ſhells with punctated ſtriæ. Found in Belgium.

* Curvipes. Ovate, pitchy; ſhells punctated-ſtriate; thighs crenated; the hinder beneath ciliated.

* Bicolor. Ovate; ſhells ſtriated; above black; the antennæ beneath and feet ferruginous.

* Ater. Black; antennæ ferruginous.

* Lunatus. Black; depreſſed thorax lunated; ſhells ſtriated; feet ferruginous.

* Hispidus. Black, rough; ſhells ſtriated; a ſpot at the baſe on both ſides red; the antennæ and legs red.

* Glaber. Ferruginous; head and thorax ſmooth, and ſhells black; theſe ſtriated; mouth ferruginous; feet livid.

Tenebrio *Mortiſagus*, a ſpecies of the *Pimelia*, (which ſee,) in the Gmelinian edition of the Linnæan ſyſtem, thus deſcribed by Dr. Shaw. It is a coal-black inſect, meaſuring about an inch in length, of rather ſlow motion, and diſtinguiſhed by the remarkably pointed appearance of the wing-ſheaths, which at their extremities project a little beyond the abdomen; they are alſo perfectly connate or undivided, forming a complete covering to the body, and being carried over the ſides to ſome diſtance beneath, and the inſect is totally deſtitute of real or under wings. It is uſually found in dark neglected places, beneath boards, in cellars, &c. and if handled, eſpecially if cruſhed, diffuſes a very unpleaſant ſmell.

TENEBRIUM, in *Ancient Geography*, a promontory of Spain, belonging to the Ilercaones. Ptol. It lay S. of the mouth of the river Iberus.

TENEDOS, in *Geography*, an iſland of the Grecian Archipelago, near the coaſt of Aſia, and very near the Troade. This iſland has been ſucceſſively celebrated by Homer and Virgil. The latter thus deſcribes it:

> "Eſt in conſpectu Tenedos, notiſſima famâ
> Inſula, dives opum, Priami dum regna manebant;
> Nunc tantum ſinus et ſtatio maleſida carinis."

According to Diodorus Siculus, it had anciently been called Leucophris; but when Tenes or Tennes built a town upon it, he called it Tenedos. Bochart, however, derives its name from the Phœnician word Tin-edum, red clay, which was found here, and uſed for making earthen-ware. Pauſanias ſays, that this iſland, which was ſituated within ſight of the city of Troy, became miſerable after the capture of that city, and was obliged to ſurrender to its neighbours, who had built Alexandria upon the ruins of Troy. It was one of the firſt conqueſts of the Perſians, who made themſelves maſters of it, after having defeated the Ionians at the iſle of Lada. It took part with the Athenians againſt the Lacedæmonians, when an admiral of the latter people ravaged it, and drew from it contributions. The Romans had poſſeſſion of it, and Verres pillaged the temple, and carried away the ſtatue of Tennes, the ſuppoſed founder of the town. Strabo repreſents it as 24 ſtadia in circumference, and places it at the diſtance of 11 ſtadia from the continent; but Pliny ſtates this diſtance to be 12 miles. Olivier computes the diſtance to be nearly 3000 toiſes: and he ſays, that the town is at the diſtance of about five leagues from

from the entrance of the Hellefpont. This pofition has always rendered Tenedos important. Veffels bound to Conftantinople find fhelter in the ports of this ifland, or fafe anchorage in the roads, when the winds are contrary and the weather bad. The emperor Juftinian eftablifhed in this ifland a magazine for receiving cargoes of corn tranfported from Egypt, 180 feet long, 90 broad, and proportionally high. During the troubles of the Greek empire, Tenedos fuftained many viciffitudes. It was for many years a place of rendezvous for pirates. Scantily peopled and ill defended, it paffed betimes under the Ottoman domination. The caliph Othman feized it in the year 1302, and in the poffeffion of it, he was enabled to fubdue the other iflands of the Archipelago. During the minority of Mahomet IV. the Venetians retook it after the complete defeat of the Turkifh fleet in the ftrait by the admiral Mocenigo, in 1656: but in the following year, the admiral having been killed in a fecond engagement, the Venetian fleet retired, and this ifland fell again under the power of the Turks, who have preferved it without interruption till the prefent day. The harbour is fmall, and can only receive merchant veffels: it is formed by a jetty even with the water's edge, and a tongue of land, on which is conftructed the citadel that defends the entrance, and can at moft fecure it againft being furprifed by a privateer. The town is built in form of a femicircle, in a valley, and on the declivity of two hills: its population is from 5000 to 6000 fouls, judging from its extent, and from the number of perfons who pay the karatch. Its inhabitants, who are Turks and Greeks in equal numbers, are almoft all occupied in the culture of the lands, few of them being mariners. The ifland is under the adminiftration of a waiwode or governor, an aga commandant of the citadel, and a cadi or judge. The defenders of the town are 200 or 300 janizaries. The town is commanded by a pyramidal mountain of fmall elevation, that feems to have been formed by the action of a volcano, the traces of which are difcoverable. In the environs is found a granite remarkable for pieces, of various fizes, of felfpar cryftallized. On the right of the mountain, in paffing from the town towards the W., is a fandy plain, far from fertile, and almoft entirely covered with vines. The hills, in general, are naked, dry, and little fufceptible of culture. Thofe on the fouth of the town are calcareous; and the rock is more or lefs chalky and loaded with fea-fhells.

Tenedos produces little corn, fruit, or herbage. The vine is the only article of wealth of this country, and its culture the principal occupation of the inhabitants. Mufcadel wine is made in confiderable quantities. From Tenedos are annually exported upwards of 600,000 okes of wine, producing to the farmer more than 30,000 piaftres. This wine paffes to Conftantinople, Smyrna, and Ruffia. This ifland alfo exports a fmall quantity of brandy. The climate of Tenedos is more temperate than that of the Dardanelles: it feldom freezes here, and the fummer heats are moderated by the N.N.E. wind, which blows regularly during the day. The houfes have terraces of flat roofs. The Greek inhabitants are lefs gay than thofe of the other ifland: in the ftreets they are filent and melancholy, avoiding through fear the attention of the Turks; but when they can indulge themfelves in mirth without danger, they furrender themfelves to a fort of extravagant joy and delirium. The coaft of Troy is frequently the theatre of their orgies and the field of their pleafures: thither they repair on the occafion of a wedding or of a feftival, and there, under the fhade of a planetree or oak, they pafs the whole day in dancing, finging, eating and drinking. The females, however, are kept within the bounds of decorum, and might be compared, from their features and their fhape, to the moft beautiful models which antiquity has tranfmitted to us. N. lat. 39° 53′. E. long. 26°. Sonnini. Olivier.

TENELLA, τενελλα, in *Ancient Mufic*. As fome conquerors at the Olympic games were not fo fortunate as to have poets for their friends, or fo rich as to be able to purchafe odes on their particular victories, which were rated very high by bards of the firft clafs; in honour of fuch, the old hymn to Hercules, of Archilochus, was fung by the friends of the conquerors only, if they could not afford to engage a band of profeffed muficians. The fcholiaft on Pindar's ninth Olympic tells us, that to fupply the want of a citharædift, Archilochus framed a word in imitation of the found of a cithara, which word (*Tenella*, Τενελλα), when there happened to be no mufician prefent, the leader of the chorus chanted forth, and was anfwered by the reft of the chorus, in the words of the hymn, Ω Καλλινικε, χαιρε, *O glorious Victor, hail!* at every comma, or paufe of which, this burden was again repeated.

TENEMBER, in *Geography*, an ifland in the Eaft Indian fea, 12 miles long and 3 broad. S. lat. 6° 50′. E. long. 132° 45′.

TENEMENT, Tenancy, in *Law*, a houfe or lands, depending on a manor, or lordfhip; or a fee, or farm held of a fuperior lord, and which he may recall, when the term or condition is expired.

Tenement, *Frank*, is any lands, houfe, office, or the like, in which a man has eftate for life, or in fee.

Tenement, *Bafe*, is where a man holds lands, &c. at the will of the lord.

Yet Kitchin, Briton, &c. make frank tenement and bafe tenement oppofites; on which footing, frank tenement fhould be where the tenant is at liberty to quit it when he pleafes.

TENEMENTARY Lands, among our anceftors, were the outlands of manors, which the Saxon thanes, or nobles, let out to tenants under arbitrary rents and fervices.

TENEMENTIS Legatis, in *Law*, a writ which lies in London, and other places, where the cuftom is to devife tenements by laft will as well as perfonal goods and chattels, for the hearing of any caufe relating to them.

TENEN, or Knin, in *Geography*, a town of Dalmatia, fituated on the borders of Bofnia, and the fee of a bifhop; 48 miles S. of Bihacs.

TENENDUM, in *Law*, is a claufe in a deed, in which the tenure of the land is created and limited. The office of a tenendum is to limit and appoint the tenure to the land which is held, and how, and of whom it is held. The tenendum feems now to be incorporated with the *habendum*, for we fay, to have and to hold, in which claufe the eftate is limited, &c.

TENENTES Nativi. See Nativi.

TENENTIBUS *in Affifa non Onerandis*, in *Law*, a writ which lies for him to whom a diffeifor has made over land, of which he diffeifed another; requiring that he be not difturbed in affize, for the damages awarded, if the diffeifor have wherewithal to fatisfy them.

TENEREZZA, tendernefs, feeling, equivalent to the French term *tendrement*.

TENERIA, in *Geography*, a town of the ifland of Cuba; 45 miles N.W. of Villa del Principe.

TENERIFFE, one of the Canary iflands, the fecond in dignity, but the firft probably with regard to wealth and fertility. It is about 70 miles in length, and its mean breadth is about 22 miles: its furface contains 1540 fquare miles, having, at an average, about 45 perfons to the fquare mile,

mile. The number of acres is 985,600, which, upon an average, allots about 10 acres to every individual in it; the number of inhabitants being calculated to be nearly 100,000. Of thefe there is annually a confiderable migration to the Spanifh colonies in South America. The poor of Teneriffe are eafily perfuaded to migrate, as the proprietors of the land do not give them fufficient employment throughout the year; and they have not the refource of manufactures, except a trifling one in filk, chiefly ftockings. The price of labour is under a fhilling a day; and, befide corn and roots, the principal food of the common people is confined to cod-fifh, caught on the neighbouring coaft of Africa, or imported from North America. This ifland was formerly called Nivaria, which appellation it derived from the circle of fnow that furrounded the peak of Tenda, now called the peak of Teneriffe; which name was given to it, as it is faid, by the inhabitants of Palma ifland, in whofe language *tener* fignifies fnow, and *effe* a mountain. The figure of this ifland is triangular, as it extends into three capes, the neareft being about 80 leagues or more from the coaft of Africa. The hiftorical celebrity of this ifland has been very much owing to its *Peak*, elevated to a confiderable height from a bafe lying a little to the S.W. of its centre. Of its height we have various ftatements by different writers, who have afcended to its fummit. Dr. Heberden, whofe obfervations in afcending it are publifhed in the Phil. Tranf. vol. xlvii. makes its height above the level of the fea to be 2566 fathoms, or 15,396 Englifh feet; and he fays that this meafure was confirmed by two fubfequent obfervations by himfelf, and another made by Mr. Croffe, the conful. Neverthelefs, chevalier de Borda, who meafured the height of this mountain in Auguft 1776, makes it to be only 1931 French toifes, or 12,340 Englifh feet. Mr. Johnftone, a merchant of Madeira, being on board fhip in the offing of Orotava, took the angles made by a line from the horizon to the fummit of the Peak, at two different fpots, and meafuring the diftance between them by the log, determined the perpendicular height of the Peak to be 2023 Englifh fathoms, being nearly the fame as Chev. de Borda had calculated from a bafe meafured upon land. From the comparative obfervations of Monf. de Borda's barometers, upon the Peak, and by the fea-fide, the mountain's height came within two fathoms of the geometrical meafurement. The Hon. Grey Bennet, who made a journey to the top of the Peak in 1810, ftates its height to be about 12,500 feet. M. de Lemanon and Monges, on the 26th of Auguft 1785, afcended the Peak, and ftating its elevation above the level of the fea to be near 1900 toifes, made fome chemical experiments, in order to compare the phenomena at that height with thofe which occur in our laboratories. They obferve, that the crater of the Peak is a perfect folfatara or laboratory of fulphur; its diameter being about 50 toifes by 40, rifing with a fteep and rapid afcent from W. to E. On the edges of the crater, and particularly towards the loweft part, are feveral apertures or vents, exhaling watery and fulphuric acid vapours, the heat of which raifed the thermometer from 9° to 34°. The interior of the crater is covered with yellow, red, and white clay, and fragments of lava partly decompofed. Under thefe were found beautiful cryftals of fulphur, forming rhomboidal octohedra, fome of which were an inch thick. The fteam exhaled from the apertures was pure water, not at all acid. The evaporation of liquids, and the cold thus produced, were very confiderable. The action of the acids on metals, earths, and alkalies was flow, and the bubbles that efcaped during the effervefcence were much larger than ufual. The production of vitriols afforded a fingular phenomenon. That of iron inftantly affumed a fine violet colour, and that of copper precipitated with a very vivid hue. The fmell and ftrength of liquors appeared not to have loft any thing at this elevation, and the volatile alkali, ether, and alcohol, retained the fame ftrength. Several experiments were made with a view of afcertaining the nature of the vapours exhaled from the crater, and whether they contained inflammable air, fixed air, or marine acid. From thefe he concluded that no fixed air exhaled from the crater, and alfo that the atmofpheric air refting upon it contains very little, and that the inflammable vapours and fulphuric acid gas alone are confiderable, and indeed perceivable. The atmofpheric electricity was confiderable and pofitive. Many new varieties of volcanic fchorls were difcovered. See La Peroufe's Voyage, vol. ii. p. 226, &c.

Dr. Heberden gave fir Jofeph Banks fome falt which he collected on the top of the mountain, where it is found in large quantities, and which he fuppofed to be the true natrum, or nitrum, of the ancients. Although the vortex appears fharp, and of the exact refemblance of a cone, yet it is flat for the extent of an acre of ground, in the centre of which is a dreadful volcano, which frequently breaks out into flames, fo violent as to fhake the whole ifland with an incredible force. Smoke conftantly iffues from the mountain, near its fummit, but no eruption has occurred fince the year 1704, when the port of Garrachica was deftroyed, and the harbour filled by the lava. The ifland of Teneriffe is divided in the middle by a ridge of mountains, which have been compared to the roof of a church, the Peak forming the fpire or fteeple in the centre. An author well acquainted with the ifland fays, that if you divide it into twelve parts, ten of thefe confift of rocks, woody and inacceffible mountains and vineyards; and yet, from the fmall remainder of arable ground, he has feen 250,000 hanackes of wheat, befides immenfe quantities of rye and barley, produced. The greateft part of the ifland is volcanic, and all its rocks are lava. Mr. Bennet (Tranf. of the Geological Society, vol. ii.) conceives, that formerly a very large crater, 12 miles in diameter, exifted, the fides of which, under the name of Las Foldas, may be ftill traced a great way. The crater at the top of the Peak is but fmall, and fomewhat in activity. The lavas vary in their appearance: fome are compofed of hornblende and felfpar, without any foreign body; thefe are porphyritic: fome are compofed of green-ftone, and contain olivin, augite, and zeolites: fome are bafaltic; thefe decompofe the fooneft, and conftitute the moft fertile foil: there are alfo pumice in abundance, tufa afhes, and a lava refembling obfidian. Every circumftance, it is faid, argued in favour of a volcanic formation, except the form of the mountains, whofe irregular ridges, declivities, and afcents, appeared very different from thofe exhibited by volcanic mountains. In the plain beyond Laguna, on the Orotava fide, the foil was not in the leaft volcanic, but compofed of fine mould, or virgin earth; a mixture of clay, vegetable earth, and fand. Hollows, 30 feet deep, left dry by rivulets, exhibit no volcanic appearance. Immediately under the fuperficial foil was a layer of deep loam, next, one of tough clay, and all below was an irregular mixture of clay and fand. Elfewhere the hills confifted of indurated clay, and clay and iron, without any marks of the action of fire. In the whole ifland, there is no pure flint or fand-ftone. Its mountains are of two forts; one, evidently volcanic; the other, primary and compofed of indurated clay, or of clay and calx of iron. In the low plains are layers of loofe and foft argillaceous earth. (See Dr. Gillan's remarks in the 1ft vol. of the Embaffy to China, p. 118—120.) Although the people live on fcanty and coarfe fare, they are not much fubject to difeafe, and inftances of longevity, even to 100 years,

years, are said not to be rare amongst them. The air is dry and pure. The variations of the thermometer seldom exceed 14°, from 68° to 82°, in the inhabited part of the island. (See GUANCHES.) To the eastward of Santa Cruz, says Mr. Anderson (Cook's Third Voyage, vol. i. p. 22. &c.) the island appears perfectly barren. Ridges of hills run towards the sea, between which ridges are deep vallies, terminating at mountains or hills that run across and are higher than the former. Those that run towards the sea are marked by impressions on their sides, which make these appear as a succession of conic hills, with their tops very rugged. The higher ones that run across are more uniform in their appearance. The basis of the hills is a heavy, compact, blueish stone, mixed with some shining particles; and on the surface, large masses of red friable earth, or stone, are scattered about. The little earth, that appeared here and there, was a blackish mould. There were likewise some pieces of slag, one of which, from its weight, and smooth surface, seemed almost wholly metalline. The mouldering state of these hills is, without doubt, owing to the perpetual action of the sun, which calcines their surface.. "After walking about three miles," says Mr. Anderson, "I found no alteration in the appearance of the lower hills, which produce great quantities of the euphorbia Canariensis. I met with nothing else growing there, but two or three small shrubs, and a few fig-trees near the bottom of the valley. Most of the laborious work in this island is performed by mules, horses being to appearance scarce, and chiefly reserved for the use of the officers: they are of a small size, but well shaped and spirited. Oxen are also employed to drag their casks along, upon a large clumsy piece of wood. In my walks and excursions I saw some hawks, parrots, which are natives of the island, the sea-swallow or tern, sea-gulls, partridges, wagtails, swallows, martins, blackbirds, and Canary birds in large flocks. There are also lizards of the common, and another sort; some insects, as locusts; and three or four sorts of dragon-flies." Mr. Anderson was informed that a shrub is common here, agreeing exactly with the description given by Tournefort and Linnæus of the tea shrub, as growing in China and Japan. Another botanical curiosity, mentioned by him, is what they call the impregnated lemon. It is a perfect and distinct lemon, inclosed within another, differing from the outer one only in being a little more globular. The leaves of the tree that produces this sort, are much longer than those of the common one; and it was represented to him as being crooked, and not equal in beauty. Mr. Anderson learnt also, that a certain sort of grape growing here is reckoned an excellent remedy in phthisical complaints; and the air and climate in general are remarkably healthful, and particularly adapted to give relief in such diseases. This he endeavoured to account for by its being always possible to procure a different temperature of the air, by residing at different heights in the island: and he expressed his surprize that the English physicians had never thought of sending their consumptive patients to Teneriffe, instead of Nice or Lisbon. They reckon that 40,000 pipes of wine are annually made, the greatest part of which is either consumed in the island, or made into brandy, and sent to the Spanish West Indies and North America.

In the Embassy to China (vol. i.) the quantity of wine, consisting principally of white wine, said to be exported from Teneriffe, is about 25,000 pipes annually made in the island. Part is sent to South America: and the English take off a considerable quantity in return for manufactures; and the North Americans in payment of corn, staves, horses and tobacco, which last article is contraband and smuggled. Tobacco or snuff is in universal use; and that which is legally imported is sold at so high a price, that the temptation to smuggling is irresistible. The royal monopoly extends even to orchilla or archil, a substance used in dyeing. Formerly there was made at Teneriffe a great quantity of Canary sack, which the French call "vin de Malvasia," and we, corruptly after them, name Malmsey (from Malvasia, a town in the Morea, famous for such luscious wine.) In the 17th century, and still later, much of this was imported into England, and little wine is now made there except that described by Capt. Cook, and which he compares with Madeira, the latter being as much superior to the former, as strong beer is to small. But the great difference of price is a recommendation of it. Besides wine, which is the chief produce of the island, beef may be had at a moderate price. The oxen are small and bony, and the meat lean. Hogs, sheep, goats, and poultry, may also be bought at a moderate rate: and fruits, such as grapes, figs, pears, mulberries, plantains, and musk melons, are in great plenty. Their pumpkins, onions, and potatoes, are also very good of their kind. The Indian corn, which is their produce, and also their fruits and roots, may be had at a very reasonable rate. They have no plentiful supply of fish from the adjoining sea; but a considerable fishery is carried on by their vessels upon the coast of Barbary; and the produce of it sells at a reasonable price. Capt. Cook says that he found Teneriffe to be a more eligible place than Madeira for ships bound on long voyages to touch at. At Teneriffe they make a little silk; but unless we reckon the filtering-stones, brought in great numbers from Grand Canary, the wine is the only considerable article of the foreign commerce of Teneriffe. None of the race of inhabitants found here when the Spaniards discovered the Canaries, now remain a distinct people, having intermarried with the Spanish settlers; but their descendants are known from their being remarkably tall, large-boned, and strong. The men are in general of a tawny colour, and the women have a pale complexion, entirely destitute of that bloom which distinguishes our northern beauties. The Spanish custom of wearing black clothes continues amongst them; but the men seem more indifferent about this, and in some measure dress like the French. According to Capt. Cook, the peak of Teneriffe is situated in N. lat. 28° 18′, and upon this supposition its longitude will be

$$\text{By}\begin{cases}\text{The time-keepers} & 17^\circ\ 0'\ 30'' \\ \text{Lunar observations} & 16\ \ 30\ \ 20 \\ \text{Mr. Varila} \quad - & 16\ \ 46\ \ \ 0\end{cases}\text{West.}$$

But if its latitude be 28° 12′ 54″, as in Maskelyne's British Mariner's Guide, its longitude will be 13′ 30″ more westerly. The variation (August 1776) by a mean of all Capt. Cook's compasses was found to be 14° 41′ 20″ W. The dip of the N. end of the needle was 61° 52′ 30″.

TENERIFFE, a town of South America, in the government of the Caraccas, and province of St. Martha; 80 miles S.S.W. of St. Martha. N. lat. 10° 2′. W. long. 74° 30′.

TENESMUS, in *Medicine*, an incessant and urgent desire to go to stool, while the evacuations are exceedingly scanty, of a mucous or bloody appearance, and are attended with scarcely any relief of the distressing sensation which preceded them. It may be brought on by any cause which excites excessive irritation in the rectum, either directly, or by sympathy with neighbouring organs, such as the bladder, uterus, prostate gland, or urethra. Thus it is frequently a symptom of a stone in the bladder, of inflammation of the neck of that organ, of fistula, of gonorrhœa virulenta, and also of pregnancy. In its most acute form, tenesmus more commonly

commonly occurs as a consequence of disease affecting the intestines themselves, and more especially of dysentery: it is also frequently excited by ascarides, or hæmorrhoidal tumours within the rectum. See DYSENTERY.

The treatment of this affection must of course be adapted to the nature of the irritation which has occasioned it; and the removal of the irritating cause will generally be followed by the cessation of the effect. When this, however, cannot be accomplished, the introduction of opium as a suppository into the rectum, or united with a starch glyster, will often procure essential relief.

TENESSEE, in *Geography*. See TENNESSEE.

TENESUR, a town of Egypt, on the west branch of the Nile; 3 miles S. of Amrus.

TENET, a particular opinion, dogma, or doctrine, professedly held by some divine, philosopher, &c.

The distinguishing tenets of the several sects in religion, and philosophy, see under the names of the sects themselves.

TENEZ, or TENES, in *Geography*. See TENNIS.

TENEZA, a town of Morocco; 43 miles W.S.W. of Morocco.

TENGA, in *Botany*, a name by which some authors have called the cocoa-nut tree, or palma indica nucifera of other writers.

TE-NGAN, in *Geography*, a city of China, of the first rank, in Hou-quang; 550 miles S. of Peking. N. lat. 31° 20'. E. long. 113° 17'.

TENGAPATAM, a town of Hindoostan, on the sea-coast, in the country of Travancore; 20 miles S.W. of Travancore.

TENGI, a town of Persia, in the province of Schirvan; 25 miles N. of Scamachie.

TENGILO, a river of Lapland, which falls into the Tornea, which, as well as the lake and mountain of Niemi, has been celebrated by Maupertuis for picturesque beauty.

TENGIS, a lake of Independent Tartary, about 140 miles in length by half that breadth, being the largest lake in Asia after the seas of Aral and Baikal. It is also called Balkash or Palcatè. This lake, with two others that are very considerable, belong to the Kalmucks subject to China.

TENGMO, a small island on the E. side of the gulf of Bothnia. N. lat. 63° 10'. E. long. 21° 52'.

TENG-TCHOUEN, a city of China, of the second rank, in Yun-nan; 1182 miles S.W. of Peking. N. lat. 26° 2'. E. long. 99° 49'.

TENGZEGZET. See TENZEGZET.

TENIA. See TÆNIA.

TENIERS, DAVID, the elder, in *Biography*, was born at Antwerp in 1582. He received his education in painting in the school of Rubens, and under that great artist's immediate tuition, obtained the mode of preparing his grounds, and managing his materials. Intending to continue the study of historic painting, he went to Rome; but there abandoned it, and attached himself to his countryman, Adam Elsheimer, under whom he continued for six years to study landscape, and from him most probably acquired the neatness of pencilling for which his works are esteemed.

On his return to his native country, he blended the styles of both his masters, and employed the compound in a novel and ingenious manner, upon subjects original and at the same time agreeable; such as merry-makings, both interior and at the doors of cabarets; rural sports, cattle, sheep, and those who tended them; numerous groups and grotesque combinations; such as the temptation of St. Anthony, &c. For pictures of these kinds, he was fortunate enough to find admirers and purchasers; and they would still have been the theme of admiration, had not his son, following the same track, have proved how possible it was to proceed infinitely farther. He died in 1649, aged sixty-seven.

TENIERS, DAVID, the younger, son of the foregoing artist, was born at Antwerp in 1610, and was initiated in the art of painting by his father; but he afterwards became a disciple of Adrian Brauwer, and is also said to have had the happiness and honour of receiving instructions from Rubens. The subjects and the style he adopted were, as we have said, the same with those employed by his father; but with a more fertile imagination, he produced compositions infinitely more varied and ingenious, with colouring and effect more vivid and engaging, more rich and transparent; and with a facility of execution perfectly enchanting. It is true they seldom exhibit much research of character or expression; what there may be of those qualities, was more probably a fortunate hit, than any result of meditation or intention. In this respect Jan Stein, and our own Wilkie, have as much the superiority over Teniers, as he possesses by the power of his execution.

At the first display of his powers he was not so successful as he merited, but it was not long that he lay neglected: the archduke Leopold being made acquainted with his merits, immediately distinguished him by his patronage; appointed him his principal painter; honoured him by making him a gentleman of his bed-chamber; presented him with a chain of gold, to which his portrait was affixed; and gave him the superintendance of his gallery of pictures, which contained works of the most distinguished masters of the Italian and Flemish schools. Of this gallery, Teniers made several pictures, in which he imitated the manners of the various masters so successfully, as to obtain the name of the Proteus of painting. He also amused himself by making compositions in the styles of different painters of renown, as Titian, Tintoretto, the Bassans, Rubens, &c.; and in their execution endeavoured to imitate the touch of those great men. These imitations are generally known under the name of pasticcios, and have frequently been mistaken for originals, and sold as such.

These were the amusements or indulgencies of idle fancy; his fame rests for more full and honourable support upon his original productions in his own proper style. He was a constant and faithful observer of nature; and in his favourite subjects, village festivals, fairs, and merry-makings, he has exhibited, with a most engaging freedom, the manners and characters of his countrymen. That he might conveniently mingle with the scenes he chose to represent, he established himself in the village of Perk, between Antwerp and Mechlin, and there, with a painter's eye, he observed the undisguised impulse of the natural character of the lower class among the people, and has left many beautiful and pleasing remembrances of occurrences uninteresting, nay sometimes disgusting in themselves, but rendered engaging by his delightful mode of representing them. One peculiar charm there is to be found in the best pictures of Teniers, more perfectly obtained than in the works of other artists, and that is, the complete effect of atmosphere, silvery, pure, and natural; Claude de Lorraine himself does not surpass him; and this truth, though yielded on simple materials, in scenes flat and insipid in their forms, yet makes amends for their natural want of interest by its truth and simplicity.

In the interior of apartments, of the cottage, the cabaret, the guard-room, or chemist's laboratory, he is not less admirable by his clearness and precision than in his exteriors. He surpassed Ostade in his knowledge of perspective, and in his freedom, as much as he is excelled by the latter in truth of of tone and completion of character. His pencil is exceedingly light and dexterous; and by continual practice upon the same system, he had acquired a promptness almost unparalleled. This freedom of execution enabled him to paint an immense number of pictures: it was not unusual for him to finish a picture in a day; and he used jocosely to observe, that to contain all the pictures he had painted, it would be necessary to have a gallery two leagues long. He not unfrequently assisted the landscape painters of his day, by putting figures into their pictures; and many works of Artois, Van Uden, Breughel, and many others, owe an increased value to this circumstance. His works are numerous in the collections of this country, and still bear very high prices. Teniers lived to the advanced age of eighty-four, and died at Brussels in 1694.

He had a younger brother named Abraham, who also painted the same kind of subjects in the same style, and from this circumstance his works are sometimes mistaken for those of David, though they are much inferior in taste and execution.

TENINE, in *Geography*, a town of South America, in the province of Tucuman; 20 miles S.W. of St. Yago del Estero.

TENIS, a lake of Russian Tartary, 60 miles in circumference. N. lat. 53° 20′. E. long. 74° 4′.

TENISON, Thomas, in *Biography*, archbishop of Canterbury, was the son of the Rev. John Tenison, rector of Mundesley, in Norfolk, and born in the year 1636. He received his university education at Benet college, Cambridge, of which he became a fellow in 1662. Having officiated for some time as a tutor in his college, he was presented in 1665 to the cure of St. Andrew the Great in Cambridge, and continued his attention to his parochial duty during the plague. In 1667 he became chaplain to the earl of Manchester, and obtained a rectory at Huntingdonshire. His first publication appeared in 1670, and was entitled "The Creed of Mr. Hobbes examined, in a feigned Conference between him and a Student in Divinity." In 1674 he was chosen principal minister to the church of St. Peter's Mancroft, Norwich; and in 1678 he published a "Discourse of Idolatry," and in 1679 "Baconiana," or some pieces of the great lord Verulam, with a general account of his writings. As he was one of the royal chaplains in 1680, he graduated D.D., and was presented by the king to the vicarage of St. Martin's-in-the-Fields, London. As an antagonist to popery, the apprehension of which was then very prevalent, he wrote several works against it, and also against Socinianism; and whilst he was guarding the church against those whom he conceived to be its enemies, he acquired still greater honour by liberal benefactions to the poor, and by laying the foundation of an endowed school and public library, which he afterwards completed. He blended gravity with moderation to such a degree, as to command general esteem; and accordingly he was selected by the unfortunate duke of Monmouth to prepare him for his execution. He also conducted himself with so much prudence at court, that he is said to have had a personal interest even with James II. In the reign of William he avowed himself a friend to the dissenters and toleration; and after his promotion to the archdeaconry of London, he was appointed one of the commissioners for reviewing the Litany, with a view to the comprehension of the Separatists. He thus recommended himself to queen Mary, and by her interest he obtained the see of Lincoln, in 1691. Within three years he was unexpectedly advanced to the archiepiscopal see of Canterbury, more on account of his moderate and pacific principles, than for any pre-eminence to which he had attained among men of letters or theologians. He attended queen Mary on her death-bed; and incurred the severe animadversions of the deprived bishop Ken, for not having reminded her majesty of her culpable want of duty to her father, by consenting to wear a crown which rightfully belonged to him. His conduct during the reign of king William was uniformly consistent with his principles, and both were so pleasing to his majesty, that he distinguished the prelate by many tokens of respect and confidence. In the reign of queen Anne, he was not, as we may naturally imagine, much regarded; more especially as he retained his just ideas of toleration, and resisted, though not without a share of obloquy, some of the high-church measures which were then countenanced. Nevertheless he displayed on various occasions his attachment to the established church, as well as his habitual bounty to the indigent. His last public act was the coronation of George I.; and afterwards sinking under the decay of advanced age, he closed his life at Lambeth, December 1715, in the seventy-ninth year of his age. As he left no issue, he bequeathed a considerable part of his property to charitable purposes. His character was uniformly respectable; and his conduct in difficult times was irreproachable and exemplary. Biog. Brit. Gen. Biog.

TENMENTALE, or Tenmantale, in our *Ancient Customs*, originally signifies the number of ten men, which number, in the time of the English Saxons, was called a decennary; and ten decennaries made what we call an hundred.

These ten men were bound for each other to preserve the public peace; and if any of them was found guilty of a breach of it, the other nine were either to make satisfaction, or to bring the criminal before the king.

Tenmentale was also used for a duty, or tribute, paid to the king, consisting of two shillings for each ploughland; probably thus called, because each person of the decennary was bound to see it paid.

TENNA, in *Geography*, a river which rises in the Apennines, and crossing the marquisate of Ancona, runs into the Adriatic, about 4 miles E.N.E. of Fermo.

TENNE', Tenny, or *Tawney*, in *Heraldry*, a bright colour, made of red and yellow mixed; sometimes also called *brusk*, and expressed in engraving by diagonal lines drawn from the dexter to the sinister side of the shield, traversed by perpendicular lines from the chief; and marked with the letter T.

In the coats of all below the degree of nobles, it is called *tenny;* but, in those of nobles, it is called *hyacinth;* and, in princes' coats, the *dragon's head.*

TENNEAH, in *Geography*, a town of Bengal; 35 miles N. of Midnapour.

TENNEBERG, a mountain of Saxony, in the principality of Gotha; 4 miles S.W. of Gotha.

TENNELIE'RES, a town of France, in the department of the Aube; 4 miles E. of Troyes.

TENNESSEE, one of the United States of America, situated between 35° and 36° 30′ N. lat., and 4° 26′ and 13° 5′ W. long. from Washington. It is bounded on the north by Kentucky and part of Virginia, on the south by Georgia and the Mississippi territory, on the east by North Carolina, and on the west by Missouri territory. Its extent from north to south is 102 miles, and from east to west 420 miles. Its area is 40,000 square miles, or 25,600,000 acres. The Indian claim has been extinguished in two portions of this country, the eastern and the western, comprehending one-third part of the state. The former is bounded north by Virginia, from the south-east corner of Kentucky, to the north-west of North Carolina; easterly by North Carolina;

Carolina; westerly by Cumberland mountain, Emery's river, &c.; and southerly by a line marked from place to place, as a continuation of the Cherokee boundary. The western tract, thus purchased of the Indians, lies on Cumberland river, and is bounded north by Kentucky; easterly by a line running from the north-east to the south-west; and south and west by a line of several thousand angles, run according to the Tennessee Ridge, which separates the waters of the Cumberland from those of the Tennessee river. The general course of this ridge-line is first westerly, and then north-westerly; which, imagining the zigzag reduced into two straight lines, makes the figure of the tract a trapezium. The longest side is that adjoining Kentucky, the length of which, ascertained by measurement, is nearly 160 miles. The length of the easterly side is about 90 miles. The eastern is generally called the Holston settlement, and the western the Cumberland settlement, from those two prime rivers, which traverse the countries respectively. Between these settlements lies a spacious wilderness, which the Cherokees claim and traverse in hunting, and which, from one limit of their claim to the other, as the road goes, is about 70 miles wide.

This state, as it was erected and organized in 1796, is divided into three districts. The eastern settlement is divided into two districts, Washington the eastern district, and Hamilton the middle district. The western settlement is the third or Mero district. The number of counties, &c. may be seen in the following topographical table.

East Tennessee.

Counties.	No. Inhabitants.	Chief Towns.
Anderson - - -	3959	
Bledsoe - - -	8839	Marysville.
Blount - - -	3259	Maryville.
Campbell - - -	2668	
Carter - - -	4190	Elizabethtown.
Claiborne - - -	4798	Tazewell.
Cocke - - -	5154	Newport.
Granger - - -	6397	Rutledge.
Greene - - -	9713	Greenville.
Hawkins - - -	7643	Rogersville.
Jefferson - - -	7309	Dandridge.
Knox - - -	10171	Knoxville.
Rhea - - -	2504	Washington.
Roano - - -	5581	Kingston.
Sevier - - -	4595	Sevierville.
Sullivan - - -	6847	Blountsville.
Washington - -	7740	Jonesborough.

Warren - - -	5725	M'Minville.
	160360	

The following counties have been laid out since the last census was taken:

Greenville,
Wayne.

The eastern part of this state is mountainous, the middle part hilly, and the western part mostly level. The climate among the mountains is said to be delightful; in the middle part, temperate and agreeable; in the western part, hot in summer, and mild in winter. The diseases to which the adult inhabitants have been most liable are pleurisies, rheumatisms, and rarely agues and fevers; but, upon the whole, the inhabitants are generally healthy, and this salubrity of the state has been partly attributed to its having few stagnant waters. The principal rivers of this state are the Cumberland, the Holstein or Holston, the Tennessee, the Clinch, the Notachuckey or Nolichucky, the French Broad, the Hiwassee, the Duck, the Redfoot, the Obian or Oby, the Forked Deer, and the Wolf. The chief of these rivers are described under their appropriate names. The mountains in this state are numerous; some of them, particularly the *Cumberland* (which see), or Great Laurel Ridge, are the most stupendous piles in the United States. Stone, Yellow, Iron, Bald, Smoky, and Unaka mountains adjoin each other, and form, in a direction nearly north-east and south-west, the eastern boundary of the state. In these mountains are innumerable caverns and cascades. North-west from these, and separated from each other by vallies from 5 to 15 miles wide, rise Bay's mountain, Copper Ridge, Clinch mountain, Powell's mountain, and Welling's Ridge. The four last terminate north of the Tennessee river, and these, as well as the others, are branches of Virginia mountains. They are all encircled by vallies, which open channels for rivers and roads for passage. Although the soil on the mountains is poor, that of the vallies is fertile; improving in the middle of the state, and in the western part becoming rich. It produces cotton, which is the staple commodity, and the principal article of export, tobacco, indigo, Indian corn, hemp, flax, rice, wheat, rye, oats, barley, and all kinds of vegetables in high perfection. The trees and plants found in this state are poplar, hickory, black and white walnut, all kinds of oaks, buck-eye, beech, sycamore, black and honey locust, ash, hornbeam, elm, mulberry, cherry, dogwood, sassafras, papaw, cucumber-tree, coffee-tree, and the sugar-tree. In the eastern district is a species of pitch-pine, useful for boards, timber, and tar. The under-growth, in many places, and especially in low grounds, is cane, some of which is upwards of 20 feet high, and so thick as to prevent any other plant growing: there are also Virginia and Seneca snake-root, ginseng, Carolina pink, angelica, senna, lobelia, Indian physic, spice-wood, wild plum, crab-apple, haws, hazel-nuts, sweet anise, red bud ginger, spikenard, wild hop and grape vines. The glades are covered with wild rye, wild oats, clover, buffalografs, ftrawberries, and pea vines. On the hills, at the heads of rivers, and in fome high cliffs of Cumberland, are found majeftic red cedars; many of thefe trees are four feet in diameter, and forty feet clear of limbs. The commerce of this ftate is much facilitated by the rivers Tenneffee and Cumberland, and their refpective branches. Both thefe rivers empty into the Ohio, fhortly after they pafs the north boundary of the ftate. As the waters of the Cumberland from Nafhville, and of the Tenneffee from the Mufcle Shoals to the Ohio, are navigable to the Ohio and Miffifippi, the people of courfe, who live in this or the adjacent country, have the fame advantages of water conveyance for trade, as thofe who live on the Ohio or Miffifippi, to New Orleans or elfewhere. Befides, there is another probable avenue through which trade will be carried on with this and the adjacent country, which is from Mobile, up the waters of the Mobile river as far as it is navigable; thence by a land carriage, of about 50 miles at moft, to Ocochappo creek, which empties into the Tenneffee at the lower end of the Mufcle fhoals. The mouth of this creek is the centre of a piece of ground, the diameter of which is five miles, ceded by the fouthern Indians at the treaty of Hopewell, on Keeowee, to the United States, for the eftablifhment of trading pofts. The iron works of Tenneffee are large and numerous. The minerals of this country are iron-ore, limeftone, coal, copperas, alum, nitre, lead, and fome filver. Mineral fprings, ftrongly impregnated with fulphur, are found in various parts of the country. On the waters of French Broad river is a fine, large, clear, medicinal, warm fpring, the beneficial effects of which have been experienced by many perfons who have reforted to it from the Carolinas, Georgia, and northern parts of Virginia. Salt is manufactured in confiderable quantity, particularly on the north fork of Holfton. Some herds of the bifon are ftill found on the branches of the Cumberland river, though multitudes of them have been wantonly deftroyed. The ftag is occafionally found among the mountains; deer are fcarce; bears, panthers, wild cats, and wolves, ftill remain. Beavers, mufk-rats, and otters, are plentiful in the upper branches of Cumberland and Kentucky rivers. Racoons, foxes, opoffums, and fquirrels abound; as do alfo pheafants, partridges, pigeons, fwans, wild turkies, ducks, and geefe; as well as bald eagles, parroquets, loons, cranes, and buzzards. The rivers are well ftocked with all kinds of frefh-water fifh.

The chief towns of Tenneffee are *Knoxville*, *Nafhville*, and *Jonefborough;* which fee refpectively.

The prevailing denomination of Chriftians in this ftate is compofed of Prefbyterians, intermixed with Baptifts, Methodifts, and Friends. With a view to mental and moral improvement, feveral fchools and colleges are eftablifhed in this ftate. Three colleges are eftablifhed, one in Knox, one in Wafhington, and one in Greene county.

By the conftitution of this ftate, which was formed and ratified at Knoxville, February 6, 1796, the legiflative authority is vefted in a general affembly, confifting of a fenate and houfe of reprefentatives. The number of reprefentatives is to be fixed once in feven years, by the legiflature, according to the number of taxable inhabitants, who are to be numbered feptennially; the number of reprefentatives not to exceed twenty-fix, until the taxable inhabitants fhall be 40,000. The fenators are never to be lefs than one third, nor more than one half the number of the reprefentatives, and are to be chofen upon principles fimilar to thofe for the choice of reprefentatives. The election for members of both houfes is biennial. The executive power of the ftate is vefted in a governor, chofen by the electors of the members of the legiflature: he is appointed biennially, and is commander-in-chief of the army and navy, except in the fervice of the United States. Every freeman of 21 years of age, poffeffing a freehold in the county, and having been an inhabitant of the ftate for fix months preceding, may vote for the members of the legiflature. The houfe of reprefentatives has the fole power of impeaching, and the fenate of trying impeachments. The judicial power is vefted in courts of law and equity. County officers are fheriffs, coroners, truftees, and conftables. Military officers are to be elected by perfons fubject to military duty. Minifters of the gofpel are not eligible to a feat in the legiflature. No perfon who denies the exiftence of God, or a future ftate, can hold any civil office. The oath of allegiance and of office is to be taken by perfons holding any office of truft or profit.

In the character of the inhabitants there is nothing peculiarly difcriminating; but, in general, a great fimplicity of manners prevails. Among the curiofities of the country we may reckon its numerous caves; and on the Enchanted mountain there are on feveral rocks impreffions refembling the tracks of turkies, bears, horfes, and human beings, the latter having uniformly fix toes each. Befides thefe, there are many other fanciful figures. The Indian tribes within and in the vicinity of this ftate are the *Cherokees* and *Chickafaws;* which fee refpectively.

The country now called Tenneffee was included in the fecond charter granted by king Charles II. to the proprietors of Carolina; and in a fubfequent divifion, it conftituted a part of North Carolina. In 1754, at the commencement of the French war, not more than fifty families had fettled here, who were either deftroyed, or driven away by the Indians before the clofe of the following year. It remained uninhabited till 1765, when the fettlement of it commenced; and in 1773, (fuch was the rapid acceffion of emigrants,) the country as far weftward as the long ifland of Holfton, an extent of more than 120 miles in length from eaft to weft, was well peopled. In 1789, after fome preparatory meafures, the territory was ceded by the North Carolina legiflature, on certain conditions, to the United States. In 1790, February 25, congrefs paffed an act, accepting this ceffion; and, by another act, paffed May 26, 1790, provided for its government under the title of "The Territory of the United States of America fouth of the River Ohio." On the 8th of June following, the prefident of the United States, by and with the advice and confent of the fenate, appointed the Hon. William Blount, efq. a citizen of North Carolina, governor in and over the faid territory; in which office he continued during the territorial government, and was prefident of the convention that formed the conftitution under the title of "The Conftitution of the State of Tenneffee," of which we have given an abftract. The peace of the citizens of this territory has been difturbed many years paft, by Indian wars, or incurfions from the favages for the purpofes of murder and plunder: they are now at peace. In the year 1796, this territory was in due form erected into an independent ftate, making the fixteenth in the Union. Morfe. Melifh.

TENNESSEE *Ridge*, the moft confiderable range of mountains in the ftate of Tenneffee, feparating the ftreams which run to the Cumberland and Tenneffee rivers. In fome parts it rifes into abrupt hills, but in others admits of good roads. See CUMBERLAND *Mountain*.

TENNESSEE, called by the French Cherokee, and abfurdly by others the Hogohege river, is the largeft branch of the Ohio: it is 600 yards wide at its mouth. It rifes in the mountains of Virginia, N. lat. 37°; and purfues a courfe of about 1000 miles fouth and fouth-weft, nearly to

N. lat. 34°, receiving from both fides a number of large tributary ftreams. It then wheels about to the north, in a circuitous courfe, and mingles with the Ohio, nearly 60 miles from its mouth. From its entrance into the Ohio to the Mufcle fhoals, 250 miles, the current is very gentle, and the river deep enough, at all feafons, for the largeft row boats. The Mufcle fhoals are about 20 miles in length. The bed of the river in this diftance confifts of broken ftones, eafily removed; and the navigation will admit of much improvement. At thefe fhoals the river fpreads to the width of three miles, and forms a number of iflands, and is of difficult paffage, except when there is a fwell in the river. From this place to the "Whirl," or "Suck," where the river breaks through the Great Ridge, or Cumberland mountain, is 250 miles, the navigation all the way excellent. The Whirl, as it is called, is in about N. lat. 35°. It is reckoned a greater curiofity than the burfting of the Patowmack through the Blue Ridge. The river, which a few miles above is half a mile wide, is here compreffed to the width of about 70 yards. Juft as it enters the mountain, a large rock projects from the northern fhore, in an oblique direction, which renders the bed of the river ftill narrower, and caufes a fudden bend: the water of the river is of courfe thrown with great rapidity againft the fouthern fhore, whence it rebounds around the point of the rock, and produces the whirl, which is about 80 yards in circumference. Boats pafs the whirl without danger or difficulty. Such is the fituation of the fhore, that boats afcending the river may be towed up. In lefs than a mile below the whirl, the river fpreads into its common width, and except the Mufcle fhoals, already mentioned, flows beautiful and placid, till it mingles with the Ohio. Six miles above the whirl are the Chiccamogga towns, on the banks of the river, and of a large creek of the fame name.

TENNIS, a paftime, or well-known game at ball, introduced among our anceftors about the year 1222, the fixth year of Henry III., by perfons of fuperior rank and family, who erected courts or oblong edifices for the performance of this exercife. Some have afcribed the etymology of the word *tennis* to the French language, and accordingly have derived the game from France. But the word *tenez* does not afford fufficient evidence of its French origin. For the holding or keeping poffeffion of the ball is no part of the game; for, during the play, the ball is in continual motion, or paffing from one to another. Others feek the etymology of the name and the origin of the game in a place in France called Tennois, (or, by a change of one letter, Sennois, in the diftrict of Champagne,) where balls were firft made, and the game, as it is faid, firft introduced.

TENNIS, in *Geography*, the ruins of a town of Egypt, fituated on an ifland in a lake of the fame name; once a large city, built by the Romans, on the feite of a more ancient Egyptian town; 28 miles S.E. of Damietta. N. lat. 31° 2'. E. long. 32° 14'.

TENNIS, a lake of Egypt, 55 miles long, and about feven wide, which reaches from Damietta to Tineh, feparated only by a narrow tongue from the Mediterranean.

TENNIS, or *Tnifs*, a fea-port of Algiers, in the province of Tremecen, at the mouth of a river which runs into the Mediterranean oppofite a fmall ifland. Some geographers fuppofe this to be the ancient Jol, or Julia Cæfarea. Before the Turkifh conquefts, it was the metropolis of one of the petty royalties of this country; though a few miferable hovels are all that remains of it at prefent. Tennis has been long famous for the many loads of corn that are fhipped off from thence to Chriftendom; but the anchoring ground (for a harbour it cannot be called) that lies before it, being too much expofed to the north and weft winds, is the occafion that veffels are frequently caft away, unlefs they meet with calm weather. The Moors have a tradition, that the Tenniffians were formerly in fuch reputation for forcery and witchcraft, that Pharaoh fent for the wifeft amongft them to difpute miracles with Mofes. It is certain that they are the greateft cheats in this country, and are to be as little trufted to as their road; 24 miles W. of Sherfhell. N. lat. 36° 33'. E. long. 1° 10'.

TENNOLTEI, a town of Thibet; 63 miles N.E. of Harachar Hotun.

TENO, a river of Norway, which runs into the fea, 56 miles W.N.W. of Wardhuys.

TENON, in *Building*, &c. the fquare end of a piece of wood, or metal, diminifhed by one-third of its thicknefs, to be received into a hole in another piece, called the *mortife*, for the jointing or faftening the two together.

Among joiners, &c. the tenon is made in various forms, fquare, dove-tailed, for double mortifes, &c.

Vitruvius calls the tenons, *cardines;* dove-tailed tenons he calls *fubfcudes*, or *fecuriculæ*.

TENON-*Saw*. See SAW.

TENOR, TENOUR, the purport or contents, or tranfcript, of a writing, or inftrument in law, &c.

Warrants iffued for the confirmation of fentences, exprefs, that they fhall be executed according to their form and tenor. —It was impoffible to retain fo long a fpeech word for word, but the fubftance, or the tenor, is this.

TENOR, *Tenore*, Ital., in *Vocal Mufic*, implies the natural pitch or *tenour* of a man's voice in finging. In the vocal mufic of Italy, France, and Germany, there are three feveral tenor clefs in ufe at prefent: the *foprano* on the firft line, for the higheft part; the *contralto* on the third line, for the counter-tenor part; and the *alto tenore* on the fourth line, for the tenor part. (See CLEF.) In old mufic of the 15th, 16th, and 17th centuries, a tenor clef, called the *mezzo foprano*, on the fecond line, and even on the fifth line, frequently occurs, inftead of the *baritono*, or F clef, on the third line.

In inftrumental mufic, the tenor clef on the third line is ufed for the *alto viola*, and fimply *viola*, or tenor part. The tenor clef on the fourth line frequently occurs in violoncello parts and harpfichord leffons of the early part of the laft century; but at prefent, the high notes in the violoncello part, and in the bafe of pieces for the piano forte, are more frequently written in the treble clef.

TENOR, or *Tenorifta*, is alfo ufed for a perfon who fings the tenor part in concert; and alfo for an inftrument proper to play it.

TENORE *Indictamenti mittendo*, in *Law*, is a writ by which the record of an indictment, and the procefs thereupon, are called out of another court into the king's bench.

TENOS, in *Ancient Geography*, one of the iflands called Cyclades, S.E. of the ifland of Andros, and very near it, N.W. of Delos, and N.E. of Syros. All hiftorians agree in reporting that this ifland abounded with ferpents, whence it took the name of Ophiuffa, and in Greece that of the viper, or Tænia. It is faid that the inhabitants muft have abandoned it on this account, if Neptune had not refcued it from them. In confequence of this deliverance, they erected a magnificent temple to his honour, in a wood near the town of Tenos, and here they celebrated feafts in commemoration of him. This temple had very extenfive rights of afylum, which were afterwards regulated by Tiberius. The ifland was alfo called Hydraffa, on account of its waters. The town of the fame name was fituated near the fea, in the S.W.

S.W. part of the iſland. See Tino.—Alſo, a town of Greece, in Theſſaly.

TENOUR. See Tenor.

TENSA, in *Geography*, a river of Louiſiana, which forms with the Waſhita and bayou Long, an iſland of an oval ſhape, about 50 miles in circumference. Immediately above this iſland, there is another, called Sicilly iſland, about 30 miles in circumference. At the lower end of Sicilly iſland, the bayou Tenſa ſpreads into a lake of 15 or 20 miles in length, and nearly parallel with the Miſſiſippi. The Tenſa lake receives two conſiderable ſtreams, the river Aux Boeufs, and the bayou Maſçon.

TENSE, Time, in *Grammar*, an inflexion of verbs, by which they are made to ſignify, or diſtinguiſh, the circumſtance of time of the thing they affirm or attribute.

The affirmations made by verbs are different as to point of time; ſince we may affirm a thing *is*, or *was*, or *will be*: hence a neceſſity of a ſet of inflexions, to denote thoſe ſeveral times; which inflexions our Engliſh grammarians call by a barbarous word, *tenſes*; from the French *temps*: moſt other languages call them ſimply *times*.

There are but three ſimple tenſes; the *preſent*, as, *I love*, *amo*; the *preter*, *preterite*, or *paſt*, as, *I have loved*, *amavi*; and the *future*, as, *I will love*, *amabo*.

But, in regard that in the preter tenſe one may either expreſs the thing as juſt done or paſt, or indefinitely and barely that it was done: hence, in moſt languages, ariſe two kinds of preterite; the one *definitive*, marking the thing to be preciſely done; as, *I have written*, *I have ſaid*: and the other *indefinite*, or *aoriſt*, denoting a thing done indeterminately; as, *I wrote*, *I went*.

The *future* tenſe admits alſo of the ſame variety.

Beſides the three ſimple tenſes, others have been invented, called *compound* tenſes; expreſſing the relation of the ſimple ones to each other.—The firſt expreſſes the relation of the *paſt* to the *preſent*, and is called the *preterimperfect* tenſe, becauſe it does not mark the thing ſimply and properly, as done, but as imperfect, and preſent with reſpect to another thing paſt; as, *I was at ſupper when he entered; cum intravit, cœnabam.*

The ſecond compound tenſe marks the time paſt doubly, and is therefore called the *pluſquamperfect* tenſe; as, *I had ſupped; cœnaveram.*

The third compound tenſe denotes the future with reſpect to the paſt; as, *I ſhall have ſupped; cœnavero.*

The ſeveral tenſes, or times, it is to be obſerved, are properly denoted in the Greek and Latin by particular inflexions; in the Engliſh, French, and other modern tongues, the auxiliary verbs *to be*, and *to have*, *être* and *avoir*, are called in. As to the Oriental languages, they have only two ſimple tenſes, the *paſt* and *future*, without any diſtinctions of imperfect, more than perfect, &c.; but this renders thoſe languages ſubject to abundance of ambiguities, from which others are free.

The ingenious Mr. Harris, in his Hermes, p. 119, &c. propoſes the following theory of tenſes. The tenſes, he ſays, are uſed to mark preſent, paſt, and future time; either indefinitely, without reference to any beginning, middle, or end; or elſe definitely, in reference to ſuch diſtinctions. If indefinitely, then we have three tenſes, an aoriſt of the preſent, an aoriſt of the paſt, and an aoriſt of the future. If definitely, then we have three tenſes to mark the beginnings of theſe three times; three to denote their middle; and three to denote their ends: in all, nine. The three firſt of theſe tenſes he calls the inceptive preſent, the inceptive paſt, and the inceptive future. The three next, the middle preſent, the middle paſt, and the middle future. And the three laſt, the completive preſent, the completive paſt, and the completive future. Thus the tenſes in their natural number appear to be twelve; three to denote time abſolute, and nine to denote it under its reſpective diſtinctions. The following examples will illuſtrate the application and uſe of each tenſe. Aoriſt of the preſent, γραφω, *ſcribo*, *I write*; aoriſt of the paſt, ἔγραψα, *ſcripſi*, *I wrote*; aoriſt of the future, γραψω, *ſcribam*, *I ſhall write*. Inceptive preſent, μέλλω γραφειν, *ſcripturus ſum*, *I am going to write*; middle or extended preſent, τυγχανω γράφων, *ſcribo*, or *ſcribens ſum*, *I am writing*; completive preſent, γέγραφα, *ſcripſi*, *I have written*. Inceptive paſt, ἐμελλον γράφειν, *ſcripturus eram*, *I was beginning to write*; middle or extended paſt, ἔγραφον, or ἐτυγχανον γράφων, *ſcribebam*, *I was writing*; completive paſt, ἐγεγράφειν, *ſcripſeram*, *I had done writing*. Inceptive future, μελλήσω γράφειν, *ſcripturus ero*, *I ſhall be beginning to write*; middle or extended future, ἔσομαι γράφων, *ſcribens ero*, *I ſhall be writing*; completive future, *ſcripſero*, *I ſhall have done writing*. The author has particularly ſhewn what traces are diſcoverable in favour of this ſyſtem, either in languages themſelves, or in thoſe authors who have written upon this part of grammar, or in the nature and reaſon of things. Dr. Ward enumerates ſeven tenſes; *viz.* the preſent, paſt, and future imperfect; the paſt indefinite; the preſent, paſt, and future imperfect. See his Four Eſſays upon the Engliſh Language, p. 84.

TENSIFT, in *Geography*. See Tansift.

TENSION, Tensio, the ſtate of a thing bent, or the effort made to bend it.

Animals only ſuſtain and move themſelves by the tenſion of their muſcles and nerves. A chord or ſtring gives an acuter or deeper ſound, as it is in a greater or leſs degree of tenſion.

Tension, *Tenſio*, Τασις, in the *Ancient Muſic*, was uſed to ſignify any pitch of ſound, whether produced by intenſion or remiſſion. Vide Ariſtoxen. p. 10. 13. edit. Meibom.

Ariſtoxenus obſerves, there are five things to be conſidered about ſounds, *viz.* τασις, tenſion; ἐπιτασις, intenſion; ἀνεσις, remiſſion; οξυτης, acumen; and βαρυτης, gravitas.

TENSITES, in *Geography*, a mountain of Africa, in the empire of Morocco, on the borders of Sugulmeſſa; 60 miles E. of Morocco.

TENSOR, in *Anatomy*, a name given to different muſcles.

Tensor *Palati*, a muſcle of the ſoft palate. See Deglutition.

Tensor *Tympani*, a muſcle of the internal ear. See Ear.

Tensor *Vaginæ femoris*; *muſculus faſciæ latæ*; is an elongated and flattened muſcle, narrow above, and becoming conſiderably broader below, ſituated at the upper and outer part of the thigh, and extending from the anterior ſuperior ſpine of the ilium, to a ſhort diſtance below the great trochanter. It is covered by a thin layer of the faſcia; and it lies upon the rectus cruris, the vaſtus externus, and a ſmall part of the gluteus medius and minimus, ſeparated from them by a thin production of faſcia, and by copious cellular tiſſue. Its front edge is parallel, above, with the outer margin of the ſartorius: below, they are parted by an interval, occupied by the rectus anterior. The poſterior edge is connected above to the gluteus medius; being ſeparated from it below by cellular tiſſue. The upper extremity is attached to the anterior ſuperior ſpine of the os innominatum, between the ſartorius and the gluteus medius. The muſcle, which is here narrow, paſſes obliquely downwards and outwards, growing conſiderably broader and thinner, and terminates below the great trochanter, at the angle of ſeparation of the two layers of the faſcia, between which it is ſituated: this angle is its point

point of infertion. Its upper attachment is by means of a tendon, from which the fibres run to the fafcia.

It will bend the thigh on the pelvis; or carry it outwards; or rotate it inwards. When the thigh is fixed, it will incline the pelvis on that limb.

TENSTADT, in *Geography*, a town of Saxony, in Thuringia; 11 miles N.W. of Erfurt.

TENT, Tabernacle, a pavilion, or portable lodge, under which to fhelter, in the open field, from the injuries of the weather. See Tabernacle.

The word is formed from the Latin, *tentorium*, of *tendo*, *I ftretch*; in regard tents are ufually made of canvas, ftretched out, and fuftained by poles, with cords and pegs.

Armies encamp under tents: thefe are made of canvas, and are of various fizes. A captain's tent and marquée is generally $10\frac{1}{2}$ feet broad, 14 deep, and 9 high; thofe of the fubalterns are a foot lefs; the major's and lieutenant-colonel's a foot larger; and the colonel's two feet larger. The fubalterns of foot lie two in a tent, and thofe of the horfe one. The tents of private men are $6\frac{1}{2}$ feet fquare, and 5 feet high, and accommodate five foldiers. The tents for the horfe are 7 feet broad, and 9 feet deep; they hold five men, and their horfe-accoutrements.

Tents, *Bell*, are fo called from their refemblance to a bell, and ferve to fhelter the fire-arms from rain.

To pitch the tents, is to fix them up ready for habitation, by the affiftance of a ridge-pole, two ftandards, and a number of tent-pins.

Moft of the Tartars and Arabs are wandering people, that always lodge under tents.

The Hebrews lodged forty years under tents in the defarts; which gave occafion to the Scenopegia, or feaft of tabernacles.

Tent, *Dark*. See Dark.

Tent, in *Surgery*, fignifies a roll of lint or linen, for preventing the healing of openings, from which matter, or fome other fluid, makes its efcape. Tents are alfo employed for dilating openings. There are fome tents which are made of fponge that has been compreffed into as fmall a compafs as poffible, while filled with fluid wax, and then allowed to become cold. Thefe are called *fponge-tents*, and, on becoming warm, after being introduced into parts, they have the property of fwelling in a remarkable degree. We fhall only fay further upon this fubject, that, upon the whole, tents are not fo much employed in modern as in ancient practice; and there is no doubt, that, unlefs their ufe be guided by moderation and judgment, they may do confiderable mifchief.

TENTAMOODY, in *Geography*, a town of Hindooftan, in the circar of Rajamundry; 35 miles S.E. of Rajamundry.

TENTATIVE is fometimes ufed adjectively: thus we fay, a tentative *method*, meaning a kind of unartful or indirect method, which only proceeds by trying.

Tentative is alfo ufed fubftantively, for an effay or effort, by which we try our ftrength, or found an affair, &c. to fee whether or no it will fucceed.

In the French univerfities, tentative is the firft thefis, or act, which a ftudent in the theology-fchool holds, to fhew his capacity: if he anfwers well in this, the degree of bachelor is conferred on him.

TEN-TCHEOU-FOU, or Ten-choo-foo, in *Geography*, a city of China, of the firft clafs, in the province of Chang-tong, having under its jurifdiction one city of the fecond clafs, and feven of the third. It is fituated on a rifing ground, and fortified by a ftrong wall round it, and defended by a numerous garrifon. The fortifications of this city include a large fpace not occupied by buildings; and when it was laid out, it muft either have been expected that it would increafe in houfes to a greater number than that of thofe who now occupy it, or the vacant fpace was allotted for military or other exercifes. The bay, or rather road, of Ten-choo-foo, is not only open to the eaft and weft, but partially fheltered towards the north by groups of fmall iflands, fcattered about at different diftances, from five miles to twice as many leagues, off the main fhore. The Mi-a-tau iflands are too diftant to break off much of either wind or fwell from that quarter. The anchoring ground confifts in great part of hard fharp rocks; and at about $1\frac{1}{4}$ mile from the fhore is a dangerous reef, covered at high water, extending nearly a mile eaft and weft, round which the water fhoals fo fuddenly as to render any approach to it very perilous. At Ten-choo-foo is conftructed a kind of dock, or bafon, for veffels to load or difcharge their cargoes. The entrance into it is between two piers, and is from 30 to 40 feet wide. The ground near the coaft of the Yellow fea is richly cultivated, and rifes in a gentle afcent, which is terminated by high, broken, and barren mountains, apparently granitical. The paffage between Ten-choo-foo and the Mi-a-tau iflands is called in the chart the ftrait of Mi-a-tau, in which ftrait the rife and fall of the tide are about feven feet. Staunton's Embaffy, &c. vol. i.

TENTER, Trier, or *Prover*, a machine ufed in the cloth manufactory, to ftretch out the pieces of cloth, ftuff, &c. or only to make them even, and fet them fquare.

It is ufually about four feet and a half high, and, for length, exceeds that of the longeft piece of cloth. It confifts of feveral long, fquare pieces of wood, placed like thofe which form the barriers of a manege; fo, however, as that the lower crofs-pieces of wood may be raifed or lowered, as is found requifite, to be fixed at any height, by means of pins. Along the crofs-pieces, both the upper and under one, are hooked nails, called *tenter-hooks*, driven in from fpace to fpace.

To put a Piece of Cloth on the Tenter.—While the piece is yet quite wet, one end is faftened to one of the ends of the tenter; then it is pulled by force of arms towards the other end, to bring it to the length required: that other end being faftened, the upper lift is hooked on to the upper crofs-piece, and the loweft lift to the loweft crofs-piece, which is afterwards lowered by force, till the piece have its defired breadth. Being thus well ftretched, both as to length and breadth, they brufh it with a ftiff hair-brufh, and thus let it dry. Then they take it off; and, till they wet it again, it will retain the length and breadth the tenter gave it.

TENTERDEN, in *Geography*, is a fmall market-town in the hundred of the fame name, in the lathe of Scray, and county of Kent, England, fituated 18 miles S.S.E. from Maidftone, and 56 miles S.E. by S. from London. N. lat. 51° 4′ 8″. E. long. 0° 41′ 8″. At a remote period it was incorporated by the name of the "barons of the town and hundred of Tenterden;" which ftyle was changed to that of the "bailiff and commonalty," by letters patent of Henry VI., who at the fame time annexed it as a member to the town and port of Rye, in Suffex, to which it is yet fubject. Queen Elizabeth, in her forty-fecond year, granted the inhabitants a new charter, by which, in the place of a bailiff, &c. the future government of the town was vefted in a mayor, twelve jurats, twelve common-council men, a chamberlain, and a town-clerk. The prefent town-hall, which is occafionally ufed as an affembly-room, was built about the year 1792; the old one having been burned by an accidental fire. The market-houfe is a fmall, mean edifice of timber, now little frequented; the market itfelf being almoft difufed, though ftill nominally held on Fridays. A large fair is annually held for the fale of cattle, wool, fhop-goods, &c. According to the returns under the population act of the year 1811, the number of inhabitants in this town was 2786, that of houfes 459. Many of the latter are refpectable buildings, occupied by perfons whofe families have derived affluence from the grazing bufinefs carried on in the neighbouring marfhes. The parifh church is a fpacious ftructure, and confifts of a nave, north aifle, and chancel, with a well-built and lofty tower at the weft end, on which is fculptured the arms of St. Auguftine's monaftery, to which foundation this church was appropriated in 1259. Befides the church, here are two places of religious worfhip for diffenters of different denominations. Dr. Harris mentions an ancient free-fchool, founded here by one of the family of Heyman of Somerfield, and records fome donations made for its fupport. The truftees are the mayor and jurats, who, according to Hafted, are fo inattentive to the charity, that not any children are now educated on this foundation.

The chapelry of Small Hithe, in Tenterden parifh, was formerly, according to traditional report, a very confiderable place, but is now reduced to a few farm-houfes and cottages. The chapel was licenfed by archbifhop Warham, in 1509, "on account of the badnefs of the roads, and the dangers which the inhabitants underwent in their way to the parifh church, from the waters being out."—Beauties of England and Wales, vol. viii. Kent, by E. W. Brayley.

TENTH, in *Englifh Hiftory*. See LAND-*Tax*.

Tenths are faid to have been firft granted under Henry II., who took advantage of the fafhionable zeal for croifades to introduce this new taxation, in order to defray the expence of a pious expedition to Paleftine, which he really or feemingly had projected againft Saladine, emperor of the Saracens; whence it was originally denominated the Saladine tenth. But afterwards fifteenths were more ufually granted than tenths.

TENTH, *Decima*. See FIRST-*Fruits*, and TITHE.

TENTHS, *Office of*, is kept in the Temple, under the direction of a receiver and his clerks.

TENTH, in *Mufic*, the octave above the third, and an octave below the feventeenth, or ftop in the organ called the tierce. The tenth is a very pleafing confonance, but inferior in fuavity to the third; for which reafon the duets at the opera, fince the principal firft man's part has been performed by a tenor, have never given the audience that exquifite pleafure which they ufed to do, when fung by two fopranos.

TENTHREDO, in *Entomology*, a genus of the Hymenoptera order of infects, the characters of which are, that the mouth has a horny, arcuated mandible, within dentated; a ftraight jaw, obtufe at the apex; a cylindric, trifid lip, with four unequal filiform feelers; the wings flat, and tumid or flightly inflated; the piercers confifting of two ferrated, fcarcely prominent laminæ; and the fcutellum with two diftant granules.

The larvæ of this genus refemble thofe of the order Lepidoptera, or real caterpillars; but are diftinguifhed from them by their more numerous feet, which are never fewer than fixteen, exclufive of the three firft or thoracic pairs. When difturbed or handled, they ufually roll themfelves into a flat fpiral. They feed, like the caterpillars of the lepidoptera, on the leaves of plants; and undergo their chryfalis ftate in a ftrong gummy cafe or envelopement, prepared in autumn, out of which, in the enfuing fpring, emerges the complete infect. The tenthredines form a numerous genus, and are divided into tribes or fections, according to the form of the antennæ. Gmelin reckons 143 fpecies.

N. B. The European fpecies are marked with a ftar *, and the Englifh with a crofs †.

Species.

A. *Antennæ clavated.*

* FEMORATA. Antennæ yellow; black body; hinder thighs largeft; the larva green, with a blueifh line on the back, and yellow at the fides.

* MARGINATA. Antennæ yellowifh at the apex; black body; the hinder fegments of the abdomen white at the margin.

LUTEA. Antennæ yellow; fegments of the abdomen moftly yellow. This infect proceeds from a large green larva, of a finely granulated furface, with a double row of black fpecks on each fide, and a dufky dorfal line bounded on each by yellow. It feeds on various fpecies of willow, alder, and beech. The parchment-like cafe in which it envelopes itfelf in autumn is of a pale yellowifh-brown colour; and the chryfalis, which is of a pale dufky or brownifh caft, exhibits the limbs of the future fly, in fize equal to a common wafp, and of a yellow colour, bound with black; the antennæ rather fhort, and ftrongly clavated.

AMERINÆ. Body cinereous; abdomen beneath red; white lip. This infect is fomewhat fmaller than the preceding: its caterpillar, like that of the former, is of a green colour, and of a finely roughened furface, powdered with numerous whitifh fpecks. Feeds on the willow.

TRISTIS. Black, with yellow antennæ, and wings brown at the apex; green larva, with an azure line on the back, black and yellow fringed.

VITELLINÆ. Abdomen above black; fides red; hinder thighs dentated; larva greenifh.

LUCORUM. Antennæ black; body villous black. Found on the beech and alder.

* FASCIATA. Black; antennæ black; primary wings with a brown band.

* SERICEA. Antennæ yellow; thorax black; abdomen braffy; larva green, with two yellow lines.

OBSCURA. Body fmooth and black. Found in the groves of Sweden.

CONNATA. Black; abdomen with yellow bands. Found on the alder.

* NITENS. Antennæ yellow; abdomen green-blueifh, fhining. Suggefted to be a variety of the fericea.

B. *Antennæ exarticulate, the outer ones thicker.*

CLAVICORNIS. Black; abdomen yellow; apex black. Found in North America.

ANNULATA. Black; abdomen yellow; hinder tarfi black, annulated with white.

* ENODIS. Antennæ fmooth; body black-blueifh; larva green, fpotted with black, a rough lateral line yellow, fharp tail.

CILIARIS. Antennæ beneath ciliated; hinder legs white. Found in Germany.

* USTULATA. Body black; abdomen blueifh; legs pale. On the canine rofe. Larva green, with two white lines; head teftaceous; obfcure band.

† CYANOCROCEA. Head and thorax bright-blue; abdomen faffron-coloured.

† ATRATA. Black; back, zone, and three arcs, yellow-greenifh.

BICOLOR. Black-blue; abdomen and bafe of the wings yellow; wings with a black band. Found in Auftria.

* MELANOCHRA. Black; abdomen yellow; a fmall black line

line on both ſides of the anus; legs and ſoles yellow; wings with a black ſpot.

* Tricolor. Head and thorax black; wings and feet brown; abdomen yellow.

* Ochropus. Head, thorax, middle of the breaſt, and apex of the hinder legs, black; abdomen and feet yellow.

C. *Antennæ pectinated.*

Cephalotes. Black; abdomen with four yellow zones or belts. Found in Germany.

† Dorsata. Whitiſh; head and back of the thorax and abdomen black.

D. *Antennæ pennated.*

* Pini. Antennæ lanceolate, and thorax ſubvillous; larva blueiſh, and yellow at the tail end.

Juniperi. Antennæ obtuſe; thorax ſmooth; larva green, pointed with black.

E. *Antennæ filiform, with from ſeven to nine Joints.*

Americana. Thorax yellow; abdomen blue; wings black. Found in Surinam.

Costalis. Black, with the rib of the wings ferruginous. Found in Germany.

Lateralis. Black; middle of the back red; ſides white. Found on the flowers of Sweden.

† Arcuata. Abdomen black; five arcs, with a band at the baſe and ſides, yellow-greeniſh.

* Rustica. Black; abdomen with three yellow belts, the hinder two interrupted; larva cinereous, with triangular brown ſpots on the back.

* Scrophulariæ. Antennæ yellow; abdomen with five yellow belts, the firſt more diſtant.

Abietis. Body black, with four ferruginous ſegments of the abdomen.

Germanica. Body black; thorax before and abdomen red. Found in the groves of Germany.

Padi. Black, with thighs and legs white.

Cynipiformis. Green-braſſy; yellow feet; hinder thighs braſſy.

Cerasi. Body black; ſcutellum and feet yellow; larva gelatinous, black.

Salicis. Body variegated. Found on the elder and willows.

Flavicornis. Yellow; head and tail black. Found in Germany and Italy.

Luteicornis. Bla k; with antennæ, mouth, baſe of the abdomen, and legs, yellow.

Mesomelas. Abdomen yellowiſh; back black; arcs yellowiſh.

Punctum Album. Body black; abdomen at the ſides white; hinder thighs red. Found in Germany.

† Blanda. Black; abdomen in the middle red; hinder thighs with a white ſpot.

Quadrimaculata. Black; hinder feet red; two ſpots at the baſe white.

* Rufipes. Body black; abdomen with two yellow belts; feet red.

* Campestris. Body black; abdomen with an unequal yellow belt; antennæ and legs yellow.

* Atra. Body black; feet red.

* Viridis. Body green; abdomen above brown.

* Ovata. Body black; thorax above red; larva greeniſh, ſprinkled with a kind of white powder.

Alni. Body black; head and thorax red.

* Cæruleſcens. Violet; abdomen yellow; wings with a brown ſpot.

* Pavida. Black; the abdomen with three ſegments, and feet ferruginous; larva green, ſprinkled with white farina; head yellow.

* Rosæ. Black; abdomen yellow, and ridge of the primary wings black; larva yellow, pointed with black.

* Bicincta. Body black; belt of the abdomen, anus, mouth, and legs yellow.

Cincta. Body black; the abdomen with a white belt; perhaps a variety of the former.

* Livida. Body black; antennæ before the apex white.

Albicornis. Black; antennæ at the apex white; legs teſtaceous; wings at the apex brown. Found in Italy.

Gonogra. Body black; knees teſtaceous. Found in Germany.

Nigra. Whole body black. Found at Upſal.

* Æthiops. Smooth, black; with the four fore-legs pale.

Rapæ. Body black; belly, feet, and ſcutellum whitiſh.

Septentrionalis. Feet poſterior, compreſſed and dilated; larva gregarious, green, ſpotted with black; yellow apices.

Opaca. Black; thorax with a ſpot on both ſides, red at the apex. Found in the gardens of Sweden.

Carbonaria. Black, with a white mouth; fore-legs teſtaceous. Found in Germany.

* Nassata. Yellow; ſcutellum and point of the wings white.

* 12-Punctata. Body black, with twelve white points.

Capreæ. Yellow; head, thorax, and abdomen above, black; wings with a yellow point.

Morio. Black; with pale feet. Found in Germany.

Annularis. Black, ſhining; antennæ white at the apex; legs ferruginous. In the gardens of Auſtria, perhaps a variety of the livida.

Ferruginea. Antennæ black, annulated with white; body ferruginous; thorax, breaſt, and vertex black. Found as the laſt.

Crassa. Black; feet and double points under the ſcutellum elevated, red. In Auſtria and Carniola.

Albicincta. Black; the belt at the baſe of the abdomen and legs with a ring milky. In Auſtria and France.

Vespiformis. Antennæ yellow; all the ſegments of the abdomen with yellow margins. In Auſtria.

Semicincta. Black; the belt of the abdomen broken behind, yellowiſh; the feet and abdomen beneath yellow. In Auſtria.

Viennensis. Black; abdomen with five yellow belts; the baſe of the antennæ fulvous. In Vienna.

Ribis. Black; legs and apophyſes of hinder thighs white at the exterior ſide. In Auſtria.

Fuliginosa. Black, with fuliginous wings. In Auſtria.

Dealbata. Black; the abdomen on both ſides marked with a white ſpot, hinder thighs clavated, yellowiſh. In Auſtria.

Alneti. Yellow; abdomen above black. In Auſtria.

Hæmatodes. Black, thorax before on both ſides red. In Auſtria.

Erythrogona. Black; the apex of the thighs and baſe of the legs red. In Auſtria and France.

Fulviventris. Black; with red and deep yellow abdomen. Found in Auſtria and Carniola.

Fulvivenia. Black; with the exterior margin of the wings fulvous, or deep yellow. Found at Vienna.

* Sulphurata. Black; antennæ ſubclavated; four fore-

fore-feet fulphureous; the hinder foles with three intermediate white joints.

* Flaveola. Antennæ fubclavated, black; bafe, mouth, fides, and five firft fegments of the abdomen and feet, yellow.

* Annulata. Yellow; antennæ fubclavated, black; apex of the thighs and foles annulated with black.

* Rubiginosa. Black; antennæ fubclavated, and bafe with feet yellow; third, fourth, and fifth fegments of the abdomen ferruginous.

* Subulata. Black; antennæ fubulate at the apex; fecond to the fifth fegments of the abdomen, as far as the hinder margin, legs and foles, yellow, and thefe annulated with black.

* Mucronata. Black, with the feven-knotted antennæ and abdomen yellow; the laft fegments from the fecond to the fourth black; the apex of the wings brown.

* Varia. Black; mouth, fcutellum, and fcutellar fpots, white; the hinder fegments of the abdomen and feet ferruginous.

* Sanguinolenta. Black; with the hinder feet fanguineous.

* Dealbata. Black; the three laft joints of the antennæ and jaws white; legs and foles yellow.

* Canescens. Grey-downy, brown, with grey wings.

* Bifasciata. Brown, with black thorax; mouth, fcutellum, and four fpots at the fcutel, white; abdomen with two interrupted yellow bands; margin of the wings and feet yellow.

* Braccata. Black, with red thighs; the bafe of the four hinder legs, and the three penultimate joints of the antennæ, white.

* Rufipes. Black; the bafe of the abdomen, with a fpot on both fides, and jaws, white; four fore-legs red.

* Melanoleuca. Black; mouth, thorax with a fmall line on both fides before the wings; a fpot on the hinder thighs; legs, the fides of the abdomen from five to feven fegments, and apex, white.

* Melanochra. Black; mouth, four fore-feet, and bafe-flexure of the hinder thighs, yellow.

* Leucopus. Black; the bafe-flexures of the thighs white; four anterior legs without, and middle of the hinder, white.

* Varicornis. Black, with red feet; fourth and fifth joints of the antennæ and hinder legs at their bafe, white.

* Obscura. Brown; with the rib of the wings as far as the fpot and feet teftaceous.

* Limbata. Black; the hinder margins of the fegments of the abdomen white; feet reddifh.

* Exalbida. Black; with feelers and four legs obfoletely white.

* Ferruginosa. Black; the antennæ ferruginous forwards; the bafe and anterior margin of the wings, the firft and fifth fegment of the abdomen, the legs and foles, white.

* Angusta. Black; body narrow and grey-downy.

* Lutescens. Black; with the abdomen beneath and feet yellow-reddifh.

* Albipes. Black; with legs and foles white.

* Flaviventris. Black; mouth white; abdomen yellow; back and apex black; feet teftaceous.

* Picea. Pitchy; anterior legs before, fpot of the hinder thighs, and bafe, white; hinder feet red; the knees and foles black.

* Fuscipes. Black; feet red; pofterior foles brown.

* Bimaculata. Pale; eyes, abdomen above the bafe, breaft and two fpots, black.

* Lata. Broad, black; the pofterior fegments of the abdomen white, from the fecond to the fifth interrupted.

* Annalicornis. Pale, the antennæ fpotted with black at the bafe; vertex of a branchy figure, eyes, and the conjugate points at the back of the thorax and abdomen, black.

* Scripta. Pitchy; mouth, and on the middle of the fore-part of the thorax the mark refembles V; the fpot on both fides the fcutellum white; two fcutellar points white; feet, and under margin of the fegments of the belly, yellow.

* Literata. Black; fegments of the abdomen from the fecond to the fifth in the back, ovated fpot on both fides and margins white; anterior feet, and four hinder legs on the fore-part, white.

* Melanorhœa. Black, with yellow abdomen; the tranfverfe fpots of the back and anus black.

* Geminata. Black, with geminated antennæ, and joints and legs pale.

* Ochrogustes. Pitchy; with the abdomen beneath and feet yellow.

* Ruficapilla. Head and thorax red; the pofterior margin of the latter and eyes black; the abdomen and feet yellow.

* Dubia. Black; thorax before red; joints whitifh.

* Pallescens. Black; mouth and feet pale.

F. *Antennæ fetaceous; many Joints.*

Erythrocephala. Body cæruleous; head red.

* Sylvatica. Body black: feet and marks of the thorax yellow.

* Nemoralis. Body black; fegments of the abdomen white at the fide.

* Cynosbati. Body black; feet ferruginous, hinder annulated with white and black.

Signata. Pale; thorax and three dorfal longitudinal fpots black. Found in Germany.

Populi. Black-blueifh; mouth, feelers, and legs yellow.

Vafra. Head black, variegated with white; feet teftaceous. Found in Sweden.

Reticulata. Wings varied with pale and brown, with elevated veins, white and reticulated. Found in Finland.

* Betulæ. Body red; thorax, anus, and eyes black; wings behind brown.

* Flava. Yellow, with the fpot on the wings ferruginous.

Hæmorrhoidalis. Black; with the anus and feet teftaceous. In Germany.

† Nemorum. Middle of the abdomen red; fcutellum and point on the wings white.

Depressa. Head and thorax black; marks yellow; abdomen and feet ferruginous. In Auftria and France.

Linearis. Black; legs, and five bands of the filiform abdomen, yellow. In Auftria.

Bipunctata. Antennæ fub-fetaceous; nine joints black, and two points of the black fcutellum white.

G. *Of doubtful Order.*

Intercus. Black; with yellow feet and fubclavated antennæ.

Rumicis. Found on the dock.

Ulmi. Found on the leaves of the wild elder.

Pruni. Found on the plum-tree.

Loniceræ. Brown, tomentofe, fhining, with fubclavated antennæ, and fubferruginous wings.

* Polygona. Black; antennæ fubclavated with eighteen knots;

knots; the hinder margin of the fegments of the abdomen from the third to the fifth yellow-greenifh; the thighs black; the face anterior at the apex and the legs yellow; the hinder at the apex black; the foles yellow; the linear abdomen compreffed.

TENTOLI, in *Geography*, a town of the ifland of Celebes, near the north extremity, on the weft coaft, which gives name to a road. N. lat. 1°.

TENTORES, among the Romans, were perfons appointed to hold the clothes of the charioteers that contended in the circus.

TENTUGAL, in *Geography*, a town of Portugal, in the province of Beira; 7 miles W.N.W. of Coimbra.

TENTYRA, or TENTYRIS, in *Ancient Geography*, a town of Egypt, and capital of a nome, which took the name of *Tentyrites*, according to Strabo, Pliny, Ptolemy, and Steph. Byz.

TENTZEL, WILLIAM-ERNEST, in *Biography*, a German antiquary and hiftorian, was born, in 1659, at Greuffen, in Thuringia, and finifhed his education at Wittemberg, directing the courfe of his ftudies to philofophy and the Oriental languages, and alfo to hiftory, both facred and profane. In 1685 he was appointed a teacher in the gymnafium at Gotha, and entrufted with the care of the duke's collection of antiquities and coins. In order to qualify himfelf for the more honourable difcharge of his duties as hiftoriographer to the houfe of Saxony of the Erneftine line, to which office he was appointed in 1696, he vifited various courts in Germany, and carried on an epiftolary correfpondence with many diftinguifhed foreigners. In 1702 he removed to Drefden, where he was made hiftoriographer to the elector of Saxony, king of Poland, by whom he was honoured with the title of counfellor; but his manners not being adapted to a court, he obtained leave to retire. What remained of his life was devoted to literary purfuits; and he died, very poor, in November 1707, in his 49th year. His works were numerous, among which we may reckon the following: *viz.* "De Phenice," Vitemb. 1682, 4to.; "De Ritu Lectionum Sacrorum," Vitemb. 1685, 4to. a work highly commended by Bayle; "Judicia Eruditorum de Symbolo Athanafiano ftudiofè collecta et inter fe collata," Francf. et Lipf. 1687, 12mo.; "Animadverfiones in Cafimiri Ordine Supplementum de Scriptoribus Ecclefiafticis," 1688, 12mo.; "Cafparis Sagittarii Hiftorici Saxonici Hiftoria Gothona plenior, &c." Jena, 1700, 4to.; "Supplementum Hiftoriæ Gothonæ," ibid. 1701, 4to.; "Supplementum Hift. Goth. fecundum," ibid. 1701, 4to.; "Saxonia Numifmatica, Pars I." Francf. et Lipf. 1705, 4to.; "Pars II." 1705. Tentzel was alfo a contributor to feveral literary journals. Gen. Biog.

TENUIROSTRÆ, in *Ornithology*, the name of a genus of fmall birds, which feed on infects, and have flender and fharp beaks; of this genus are the lark, fwallow, red-breaft, and a number of others. Ray's Ornithology.

TENUME, in *Geography*, a town of Arabia, in the province of Nedsjed; 40 miles N. of Aniza.

TENURE, in *Agriculture*, the manner in which proprietors and tenants hold their lands, &c. of their landlords, or other perfons.

It may be noticed, that the tenures of lands are extremely various in almoft every diftrict of the kingdom, being, however, chiefly *freehold*, *free-farmhold*, *copyhold*, *long-leafehold*, or *life-leafehold*, though there are many other local forts of tenures of land. The freehold is moft probably in the largeft proportion over the whole country, the copyholds in the next, and the leafehold tenures in the fmalleft extent. It has been remarked in the Shropfhire Agricultural Report, that it appears beautiful in theory, that there fhould be one rule of defcent in a kingdom only, one tenure of property, and one fcale of political rights; but that it may be doubted whether fo much uniformity is fuitable to an imperfect ftate; or at leaft to our prefent degree of improvement. At all events, irregularities that are not attended with much practical inconvenience, fhould not be pointed out as obnoxious, in a fcheme that has produced fo much pofitive happinefs, and fo much comparative good, as the conftitution of thefe kingdoms has afforded.

It is ftated too, in the Agricultural Survey of Effex, that freehold eftates are the moft valuable to the immediate proprietor, there can be no doubt; but the purchafer of a copyhold may remember, that the original purchafe is by fo much the lower; and whether he lets the occupation to a tenant, or farms and cultivates it himfelf, he may poffibly make as good intereft of his capital as if he had bought a freehold. Perhaps, alfo, its general and final utility to the public, may be nearly or quite the fame. This, the writer thinks, is certain, that copyhold eftates, whether in the hands of the proprietors or tenants, are as well cultivated as the free, excepting only in the article of timber, and even in that the difference is feldom vifible. The like may be faid of leafehold eftates, and even of thofe in mortmain.

In Hertfordfhire, where a large portion of the property is held by copyhold tenure, with a fine certain or at the will of the lord, but which fine never exceeds two years' rent, the land fells at about fix years' purchafe under the price of freehold, according to the Report of the ftate of agriculture for that diftrict. And it is further fuggefted in the latter of the two former of the above agricultural furveys, that, with regard to the tenures by which the more temporary occupiers hold their farms, they are, as already obferved, extremely various, fome upon leafes of longer or fhorter duration, fome without any leafe at all, agreeably to the tafte and pleafure of the landlord; though by far the greateft number, efpecially of thofe in the poffeffion of the fmaller proprietors, are let upon leafes of from eight or ten to twenty-one years. And it is obferved, from what has been done in Norfolk and other counties where the tenures are of more length, as from feven to twenty-one years, that the improvement of the land is much connected with the practice of fuch tenures. And it is likewife fuggefted in the Gloucefter Report on Agriculture, that it were much to be wifhed that a general rule could be adopted for the commencement and end of tenures; as it would ultimately, the writer thinks, be highly advantageous to landlords and tenants, and will probably be one refult of the labours of agricultural focieties.

Some fuppofe the freehold tenure to poffefs the moft numerous advantages, with the feweft inconveniences, of any fort of holding. But many are of opinion that fome other kinds are equal to it, or nearly fo. The forms of tenure throughout moft of the fouthern parts of England, are principally thofe of the freehold, copyhold, life-leafe, church-leafe, and college-leafe kinds, both for lives and years. In Cornwall they are for the moft part freehold, with the exception of the lands of ecclefiaftical corporations and ancient duchy land, which is equivalent to copyhold in fee, held under the duke of Cornwall, fubject to a fmall annual rent. This fort of land paffes by furrender in the duchy courts, nearly in the fame form as other copyhold lands. But the modern duchy is different from the above; the occupiers being leffees under the duke, and, in general, are purchafers of an intereft in the land during the continuance of the longeft liver of three lives, the confideration being, in part,

 a fine

a fine paid at the time of the grant, and alfo a referved rent during the continuance of the leafe.

There are three different kinds of church-leafe in this diftrict; as demifes to tenants for the longeft of three lives; the confiderations being money and referved rents; demifes to manorial tenants for three lives in the fame way; the takers having the liberty, during the whole time, to underleafe to other tenants in the manner of copyholds for three lives; and grants of leafes for twenty-one years abfolute, giving frefh leafes at the end of every feven, which is a renewal of the firft. Thefe are firft made in confideration of fines and referved rents, but in the renewals fines only.

In the fame diftrict, it has been much the cuftom, in refpect to the tenure of tenants, to grant leafes for lives, for the term of ninety-nine years, determinable on the death of the longeft liver of three lives, to be named by the taker. On the death of one of the lives named in the leafe, it was ufual for the landlords to confent to the adding a new life to the two which remained. The confideration in the primary grant was uniformly a fine in hand of from fourteen to eighteen years rent of the landed eftate, with a fmall referved rent, and fuit and fervice to the manor court; the renewal commonly a fine only of three years' rent for one life, or feven for two lives, without any alteration of the other rent.

A large proportion of the lands here are now held by the tenantry under thefe leafes or tenures, but it muft be noticed, that the number of new grants, or the renewal of old ones, is on the decreafe; and feldom takes place, unlefs under particular circumftances and motives.

The holders under thefe leafes or tenures, which are called leafeholds or fine-leafes, are conftantly fubjected to all taxes and repairs of every kind, excepting that a fmall proportion of the land-tax in fome manors is repaid the tenant, as the land-tax of the referved rent. Under the property-tax, they were rated both as proprietor and occupier, except only that the landlord was liable to the property-tax for his referved rent.

It admits of fome doubt whether this mode of leafing or holding property be more detrimental to the lord, the tenant, or the public in general; but it is certainly a very injudicious and unwife method of proceeding, as it is highly injurious to the agriculture of the county, though at firft fight the fecurity and great length of the leafes might be fuppofed to have the contrary effect. It is found, however, in practice, that the circumftance of moft of the holders under thefe leafes having not only exhaufted in their purchafe and renewal the whole of their capitals, but often confiderably more raifed on them with great difadvantage, counteracts every good that might otherwife have been expected. It is afferted that, in common, cultivators of this fort, from the want of capital and other means, as well as the fpeculative nature of all fuch tenures, are neceffarily feeble and fpiritlefs, and that they live worfe, work harder, and are more inconvenienced, than any other kind of holders of land. And that where the landlords do not renew, they are frequently fufferers from the dilapidated and exhaufted ftate of the premifes.

It is alfo remarked by Mr. Vancouver, in his Account of the Agriculture of the County of Devon, in regard to thefe kinds of life-leafe tenures, that the mifchievous confequences infeparably connected with, and refulting from, the want of agricultural knowledge in thofe who have the direction and management of fuch eftates, and who, to cover the want of the neceffary qualifications of a land agent, moft commonly advife the proprietors to grant thofe life-hold tenures fo frequently heard of in this county and South Wales, are more injurious and extenfive than is generally apprehended. The fame capital employed in the purchafe of a leafe for ninety-nine years, determinable on three lives, applied to the ftocking, cultivating, and improving a more extenfive occupation held at a fair annual rent, and under an encouraging term of years, muft, it is fuppofed, produce, in the contemplation of fuch property, very different emotions in the mind of the owner: to the occupier the refults are infinitely more advantageous; and to the public at large, a more abundant fupply is produced than can poffibly be derived from a capital employed in the purchafe of a more narrow occupation on an eventually undifturbed poffeffion of ninety-nine years. But notwithftanding, an opinion prevails with fome noblemen and others in this county, that it is better to realize at forty years' purchafe, than to fuffer the lifehold tenures to fall in without renewal. Fortunately for the future improvement and profperity of the county, the writer fays, this fpecies of tenure is become much leffened within the laft twenty years. In order to accomplifh this prepofterous object of the tenant's indolence and pride, it is obferved, he will employ his laft fhilling, and incur very heavy obligations among his friends and neighbours, to pay eighteen years' purchafe for a leafe only of that very farm, the fee of which might readily have been bought for about one-third more. Deftitute of capital, and encumbered with obligations contracted with his family and friends, the farmer enters his new occupation, depending upon cafual and agiftment ftock for the confumption of his pafture herbage. Having little or no referved rent to provide for, the efforts of himfelf and family are directed to the annual cultivation of fo much of his land as will pay the parochial and other fmall difburfements, and fupply the bare wants of the moft comfortlefs life it is poffible to conceive, leaving no brighter profpects to his offspring, than what the lapfe of ninety-nine years may do, by terminating a leafe fo injudicioufly purchafed. The fame is the cafe with thefe forts of tenures in many other diftricts of the kingdom.

There is a great number of tenures befides the above forts in the midland and more northern counties, fome of which are very curious and fingular. Tenures under the crown are likewife met with in thefe as well as moft other parts of the kingdom.

In that part of the country ufually denominated Scotland, the tenures by which lands are principally held may be claffed and confidered as thofe of fuperiority, property, and tack; the firft of which is merely nominal, and goes no farther than that of conferring the right of franchife; the fecond is a valuable tenure of land, as yielding and implying the full ufe and command of it to the fubject for all the purpofes of human life, excepting merely political power, which is attached as above, and may or may not be attached to the property; and the laft is the tenure for a term of years, by which profeffional farmers hold land from proprietors for the purpofes of agriculture. The origin of thefe forts of tenures, which feem to have been of a military or feudal nature, is more fully explained in Finlater's Agricultural Survey of the County of Peebles, to which the inquirer on this fubject is referred.

Tenure, *Tenura*, in *Law*, the manner or condition in which a tenant holds lands or tenements of his lord; or the fervices performed to the lord, in confideration of the ufe and occupancy of his lands.

The kinds of fervice, and confequently of tenures, are almoft infinite. See Service.

Thofe for lands held of the king are either *great*, or *petty fergeanty*, *in capite*, *knight's fervice*, &c.

Thofe held of the lords were very various, *bafe*, *frank*, &c. by *homage*, *focage*, &c. See Base, Frank, &c.

The

The common tenures at this day are, fee-fimple, fee-tail, by courtefy, in dower, for life, or for years, or by copy of court-roll.

TENURE, *Barons by ancient.* See BARON.

TENURE, *Difturbance of*, is a fpecies of injury which confifts in breaking that connection which fubfifts between the lord and his tenant, and to which the law pays fo high a regard, that it will not fuffer it to be wantonly diffolved by the act of a third perfon. If, therefore, there be a tenant at will of any lands or tenements, and a ftranger, either by menaces or threats, or by unlawful diftreffes, or by fraud and circumvention, or other means, contrives to drive him away, or inveigle him to leave his tenancy, this the law very juftly conftrues to be a wrong and injury to the lord; and gives him a reparation in damages againft the offender by a fpecial action on the cafe. Blackft. Com. vol. iii.

TENUTE, Ital. in *Mufic*, generally written *ten*, from the Italian verb *tenere*, to hold on, fuftain to the laft moment of a note's duration. See SOSTENUTO.

TENYA, in *Geography*, a town of Africa, in the country of Foota. N. lat. 10° 15′. W. long. 10° 25′.

TEN-YANG, a town of Corea; 73 miles E.S.E. of King-ki-tao.

TENZEGZET, a town of Algiers; 16 miles S. of Tremecen.

TENZYN, a town of Poland, in the palatinate of Cracow; 20 miles W. of Cracow.

TEOATZINCO, a town of Mexico, in the country of Tlafcala, where a bloody battle was fought between the natives and the Spaniards under Cortez; 20 miles E. of Tlafcala.

TEOLO, a town of Italy, in the Paduan; 7 miles S.S.W. of Padua.

TEOLY, a town of Hindooftan, in the circar of Gohud; 15 miles S.E. of Gwalior.

TEOMAHAL, a fmall ifland in the Sooloo Archipelago. N. lat. 6° 15′. E. long. 120° 51′.

TEONA, a fmall ifland near the weft coaft of Scotland. N. lat. 56° 47′. W. long. 5° 50′.

TEOPISCAN, a town of Mexico, in the province of Chiapa; 60 miles S.E. of Chiapa dos Efpagnols.

TEOS, in *Ancient Geography*, a town of Afia Minor, in Ionia, on the fouthern coaft of a peninfula, which became an ifland when the fea was high or much agitated. It was fituated over-againft the ifle of Samos, S.W. of Smyrna, and E. of the promontory of Coryceon. It is celebrated for having been the birth-place of Anacreon. The inhabitants were renowned for their courage: they preferred abandoning their city to living under the tyranny of the Perfians. Teos was treated with mildnefs by the Roman emperors. Bacchus had a magnificent temple here, which Vitruvius has particularly defcribed. Here alfo was held a general council for the management of all the affairs of Ionia, becaufe this city was in the centre of Ionia.—Alfo, the name of a town of Scythia.

TEOWENISTA CREEK, in *Geography*, a river of Pennfylvania, which runs into the Alleghany, about 5 miles below Hickery.

TEPAPA. See TAROATAIHETOOMO.

TEPEACA, in *Geography*, a town of Mexico, in the province of Tlafcala; 15 miles S.S.E. of Puebla de los Angelos.

TEPEGUANA, a diftrict of New Brafil, fituated on the Nazas.

TEPELLENE′, a town of Albania, the birth-place and favourite refidence of Ali, fituated on the banks of a river, which at the diftance of 60 miles from the fea appears to be as broad as the Thames at Weftminfter bridge. The ftreets of the town, containing about 400 ill-built houfes, are extremely dirty; but the palace of the vizier is very magnificent.

TEPE-MAXTLATON, in *Zoology*. See FELIS *Tigrina*.

TEPETISTAC, in *Geography*, a town of Mexico, in the province of Guadalajara; 60 miles N. of Guadalajara.

TEPETOTOTL, in *Ornithology*, the name of a Brafilian bird of the gallinaceous kind, more ufually called *mituporanga*. See CRAX *Alector*.

TEPHLIS, or TELPHIS, in *Ancient Geography*, a town of Afia, in the vicinity of Media.

TEPHRIA, in the *Natural Hiftory of the Ancients*, a name given to the grey ophites.

TEPHRICA, in *Ancient Geography*, a town of Afia, in the neighbourhood of Cilicia and Armenia.

TEPHROMANTIA, τεφρομαντεία, in *Antiquity*, a fpecies of divination, performed with afhes; for which fee Potter, Archæol. Græc. tom. i. p. 353.

TEPHROSIA, in *Botany*, from τεφρος, *afh-coloured*, in allufion probably to the hoary afpect of the herbage.—"Perf. Syn. v. 2. 329." Purfh 489. (Erebinthus; Mitchell in Ephem. Nat. Curiof. v. 8. 210?)—Clafs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminofæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, deeply divided into five ftraight, awl-fhaped teeth; the upper ones rather the fhorteft; the loweft rather longer than the reft. *Cor.* papilionaceous. Standard recurved, large, roundifh-obovate. Wings half-obovate, obtufe, ftraight, rather fhorter than the ftandard. Keel broad, rounded, gibbous, compreffed, the length of the wings. *Stam.* Filaments ten, all firmly united along the middle into a membranous tube; the tenth feparate at the bafe, and in its upper half; all capillary and diftinct at the extremity, fomewhat unequal in length; anthers terminal, uniform, ovate-oblong. *Pift.* Germen feffile, oblong, compreffed, very hairy; ftyle awl-fhaped, angular, afcending, hairy along the back; ftigma fimple, recurved, flightly hairy. *Peric.* Legume oblong, compreffed, hairy, fomewhat falcate or afcending, of two valves and one cell. *Seeds* feveral, compreffed, kidney-fhaped, rather angular, flightly feparated from each other by thin, imperfect, membranous partitions.

Eff. Ch. Calyx with awl-fhaped, nearly equal, teeth. Stamens all connected. Legume compreffed, rather coriaceous, of one cell, with many feeds. Stigma acute.

Obf. We have taken our characters from one certain fpecies, *T. virginiana*, comparing it with authentic original fpecimens of Mitchell's *Erebinthus*, which Linnæus thought the very fame fpecies, but in this he was certainly miftaken. It appears to be Mr. Purfh's third fpecies, *T. hifpidula*; and as far as we can judge, from fpecimens that will not admit of diffection, and from Mitchell's defcription, it is moft probably of the fame genus, for Mitchell might overlook the partial union of the ftamens, even fuppofing that character to exift in his plant. If we were certain of this, his name ought, by every right, to be preferred to the more modern one of Perfoon. (See EREBINTHUS.) The genus moreover is improperly placed in the fixth fection of *Diadelphia*, while its effential character indicates that it belongs to the firft.

1. T. *virginiana*. Virginian Grey-Vetch. Purfh n. 1. (Galega virginiana; Linn. Sp. Pl. 1062, excluding Hort. Cliff. and Mitchell's fynonyms. Willd. Sp. Pl. v. 3. 1244. Ait. Hort. Kew. v. 4. 355. Cicer aftragaloides (fortè) virginianum, hirfutie pubefcens, floribus amplis fubrubentibus; Pluk. Phyt. t. 23. f. 2.)—Erect, hoary, and

and ſhaggy. Leaflets numerous, oval-oblong. Cluſter terminal, many-flowered.—In dry ſandy woods, from Canada to Florida, flowering in June and July. *Root* perennial. *Plant* about a foot high. *Flowers* very handſome, roſe-coloured and yellowiſh-white. *Purſh.* The *ſtem* is ſimple, leafy, angular, brown, clothed with hoary pubeſcence. *Leaves* alternate, nearly ſeſſile, pinnate, of from 17 to 21, not quite oppoſite, entire *leaflets*, each about an inch long, hairy on both ſides, tipped with a minute point. *Cluſter* ſolitary, various in length, compoſed of numerous large *flowers*, not unlike thoſe of a Lupine. *Calyx* denſely hairy. *Legume* an inch and a half long, pointed, linear, hairy, ſomewhat undulated, and a little curved upward, tumid where the ſeeds are lodged. Miller appears to have cultivated this plant in 1765. We have never ſeen a living ſpecimen. That we have here deſcribed was ſent by Kalm to Linnæus. The *legumes* came from Jacquin's herbarium.

2. T. *chryſophylla.* Golden-leaved Grey-Vetch. Purſh n. 2. (Galega villoſa; Michaux Boreal.-Amer. v. 2. 67? *Purſh.*)—Proſtrate, downy. Leaflets five, ſomewhat wedge-ſhaped, very obtuſe. Flower-ſtalks oppoſite to the leaves. Legume nearly ſtraight. — Gathered in Georgia by Mr. Enſlen, flowering in July and Auguſt. Perennial. *Leaflets* wedgeſhaped-obovate; ſmooth above; ſilky at the back. *Stalks* elongated, bearing about three purple *flowers.* The ſingular circumſtance of the nearly ſeſſile *leaves* gives it the appearance of a trifoliate plant, the lower pair of leaflets reſembling *ſtipulas.* Michaux's ſynonym is rendered doubtful by his not mentioning the ſmall number of *leaflets*, one of the moſt ſtriking characters. *Purſh.*

3. T. *hiſpidula.* Hiſpid Grey-Vetch. Purſh n. 3. (Galega hiſpidula; Michaux Boreal-Amer. v. 2. 68. G? ſpicata; Walt. Carol. 188. Erebinthus; Mitch. as above. Clitoria, *n.* 3; Linn. Hort. Cliff. 498, excluding the very erroneous reference to Burmann.)—Slender, diffuſe, downy. Leaflets numerous, oblong-elliptical, abrupt, pointed. Flower-ſtalks oppoſite to the leaves. Legume falcate, hiſpid. — In pine woods and on ſlate hills, from Virginia to Georgia. Perennial, flowering from July to September. *Leaflets* 13 or 15. *Stalks* elongated, bearing from three to five pale-red *flowers.* *Purſh.* Every part of this deſcription anſwers to the original ſpecimens of Mitchell's plant, but he, as well as Linnæus, ſpeaks of the tenth *ſtamen* as being really ſeparate from the reſt. We cannot from our ſpecimens determine this point. The *ſtems* are long, branched, trailing, round, and hairy. *Leaflets* with ſtrong oblique tranſverſe veins; ſometimes ſmooth above; always ſilky beneath; their length about an inch. *Bracteas* lanceolate. *Calyx* very briſtly. Perhaps the union of the tenth *ſtamen* to the reſt, which is not in the uſual mode continued quite to the baſe, even in *T. virginiana*, may exiſt leſs, or not at all, in the ſpecies before us, and yet the plants may together conſtitute one natural genus.

TEPID, in *Natural Hiſtory*, a term uſed by writers on mineral waters, to expreſs ſuch of them as have a leſs ſenſible cold than common water.

They diſtinguiſh all the medicinal ſprings into three kinds; the hot, the tepid, and the cold: but the middle term might eaſily be miſunderſtood to mean a great deal more than they expreſs by it: all that have what can be called the leaſt ſenſible warmth, are called *hot;* and the tepid are diſtinguiſhed from the abſolutely cold, only by their being leſs cold.

Some of this claſs of mineral waters, and ſome few alſo of the cold ones, have a ſharpiſh vinous taſte, which is never obſerved in any of the hot ones. This taſte is loſt on giving the waters the ſlighteſt heat, and is therefore very difficult to be gueſſed at as to its origin. It is not only found in the aluminous and vitriolate waters, but alſo in thoſe which are manifeſtly nitrous, and which abound in ſulphureous ſalts, quite different in their nature from acids. It is therefore an additional ſomewhat, quite diſtinct from the ſaline properties of the fluid, and as eaſily connected with one kind of that as with the others.

The cauſe of heat in the mineral waters remains yet wholly unknown, notwithſtanding all that has been written concerning it. It is hard to believe, that there are continual ſubterranean fires near enough the ſurface, to give a heat that preſerves itſelf in ſo great a degree to the very place of their eruptions; and it is equally hard to conceive, that there can be beds of fermenting mineral matters, ſufficient in quantity and force to have given the ſame degree of heat to waters for ſo many ages, as ſome of our hot ſprings are known to have ſubſiſted. Duclos's Exam. des Eaux Miner.

TEPIDARIUM, among the Romans, a tepid or blood-warm bath, which was joined to the cold and hot baths, and was a medium between the two; ſo that if any perſon wanted to go from the hot to the cold bath, or *vice verſâ*, he always took the tepid bath in his way.

TEPIQUE, in *Geography*, a town of Mexico, in the province of Xaliſco; 5 miles N. of Xaliſco.

TEPIRU, a town of South America, in the province of Tucuman; 18 miles N.W. of St. Yago del Eſtero.

TEPKAS, a Ruſſian ſettlement in North America, on the eaſt ſide of Beering's ſtrait. N. lat. 66°. E. long. 112° 4′.

TEPLITZ, a town of Bohemia, in the circle of Leitmeritz, celebrated for its warm baths, diſcovered in 762; 14 miles W.N.W. of Leitmeritz. — Alſo, a town of Croatia; 8 miles S. of Varaſdin.

TEPLOW, Gregory Nicolaicuitsch, in *Biography*, a Ruſſian writer, educated in a ſeminary at Novogorod, where he diſtinguiſhed himſelf by a Latin tranſlation of prince Cantemir's Satires, and a work on the geography of Ruſſia, neither of which was ever printed. In 1740 he was employed in the Academy of Sciences, and in forming a catalogue of objects contained in the Cabinet of Natural Hiſtory. He thus acquired a taſte for that ſcience, and particularly for botany; in conſequence of which he was made an adjunct of the Society in 1741, and in the following year delivered lectures on moral philoſophy, that were much approved. The empreſs Elizabeth appointed him tutor and travelling companion to her favourite, count Raſumouſky, who, on his return from his travels in 1746, was made preſident of the Academy of Sciences. Teplow then became an honorary member, directed the inſtitution in the name of the preſident, and drew up rules for its better regulation. At the time of the empreſs's death he was a counſellor of ſtate; but as he was an enemy to Peter III., he was arreſted: afterwards he was reſtored to favour; nevertheleſs, two months after his being made a member of the council of ſtate, it was diſcovered that he had joined in a conſpiracy to dethrone that unfortunate prince. After the depoſition of Peter, he publiſhed manifeſtations, in order to render him odious, and, as Buſching ſays, was the principal agent in putting him to death. For this ſervice he is ſaid to have received a reward of 20,000 rubles. The empreſs afterwards made him a privy-counſellor and member of the ſenate, and honoured him with the orders of Alexander Newſky and St. Ann. He died in March 1779; and his works, in the Ruſſian language, are, "A General View of Philoſophy;" "Inſtructions to his Son;" "A Collection of Songs, with Melodies for three Voices;" "Inſtructions for

for the Cultivation of foreign Tobacco, in Lesser Russia," distributed by order of the empress through that province, in 1763. Gen. Biog.

TEPOTI, in *Geography*, a river of Paraguay, which runs into the Paraguay.

TEPPELWODA. See TOPPLISWODA.

TEPTERE, a name originally Tartarian, and signifying a man who cannot pay his taxes, given by the Russians to a peculiar tribe formed of Finns and Tartars in the middle of the 16th century, during the dissolution of the Khazan-Tartarian empire. They established themselves at first in that part of the Ural mountains, which belongs to the government of Ufa. At present they are so much intermingled, that their origin is scarcely discernible. They are found to increase in number at every succeeding census. In the year 1762, about 34,000 of them paid the imposts.

TEPTON, in *Geography*, a town of Thibet; 30 miles N.W. of Sgigatchee.

TEPWIA, a town on the W. coast of the island of Celebes. S. lat. 1° 4'. E. long. 119° 10'.

TEQUENDAMA, a cataract near Bogota, the capital of New Granada (see BOGOTA), which, according to Bouguer, is one of the highest in the world, being 200 or 300 fathoms in height, and its fall vertical. Its real height is probably about 1320 feet. The river Funza, which is here very considerable, passes along a narrow channel, on a high table land, and is poured as from the spout of a vase, in one arch of the enormous height above specified, the noise being heard at the distance of seven leagues. This fall is received in a vast cauldron of more than a league in circumference; and the quantity of water, and violence of its descent, form a continual mass of clouds, which renders it scarcely visible in the evening; but in the morning it is more striking, being decorated with numerous rainbows according to the position of the spectator. The vast rocks which form the cauldron also excite admiration, being as regular and polished as if cut with a chissel: the surrounding heights are covered with trees, shrubs, and flowery plants, while the splendid appearance of some of the birds, and the music of others, render the cataract of Tequendama alike sublime and beautiful.

TEQUEPA, a town of Mexico, in the province of Mechoacan, on a river near the Pacific ocean; 80 miles S.E. of Zacatula. N. lat. 17° 50'. W. long. 102° 26'.

TEQUERY BAY, a bay on the south-east coast of Cuba, near Cape Cruz.

TEQUIA, a town of New Grenada; 32 miles S.W. of Pamplona.

TEQUIXQUIACATZANATL, in *Ornithology*. See GRACULA *Quiscala*.

TER, in *Geography*, a river of Spain, which rises in the county of Cerdagne, and runs into the Mediterranean, about 20 miles E. of Gerona.

TERA, a small river of Spain, which runs into the Orbega, in the province of Leon.

TERACE, in *Rural Economy*, a term provincially applied to a coarse hair sieve, for separating the inferior flour from the bran.

TERAIN, in *Geography*, a river of France, which runs into the Oise, near Creil.

TERAKACO, a peninsula on the east coast of New Zealand, of which Cape Table forms the eastern point.

TERAMNUS, in *Botany*, so called by Browne, apparently in allusion to its delicately-shaped legume, τέραμνοτης being used particularly to express the tenderness of eatable pulse: ἀτέραμνος was a weed hostile to leguminous plants.—Browne Jam. 290. Swartz Prodr. 105. Ind. Occ. 1238. t. 25. Schreb. 489. Willd. Sp. Pl. v. 3 971. Mart. Mill. Dict. v. 4.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, two-lipped, permanent; its upper lip rather the largest, divided; lower three-cleft; all the teeth acute, erect, converging. *Cor.* papilionaceous. Standard inversely heart-shaped, spreading, somewhat deflexed. Wings nearly as long, erect, approximated, rounded at the extremity. Keel very small, concealed in the calyx between the bases of the wings, and covering the stamens, separable into two petals. *Stam.* Filaments ten, all united in their lower part into one set; only five of them perfect, the five intermediate ones being minute, without anthers, and shorter; anthers five, roundish. *Pist.* Germen cylindrical, slender, downy; style none; stigma capitate, roundish. *Peric.* Legume linear, bordered, compressed, with numerous constrictions. *Seeds* several, roundish, compressed, abrupt at the summit.

Ess. Ch. Keel minute, concealed in the calyx. Stamens all connected; the five alternate ones without anthers. Stigma sessile, capitate. Calyx two-lipped. Legume linear, with many seeds.

1. T. *volubilis*. Smaller Teramnus. Swartz Ind. Occ. 1241. t. 25. Willd. n. 1, excluding all the synonyms.—Leaflets ovato-lanceolate, downy beneath.—Native of rather moist bushy alpine places, in the southern part of Jamaica. The *stem* is herbaceous, or slightly woody at the base only, from two to four feet high, twining, slender, triangular, downy, simple or divided. *Leaves* alternate, distant, stalked, each of three *leaflets*, mostly obtuse with a small point, entire, ribbed and veiny, smooth and bright-green above; downy beneath; sometimes accompanied by a pair of smaller ones at the base. Their common *footstalk* is about an inch long, channelled, downy, with a pair of minute linear *stipulas* at the base. *Clusters* axillary, slender, simple, longer than the leaves, of several small reddish-blue *flowers*, in distant couples, on short partial stalks. *Legume* an inch long, slender, hairy, its point finally hooked; the valves spiral after bursting.

2. T. *uncinatus*. Great Hooked Teramnus. Swartz Ind. Occ. 1239. Willd. n. 2. (T. n. 1; Browne Jam. 290. Dolichos uncinatus; Linn. Sp. Pl. 1019. Phaseolus hirsutus, siliquis rectis et aduncis; Plum. Ic. 215. t. 221. Ph. sylvestris minor, flore minimo, siliquis longis teretibus albâ lanugine hirsutis; Sloane Jam. v. 1. 182.)—Leaflets oblong; silky beneath; hairy above.—Native of dry bushy places, in various parts of Jamaica. The *root* is long and slender. *Stem* herbaceous, subdivided, twining, slender, triangular, its angles hairy and somewhat bordered; the base woody. *Leaflets* one and a half or two inches long; their common *stalk* an inch, or inch and a half. *Stipulas* small, downy, deciduous. *Clusters* axillary, stalked, often a span long, twice the length of the leaves, many-flowered. *Flowers* in distant pairs, small, reddish. *Legume* two inches long, straight, narrow, compressed, hairy, ending in a bluntish hooked point.

TERAMO, in *Geography*, a town of Naples, in Abruzzo Ultra; the see of a bishop, immediately under the pope; 22 miles N.N.E. of Aquila. N. lat. 42° 37'. E. long. 13° 49'.

TERANE', a town of Egypt, on the west branch of the Nile; 18 miles N.W. of Cairo. N. lat. 30° 30'. E. long. 30° 45'.

TERANO, a town of Naples, in Calabria Citra; 3 miles W. of Bisignano.

TERASARSUK, a town of East Greenland. N. lat. 59° 55'. W. long. 43°.

TERASPURG, a town of Auſtria; 2 miles N. of Egenburg.

TERATOSCOPIA, formed of τερας, *prodigy*, and σκοπεω, *I conſider*, a kind of divination by the appearance and view of monſters, prodigies, ſpectres, and phantoms.

TERBEDH, in the *Materia Medica*, a name given by Avicenna to the *turbith*, a purging drug, mentioned by all the authors of his time; but, in general, in a very confuſed manner.

Garcias tells us, that the Indians uſe it to purge phlegm, and that they add ginger to it by way of corrective; and Avicenna ſays the ſame thing of its uſe in his time.

TERBURGH, Gerard, in *Biography*, a painter of domeſtic ſcenes of exquiſite ſkill, was born at Zwoll, in the province of Overyſſel, in 1608, the ſon of a painter little known, from whom he received the rudiments of the art. He began his career as a painter of portraits in ſmall, and had acquired conſiderable reputation, when he determined upon travelling through Germany and Italy. Unengaged by the ſublimer beauties of art which the latter country offered to his view, he never changed his ſtyle, but went thence to Paris to practiſe it; and there met with conſiderable ſucceſs. From thence he returned to Holland, and was highly appreciated, and fully employed. He attended the congreſs aſſembled at Munſter in 1648, for the negociation of the treaty of peace, and there painted his celebrated picture containing portraits of the plenipotentiaries and principal perſonages aſſembled on that occaſion, which is regarded as his maſter-piece; and of which there is a print by Suyderhoef. While engaged upon this work, he was invited by count Pigorando, the Spaniſh ambaſſador at the congreſs, to viſit Spain, and went there in conſequence; where he was moſt favourably received, and much employed. The king conferred upon him the order of knighthood, and rewarded him munificently for the pictures he painted. Beſides portraits, which conſtituted the principal part of his practice, he frequently painted converſations, muſical parties, ladies at their toilettes, and domeſtic ſubjects, which he executed with a free, but rather a heavy pencil, not equal to the brilliancy of Metzu and Netſcher, but nevertheleſs exceedingly meritorious and agreeable; particularly in the cloſe imitations of his draperies. He died in 1681, at Deventer, where he ſettled on his return from Spain.

TERCERA, or Terceira, in *Geography*, one of the Azores iſlands, ſuppoſed to have derived its name from its ſtanding the third in this cluſter of iſlands in point of ſituation, though the firſt in dignity, as appears from a number of circumſtances, and particularly from its communicating its name to the reſt. This iſland is computed at 54 miles in circumference, and about 25 miles in length, by 15 in medial breadth. Its figure is almoſt circular, the coaſts high, and ſo ſurrounded with craggy rocks, that it is deemed impregnable; every acceſſible part on the coaſt being defended by ſtrong forts, heavy cannon, and a numerous and regular garriſon. The only tolerable port in the whole iſland is the harbour of Angra. The iſland of Tercera is fertile, pleaſant, and healthy: the very rocks, which elſewhere are dry and barren, produce here excellent vines, though not equal to thoſe raiſed in the Canaries and Madeira. The land yields large crops of wheat and other grain, paſture for cattle, and a prodigious variety of lemons, oranges, and all thoſe fruits peculiar to hot and cold climates, which are obſerved to be propagated to the greateſt advantage in temperate countries. Beſides Angra, there are ſeveral other towns and large villages in Tercera, with a number of forts and garriſons, under the direction of the governor, who has the power of filling up all vacancies that happen among the military officers. N. lat. 38° 45′. W. long. 27° 6′.

Tercera, a ſmall iſland in the Atlantic, near the coaſt of Sierra Leone.

TERCERO, a river of South America, which riſes in Tucuman, and joins the Salado on the borders of Paraguay.

TERCHIZ, or Tershiz. See Turshish.

TER-CHOOUZ, in *Ornithology*. See Upupa *Epops*.

TERDINA, in the *Materia Medica*, a name by which Paracelſus, and ſome other authors, have called the great garden-valerian. Ger. Emac. Ind. 2.

TERDOPIO, in *Geography*, a river of Italy, which runs into the Po, 12 miles E.S.E. of Lumello.

TEREBELLA, in *Natural Hiſtory*, a genus of the Molluſca order of Vermes; the characters of which are, the body oblong, creeping, naked, furniſhed with branchiæ at the ſides, more frequently in the tube; the mouth labiated, toothleſs, and projecting a clavated proboſcis; the tentacula or feelers about the mouth numerous, capillary, and ciliated. Gmelin enumerates eleven

Species.

Cirrata. Round, body with triple lateral pencils. Found in the ſandy bottom of the Iceland ſea.

Lapidaria. With eight cirri at the anterior parts of the body, about the mouth four. Found in the Mediterranean ſea, within the clefts of rocks.

Conchilega. Whitiſh, with numerous filiform cirri at the mouth, the upper longeſt; the branchiæ very red. Found in the ſea waſhing the coaſt of Holland.

Complanata. Depreſſed, mouth with four cirri; the lateral pencil-bearing warts of the body arranged on both ſides in a two-fold ſeries.

Carunculata. Depreſſed-quadrangular, with a fourfold ſeries of ventral pencils, and no cirri. Found in the American and Indian ſeas.

Rostrata. Tetraedrous, with a quadruple ſeries of pencils from the body, and palate elongated. Found in the Indian ſea.

Flava. Depreſſed, with thirty-ſeven branchiæ on both ſides, and bifurcated tail. Found in the Indian ſea.

Rubra. Red, depreſſed; tail terminating with two cirri; the head with two horny moveable jaws. Found in the ſea ſurrounding the iſlands of Zealand.

Aphroditois. Round, gradually attenuated backwards, below ſomewhat depreſſed with an obſolete furrow; no branchiæ in the eight firſt ſegments, in the following three ſimple, in the laſt ſenſibly greater, one being turned, pinnated. Found in the Indian ſea.

Bicornis. With a ſimple terminal two-horned diſc of the proboſcis. Found in the America ocean.

Stellata. With a perfoliated triple diſc of the proboſcis; the anterior armed with a truncated horn, radiated with prickles. Found in the American ocean.

Terebella, (dim. of *terebra*,) in *Surgery*, a trepan, or circular ſaw, for removing portions of the ſkull.

TEREBIA, in *Ancient Geography*, a town of Aſia, in the Greater Armenia, E. of the ſources of the Tigris. Ptolemy.

TEREBINTACEÆ, in *Botany*, the 94th order in Juſſieu's ſyſtem, the 12th of his 14th claſs, ſo denominated from the genus for which he chooſes to retain the old name of *Terebinthus*, but which is the *Piſtacia* of Linnæus. Many of the plants of this order abound in an eſſential oil of the nature of turpentine, or ſomething like it. The characters are as follow.

Calyx of one leaf, inferior, with a definite number of ſegments. *Petals* definite in number, (rarely wanting,) inſerted into the lower part of the calyx, alternately with its ſegments, with which they agree in number. *Stamens* either the ſame number, alternate with the petals, or twice as many, inſerted into the ſame ſpot. *Germen* ſuperior, either ſimple, or more than one, of a determinate number. When the germen is ſingle, the *ſtyle* is ſolitary, (rarely deficient,) with a ſimple or a divided *ſtigma;* when there are ſeveral germens, the ſtigmas equal them in number. *Fruit* either capſular, a berry, or a drupa, of one or more ſingle-ſeeded cells. Where there are ſeveral germens, there are as many ſtyles, or ſimple ſtigmas; and the ſame number of diſtinct ſingle-ſeeded capſules. The *ſeeds* are generally lodged in a bony nut. The *corculum* is without an *albumen*, its radicle lateral, and reflexed upon the lobes. *Stem* arboreſcent or ſhrubby. *Leaves* alternate, without *ſtipulas*, either ſimple, or ternate, or pinnate with an odd leaflet.

Section 1. *Germen ſimple. Fruit of one cell, with a ſolitary ſeed.*

This compriſes *Caſſuvium* of Juſſieu and Lamarck, which is the Linnæan *Anacardium; Anacardium* of the ſame authors, which is *Semecarpus* of Linnæus; *Mangifera; Connarus; Rhus;* and *Rourea* of Aublet, Schreber's *Robergia.*

Sect. 2. *Germen ſimple. Fruit of many cells, ſome of which are occaſionally abortive.*

Cneorum; Rumphia; Comocladia; Canarium; Icica of Aublet; *Amyris; Toddalia*, which is *Crantzia* of Schreber, *Scopolia* of Sm. Plant. Ic. (ſee SCOPOLIA); *Scinus; Spathelia; Terebinthus* of Tournefort and Juſſieu, the Linnæan *Piſtacia; Burſera; Toluifera; Tapiria* of Aublet, which is Schreber's *Jonquetia; Poupartia* of Commerſon, perhaps not different from our SPONDIAS *Mangifea;* and *Spondias* itſelf, compoſe this ſection.

Sect. 3. *Germen ſeveral. Fruit of many ſingle-ſeeded capſules.*

Here are only three genera; *Simaba* of Aublet, which is Schreber's *Zwingera; Aylanthus* of Desfontaines; and *Brucea* of L'Heritier.

Sect. 4. *Genera akin to Terebintaceæ, but differing in being furniſhed with a fleſhy albumen, which brings them near to* RHAMNI; ſee that article.

Cneſtis of Juſſieu, Lamarck Illuſtr. t. 387; *Fagara; Zanthoxylum*; and *Ptelea.*

Sect. 5. *Genera akin to Terebintaceæ, and (like the true plants of this order) deſtitute of a fleſhy albumen.*

Dodonæa; Averrhoa; and *Juglans.*

Juſſieu announces an intention of dividing this order into *Caſſuvia*, true *Terebintaceæ*, and *Zanthoxyla;* the firſt having ſimple leaves, a ſingle-ſeeded fruit, and an aſcending radicle; the ſecond generally pinnate or ternate foliage, a drupa with ſeveral ſingle-ſeeded nuts, and a deſcending radicle; and the third pinnate or ternate foliage, moſtly marked with pellucid dots; fruit of many cells or many capſules, each with ſolitary ſeeds; and a fleſhy albumen ſurrounding a ſtraight corculum. A fourth order would ariſe out of certain genera now intermixed with the reſt, but not properly coming under any of the three juſt defined, being themſelves perhaps entitled to lay the foundation of future orders, not as yet diſcovered.

TEREBINTHINA, in *Medicine, Natural Hiſtory*, &c. See TURPENTINE.

TEREBINTHUS, in *Botany*, τερμιθος of Dioſcorides. See PISTACIA and TEREBINTACEÆ.

TEREBOTIN, a word uſed by Paracelſus for the common turpentine.

TEREBRA, from τερεω, *to bore*, a trepan, or trephine. Alſo, an inſtrument called a perforator, ſuch as is contained in the generality of caſes of trephining inſtruments, and is uſed for making a hole, in which the centre pin of the trephine is to work.

TEREBRATULA, in *Natural Hiſtory*, a name given by Mr. Lhuyd and Gualtieri to ſome ſpecies of the ſmooth conchæ anomiæ, which have near the head of the ſhell a ſmall hole, which looks as if bored by art. See CONCHÆ *Anomiæ*, and SHELLS.

TERECOL, in *Geography*, a town of Hindooſtan, in Concan; 16 miles N.N.W. of Goa.

TEREDO, in *Natural Hiſtory*, a genus of the Teſtacea order of Vermes, the characters of which are, that the animal is a terebella, with two hemiſpheric calcareous valves, cut off before, and two lanceolated; the ſhell is round, flexuous, and capable of penetrating wood. Gmelin reckons three

Species.

NAVALIS. The ſhell very ſlender, cylindric and ſmooth.

UTRICULUS. Shell ſolid, cylindric and undulated.

CLAVA. Shell clavated at one end, the other curved, narrower, obtuſe, and perforated in the middle.

The head of the Teredo navalis, called by Linnæus *calamitas navium*, is well prepared by nature for the hard offices it is to undergo, being coated with a ſtrong armour, and furniſhed with a mouth like that of the leech; by which it pierces wood, as that animal does the ſkin: a little above this it has two horns, which ſeem a kind of continuation of the ſhell; the neck is as ſtrongly provided for the ſervice of the creature as the head, being furniſhed with ſeveral ſtrong muſcles; the reſt of the body is only covered by a very thin and tranſparent ſkin, through which the motion of the inteſtines is plainly ſeen by the naked eye; and by means of the microſcope, ſeveral other very remarkable particulars become viſible there.

This creature is wonderfully minute when newly excluded from the egg, and at its utmoſt bigneſs is a foot long; three or four inches are however its more frequent length.

When the bottom of a veſſel, or any other piece of wood conſtantly under water, is inhabited and injured by ever ſo great a number of theſe worms, there is no ſign of the damage to be perceived on the ſurface, nor are the creatures viſible till the outer part of the wood is cut or broken away; then their ſhelly habitations come in ſight: theſe lie ſo near the ſurface, however, as to have an eaſy communication with the water, and there is a multitude of little perforations in the very ſurface through which the inhabitant inſects throw out the extremities of their little ſhelly horns; theſe are of a reddiſh colour, and may be diſtinguiſhed by an accurate obſerver in form of ſo many red prominent points; they all are retracted on the leaſt touch, and are thrown out again as ſoon as all is quiet. From theſe points, or the ſmall apertures which give them a way out, are the cells of the teredines to be traced. They are compoſed of a pearly or ſhelly matter, which forms a long tube with various windings and turnings, which mark the abode of the creature; but which uſually neither adheres to the body of the animal nor to the wood. Theſe caſes or tubes are always more or leſs looſe in the wood, and there is ever a large ſpace within them, for the body of the animal to be ſurrounded every way with water. They are very ſmooth on the inner ſurface, and ſomewhat rougher without; and are much harder and firmer in the cells of the older and larger animals than in thoſe of the young ones.

Theſe ſhelly tubes are compoſed of ſeveral rings, or annular

nular parts; but thefe differ greatly in their length. There is an evident care in thefe creatures, never to injure one another's habitations; by this means each tubule or cafe is preferved entire, and in fuch pieces of wood as have been found eaten by them into a fort of honey-comb, there never is feen a paffage or communication between any two of the tubules, though the woody matter between them often is not thicker than a piece of writing-paper.

The vaft increafe of thefe animals, and their fhelly tubules, naturally lead to a confideration of the manner of their generation; and when we confider that each of thefe creatures is, from the time when it is produced from the egg, immediately lodged in a cell, in which it lives without the leaft poffibility of getting into that of another animal of its own kind, or receiving one of them into its own, it is not eafy to account for the propagation of the fpecies in the common way. This, however, is folved by an accurate anatomical obfervation of the animals themfelves, fince in every individual the parts of generation in both fexes, and both the femen and ovula are found. Each individual therefore evidently ferves by itfelf for the propagation of the fpecies; and this is probably very often the cafe in earth-worms, and other of the hermaphrodite animals. All the yet known kinds of thefe being foft-bodied; and probably, though they often meet one another, and copulate in pairs, yet when they have not opportunity, the parts copulate in the individual.

Eggs are found in great plenty in the bodies of thefe animals in June, and are difcharged with the water into the fea, where the far greater part of them, doubtlefs, become food for other fmall marine animals; and the few that affix themfelves to any piece of wood they are wafhed againft, hatch and get into its fubftance in the manner of their parents.

The kind of wood in which thefe worms are lodged, makes a great difference in the appearance of their cells, as they work much more fpeedily and fuccefsfully in fome kinds than in others. The fir and alder are the two kinds they feem to eat with the greateft eafe, and in which they grow to the greateft fize. In the oak they feem to make but a very flow progrefs, and ufually appear very fmall, and poorly nourifhed. The colour of their fhelly tubules is often brown in this wood; which feems plainly owing to the effect of its juices.

Poifonous ointments are alfo found to be of fome ufe in deftroying them, on rubbing over the wood: fome have thought that burning the furface was an effectual way of preferving them, but this has been found to be otherwife. The fureft method of avoiding them in particular works, is the ufing of bitter or very folid woods; the firft kind they are found never to touch, and in the other they make but flow progrefs. Mixtures of lime, fulphur, and colocynth, with pitch, for covering over the furfaces of boards, &c. have been found of fome ufe.

It feems very evident, that boards and other pieces of wood have been fubject to be eaten by thefe animals, from all times that we have any knowledge of; for the ftone called *Lapis fyringoides* is evidently no other than wood thus eaten, petrified by long lying in the earth, together with the tubules of the worms. The maffes of this with the grain of wood yet plain in them, are common in many places among fea-fhells, and other marine remains at great depths, and have evidently been brought thither in very diftant times, and before thofe changes were made in the furface of the earth of which we have no accounts in our earlieft hiftories. Sellii Hift. Natur. *Teredinis*.

TEREDON, in *Ancient Geography*, a town of Afia, in Babylonia, on an ifland which was formed by the Tigris at its mouth. (Ptol.) Dionyfius Periegetes places the town of Teredon at the mouth of the Euphrates.

TEREK, in *Geography*, a mountain of Afia, between Great and Little Bucharia.

TEREK, one of the rivers that fall into the Cafpian fea. It originates in the Caucafian mountains, runs at firft towards the W. and S., but turns afterwards entirely to the E. and in about N. lat. 44°, and E. long. 65°, difcharges itfelf into the Cafpian. It takes up in its courfe the Bakfan, the Malka, and the Soonfha, among many other mountain-brooks and rivers. Its fource lies properly in the Snow-mountains of Caucafus, on the higheft partition-ridges of the frontiers of Georgia. It is rapid in its courfe; and, in the months of July and Auguft, when the fnow melts, fwells to the height of eight or ten feet above its ufual level in autumn, winter, and fpring; overflowing its banks, and inundating the adjacent country, forming for itfelf new beds, and choaking the old with fand. In its lower courfe, as far as Kitzliar, it is almoft entirely unaccompanied by woods; farther up, to Starogladka, by a few; and thence upwards, its banks are richly garnifhed with forefts, particularly of oaks, wild fruit-trees, and a variety of others. It does not freeze over every year, though in winter it abounds with driving ice. In this feafon its water is tolerably clear, which at other times, above Kitzliar, is turbid, with earthy particles; but when taken up, it foon becomes clear, and is then bright, well-tafted, and of good quality. Below Kitzliar, the river has a lefs fall, and feparates into feveral arms, in which the parted ftream flows fo gently, that it has time to depofit its earthy particles, which alternately fill up thefe arms; fo that one or the other occafionally reprefents the main river. In the lower regions, on the fhores of the Terek, are feen vineyards, mulberry and other fruit-trees, to which fucceed falt-lakes, and fprings of the fame nature. Its bed is formed moftly of fand and clay. With regard to fifh, the Terek, as well as all its collateral rivers, is poor. Yet there are caught in it fturgeon (acipenfer fturio), beluga (acipenfer hufo), ferruga (acipenfer ftellatus, Pall.), plenty of falmon, fat-fifh (cyprinus chalcoides), carp, barbel (cyprinus barbus), fhad, pike, fudak (lucio perca), perch (perca fluviatilis), lefchtfe (cyprinus barba,) otters, beavers, tortoifes, &c.

TEREK, in *Ornithology*. See SCOLOPAX *Cinerea*.

TERELLA, in *Geography*, a town of Naples, in the Molife; 4 miles N. of Molife.

TERENCE, PUBLIUS TERENTIUS, in *Biography*, a Latin writer of comedies, was born, as it is fuppofed, at Carthage about the year of Rome 560 (B.C. 194.) Being brought to Rome as a flave, when young, he was in the fervice of a perfon named Terentius, a fenator, from whom he derived his name. The purity and politenefs of his language evince his having enjoyed the benefit of a good Roman education. After his emancipation, he was honoured with the friendfhip of feveral Romans of rank, fuch as Scipio Africanus the younger, and the younger Lelius. His comedies were founded upon the Greek model, and tranflated, either wholly or in part, from the Greek. The firft comedy which he is faid to have brought upon the ftage, was the "Andrio," reprefented in the year B.C. 166. But though this was the firft of his comedies that was acted, it appears that it was not the firft which he had written. The fix comedies of Terence that are ftill extant were exhibited at Rome from the year B.C. 166 to 160. They were heard with great applaufe; the "Eunuchus" was repeated twice in the fame day, and he is faid to have received for it 8000 fefterces (about 64*l.*) Scipio and

Lelius, as tradition reports, had a great part in the composition of Terence's comedies. Terence himself in a prologue seems tacitly to acknowledge the fact. But modern writers and critics, who have reasoned on this fact, think it very improbable. Generals and statesmen were not persons likely to possess the habit of dramatic composition, whatever previous hints or subsequent corrections they might furnish; and besides it is observed, that no writings more strongly indicate by their style and manner that they are the production of a single hand than those of Terence. After he had presented these comedies to the public he departed for Greece, and never returned to Rome. Some have accounted for this circumstance, by supposing that he perished by shipwreck; others affirm that he died in Greece, from the grief he experienced on account of the loss of his baggage and some new comedies, which he had composed, by an accident at sea.

The judgment of critics on the performances of Terence has been very different, though their real merit is said not to be of difficult estimation. It is generally allowed that he is defective in invention and originality of observation. This sufficiently appears from his having Greek manners and characters in all his plays. He was likewise a plagiarist, with regard to the sentiments, as well as to the plots and incidents of his pieces; but a very competent judge observes, "that he is justly entitled to the praise of judicious selection, happy disposition, and purity and neatness of language; and that, as a Latin writer, in a style of elegance of which there are so few examples, he was highly prized in his own times, and is invaluable in ours. Cicero, who speaks of him as a translator of Menander, applauds him as the only one who had expressed in the Latin language all the politeness and amenity of the original; and Cæsar, in some well-known lines, calls him 'the lover of pure diction;' and also by the epithet of the *halved Menander;* and his regret that Terence did not possess the *vis comica*, as well as the other excellencies of his model, points out his deficiencies." Of the numerous editions of Terence, the most esteemed are the following; *viz.* the "Variorum," Amst. and Lugd. Batav. 1686; "Bentleii," Cantab. 4to. 1726; "Westerhovii," Hag. C. 4to. 1726; "Zeunii," Lipf. 8vo. 1774; "Brunckii," Basil, 4to. 1779. Voss. Poet. Lat. Gen. Biog.

TERENJABIN, in the *Materia Medica of the Ancient Arabians*, a word used to express a kind of manna called by some *manna mastichina*, from its round globules resembling the drops of mastich, and by the physicians of many parts of the world at present, MANNA *Persicum;* which see. See farther about this drug in Philos. Trans. N° 472. vol. xliii. p. 87.

TERES LIGAMENTUM, in *Anatomy*, one of the ligaments of the hip-joint. See EXTREMITIES.

TERES *Ligamentum Uteri.* See GENERATION.

TERES *Major* and *Minor*, two muscles of the shoulder, so called, because their figure is somewhat rounded.

The *teres major* (scapulo-humerien, le grand rond) is elongated and flattened, placed at the lower and back part of the shoulder, and extending from the inferior angle of the scapula to the posterior edge of the bicipital groove of the humerus. The latissimus dorsi, the skin, and the long head of the triceps, cover it behind; in front, it is covered by the latissimus, the axillary vessels and plexus of nerves, the short head of the biceps, and the coraco-brachialis. Its upper edge corresponds first to the teres minor, then is separated from that muscle by the long head of the triceps, and lastly corresponds to the subscapularis, from which the circumflex vessel and nerve separate it. The lower edge, covered by the skin, forms, with the latissimus, the border of the axilla. The inferior or external extremity of the muscle is fixed to the external surface of the inferior angle of the scapula, and to the neighbouring part of its lower edge: thence it ascends, passing obliquely outwards, retaining nearly an uniform breadth (about three fingers) throughout; and is attached to the posterior margin of the bicipital groove. The latter attachment takes place by means of a flattened tendon, about an inch broad, which corresponds in front to that of the latissimus dorsi. There is a small bursa mucosa between its posterior surface and the humerus. It lines the bicipital groove by some fibres, which meet those of the pectoralis major. Muscular fibres arise from the outer surface and inferior angle of the scapula, from the lower portion of the inferior costa, and from a septum between this muscle and the infraspinatus; and they terminate on the tendon just described. It carries the arm backwards; depresses it when it has been raised; rotates the humerus on its axis, so as to turn the arm inwards or forwards. In conjunction with the latissimus, and pectoralis major, it will fix the arm against the side. It will pull the scapula forwards or upwards to the arm, when that is fixed.

Teres minor (petit rond) is a small elongated muscle, lying at the posterior and under part of the shoulder, extending from the inferior edge of the scapula to the external tubercle of the humerus. Covered behind by the deltoid and skin, it covers in front the edge of the scapula, the infrascapular artery, the long head of the triceps, and the orbicular ligament of the shoulder-joint. Its upper edge is either continuous with the infraspinatus, so that they form but one muscle, or is separated from it by a cellular line. Towards the back part there is an aponeurotic septum between them. The lower edge is close to the teres major behind, but separated from it anteriorly by the long head of the triceps. The lower or posterior extremity is small and pointed, and begins its attachment to the scapula, just where that of the teres major ends, between the latter muscle and the infraspinatus: it passes obliquely upwards and outwards, fixed to the lower and outer edge of the scapula, and is inserted in the lower or back part of the great tubercle of the humerus. This insertion is effected by means of a tendon, closely connected to that of the infraspinatus, dispersing some of its fibres on the orbicular ligament, and receiving the fleshy fibres in all directions from the origin of the muscle. Its action has exactly the same effect with that of the *infraspinatus;* which see.

TERES *Folium*, in *Botany*. See LEAF.

TERESA, or THERESA, in *Biography*, a saint in the Roman Catholic church, was born, of a noble family, at Avila, in Old Castile, in March 1515. Her father, by reading the lives of saints to his family, inspired her, at an early age, with an enthusiastic fervour, which induced her to elope with one of her brothers, to seek martyrdoms among the Moors. When they were brought back, they indulged the same passion by constructing little hermitages in the garden, whither they retired to perform their exercises of devotion at twelve years of age. Teresa lost her mother, and was boarded in an Augustine convent, and this situation prevented her being seduced by the pleasures of the world, for which she began to indulge a propensity in consequence of reading romances; but for her farther security she took the veil in the Carmelite monastery of the Incarnation at Avila, in her twenty-second year. Her person was beautiful, and attracted the admiration and love of all who saw her; but her religious ideas, though tender and rapturous, were austere; and perceiving that the discipline of the house in which she resided was relaxed, she undertook a reform of the Carmelite order. After much opposition, she succeeded in establishing the firft monaftery of the female reform at Avila, in 1562, and having extended her plan to the religious males of the order, fhe founded in 1568 the monaftery of Dorvello, which was the origin of the more rigid, or barefooted, Carmelites. Her zeal and affiduity enabled her to found thirty religious houfes of the reform, fourteen for men and fixteen for women; and after her death it extended through all the Catholic countries of Chriftendom. Terefa died at Alva in October 1582, in the 68th year of her age. She was canonized by Gregory XV. in 1621; and afterwards became the patron faint of Spain. See CARMELITES.

TERESA, in *Geography*, a town of Spain, in the province of Valencia; 10 miles N.W. of Segorbe.

TERESSA. See TERRESSA.

TERETES, in *Horfes*, one of the three forts of worms which infeft the bodies of them, and which are very troublefome and injurious. See ASCARIDES, BOTS, and WORMS.

This fort of worm, which is found in horfes, refembles the common earth-worms in many refpects, being only fharper at both ends, callous towards the middle, and they do not contract or dilate themfelves fo eafily. Some of thefe, which have been feen to come from horfes, hinder them from thriving till they are diflodged by proper remedies.

TERETRUM, in *Surgery*. See TEREBRA.

TERFEZ, in *Natural Hiftory*, the name given by the Africans to the truffles found in the defarts of Numidia, and other places in that part of the world, in great abundance.

Thefe are much more delicately tafted than the European truffles, and are white on the outfide. They are called by fome of the Africans *kema*, and by the Arabian writers *cantha* and *camahe*.

TERFOWA, in *Geography*, a town of Africa, in the kingdom of Tunis; 120 miles S. of Tunis.

TERFOWY, a town of Nubia; 150 miles S. of Syene. N. lat. 21° 40′. E. long. 34° 5′.

TERGA, a town of Morocco, on the Morbeya; 90 miles N. of Morocco.

TERGA. See HAIR.

TERGARRY, a town of Hindooftan, in Bednore; 14 miles S.E. of Simogu.

TERGAZA, in *Ancient Geography*, a town of Africa, which was one of thofe which Manlius took poffeffion of in the third Punic war, and which he pillaged.

TERGESTE. See TRIESTE.

TERGESTICUS SINUS, a gulf of Italy, on the coaft of the Adriatic fea. It took its name from the town Tergefte, which was fituated there.

TERGIFOETOUS PLANTS, fuch as bear their feeds on the backfides of their leaves: fuch are the capillaries. See CAPILLARY.

TERGIL, in *Geography*, a town of Afiatic Turkey, in the province of Erzerum; 30 miles E. of Palu.

TERGIS, in *Ancient Geography*, a town of Africa, in Libya, on the confines of Ethiopia.

TERGISONUS, a river of Italy, in Venetia, N. of the river Padus.

TER-GOUD, or TER-GOUW, in *Geography*. See GOUD.

TERGOVITZ, or TERGOVISTA, a town and capital of Walachia, where the waiwode has a palace; 64 miles S.E. of Hermenftadt. N. lat. 45° 3′. E. long. 25° 29′.

TERHALTEN, a fmall ifland near the coaft of Terra del Fuego. S. lat. 55° 20′.

TERHEY, a town of Holland; 10 miles W. of Delft.

TERIDATA, in *Ancient Geography*, a town of Afia, in Mefopotamia, on the banks of the Euphrates. Ptolemy.

TERINA, a town of Italy, upon the weftern coaft of Brutium, and in the northern part of the gulf Hipponium.—Alfo, a town of Afia, fituated in the mountains W. of Moxouné.

TERIUM, a town of Macedonia, in Pieria.

TERKAT, in *Geography*, a town of Afiatic Turkey, in the government of Sivas; 20 miles N.W. of Tocat.

TERKELA, a river of Africa, which joins the Tafilet, 20 miles S. of Togda.

TERKI. See TEREK.

TERKI. See TURKIN.

TERKIRI, a lake of Thibet, about 80 miles long and 25 broad. N. lat. 32°. E. long. 91° 14′.

TERKUL, a river of Ruffia, which runs into the Ural, at Uralfk, in the government of Caucafus.

TERLIZZI, a town of Naples, in the province of Bari; 7 miles S.E. of Trani.

TERLON, a river of France, which runs into the Sambre, about 3 miles below Landrecy.

TERM, TERMINUS, the extreme of any thing, or that which bounds and limits its extent. See EXTREME.

TERM, in *Geometry*, is fometimes ufed for a point, fometimes for a line, &c. A line is the term of a fuperficies, and a fuperficies of a folid.

This is what the fchools call *terminus quantitatis*.

TERM, in *Law*, fignifies a boundary, or limitation of time, or eftate.

In this fenfe we fay, a leafe for term of life, for term of years, &c.

TERMS, *Termes*, *Termini*, in *Architecture*, denote a kind of ftatues, or columns, adorned at top with the figure of a man's, woman's, or fatyr's head, as a capital; and the lower part ending in a kind of fheath, or fcabbard. See HERMES.

Some write the word *thermes*, from *Hermes*, a name the Greeks gave the god Mercury; whofe ftatue, made after this manner, was placed in feveral of the crofs ways in the city of Athens, &c. Others bring the etymology of the word from the Roman god Terminus, the protector of landmarks; whofe ftatue (made without hands or feet, that he might not change his place) was ufed to be planted at the bounds of lands, to feparate them.

Terms are fometimes ufed as confoles, and fuftain entablatures; and fometimes as ftatues, to adorn gardens. Of thefe termini, the architects make great variety; viz. *angelic*, *ruftic*, *marine*, *double*, in *buft*, &c.

TERMS, *Miliary*, *termini miliares*, among the ancient Greeks, were the heads of certain divinities, placed on fquare land-marks of ftone, or on a kind of fheath, to mark the feveral ftadia, &c. in the roads. Thefe are what Plautus calls *lares viales*.

They were ufually dedicated to Mercury, whom the Greeks believed to prefide over the highways.

Some of them were reprefented with four heads, fuch as we ftill fee in Rome, at the end of the Fabrician bridge; which is hence called *ponte di quattro capi*. It is known that Mercury was thus reprefented, and alfo called by the Latins *Mercurius quadrifrons;* as being fuppofed the firft who invented the ufe of letters, mufic, wreftling, and geometry. See HERMES.

TERMS are alfo ufed for the feveral times or feafons of the year, in which the tribunals, or courts of judicature, are open to all who think fit to complain of wrong, or to feek their rights by due courfe of law, or action; and during which the courts in Weftminfter-hall fit and give judgment. But the high court of parliament, the chancery, and inferior courts, do not obferve the terms; only the courts of king's bench, common pleas, and exchequer, which are the higheft courts

courts at common law. In contradiftinction to thefe, the reft of the year is called *vacation*.

Of thefe terms there are four in every year, during which time matters of juftice are difpatched.

Hilary term, which, at London, begins the 23d of January, or if that be Sunday, the next day after; and ends the 12th of February following.

Eafter term, which begins the Wednefday fortnight after Eafter-day, and ends the Monday next after Afcenfion-day.

Trinity term, beginning the Friday next after Trinity-Sunday, and ending the Wednefday fortnight after.

Michaelmas term, which begins the 6th of November, and ends the 28th of November following.

Each of thefe terms has alfo their *returns*; which fee.

Thefe terms are fuppofed by Mr. Selden to have been inftituted by William the Conqueror; but fir H. Spelman hath fhewn, that they were gradually formed from the canonical conftitutions of the church; being no other than thofe leifure feafons of the year, which were not occupied by the great feftivals or fafts, or which were not liable to the general avocations of rural bufinefs. Throughout all Chriftendom, in very early times, the whole year was one continued term for hearing and deciding of caufes. For the Chriftian magiftrates, in order to diftinguifh themfelves from the Heathens, who were very fuperftitious in the obfervation of their *dies fafti* and *nefafti*, adminiftered juftice upon all days alike; till at length the church interpofed, and exempted certain holy feafons from being profaned by the tumult of forenfic litigations; as, particularly, the time of Advent and Chriftmas, which gave rife to the winter vacation; the time of Lent and Eafter, which created that in the fpring; the time of Pentecoft, which produced the third; and the long vacation, between Midfummer and Michaelmas, which was allowed for the hay-time and harveft. All Sundays alfo, and fome peculiar feftivals, as the days of the Purification, Afcenfion, &c. were included in the fame prohibition, which was eftablifhed by a canon of the church, A.D. 517, and fortified by an imperial conftitution of the younger Theodofius, comprifed in the Theodofian code. Afterwards, when our own legal conftitution was eftablifhed, the commencement and duration of our law terms were appointed, with a view to thefe canonical prohibitions; and it was ordered by the laws of king Edward the Confeffor, that from Advent to the octave of the Epiphany, from Septuagefima to the octave of Eafter, from the Afcenfion to the octave of Pentecoft, and from three in the afternoon of all Saturdays till Monday morning, the peace of God and holy church fhall be kept throughout the whole kingdom.

And fo extravagant was afterwards the regard paid to thefe holy times, that though the author of the Mirror mentions only one vacation of confiderable length, containing the months of Auguft and September, yet Britton fays, that in the reign of king Edward I. no fecular plea could be held, nor any man fworn on the Evangelifts, in the time of Advent, Lent, Pentecoft, harveft, and vintage, the days of the great litanies, and all folemn feftivals. He adds, that the bifhops and prelates granted difpenfations for taking affizes and juries in fome of thefe holy feafons, upon reafonable occafions; and foon after a general difpenfation was eftablifhed in parliament by ftat. Weftm. 1. 4 Edw. I. cap. 51, that affizes of novel diffeifin, mort d'anceftor, and darrein prefentment, fhould be taken in Advent, Septuagefima, and Lent, as well as inquefts; at the fpecial requeft of the king to the bifhops. The portions of time that were not included within thefe prohibited feafons, fell naturally into a fourfold divifion; and from fome feftival, or faint's day that immediately preceded their commencement, were denominated the terms of St. Hilary, of Eafter, of the Holy Trinity, and of St. Michael: which terms have been fince regulated and abbreviated by feveral acts of parliament; particularly Trinity term by ftat. 32 Hen. VIII. c. 2. and Michaelmas term by ftat. 16 Car. I. c. 6. and again by ftat. 24 Geo. II. c. 38. Blackft. Com. vol. iii.

Terms, *Oxford*. Hilary or Lent term begins January 14th, and ends the Saturday before Palm-Sunday. Eafter term begins the tenth day after Eafter, and ends the Thurfday before Whitfunday. Trinity term begins the Wednefday after Trinity-Sunday, and ends after the act, or 6th of July, fooner or later, as the vice-chancellor and convocation pleafe. Michaelmas term begins October 10th, and ends December 17th.

Terms, *Cambridge*. Lent term begins January 14th, and ends the Friday before Palm-Sunday. Eafter term begins the Wednefday after Eafter-week, and ends the week before Whitfunday. Trinity term begins the Wednefday after Trinity-Sunday, and ends the Friday after the commencement, or 2d of July. Michaelmas term begins October 10th, and ends December 16th.

Terms, *Scottifh*. In Scotland, Candlemas term begins January 23d, and ends February 12th. Whitfuntide term begins May 25th, and ends June 15th. Lammas term begins July 20th, and ends Auguft 8th. Martinmas term begins November 3d, and ends November 29th.

Terms, *Irifh*. In Ireland the terms are the fame as at London, except Michaelmas term, which begins October 13th, and adjourns to November 3d, and thence to the 6th.

Term, in *Grammar*, denotes fome word or expreffion in a language. See Word.

The word *term*, *terminus*, is borrowed metaphorically, by the grammarians and philofophers, from the meafurers or furveyors of lands: as a field is defined and diftinguifhed by its *termini*, or limits, fo is a thing or matter fpoken of, by the word or term by which it is denoted.

Term, in the *Arts*, or *Term of Art*, is a word which, befides the literal and popular meaning which it has, or may have, in common language, bears a farther and peculiar meaning in fome art or fcience. See Art.

Or, a term is a word which has one or more meanings befide its grammatical one; or which has a peculiar force or import in the language of fome particular fcience or art.

A word then becomes a term when its idea is rendered more complex, confifts of more parts, and includes more fpecial circumftances, on fome occafions than others.

It is this greater complexnefs, this excefs of conftituent parts of the idea, that denominates it a term in the general. Farther, as the parts of the idea, fignified by any word, are arbitrary; and as one may not only add new parts to thofe contained in the literal meaning, but alfo fuperadd others to them, alter them, extend them, and otherwife modify them at pleafure; hence the fame word becomes a term of this or that art, or both, as the inventors or improvers of thofe arts have thought fit to adopt it for the common bafis of certain ideas, and to modify and circumftantiate its meaning to the ufe of their refpective arts. See Definition.

Terms, *abftract*, *complex*, *concrete*, *equivalent*, *equivocal*, *general*, *relative*, *fynonimous*, *univocal*. See the adjectives.

Term, in *Logic*. A propofition is faid to confift of two terms, *i. e.* two principal and effential words, the *fubject* and the *attribute*.

A fyllogifm confifts of three terms, the *major*, *minor*, and *conclufion*. See Syllogism.

Terms *of an Equation*, in *Algebra*. See Equation.

Terms *of Proportion*, in *Mathematics*, are fuch numbers, letters,

letters, or quantities, as are compared one with another. See Proportion.

Terms, or *courses*, in *Medicine*, the menses, or women's monthly purgations.

TERMALY, in *Geography*, a town of Hindooſtan, in Myſore; 15 miles N.E. of Anantpour.

TERMED, or Tarmad, a town of Grand Bucharia, at the union of two large rivers, whoſe united ſtreams form the Jihon; the capital of a conſiderable diſtrict. In 1221, this town was beſieged by Jenghis Khan, and, after eleven days, taken by aſſault: after which the conqueror put moſt of the inhabitants to the ſword, and deſtroyed the town. It was rebuilt in the following century; 130 miles S. of Samarcand. N. lat. 37° 30′. E. long. 65° 48′.

TERMEH, or Karmili, a river of Aſiatic Turkey, which runs into the Black ſea, 30 miles N.E. of Samſoun.

TERMERA, or Termerium, in *Ancient Geography*, a free town of Aſia Minor, in Caria.

TERMES, called *Tierme*, a town of Hither Spain, belonging to the Arevaci, S. of Numantium.

Termes, in *Entomology*, a genus of the Aptera order of inſects. Its characters are, that it has ſix legs formed for running; two eyes; ſetaceous antennæ, and a mouth with two jaws. According to Gmelin, the characters are, that the mouth has two horny jaws, with a horny, quadrifid lip, linear acute fringes, four equal filiform feelers, or palpi, antennæ (moſtly) moniliform, and two eyes. Linnæus enumerates three, and Gmelin eight

Species.

Fatale. Above brown; thorax with three ſegments; wings pallid, and coſta, or rib, teſtaceous. This is the deſtructor of Degeer, and T. bellicoſum of Smeathman. It is found in the ſhady parts of the equinoctial regions of India and Africa. See the ſequel of this article.

Destructor. Above teſtaceous; head black; antennæ yellow. Found in the iſlands oppoſite to South America, Africa, and India.

Arda. Black; abdomen with ſegments white at the apex; legs pallid. Found in the equinoctial parts of Africa.

Mordax. Black; the ſegments of the abdomen white at the apex; legs black. Found in the equinoctial parts of Africa.

Capense. Yellow, with hyaline wings; brown at the margin. Found in India and Southern Africa.

Fatidicum. Abdomen ovate; mouth pallid; brown eyes; antennæ ſetaceous. Found in Europe, chiefly the ſouthern part.

Pulsatorium. Abdomen oblong; mouth red; eyes yellow; antennæ ſetaceous. Found in Europe and America.

Divinatorium. Abdomen tranſverſely ſulcated; brown mouth, and black eyes. Chiefly found in books; very lively, irritable, and whitiſh.

It is obſerved, that the European ſpecies of termes are very ſmall, compared with thoſe of the warmer regions of Africa and America; and inſtead of being gregarious, as in thoſe climates, are uſually found ſingle. Of theſe, the moſt known is the T. pulſatorius of Linnæus, a ſmall inſect of a whitiſh colour, and diſtinguiſhed by Derham and ſome other naturaliſts, by the appellation of "Pediculus pulſatorius." During the months of ſummer it is common in houſes, particularly in decayed wainſcots, and is remarkable for emitting a long-continued ſound, reſembling the ticking of a watch; it is commonly met with in collections of dried plants, &c. to which it is very injurious. It cannot bear, on account of its tender frame, the ſlighteſt preſſure, and it is very quick in its motion. When magnified, the head appears large, the eyes very conſpicuous, of a beautiful golden colour, and divided into innumerable hexagonal convexities; the antennæ long and ſetaceous; the palpi two in number, moderately long, and terminating in a large club-ſhaped top; the thorax rather narrow, and the abdomen obtuſely oval; the thighs, or firſt joints of the legs, thick, the remaining ones ſlender, and the feet furniſhed with very ſmall claws. The whole animal is beſet with ſcattered hairs. This inſect, according to the obſervations of Derham, when firſt hatched from the egg, is white, oval, and very ſmall, exactly reſembling a common mite; furniſhed with eight legs, and beſet with long hairs. After a certain time it caſts its ſkin, and appears in the form already deſcribed. Degeer has found on each ſide of the thorax the appearances of rudiments of wings, reſembling a pair of oblong ſcales; and Dr. Shaw affirms, from his own obſervations, that ſome individuals of this ſpecies become winged at their full growth; the wings, four in number, being very large, of a ſlightly indiſtinct appearance, and variegated with blackiſh and brown clouds or ſpots. In the beginning of July this change takes place, and ſeveral inſects may be ſeen with the wings half-grown; in a few days they gain their full ſize.

Dr. Derham is of opinion, that the ticking ſound of theſe animals is analogous to the call of birds to their mates during the breeding ſeaſon; and this opinion is very probable. This ſound, ſays Dr. Shaw, as well as that produced by the "Ptinus fatidicus," or death-watch, ſeems to prove in a convincing manner, that inſects poſſeſs the faculty of hearing, though this be denied by ſome naturaliſts.

Of the exotic termites, the moſt remarkable is the T. bellicoſus. The animals of this ſpecies have lately been minutely deſcribed by Mr. Smeathman, from whoſe account the following particulars are extracted.

The termites, which have been taken notice of by various travellers in different parts of the torrid zone, and called by the name of white ants, reſemble the ants in their manner of living, which is in communities, forming extraordinary neſts in the ſurface of the ground, and various ſubterraneous paſſages, and alſo in their provident and diligent labour; but in both reſpects much ſurpaſs them. The termites are repreſented by Linnæus as the greateſt calamity of both Indies, becauſe of the havoc they make in all kinds of wooden buildings, utenſils, and furniture, ſo that nothing but metal or ſtone can eſcape their deſtructive jaws.

Smeathman obſerves, that the inſect in its perfect ſtate has four wings without any ſting, and ſhould therefore be ranged under the *neuroptera*, and not under the *aptera* of the Linnæan ſyſtem. The communities of termites conſiſt of one male and one female, generally the parents of all the reſt, and of three orders of inſects, apparently of very different, though really of the ſame ſpecies. Thoſe of the firſt order are the working inſects, or labourers; the ſecond comprehends the fighting inſects, or ſoldiers, which do no labour; and the third are the winged ones, or perfect inſects, which are male and female, and capable of propagation, but neither labour nor fight; the kings and queens belong to this order, and within a few weeks after they are elected and elevated to this rank, they migrate, and either eſtabliſh new kingdoms, or periſh within a day or two. The largeſt ſpecies, called *termes bellicoſus*, is the beſt known on the coaſt of Africa; it erects immenſe buildings of well-tempered earth or clay, which are conſtructed with ſignal ingenuity: it does infinite miſchief in one reſpect, and in another it is peculiarly important and uſeful, by deſtroying thoſe vegetable or animal ſubſtances which incumber the earth, and are noxious on account of their putridity. The

buildings

buildings (usually termed hills) which these insects erect, are in their general form like sugar-loaves, and about ten or twelve feet high; and consist of an exterior part, which is large and strong, intended partly for defence, and partly for preserving a regular degree of warmth in order to hatch the eggs and cherish the young: and an interior, which is the habitable part, divided into many apartments for the residence of the king and queen, the nursing of their progeny, the accommodation of the soldiers and labourers, or magazines of provision. The royal chamber, in the interior building, or that occupied by the king and queen, is situated near the centre, and usually in the shape of a semi-oval within.

In the infant state of the colony, it is not more than about an inch in length, but in time it is enlarged to six or eight inches in the clear, being in size adapted to that of the queen. It has doors or entrances, at pretty equal distances from each other, which entrances are of a size not to admit any animal larger than the soldiers and labourers: so that the king and queen, when once immured, can never go out. The royal chamber is surrounded by many others of different sizes, shapes, and dimensions; and they either open into each other, or communicate by passages suitably contrived. These apartments are connected with the magazines, formed altogether of clay, and nurseries. The provisions lodged in the former appear by the microscope to consist principally of the gums or inspissated juices of plants. The nurseries are composed entirely of wooden materials, joined together apparently with gums. These nurseries are occupied by the eggs, and young insects, which appear at first in the shape of labourers, but white as snow. They are very compact, and divided into small chambers, not one of which is to be found of half an inch in width. They are placed round and near the royal apartments. As the queen enlarges, her chamber is also enlarged; and new apartments are fitted up for her attendants; and also new nurseries at a remoter distance. Thus, says Mr. Smeathman, they continually enlarge their apartments, pull down, repair, and rebuild, according to their wants, with a degree of sagacity, regularity, and foresight, not even imitated by any other kind of animals or insects which he has ever heard of. These nurseries are always found slightly overgrown with or plentifully sprinkled with small white globules, about the size of a small pin's head, first supposed to be the eggs, but found by the microscope to be small mushrooms. The royal chamber is situated at about a level with the surface of the ground, at an equal distance from all the sides of the building, and in every direction surrounded by the apartments of labourers or soldiers, for the purpose of attendance. These apartments compose an intricate labyrinth, extending a foot or more in diameter, from the royal chamber on every side. Here the nurseries and magazines of provisions commence, and being separated by small empty chambers or galleries, are continued on all sides to the outward shell, and reaching up within it two-thirds or three-fourths of its height. All these chambers, and passages leading to and and from them, being arched, help to support one another: and the exterior building supports them on the outside. Our limits will not allow our describing all the subterranean galleries or passages, and the manner in which they are artfully made to communicate with different parts of the building, and to suit the convenience of the labourers and soldiers, as thoroughfares for passing and repassing with their loads of materials and provisions.

There are other nests or habitations constructed by other species, which are in the form of turrets, or upright cylinders, and contain a number of cells: they are of two sizes, for the accommodation o a larger and smaller species: and again another kind of nests, which is the habitation of a distinct species; this is generally spherical or oval, and built in trees.

Of the three orders above-mentioned, the labourers, which are about one-fourth of an inch long, and twenty-five of them weigh about a grain, are the most numerous; *e. g.* in the T. bellicosus, there seem to be at least one hundred labourers to one of the fighting insects or soldiers. The soldiers are about half an inch long, and equal in bulk to fifteen of the labourers; the mouth of the latter is evidently calculated for gnawing and holding of bodies, whereas that of the former, or soldiers, has its jaw shaped like two sharp awls, a little jagged, and as hard as a crab's claws, so that they are incapable of any thing but piercing or wounding: in insects of the third order, which have arrived at their perfect state, the head, thorax, and abdomen, are wholly different from those of the other orders, and they are furnished with four large brownish transparent wings; their length is six or seven-tenths of an inch, and each is equal in bulk to thirty labourers: they have now two eyes which are visible, whereas if they had them before they are not distinguishable. These insects are gathered and eat by the inhabitants, and reckoned both delicious and nourishing food. The king and queen are lodged in apartments, which are closed up, so that a passage remains merely for the ingress and egress of the labourers and soldiers, but at which (as we have already said) neither of the royal pair can come out: and in the business of propagation the abdomen of the female extends to an enormous size, so that an old queen's will be fifteen hundred or two thousand times the bulk of the rest of her body, and twenty or thirty thousand times the bulk of a labourer, and by its peristaltic motion, are protruded eggs to the amount of sixty in a minute, or eighty thousand and more in twenty-four hours: the eggs are removed by the attendants into the nurseries, and after they are hatched, the young are provided with every thing necessary till they are able to shift for themselves. It is remarkable of all the different species of termites, that the working and fighting insects never expose themselves to the open air; but either travel under ground, or within such trees or substances as they destroy, or through pipes made of the same materials with their nests. The termites which build in trees, frequently construct their nests within the roofs and other parts of houses, to which they do considerable damage, unless soon extirpated; and the larger species enter under the foundations of houses, through the floors, or bore through the posts of buildings, making lateral perforations and cavities, as they proceed. They are equally destructive when they get into a trunk containing clothes and other things, and into stores, &c.

Upon opening the hills in which the termites lodge, the behaviour of the soldiers excites admiration. When a breach is made, however quickly it be done, a soldier will run out, and walk about the breach, as if to see whether the enemy is gone, or to examine what is the cause of the attack. He will sometimes return again, as if to give the alarm; but in a short interval he is followed by two or three others, running as fast as they can, and these are followed by a large body, others also succeeding them, as long as any one continues to batter their building: nor is it easy to describe the rage and fury which they manifest on the occasion; biting every thing in their way, and making a vibrating noise, like the ticking of a watch, perceptible at the distance of three or four feet. If they get hold of any one who attacks their habitation, they will in an instant suck out blood enough to weigh against their whole body; and if they chance to wound the leg, the stain upon the stocking will be seen to extend an inch in in width. They make their hooked jaws to meet at the firſt ſtroke, nor will they quit their hold, but ſuffer themſelves to be pulled away leg by leg, and piece after piece, without the leaſt attempt to eſcape. If, however, they are left to themſelves undiſturbed, they will in leſs than half an hour retire into the neſt, as if they conceived their caſtle to be ſecure. Before they all get in, the labourers will be ſeen in motion, haſtening to bring materials for repairing the breach. This they do without mutual obſtruction, though their number be immenſe, and the work is ſoon finiſhed. While the labourers are thus employed, the ſoldiers take no part with them. On a renewed attack, the labourers run with celerity into the numerous pipes and galleries with which the building is perforated; and the ſoldiers ruſh out as numerous and as vindictive as before. One circumſtance more deſerves to be mentioned; and that is the loyalty and fidelity diſplayed by the labourers and ſoldiers in their attendance on the royal chamber. This chamber is a large neſt, is capacious enough to hold many hundreds of the attendants, beſides the royal pair, and it is always found full. Theſe faithful ſubjects never abandon their charge in the laſt diſtreſs, but rather die in their defence than deſert them. If in an attack upon the hill, you ſtop ſhort of the royal chamber, and cut down about half of the building, and leave open ſome thouſands of galleries and chambers, they will all be ſhut up with their ſheets of clay before the next morning. If even the whole is pulled down, and the different buildings are thrown together in a heap of confuſed ruins, provided the king and queen are not deſtroyed or taken away, every interſtice between the ruins, at which either cold or wet can poſſibly enter, will be ſo covered, as to exclude both; and if the inſects are left undiſturbed, in about a year they will raiſe the building to nearly its priſtine ſize and grandeur.

There is another ſpecies, called the *marching* termites, which is much larger, and ſeems to be leſs frequent than the other. For an account of thoſe, and many other curious particulars, we muſt refer to Philoſ. Tranſ. vol. lxxi. part i. art. 11. p. 139—192.

TERMIGON, in *Geography*, a town of France, in the department of Mont Blanc, on the Arc; 12 miles E.N.E. of St. André.

TERMINALIA, in *Antiquity*, feaſts celebrated by the Romans, in honour of the god Terminus.

Varro is of opinion, that this feaſt took its name from its being at the term or end of the year; but Feſtus is of a different ſentiment, and derives it from the name of the deity in whoſe honour it was held.

In reality, the Terminalia, or feaſts of land-marks, were held in honour of Jupiter, conſidered in the capacity of conſervator of land-marks or bounds. Dionyſius Halicarnaſſeus tells us, that it was Numa Pompilius who firſt conſecrated land-marks to Jupiter; and adds, that the ſame prince appointed an anniverſary day, on which the country-people, aſſembling together on the bounds of the lands, ſhould offer ſacrifices in honour of the tutelary gods thereof.

The Terminalia were held on the ſeventh, or, as Struvius will have it, on the tenth of the calends of March. No animal is to be ſacrificed herein, it being deemed unlawful to ſtain the land-marks with blood: they only offered ſacrifices of the firſt fruits of the earth; and this in the open air, and on the ſpot where the land-marks were.

TERMINALIA, in *Botany*, from the terminal mode of growth and foliation in ſeveral of the ſpecies, the ſtem being a ſtriking example of what Linnæus latterly called *determinatè ramoſus*, and the leaves being crowded at the ends of the branches, which are ſwelled in that part.—Linn. Mant. 21. Schreb. Gen. 728. Willd. Sp. Pl. v. 4. 967. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 441. Jacq. Coll. v. 1. 130. Juſſ. 76. Lamarck Illuſtr. t. 848. (Pamea; Aubl. Guian. 946. Tanibouca; ibid. 448? Badamia; Gærtn. t. 97. Myrobalanus; Gærtn. ibid. Lam. Illuſtr. t. 849.)—Claſs and order, *Polygamia Monoecia*, Linn. Rather *Decandria Monogynia*.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, internally coloured, in five ovate, acute, equal ſegments. *Cor.* Petals none. Nectary pitcher-ſhaped, compoſed of five ſmall hairy lobes, in the bottom of the calyx. *Stam.* Filaments ten, awl-ſhaped, ſlightly ſpreading, longer than the calyx, inſerted into its lower part; anthers roundiſh, erect. *Piſt.* Germen inferior, ovate-oblong; ſtyle thread-ſhaped, erect, the length of the ſtamens; ſtigma ſimple. *Peric.* Drupa oval, ſomewhat compreſſed, acute. *Seed.* Nut oval-oblong, angular, ſmooth, with an oblong ſolitary kernel.

Numerous flowers, above the others, and later, are entirely male.

Eſſ. Ch. Calyx in five ſegments, internally coloured. Petals none. Nectary five-cleft, hairy. Drupa inferior.

1. T. *Catappa*. Broad downy-leaved Terminalia. Linn. Mant. 128. Willd. n. 1. Ait. n. 1. Jacq. Coll. v. 1. 130. Ic. Rar. t. 197. (Adamaram; Rheede Hort. Malab. v. 4. 5. t. 3, 4.)—Leaves obovate, obtuſe, very ſlightly toothed, deſtitute of glands at the baſe; finely downy beneath.—Native of the Eaſt Indies, in Java and in woods on the coaſt of Malabar, where the ſoil is ſandy. Meſſrs. Lee and Kennedy are ſaid to have introduced this tree into the Engliſh ſtoves in 1778, but it has not yet bloſſomed, nor, conſidering its natural and lofty growth, is that event to be expected. The *branches* grow in a whorled manner; their extremities, clothed with ruſty down, bearing each a cloſe tuft of large broad *leaves*, a foot long, on ſhort downy ſtalks. Each *leaf* is tipped with a ſmall point, and is abrupt or ſomewhat heart-ſhaped, though much contracted, at the baſe. *Cluſters* numerous, axillary, ſtalked, cylindrical, denſe, many-flowered. *Flowers* greeniſh-yellow, half the ſize of a currant-bloſſom, moſt of them males. *Fruit* oval, compreſſed, larger than that of the almond-tree, reddiſh, with a cylindrical kernel, which taſtes like a filberd, but is more tender and ſoluble. Its oil is ſaid never to turn rancid. The wood is hard and durable, and the tree is much planted about houſes, for the ſake of its ſhade.

2. T. *moluccana*. Molucca Terminalia. Lamarck Dict. v. 1. 349. Willd. n. 2. Ait. n. 2. (T. glabrata; Forſt. Prodr. 74. Pl. Eſcul. 52. Spreng. Antiq. Bot. 102. t. 2. Catappa; Rumph. Amboin. v. 1. 174. t. 68.)—Leaves obovate, obtuſe, entire, deſtitute of glands at the baſe; ſmooth on both ſides.—Native of the Molucca and Society iſles. Introduced into the Engliſh ſtoves by the earl of Powis, in 1804. This is ſaid to be of a more humble ſtature than the foregoing, and the *leaves* are ſmaller, ſmooth at the back, though their *footſtalks* are covered with denſe ruſty down. The ſpecific name of *glabrata* ought to have been retained in preference to *moluccana*. This is conſidered as a ſacred tree in Otaheite, though uſed in building boats as well as houſes.

3. T. *ſubcordata*. Heart-leaved Terminalia. Willd. n. 3.—"Leaves obovate, obtuſe, ſomewhat wavy; ſmooth on both ſides, heart-ſhaped at the baſe, without glands."—Gathered by Humboldt and Bonpland, in South America. Willdenow, who had examined one of their dried ſpecimens, ſays "this ſpecies is very like the laſt, but the baſe of the *leaves* is heart-ſhaped, and their margin very ſlightly and unequally waved; the *footſtalks* ſomewhat downy. It differs from *T. Catappa*, in having the *leaves* ſomewhat wavy, very ſmooth

ſmooth on both ſides, and heart-ſhaped at the baſe."—This laſt character ſeems to us to exiſt in *T. Catappa*.

4. T. *latifolia*. Broad wedge-leaved Terminalia. Swartz Ind. Occ. 747. Willd. n. 4. (Arbor maxima, fortè prunifera, cortice cannabino, folio longiſſimo latiſſimoque; Sloane Hiſt. v. 2. 130.)—Leaves obovate, obtuſe, ſomewhat ſerrated, ſmooth on both ſides, deſtitute of glands at the baſe: their midrib downy beneath.—Native of mountainous woods in the north part of Jamaica. A tall, ſtout, umbrageous *tree*, riſing to the height of one hundred feet, or more, with horizontal *branches*, downy when young. *Leaves* crowded about the ends of the branches, on ſmooth ſtalks, thickiſh, ſcarcely pointed, bluntly ſerrated, or nearly entire, tapering (not dilated or heart-ſhaped) at the baſe. *Flowers* ſmall, whitiſh or yellowiſh, in long axillary cluſters; the upper ones chiefly male. *Fruit* pulpy, greeniſh-red, ſweet, boat-ſhaped, larger than a peach, eaten chiefly by hogs. Its kernel taſtes like an almond. The wood is valuable for its hardneſs. The inhabitants of Jamaica know this ſpecies by the name of Broad-leaf Tree. *Swartz*.

5. T. *Chebula*. Oval-leaved Terminalia. Retz. Obſ. faſc. 5. 31. Willd. n. 5. Ait. n. 3. Roxb. Coromand. v. 2. 52. t. 197. (Myrobalanus Chebula; Gærtn. v. 2. 91. t. 97.)—Leaves obovate-oblong, obtuſe, entire, oppoſite, ſmooth on both ſides; ſilky when young. Footſtalks with two glands near the top. Cluſters terminal.—Native of hills in the Eaſt Indies. Retzius, who received his ſpecimens from Koenig, deſcribes this *tree* as not more than three or four times the height of a man, with no very widely ſpreading top. Our ſpecimens, from Dr. Rottler, agree with every particular of his deſcription. The young *leaves* are beautifully ſilky. We find none of the marginal glands repreſented by Roxburgh, nor are our *leaves* pointed, as in his plate. The *flowers* in both are yellow, in terminal, often aggregate, cluſters. Dr. Roxburgh mentions the wood of the tree he deſcribes as hard and valuable, and the head as evergreen, and widely ſpreading. The rind of its *fruit* is much uſed by painters of chintz for drawing a permanent outline, and by dyers to fix their colours. With ſalt of ſteel it makes an excellent ink.

6. T. *elliptica*. Rounded-leaved Terminalia. Willd. n. 6.—" Leaves oblong-elliptical, bluntly rounded, entire; ſlightly hairy beneath, with two glands at the baſe."—Native of the Eaſt Indies. The *branches* are round, brown; downy when young. *Leaves* two or three inches in length; contracted at the baſe; very obtuſe at the extremity, with a ſlight point; dark green and ſmooth above; pale, and beſprinkled with cloſe-preſſed ſcattered hairs, beneath; furniſhed at the baſe with two cup-ſhaped, ſomewhat ſtalked, glands. *Spikes* terminal, panicled. *Willdenow*. We have been inclined to ſuſpect this might not be diſtinct from the following, but the *infloreſcence* does not agree, nor could Willdenow ſurely have omitted to notice the great length of the *footſtalks* in *T. Bellerica*.

7. T. *Bellerica*. Long-ſtalked Terminalia. Roxb. Corom. v. 2. 54. t. 198. (Myrobalanus Bellerica; Breyn. Ic. 18. t. 4. Gærtn. v. 2. 90. t. 97. Tani; Rheede Hort. Malab. v. 4. 23. t. 10.)—Leaves obovate, wavy, ſmooth. Footſtalks about half as long as the leaves, with two glands at the top. Spikes axillary, ſolitary, hardly longer than the footſtalks.—Native of hills in the Eaſt Indies. A large *tree*, with a very widely ſpreading head; the wood is white, but ſoft, and not durable. The *bark*, when wounded, exudes a copious inſipid gum, like gum arabic, ſoluble in water. The *leaves* are firm and ſmooth, ſix or ſeven inches long when full-grown, but in the flowering ſeaſon they ſeem ſcarcely to exceed their *footſtalks*, which then meaſure half that length. *Flowers* fetid, dirty yellow, in copious axillary ſpikes, not cluſters. *Fruit* the ſize of a nutmeg; its kernel eatable, but reported to intoxicate if taken in any great quantity.

8. T. *mauritiana*. Mauritius Terminalia. Lamarck Dict. v. 1. 349. Willd. n. 7. (Badamia Commerſoni; Gærtn. v. 2. 90. t. 97? Pamea guianenſis; Aubl. Guian. v. 2. 946. t. 349?)—Leaves lanceolate, ſlightly crenate, tapering at each end, ſmooth on both ſides. Spikes axillary, the length of the leaves.—Native of the iſles of Mauritius and Bourbon, and probably of Madagaſcar. Commerſon deſcribes it as the largeſt and talleſt tree of the two former iſlands. He took it for a new genus, and named it *Reſinaria*, under which name, and that of *le faux benjoin*, his ſpecimens are preſerved in the Linnæan herbarium. The *wood* is much eſteemed for making canoes. The *branches* are ſwelled at the ends, where they bear ample tufts of *leaves* three or four inches long, on downy ſtalks, three-quarters of an inch in length; when full-grown both appear, by Lamarck's account, to be much larger. *Flowers* copious, in ſimple axillary ſpikes. *Fruit* an inch or inch and half long, with a dilated compreſſed border, not altogether anſwering to Gærtner's figure, which makes us doubt his ſynonym. He has formed his barbarous generic name, *Badamia*, out of the French *Badamier*, which is ſynonimous with *Terminalia*. Aublet's plate of his *Pamea* greatly reſembles our plant, and our chief doubt ariſes from their diſtant places of growth. That they are of the ſame genus cannot be diſputed.

9. T. *anguſtifolia*. Narrow-leaved Terminalia. Jacq. Hort. Vind. v. 3. 51. t. 100. Willd. n. 8. Ait. n. 4. (T. Benzoin; Linn. Suppl. 434. Lamarck Dict. v. 1. 349. Croton Benzoe; Linn. Mant. 297. Willd. Sp. Pl. v. 4. 533.)—Leaves linear-lanceolate, wavy, downy on both ſides.—Native of the Eaſt Indies. Jacquin reports that ſeeds of this ſpecies were ſent him by Lemonnier, under the French name of *Bien-joint*, from the iſle of Bourbon. Hence he ingeniouſly and ſatisfactorily conjectures, that this appellation, which alludes to the mode of growth of the tree, may have been confounded with *Benjoin* or *Benzoin*, the French word for gum Benjamin, or *Benzoe*, and thus the ſaid gum was ſuppoſed to come from the plant before us. (See STYRAX.) *T. anguſtifolia* has long been cultivated in our ſtoves, but the flowers are unknown. Its manner of branching is like *T. Catappa*, *mauritiana*, &c. nor does it much differ from the laſt named, except that the *leaves* are narrower, often quite linear, and clothed, more or leſs completely, with brown, rather rigid, hairs. Their veins, rib, and margin are tinged with a blood-colour. The *fruit* appears to be ſimilar to the laſt. Linnæus raiſed a plant from ſeed in the Upſal ſtove, and remarked that the ſeed-leaves were of a blood-red. The *leaves* of his ſpecimen hardly exceed a line in breadth.

10. T. *Vernix*. Varniſh Terminalia. Lamarck Dict. v. 1. 350. Willd. n. 9. (Arbor vernicis; Rumph. Amboin. v. 2. 259. t. 86.)—Leaves linear-lanceolate, entire, ſmooth on both ſides.—Native of the Molucca iſles. It is preſumed to belong to this genus from the imperfect deſcription of Rumphius, and its evident reſemblance to the two laſt ſpecies. The *leaves* however are more diſperſed, and of larger dimenſions, being from nine to eleven inches long, and the breadth of three or four fingers, ſo that they are ſcarcely to be termed *linear*-lanceolate. The rib is very prominent beneath. *Flowers* yellow or whitiſh, with red *ſtamens*, in drooping cluſters or ſpikes. *Fruit* oblique and compreſſed, two inches broad. The *nut* exudes a large quantity of reſin, ſoon turning brown, and a milky reſinous fluid is lodged under the bark of the tree, at firſt of an acrid quality, but

hardening into a valuable varnifh, deftitute of acrimony, and much ufed in the Moluccas. A noxious vapour is faid to proceed from this tree, fo that the natives of the countries where it grows avoid fleeping, or even fitting for any length of time, under its fhade. Whether this be the moft famous varnifh-tree of the Chinefe, as Rumphius indicates, may perhaps admit of doubt.

11. T. *Tanibouca.* Guiana Terminalia. (Tanibouca guianenfis; Aubl. Guian. 448. t. 178.)—Leaves fcattered, obovate, pointed, entire, fmooth. Clufters terminal and axillary. Native of marfhy places in Guiana. For an account of this fpecies, fee TANIBOUCA. Its genus muft be very doubtful, unlefs the fruit were known, but the fuggeftion of our learned friend Mr. Brown, Prodr. Nov. Holl. v. 1. 351, induces us, for the prefent at leaft, to refer the plant hither.

TERMINANDO *et Audiendo.* See AUDIENDO.

TERMINANS, PUNCTUM. See PUNCTUM.

TERMINATION, TERMINATIO, in *Grammar*, the ending of a word, or the laft fyllable of it.

They are the different terminations of one and the fame words on different occafions, that conftitute the different cafes, numbers, tenfes, moods, &c.

TERMINATION *Ifland*, in *Geography*, an ifland in the South Pacific ocean, fo named by captain Vancouver, as being the termination of his refearches on the S.W. coaft of New Holland, near which it lies. S. lat. 34° 32′. E. long. 122° 8′.

TERMINATOR, in *Aftronomy*, a name fometimes given to the *circle of illumination*, from its property of terminating the boundaries of light and darknefs.

TERMINE, in *Commerce*, a weight for gold, filver, and pearls at Tunis; 8 termini being equal to an ounce; and 80 ounces of Tunis being equal to 81 ounces Englifh troy.

TERMINE, in *Geography*, a town of Naples, in Principato Ultra; 10 miles S.E. of Avellino.

TERMINER, in *Law.* See OYER.

TERMINI, in *Architecture.* See TERMS.

TERMINI, in *Geography*, a town of Sicily, in the valley of Mazara, fituated on the north coaft, celebrated for the warm baths near it, from which it received its name; 18 miles E. of Palermo. N. lat. 38° 5′. E. long. 13° 45′.—Alfo, a river of Sicily, which runs into the Mediterranean, a little to the W. of Termini.

TERMINI. See TERMOLI.

TERMINISTS, TERMINISTÆ, in *Ecclefiaftical Hiftory*, a fect or party among the Calvinifts, whofe particular tenets are reducible to five points:

1. That there are feveral perfons, both in and out of the church, to whom God has fixed a certain term before their death, after which he no longer wills their falvation, how long foever they live afterwards. 2. That God has fixed this fatal term of grace by a fecret decree. 3. That this term once elapfed, he makes them no farther offer of repentance or falvation, but takes away from his word all the power it might have to convert them. 4. That Pharaoh, Saul, Judas, moft of the Jews, and many of the Gentiles, were of this number. 5. That God ftill bears with feveral of this fort of people, and even confers benefits on them after the term is expired; but that he does not do it with any intention they fhould be converted.

All the other Proteftants, and particularly the Lutherans, look on thefe articles with abhorrence, as repugnant to the goodnefs of God, and deftructive to all Chriftian virtue; and as contrary to Scripture, particularly the following texts, Ezek. xviii. 23. 30, 31, 32. xxxiii. 11. 1 Tim. iv. 1. 16. 2 Pet. iii. 9. Acts, xvii. 30, 31. Matt. xi. 28. Ifa. lxvi. 2. Heb. iii. 7. 13. Rom. ii. 5, &c.

TERMINOS, in *Geography*, a lake or bay on the coaft of Tabafco, in the bay of Campeachy. N. lat. 18° 12′. W. long. 92° 46′.

TERMINTHUS, from τερμινθος, *a pine-nut*, in *Surgery*, a large painful tumour, or puftule on the fkin, thought to refemble a pine-nut.

TERMINUM, *ad qui præteriit.* See AD TERMINUM.

TERMINUM, *Infra, quare ejecit.* See QUARE.

TERMINUS, τερμα, fignifies a bound or limit.

TERMINUS, *a quo*, in *Metaphyfics*, denotes the place from whence any motion commences: in contradiftinction from the other extreme, which is called the *terminus ad quem.*

The fchoolmen call privation a *terminus a quo*, in fpeaking of generation, which they confider as a fpecies of motion.

TERMINUS, in *Mythology*, the god of fields and landmarks. M. de Boze, in a learned differtation on this fubject (Mém. de l'Acad. t. i.), obferves, that the Egyptians received from the Hebrews the cuftom of bounding the fields. In procefs of time, as the laws eftablifhed for the fecurity of the land-marks were not a fufficient reftraint on avarice, Numa perfuaded the people that there was a god who protected land-marks and avenged incroachments. He built a temple to him upon the Tarpeian mount, and regulated the ceremonies of his worfhip. He caufed this god to be reprefented under the form of a ftock or ftone, as we learn from Tibullus and Ovid: but afterwards this god was reprefented with a human body placed upon a pyramidical land-mark. It is faid that this god acquired peculiar honour by maintaining his ftation when the other gods were removed by Tarquin the Proud, for the purpofe of building the temple which Tarquin the elder had vowed to erect to Jupiter.

TERMIOVA, in *Geography*, a town of Iftria; 18 miles N.E. of Pedena.

TERMISSUS, or TELMISSUS, in *Ancient Geography*, a town of Afia, in the fouthern part of Pifidia.

TERMITES, in *Entomology.* See TERMES.

TERMOLI, or TERMINI, in *Geography*, a town of Naples, in the province of Capitanata; the fee of a bifhop, fuffragan of Benevento; 57 miles W. of Viefte. N. lat. 42° 2′. E. long. 15° 5′.

TERMOR, *Tenens ex termino*, in *Law*, he that holds lands or tenements for a term of years, or life.

TERMUS, in *Ancient Geography*, a river in the ifle of Sardinia.

TERN, in *Geography*, a river of England, which rifes in Staffordfhire, 5 miles N.E. of Drayton, and runs into the Severn, 7 miles below Shrewfbury.

TERN. See TYRAN.

TERN, in *Ornithology.* See STERNA.

TERN, *Brown*, or *Sterna obfcura* of Linnæus, is by fome authors called the *brown gull.* Mr. Ray defcribes it as having the whole under fide white, the upper brown; the wings partly brown, partly afh-colour; the head black; and the tail not forked: but Mr. Pennant conjectures, that this bird is the young of the greater tern. See STERNA.

TERN, *Great*, or *Sea-fwallow*, *Sterna hirundo* of Linnæus, has the bill and feet of a fine crimfon, the former tipt with black, ftraight, flender, and fharp-pointed; the crown and hind part of the head black; the throat and whole under fide of the body white; the upper part, and coverts of the wings, a pale grey; the tail confifting of twelve feathers, the outer edges of the three outmoft grey, the reft white, and the

the exterior on each fide two inches longer than the other, and clofed in flying, fo as to appear one flender feather.

Thefe birds frequent the fea-fhores, banks of lakes, and rivers; they feed on fmall fifh and water infects, hovering over the watr, and fuddenly darting into it to catch their prey. They breed among fmall tufts of rufhes, and lay three or four eggs of a dull olive-colour, fpotted with black. All the birds of this genus are very clamorous. Pennant.

TERN, *Black*, or *Scare-crow*. See STERNA *Filipes*.

TERN, *Surinam*, or *Darter*. See PLOTUS *Surinamenfis*.

TERNA, a word ufed by fome authors to exprefs an impetigo.

TERNA, *Folia*, in *Botany* and *Vegetable Phyfiology*, are leaves, whether fimple or compound, feffile or ftalked, which grow three together in a whorl, on any ftem or branch, as in *Verbena triphylla*, Curt. Mag. t. 367. Such a difpofition of the foliage appears to prevail remarkably among the plants of Mexico, Chili, and Peru, of which, befides the example juft named, many others may be found. (See the genera FUCHSIA and HEMIMERIS.) Among Britifh plants, *Erica cinerea* has naturally *folia terna;* while the generally oppofite leaves of *Lyfimachia vulgaris* and *Lythrum Salicaria* occafionally become fo. See LEAF.

TERNALLA, in *Geography*, a town of Hindooftan, in Myfore; 45 miles E. of Rettinghery.

TERNARY MEASURE. See MEASURE.

TERNARY *Number*, in *Antiquity*, was efteemed a fymbol of perfection, and held in great veneration among the ancient mythologifts. Whence Virgil,

——"Numero Deus impare gaudet." Ecl. viii. ver. 75.

Servius on this place remarks, that the Pythagoreans afcribed the ternary number to the Supreme God, as being the beginning, middle, and the end of all things. All the heathen gods had a three-fold power attributed to them, as the *tria virginis ora Dianæ*, the three-forked thunderbolt of Jupiter, the trident of Neptune, the three-headed dog of Pluto. Again, the Parcæ were three, the Furies three, Hercules was three nights in begetting, the Mufes were anciently three, the Graces three, &c.

This number was likewife ufed in moft religious ceremonies, but efpecially in luftrations; whence Virgil, Æn. lib. xi. v. 188.

"Ter circum accenfos, cincti fulgentibus armis,
Decurrere rogos."——

TERNATA, FOLIA, in *Botany* and *Vegetable Phyfiology*, are compound leaves, each of which confifts of three leaflets, as in the Trefoil and Strawberry. Thefe are called in Englifh Ternate Leaves, and muft not be confounded with *Folia* TERNA, fee that article, for which laft we have no appropriate term in our language. Some plants bear twice, or thrice, ternate leaves. See LEAF.

TERNATE, in *Geography*, an ifland in the Eaft Indian fea, and the principal, though not the largeft, among thofe called Moluccas or Spice Iflands, of a circular form, and about 21 miles in circumference. In the centre is a lofty volcanic mountain, whofe bafe extends almoft to the fea every way. The upper parts are uncultivated, and covered over with fhrubs and low trees; but in the plain are many gardens, and abundance of fruit-trees. On this mountain are found many hollows or caverns full of fulphur, which emit a thick fmoke, and flame fometimes appears from the fummit, with a noife refembling thunder. The productions are cocoa-nuts, bananas, yams, oranges, and other fruits; but the principal article of commerce is cloves: many birds of paradife, and other beautiful birds, are found here, and plenty of game. The chief quadrupeds are goats, deer, and hogs. The boa ferpent is fometimes found of the length of thirty feet. This ifland was firft fettled by the Spaniards, who were driven away by the Dutch, to whom the king of the ifland is, in fome degree, fubject. The Europeans have two forts, called "Orange" and "Terloehe," between which is a lake, called "Saffe," three miles in circumference, and 60 fathoms deep, feparated from the fea by a narrow dike, which the Spaniards made a fruitlefs attempt to cut through, to form a port. On this ifland are three mofques, and a Dutch church, but no place of worfhip for the Portuguefe. The province or government of Ternate includes the iflands of Ternate, Tidore, Motir, Machian, and Bachian, which are what are properly the Moluccas; they are the original places of growth of the finer fpices; and larger nutmegs are ftill found in the woods of Ternate, than any other produced out of Banda. Some places, fituated in the eaftern part of the ifland of Celebes, belong likewife to this government; and the object of the Company in fettling there is principally to furnifh provifions for Ternate, that part of Celebes being very fruitful in rice and other neceffaries. They alfo yield a confiderable quantity of gold, about 24,000 taels, of a dollar and a half in weight, yearly, amounting, at 5*l. per* tael, to 120,000*l.*, and efculent bird's-nefts, which are efteemed a great delicacy by the Orientals, and efpecially by the Chinefe; in exchange for which the inhabitants take opium, Hindooftan piecegoods, chiefly blue cloth, fine Bengal coffaes and hummums, together with fome cutlery. Ternate does not, in general, require any fupply of provifions from Java, as the ifles of Banda do. This ifland fuffered greatly in Auguft 1770, by earthquakes. More than fixty violent fhocks were felt in the fpace of twenty-four hours, and the fortifications were much injured. N. lat. 0° 50′. E. long. 127° 10′.

TERNATE, in *Zoology*, a fpecies of bat. See VAMPYRE, and VESPERTILIO *Vampyrus*.

TERNATEA, in *Botany*, a genus fo named by Tournefort, from Ternate, the native country of the plant. See CLITORIA.

TERNAVASSO, in *Geography*, a town of France, in the department of the Po; 6 miles N.E. of Carmagnola.

TERNAY, *Bay of*, a bay or harbour on the E. coaft of Chinefe Tartary, fo called by M. Peroufe in 1787. The Dutch navigators called it Port Acqueis. N. lat. 45° 13′. E. long. 137° 29′.

TERNBERG, a mountain of Auftria, near the river Enns; 6 miles S. of Steyr.

TERNEUSE, a town and fortrefs of Flanders, fituated on the W. branch of the Scheld, called the "Hondt," begun by the count of Hohenloe, lieutenant of the prince of Orange, in the year 1583, afterwards augmented by the States: the fortifications have been fince deftroyed; 12 miles S.E. of Flufhing.

TERNI, a town of the Popedom, in the duchy of Spoleto, fituated between two arms of the Nera, and, therefore, anciently called "Interamnium," or "Interamna." It is well built, and the fee of a bifhop, immediately fubject to the pope. Its greateft trade confifts in oil, befides which it alfo reaps confiderable advantage from its excellent vineyards. This was the birth-place of the emperors Tacitus and Florianus, and of Tacitus the famous hiftorian. Between fix and feven Italian miles from Terni, to the N.W. clofe by the little town of Cefi, is Mount Eolo, remarkable for its cool breezes, which, efpecially in fummer, iffue from the chafms and crevices in the rocks of this mountain; 14 miles S.S.W. of Spoleto. N. lat. 2° 34′. E. long. 12° 37′.

TERNIER, a town of France, in the department of the Leman; 5 miles S.S.W. of Geneva.

TERNOIS, Le, a river of France, which runs into the Cauche, near Hefdin.

TERNOSKAIA, a town of Ruffia, in the country of the Coffacs, on the Don; 136 miles E.N.E. of Azoph.

TERNOVA, a town of European Turkey, in Bulgaria. This town was anciently one of the ftrongeft in the country, and the refidence of the princes; at prefent it is thinly inhabited, and the fortifications are ruined. It is the refidence of an ecclefiaftic, who is called the archbifhop of Bulgaria; 95 miles E. of Sophia. N. lat. 43°. E. long. 25° 24'.—Alfo, a town of European Turkey, in Theffaly; large and commercial; on the Peneus; 5 miles W.N.W. of Lariffa.

TERNSTROEMIA, in *Botany*, was fo called by Linnæus at the fuggeftion of Mutis, in memory of one of the pupils of the former, named Ternftroem, who having undertaken a voyage to China, in 1745, died at Poulicandor, at an early age. His illuftrious teacher has not, as in other inftances, given us any account of the voyage, difcoveries, or talents of this unfortunate young man, who, though not one of his favourite pupils, deferves commemoration as a martyr to fcientific refearch.—Linn. Suppl. 39. Schreb. 347. Willd. Sp. Pl. v. 2. 1128. Mart. Mill. Dict. v. 4. Swartz Prodr. 81. Juff. 262. (Cleyera; Thunb. Jap. 12. Nov. Gen. 68. Juff. 433. Taonabo; Aubl. Guian. 569. Tonabea; Juff. 262. Tanabea; Lamarck Illuftr. t. 456.)—Clafs and order, *Polyandria Monogynia*. Nat. Ord. akin to *Thea* and *Camellia*. Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, orbicular, concave, rather unequal fegments, with two fmaller ones clofely applied to its bafe, all permanent and coriaceous. *Cor.* of one petal, bell-fhaped, in five deep, orbicular, concave, emarginate fegments, longer than the calyx, without any tube. *Stam.* Filaments numerous, awl-fhaped, fhorter than the corolla, and inferted into its bafe in a double row; anthers linear, erect, the length of the filaments. *Pift* Germen fuperior, roundifh; ftyle cylindrical, as long as the ftamens; ftigma capitate. *Peric.* Berry dry, ovate, fmooth, of two cells. *Seeds* about eight, convex on one fide, flat on the other.

Eff. Ch. Corolla bell-fhaped, in five deep fegments, without a tube. Calyx in five deep fegments, with two fmaller at the bafe. Berry dry, of two cells.

1. T. *meridionalis*. Mexican Ternftroemia. Linn. Suppl. 264. Willd. n. 1.—Leaves obovate, obtufe, emarginate, entire. Flower-ftalks axillary, compreffed, recurved. Two outer fegments of the calyx orbicular, fharply keeled.—Gathered by Mutis in Mexico and New Granada. A tree, determinately branched; the branches thick, rigid, leafy, nearly round, with a fmooth grey bark. *Leaves* alternate, an inch or rather more in length, on fhort, thick, channelled, purplifh footftalks, obovate, or nearly elliptical, peculiarly rigid and coriaceous, fingle-ribbed, fmooth, with a thick fomewhat revolute margin; their upper furface often dotted with either prominent or depreffed points; the under purplifh or rufty, efpecially when young. *Stipulas* none. *Flower-ftalks* numerous, axillary, folitary, half the length of the leaves, very thick and rigid, two-edged, brown or purple, curved downwards, deftitute of pubefcence, but, in the dried plant at leaft, wrinkled and uneven. *Flowers* larger than a hawthorn-bloffom, white. The two fmaller external fcales of the *calyx* furnifhed with a fharp keel, ending in a minute point; the reft without any keel, thin and membranous at the edge; all fmooth, orbicular, coriaceous, permanent. *Corolla* occafionally with fix fegments, at firft globofe, then bell-fhaped. *Berry* dry, deftitute of valves. *Seeds* filky, deep red. Such is the plant of Mutis. We have no means of afcertaining whether the Weft Indian one, defcribed by Swartz in his *Obfervationes*, be the fame or not; but he fays the *flower-ftalks* are terminal, nor does he advert to their clumfy two-edged figure, fo different from the reft of the fpecies, that it could fcarcely have efcaped his notice.

2. T. *elliptica*. Elliptical Ternftroemia, or Rottenbane. Swartz Ind. Occ. 929. Willd. n. 2. Vahl Symb. v. 2. 61.—Leaves obovate, obtufe, entire. Flower-ftalks lateral, elongated, nearly thread-fhaped. Outer fegments of the calyx ovate, acute, bluntly keeled.—Native of the Weft Indies, on the Sulphur mountains of Montferrat and Guadeloupe, as well as in St. Vincent's. It is faid to be the pretended Jefuit's bark, mentioned by Labat. This is a *fhrub* with ftout, round, fmooth, difperfed or clultered *branches*, leafy towards their extremities. *Leaves* like the laft, but twice as long, and not emarginate; their *footftalks* longer and more flender. *Flower-ftalks* an inch and half or two inches long, but flightly drooping or recurved, nearly round, not a quarter fo ftout as the laft, flightly fwelling upward, red or purplifh. *Flowers* rather larger than the foregoing, yellowifh-white, fome of them deftitute of a piftil. The fcales of the *calyx* are all pointed, the outer ones narrow and ovate, of a fmaller proportion than in *T. meridionalis*, and fometimes more than two.

3. T. *japonica*. Japan Ternftroemia. Thunb. Tr. of Linn. Soc. v. 2. 335. Willd. n. 4. (Cleyera japonica; Thunb. Jap. 224. Mokokf; Kæmpf. Am. Exot. 873. t. 774.)—Leaves obovato-lanceolate, obtufe, nearly entire. Flower-ftalks lateral, fomewhat angular. Outer fegments of the calyx triangular, pointed, flightly keeled.—Gathered by Thunberg, near Nagafaki in Japan, flowering in autumn. This is a *tree*, fmooth in every part. Specimens fent us by the finder are fo very nearly akin to the two foregoing fpecies, that it is hard to eftablifh a fpecific difference between them. The *leaves* of the Japan plant however are rather more lanceolate, and their margin is fometimes, not conftantly, crenate towards the point. Their furface is quite fmooth, not vifibly dotted. The *flower-ftalks*, about an inch long, are fcattered on the branches, below the leaves, but flightly recurved, ufually triangular, not compreffed. *Flowers* white, fcarcely fo large as in *T. meridionalis*. *Style* fhort and thick. *Berry* the fize of a currant, red, pointed, with a white, fweet, fubaftringent pulp, and, according to Kæmpfer, only one pellucid *feed*.

4. T. *punctata*. Dotted-edged Ternftroemia. Swartz Prodr. 81. Willd. n. 3. (Taonabo punctata; Aubl. Guian. 571. t. 228.)—Leaves elliptic-oblong, dotted at the edge. Flower-ftalks axillary, elongated, nearly thread-fhaped. Segments of the calyx all pointed.—Gathered by Aublet on the fides of the Serpent mountain in Guiana, bearing flowers and fruit in Auguft and September. A large *tree*, whofe *leaves* are bordered with minute glandular points, rough to the touch; their extremity ufually emarginate; their length about three inches. *Flower-ftalks* flender, about half as long as the leaf with its footftalk. *Stamens* about fixty. *Fruit* ovate, pointed, of five or fix cells. Aublet having feen it in an unripe ftate only, took it for a capfule, but Swartz afferts it to be a *berry*.

5. T. *dentata*. Toothed Ternftroemia. Swartz Prodr. 81. Willd. n. 5. (Taonabo dentata; Aubl. Guian. 569. t. 227.)—Leaves elliptical, pointed, ftrongly ferrated. Flower-ftalks lateral or axillary, fingle-flowered.—Gathered by Aublet, in the fame place as the preceding, and at the fame feafon. A *tree*, whofe trunk is twenty-five feet, or more, in

in height, and two in diameter, crowned with an ample tuft of fpreading branches. The *leaves* are four inches long, and an inch and half or two inches broad, thick, fmooth, tapering at each end, befet with tooth-like ferratures in the margin. *Footftalks* flender, an inch long. *Flower-ftalks* recurved, fcattered, hardly an inch in length. *Flowers* yellowifh, the fize of hawthorn. *Fruit* like the laft. The *bark* of the tree is ufed for tanning leather. The *wood* ferves inftead of tiles for houfes.

6. T? *corymbofa*. Corymbofe Ternftroemia?—Leaves oppofite, elliptical, pointed, entire. Panicle forked, corymbofe, many-flowered, terminal.—Native of Guiana. *Mr. Rudge*. This appears to be moft akin to the laft in the fhape and fize of its *leaves*, but differs in their entire margin, and oppofite infertion. The three-forked *panicle* is, moreover, a kind of inflorefcence unexampled in *Ternftroemia*, and the *calyx* wants the two fmall external fegments. All thefe circumftances induce a fufpicion of the genus, which we have not materials to clear up.

We cannot take leave of *Ternftroemia* without adverting to the mifchiefs which arife from the barbarous and unfettled principles of French nomenclature. Juffieu profeffes to adopt the uncouth names of Aublet, only till the genera of that author are better fettled; yet he has tried to foften down *Taonabo* into *Tonabea*, a needlefs change if the name were not to remain. Lamarck prefers *Tanabea;* fo our memories and our indexes would have become burthened with three names inftead of one, all intolerable to a claffical or literary botanift, if the genus had not happily been fuperfeded.

TEROE, in *Geography*, a town of Bengal; 25 miles E. of Ramgur.

TEROUANNE. See THEROUANNE.

TEROWA, a town of the ifland of Junkfeilon, near the eaft coaft; the ufual refidence of a Siamefe governor or viceroy. Here is a pagoda, with about twenty priefts. N. lat. 8° 13′.

TERPANDER, in *Biography*, and *Mufic of the Ancients*, one of the moft renowned muficians of antiquity. It is recorded in the Oxford Marbles, that he was the inventor of characters to exprefs mufical founds in the feveral genera; which event is placed about fix hundred and feventy years before the Chriftian era. Indeed all writers who mention the progreffive ftate of mufic in Greece, are unanimous in celebrating the talents of Terpander; but though there is fuch an entire agreement among them concerning the obligations which the art was under to this mufician in its infant ftate, yet it is difficult to find any two accounts of him which accord in adjufting the time and place of his birth. It does not, however, feem neceffary to lead the reader over hedge and ditch with chronologers, after a truth, of which the fcent has fo long been loft. The Oxford Marbles, which appear to us the beft authority to follow, tell us, in exprefs terms, that he was the fon of Derdeneus of Lefbos, and that he flourifhed in the 381ft year of thefe records; which nearly anfwers to the 27th olympiad, and 671ft year B. C. The Marbles inform us likewife, that "he taught the nomes, or airs, of the lyre and flute, which he performed himfelf upon this laft inftrument, in concert with other players on the flute." Several writers tell us that he added three ftrings to the lyre, which before his time had but four; and in confirmation of this, Euclid and Strabo quote two verfes, which they attribute to Terpander himfelf.

"The tetrachord's reftraint we now defpife,
The feven-ftringed lyre a nobler ftrain fupplies."

If the hymn to Mercury, which is afcribed to Homer, and in which the feven-ftringed lyre is mentioned, be genuine, it robs Terpander of this glory. The learned, however, have great doubts concerning its authenticity. But if the lyre had been before his time furnifhed with feven ftrings in other parts of Greece, it feems as if Terpander was the firft who played upon them at Lacedæmon. The Marbles tell us that the people were offended by his innovations. The Spartan difcipline had deprived them of all their natural feelings; they were rendered machines; and whether Terpander difturbed the fprings by which they ufed to be governed, or tried to work upon them by new ones, there was an equal chance of giving offence. The *new ftrings*, or *new melodies*, and *new rhythms*, upon the old ftrings, muft have been as intolerable to a Lacedæmonian audience, at firft hearing, as an organ, and cheerful mufic would have been, to a Scots congregation fome years ago, or would be at a Quaker's meeting now. "It is not at all furprifing," fays Alcibiades, "that the Lacedæmonians feem fearlefs of death in the day of battle, fince death would free them from thofe laws which make them fo wretched."

Plutarch, in his "Laconic Inftitutions," informs us, that Terpander was fined by the ephori for his innovations. However, in his "Dialogue on Mufic," he likewife tells us, that the fame mufician appeafed a fedition at Sparta, among the fame people, by the perfuafive ftrains which he fung and played to them on that occafion. There feems no other way of reconciling thefe two accounts, than by fuppofing that he had, by degrees, refined the public tafte, or depraved his own to the level of his hearers.

Among the many fignal fervices which Terpander is faid to have done to mufic, none was of more importance than the notation that is afcribed to him for afcertaining and preferving melody, which was before traditional, and wholly dependent on memory. The invention, however, of mufical characters has been attributed by Alypius and Gaudentius, two Greek writers on mufic, and, upon their authority, by Boethius, to Pythagoras, who flourifhed full two centuries after Terpander. It will be neceffary therefore to tell the reader upon what grounds this ufeful difcovery has been beftowed upon him.

Plutarch, from Heraclides of Pontus, affures us that Terpander, the inventor of nomes for the cithara, in hexameter verfe, "fet them to mufic," as well as the verfes of Homer, in order to fing them at the public games. And Clemens Alexandrinus, in telling us that this mufician wrote the laws of Lycurgus in verfe, and "fet them to mufic," makes ufe of the fame expreffion as Plutarch, which feems clearly to imply a *written melody*. See *Mufical* GAMES.

TERPELING, in *Geography*, a town of Thibet; 8 miles S.W. of Painom Jeung.

TERPENTARIA, in *Botany*, a name ufed by fome authors for the betonica aquatica, or great water-figwort, called *water-betony*.

TERPILLUS, in *Ancient Geography*, a town of Macedonia, in Mygdonia. Ptolemy.

TERPONUS, a town of Illyria, belonging to the Japodes, of which Cæfar took poffeffion, according to Appian.

TERPSICHORE, the *Jovial*, as her name imports, in *Mythology*, the name of one of the nine *Mufes*, (which fee.) This mufe is reprefented on medals and other monuments, by the flutes which fhe holds in her hands.

TERRA, in *Geography*. }
TERRA, in *Chemiftry*. } See EARTH.
TERRA, in *Natural Hiftory*. }

Terra *Alana*, a name given to the yellowiſh-white tripoli.

Terra *Adamica*, a name given to the alkaline red mould. See Adamic *Earth*.

Terra *Armenia*. See Bole.

Terra *de Baira*, the name given by ſome to an earth of a white colour, found about Baira, near Palermo.

It is eſteemed a very great medicine in the cure of malignant fevers, and in the ſtopping of hæmorrhages of all kinds. The powder of it is commonly ſold in Italy under the name of Claramont-powder; a name it obtained from a perſon who firſt found out its virtues, and communicated them to the world in a treatiſe expreſsly written on the ſubject. Boccone, Muſ. de Fiſic.

Terra *Carioſa*. See Tripoli.

Terra, *Chio*, in the *Materia Medica of the Ancients*, an earth of the marle kind, found in the iſland of Chio, and given internally as an aſtringent; but its chief uſe among them was as a coſmetic, the ladies eſteeming it the fineſt of all things for clearing the ſkin, and ſmoothing wrinkles. What title it has to theſe qualities the world has not of late ages inquired into; but the ſubſtance is ſtill in being, and to be had in any quantities from the ſame place. And the deſcriptions Dioſcorides and Galen have left us of it are ſo accurate, that there is not the leaſt room to doubt but that the earth now found there, was the very kind they uſed. It is a denſe compacted earth, yet very ſoft, and of a texture eaſily diſunited and broken by water.

Terra *Cilicia*. See Cilicia.

Terra *Cimolia*. See Cimolite.

Terra *Cimolia Purpuraſcens*. See Soap-*Earth*.

Terra *Colonienſis*. See Cologne-*Earth*.

Terra *Damnata*. See Caput *Mortuum*.

Terra *Foliata Tartari*, *foliated earth of tartar*, is a name improperly given to a neutral acetous ſalt, with a baſis of fixed vegetable alkali; or to a combination of the acid of vinegar, ſaturated with the alkali of tartar, or of other vegetable matter. This ſalt has alſo been called *regenerated tartar*, becauſe the alkali of tartar is united with an acid, which is in ſome reſpects ſimilar to the acid of tartar, but is in others very different.

The terra foliata is made by pouring upon a quantity of alkaline ſalt of tartar, in a glaſs cucurbit, a ſufficient quantity of good diſtilled vinegar, at different times, to ſaturate all the alkali, or even a little more than is neceſſary for that purpoſe, till the effervеſcence entirely ceaſes. This ſaturated liquor is to be filtrated and evaporated to dryneſs, with a gentle heat. The dry ſalt thus obtained is to be diſſolved in ſpirit of wine, and the ſolution again evaporated to dryneſs; by which means a ſalt is obtained more or leſs white, of a ſilky appearance, and compoſed of ſmall ſcales or leaves, whence it has been called *foliata*. When the ſalt is dried, and while it is hot, it muſt be ſhut up in a well-cloſed bottle, becauſe it quickly becomes moiſt by expoſure to air.

When diſtilled vinegar is poured upon ſalt of tartar, little or no effervеſcence is made at firſt, becauſe a part of the alkaline ſalt employed is generally cauſtic, or deprived of its gas, which part unites with the acid preferably to the mild part of the alkali, and abſorbs any gas that is extricated from the latter part; and, therefore, till all the cauſtic part of the alkali be nearly ſaturated, little or no effervеſcence can happen. But when more vinegar is added, the effervеſcence becomes ſo conſiderable, that ſome of the liquor will, without care, flow over the veſſel. This effervеſcence is occaſioned by a large quantity of air that is diſengaged during the ſaturation. When the ſaturation is advanced to a certain degree, the effervеſcence diminiſhes; but the combination of the laſt portions of the acid and alkali may be facilitated by frequently agitating the liquor, which will renew the effervеſcence. The taſte of the foliated earth is ſharp, pungent, a little cauſtic, and partaking at the ſame time of the taſte of vinegar and that of fixed alkali. It is ſoluble in ſpirit of wine, and may be decompoſed merely by the action of fire, and from it may be obtained by diſtillation, a very penetrating and concentrated radical vinegar. It is little uſed except in medicine. Macquer's Chem. Dict.

Preparations of this kind are given in doſes of ten or twenty grains as mild aperients, and to a drachm or two as purgatives and diuretics. Lewis.

Terra *Goltbergenſis*. See Goltbergensis *Terra*.

Terra *Japonica*. See Japan *Earth*, and Catechu.

Terra *Lemnia*. See Lemnian *Earth*.

Terra *Lignicenſis*. See Lignicensis *Terra*.

Terra *Livonica*. See Livonica *Terra*.

Terra *Melia*. See Melia *Terra*.

Terra *Melitenſis*. See Melitensis *Terra*.

Terra *Merita*, in the *Materia Medica*, a name given by ſome authors to the curcuma, or turmeric-root.

It is from a falſe pronunciation of this name, *terri merit*, that the Engliſh turmeric has its origin.

Terra *Miſcella*. See Thraustomicthes.

Terra *Noceriana*. See Noceriana.

Terra *Samia*. See Samia *Terra*.

Terra *Seleneuſiaca*. See Seleneusiaca.

Terra *Sigillata*. See Sigillata.

Terra *Sigillata Magni Ducis*. See Etrusca *Terra*.

Terra *Sigillata Fuſca*, a bole of a beautiful brown colour, found in Germany, England, and America.

It is of a denſe texture, makes no fermentation with the ſtrongeſt acids, and if thrown into water, it ſoon ſeparates into a number of thin flakes.

The Germans give it in fluxes and malignant fevers, being an excellent aſtringent, and worthy to be introduced into our ſhops.

Terra *Sileſiaca*, *Sileſian Earth*, a fine aſtringent bole, called by ſome authors *axungia ſolis*.

It is very heavy, of a firm compact texture, and in colour of a browniſh-yellow. It breaks eaſily between the fingers, and does not ſtain the hands, is naturally of a ſmooth ſurface, and is readily diffuſible in water, and melts freely into a butter-like ſubſtance in the mouth; it leaves no grittineſs between the teeth, and does not ferment with acid menſtrua. Theſe are the characters by which it is known from all other earths of a like colour; it is found in the perpendicular fiſſures of rocks near the gold-mines at Strigonium, in Hungary, and is ſuppoſed to be impregnated with the ſulphur of that metal. It is, however that be, a good aſtringent, and better than moſt of the boles in uſe. Hill.

The terra Sileſiaca is alſo called *terra ſigillata Strigonienſis*.

Terra *Sinopica*. See Sinopica *Terra*.

Terra *Solis*, a name given by the German naturaliſts to a kind of black ſpungy earth, ſomewhat approaching to the nature of that Engliſh black earth which we call *kellow*, but containing gold. It is not properly an ore of gold, but is an earth into which ſome ſmall particles of gold have been waſhed from ſome other place, and there detained. A good microſcope will diſcover theſe particles in the richer pieces of the earth, and they are bright and pure, though very ſmall: the earth is found in fiſſures of the other ſtrata, not in any beds or ſtrata of itſelf. It is not to be had in any great quantity, nor does it contain any large portion of gold.

Terra *Strigonienſis*. See Strigoniensis *Terra*.

TERRA *Turcica*. See TURCICA *Terra*.

TERRA *Virgine Aurea*, in *Natural History*, the name of a medicinal earth, mentioned by Boccone.

It is found at a place called Sancto Paolo, in the state of Modena; and is thence sent to Venice, and many other places, where it is esteemed a very famous medicine.

Its great use is in hæmorrhages of all kinds; but it is also given with success in malignant fevers. Boccone, Mus. de Fisic.

TERRA *Viridis*. See TERRE *Verte*.

TERRA *Umbri*. See UMBER.

TERRA *Zoica*, a name given to the alkaline red mould, called also Adamic earth.

TERRA *Petita*, in *Law*. See SUMMONS.

TERRA, in our *Ancient Law-Books*, occurs in the sense of land, or ground, joined with divers additions; as,

Terra Normannorum, the lands of such Norman noblemen as were forfeited to the crown, by the owners taking part with the French king against Henry III. *Terra frusca*, such land as had not been lately ploughed. *Terra gilliflorata*, land held by the tenure of paying a gilliflower yearly. *Terra vestita*, land sown with corn, and the crop still remaining thereon. *Terra testamentalis*, land held free from feudal services, and devisable by will. *Terra culta*, land that is tilled and manured, in contradistinction to *terra inculta*. *Terra affirmata*, land let out to farm. *Terra dominica*, or *indominica*, demesne land of a manor. *Terra hydata*, was land subject to the payment of hydage. *Terra lucrabilis*, land that may be gained from the sea, or enclosed out of a waste or common to particular uses. *Terra wainabilis*, tillage-land. *Terra warecta*, fallow-land. *Terra boscalis*, wood-land, &c.

TERRA *Extendenda*, is a writ directed to the escheator, &c. ordering him to inquire and find out the true yearly value of any land, &c. by the oath of twelve men, and certify the extent in chancery.

TERRA or *Tierra Australis del Espiritu Santo*, in *Geography*, an island in the South Pacific ocean, and the most westerly as well as the largest of those called *New Hebrides*: discovered by Quiros, and visited by captain Cook in the year 1774; 22 leagues long, 60 miles in circuit, and 12 in breadth. The land of it, especially the west side, is exceedingly high and mountainous: and in many places the hills rise directly from the sea. Except the cliffs and beaches, every other part is covered with wood, or laid out in plantations. Besides the bays of St. Philip and St. Jago, the isles which lie along the south and east coast cannot, in the opinion of captain Cook, fail of forming some good bays or harbours. S. lat. 14° 40′ to 15° 40′. E. long. 166° 45′ to 167° 32′.

TERRA *Firma* is sometimes used for a continent, in contradistinction to islands.

Thus Asia, the Indies, and South America, are usually distinguished into terra firmas and islands.

TERRA *Firma*, in a more restricted sense, denotes an immense extent of country under the authority and government, direct or indirect, of the crown of Spain, comprehending several extensive provinces, and three audiences, fixed at Panama, Quito, and Santa Fé de Bogota: the large provinces are Terra Firma Proper, Popayan, Quito, and New Granada, all of which are again subdivided into several smaller provinces or jurisdictions.

TERRA *Firma*, or *Tierra Firmé*, in a still more confined sense, comprises three districts in the viceroyalty of New Granada, *viz.* Darien, Panama or Tierra Firmé Proper, and Veragua.

TERRA *Firma*, or *Tierra Firmé*, *Proper*. See PANAMA.

TERRA *del Fuego*, a large island, separated from the southern extremity of America by a narrow sea, called the "Straits of Magellan:" so named from the volcanoes observed on it. Capt. Cook was the first navigator who had the honour, from a series of the most satisfactory observations, beginning at the W. entrance of the Straits of Magellan, and carried on with unwearied diligence round this island, through the strait of Le Maire, to construct a chart of the southern extremity of America. The south-west coast of Terra del Fuego, says this distinguished navigator (Second Voyage, vol. ii. p. 199, &c.) "with respect to inlets, islands, &c. may be compared to the coast of Norway; for I doubt if there be an extent of three leagues where there is not an inlet or harbour, which will receive and shelter the largest shipping. The worst is, that till these inlets are better known, one has, as it were, to fish for anchorage. There are several lurking rocks on the coast; but happily none of them lie far from land, the approach to which may be known by sounding, supposing the weather so obscure that you cannot see it. For to judge of the whole by the parts we have sounded, it is more than probable that there are soundings all along the coast, and for several leagues out to sea. Upon the whole, it is by no means the dangerous coast it has been represented. The currents between Cape Deseada and Cape Horn set from west to east, that is, in the same direction as the coast; but they are by no means considerable. To the east of the cape, their strength is much increased, and their direction is north-east to Staten Land. They are rapid in Strait le Maire, and along the south coast of Staten Land, and set like a torrent round Cape St. John, where they take a north-west direction, and continue to run very strong both within and without New Year's Isles. While we lay at anchor within this island, I observed that the current was strongest during the flood; and that on the ebb its strength was so much impaired, that the ship would sometimes ride head to wind, when it was at west and west-north-west. This is only to be understood of the place where the ship lay at anchor; for at the very time we had a strong current setting to the westward, Mr. Gilbert found one of equal strength near the coast of Staten Land setting to the eastward; though probably this was an eddy current or tide."

Most writers who have mentioned the island of Terra del Fuego, describe it as destitute of wood, and covered with snow. The latter circumstance may occur (see Hawkesworth's Voyages of Cook, &c. vol. ii.) in winter. And by those who saw it at that season, it might be conceived to be without wood. Lord Anson was there in the beginning of March, answering to our September; but Capt. Cook was there in the beginning of January, corresponding to our July; and thus we may account for their different statements. We fell in with it, says Cook, about 21 leagues W. of the strait of Le Maire, and trees were visible with glasses; and though upon approaching it patches of snow were discoverable, yet the sides of the hills and the sea-coast appeared to be covered with a beautiful verdure. The hills are lofty, but not mountainous, though their summits are quite naked. The soil in the vallies is rich, and of a considerable depth; and at the foot of almost every hill there is a brook, the water of which has a reddish hue, but it is not ill-tasted. The most remarkable land in Terra del Fuego is a hill, in the form of a sugar-loaf, which stands on the W. side, not far from the sea; and the three hills, called the "Three Brothers," about nine miles W. of Cape St. Diego, the low point that forms the entrance of the strait of Le Maire. (See *Le* MAIRE.) In his

his second voyage, Capt. Cook, desirous of coasting the S. side of Terra del Fuego, round Cape Horn, to the strait of Le Maire, reached the W. coast of the island Dec. 17, 1774, and having continued to range it till the 20th, came to an anchor in a place which he called "Christmas Sound." Through the whole course of his navigations, he had never seen so desolate a coast. It seems to be entirely composed of rocky mountains, without the least appearance of vegetation. These mountains terminate in horrible precipices, the craggy summits of which spire up to a vast height; so that scarcely any thing in nature can appear with a more barren and savage aspect than the whole of the country. But barren and dreary as the land is about Christmas Sound, it was not wholly destitute of accommodations. Near every harbour our navigator found fresh water, and wood for fuel. The country abounds likewise with wild fowl, and particularly with geese: which, with their Madeira wine, enabled them to keep a cheerful Christmas. The inhabitants of Terra del Fuego were found by Capt. Cook to be of the same nation which he had formerly seen in Success Bay, and the same with those denominated by M. de Bougainville "Pecharas." They are a little, ugly, half-starved, beardless race, and go almost naked: but it is their own fault that they are not better clad, as nature has furnished them with ample materials for that purpose. By lining their seal-skin cloaks with the skins and feathers of aquatic birds, by making the cloaks themselves larger, and by applying the same materials to different parts of clothing, they might render their dress much more warm and comfortable. But while they are doomed to exist in one of the most inhospitable climates on the globe, they have not sagacity enough to avail themselves of those means of adding to the conveniencies of life, which Providence has put into their power. The captain, after having witnessed many varieties of the human race, pronounces the Pecharas to be the most wretched. Those on the S. are said to be uncivilized, treacherous, and barbarous; while those on the opposite side are represented as simple, affable, and perfectly harmless. The tents which they inhabit are made of poles, disposed in a conical form, covered with skins, or the bark or leaves of trees. The country, though barren, abounds with a variety of unknown plants, for exciting the curiosity of the botanist. The extent of Terra del Fuego, and consequently of the straits of Magellan, was ascertained by Cook to be less than had been laid down by the generality of navigators: nor was the coast, upon the whole, found to be so dangerous as it has been represented: the winter was also remarkably temperate. The sea-lions and sea-bears, the shags and penguins on the coast, are abundant, and intermix, like domestic cattle and poultry in a farm-yard, without attempting to molest one another. Eagles and vultures were seated on the hills among the shags in perfect tranquillity. Sir Joseph Banks, Dr. Solander, and some others, landed here in the month of January 1769, which is the time of summer in that part of the globe, notwithstanding which, two of the company fell a sacrifice only by sleeping one night, and Dr. Solander himself hardly escaped. S. lat. 52° 30′ to 55° 35′. W. long. 51° 20′ tc 58°.

Terra *Magellanica*. See Patagonia.

Terra *Niva*, a bay in Hudson's Bay. N. lat. 62° 4′. W. long. 67°.

Terra *dos Fumos*, a tract of country on the S.E. of Africa, N. of Natal.

Terra *Nova*, a sea-port town of Sicily, in the valley of Noto, situated in a gulf or bay of the Mediterranean, founded about the middle of the 13th century, by the emperor Frederick II. near the scite of the ancient Gela. The number of inhabitants is about 700; 50 miles W. of Syracuse. N. lat. 37°. E. long. 14° 10′.—Also, a river of Sicily, which runs into the sea on the S. coast. N. lat. 37°. E. long. 14° 10′.

Terra *Nuova*, a town of the island of Sardinia, situated in a bay of the Mediterranean, at the bottom of which is the harbour, built on the ruins of Civita, an ancient episcopal town; 57 miles E.N.E. of Sassari. N. lat. 40° 52′. E. long. 9° 40′.—Also, a town of Etruria; 14 miles N.W. of Arezzo.

Terra *del Palucci*, a town of Sicily, in the valley of Mazara, on the scite of the ancient Pelinus.

Terra *Vecchia*, a town of Naples, in Calabria Citra; 2 miles S. of Cariati Nuovo.

Terra *à Terra*. Gallies and other vessels are said to go terra à terra, when they never go far from the coast.

The phrase is also applied, in the manege, to horses that make neither curvets nor balotades, but run smoothly on the ground in a pressed gallop, only making little leaps or risings with the fore-feet.

The gallop is the foundation of the terra à terra, for in these two motions the principle of the action is the same, since the terra à terra is only a shortened gallop with the croupe in, and the haunches following in a close and quick time. And as the mezair is higher than the action of terra à terra, and lower than that of curvets, it may be concluded that the terra à terra is the foundation of the mezair, as well as of curvets.

In the terra à terra the horse should be more together than in the gallop, that he may mark his time and cadence more distinctly; although in a true terra à terra there are no times to be marked, for it is rather a gliding of the haunches, which comes from the natural springs in the limbs of a horse.

When a horse works terra à terra, he always ought, as in the gallop, to lead with the legs that are within the volte, his two fore-feet being in the air, and the moment they are coming down, his two hind feet following. The action of the gallop is always one, two, three, and four; the terra à terra is performed upon two lines and in two times.

To work a horse terra à terra upon large circles, take care to keep the body straight, steady, and true in the saddle, without leaning to one side or the other. Lean upon the outward stirrup, and keep the outward leg nearer the side of the horse than the other leg, taking care to do it so as not to be perceived. If you go to the right, keep your bridle-hand a little on the outside of the horse's neck, turning your little finger up without turning your nails at the same time; although, if need be, you must turn them in order to make the inner rein work which passes over the little finger. Keep your arms and elbows to your hips; by this means you will assure and confine your hand, which ought to accompany, and, as it were, run along the line of the circle with the horse. Berenger's Art of Horsemanship, vol. ii. c. 17.

The term is also applied by the French to dancers, who cut no capers, nor scarcely quit the ground.

And hence, also, it is figuratively applied to authors, whose style is low and creeping.

TERRACE, in *Gardening*, is a sort of raised bank of earth, &c. regularly formed in an oblong manner to any length, broad enough to admit of a spacious level walk at top, and elevated considerably above the level of the general surface; having the sides uniformly sloped, and laid with grass, and the top formed into a flat or level, sufficiently broad

broad for a grafs or gravel walk of proportionable width; defigned in gardens as a high, airy walk, to command a better profpect of the adjacent places around, within and without the garden occafionally, as well as to enjoy the frefh air in fummer more freely. In the former ftyle of laying out gardens, it was confidered as very ornamental, but is at prefent much in difufe.

It may be remarked, that the height of a terrace-walk may be more or lefs, as the fituation admits, as from one foot to one or two yards, or even three or four yards or more in particular fituations; and where there is plenty of earthy materials, rubbifh, &c. to form it, allowing breadth in proportion, from five to ten or twenty feet or more, and extended to any length required. They are fometimes formed on fome naturally high rifing ground, to fave as much trouble as poffible in bringing ftuff from a diftance; and fometimes raifed wholly of forced materials. But the fituation for a terrace may be varied as the natural fituation of the place may require.

In refpect to form, they fhould always be broader at the bafe than the top, and extend lengthways to any diftance required; having the fides regularly floped, of more or lefs acclivity, as the width, height, and fituation admit. Sometimes both fides are floped, and fometimes only one fide, the other perpendicular, and faced with a fubftantial wall, &c. or formed againft the fide of a hill, or fome naturally rifing ground, being finifhed always broad enough at top to admit of a proper walk. In fome naturally elevated fituations, terraces are fometimes formed one above another, in two or more ranges, each having its feparate fide flopes, and elevated walk; in all of which the flopes are to be neatly laid with grafs, and the walk at top occafionally of grafs or gravel.

The entrances leading to terrace-walks were formerly fometimes formed by an eafy acclivity of a grafs or gravelled flope, and fometimes by a grand flight of ftone fteps. Where a rifing ground of confiderable elevation naturally prefents itfelf in a proper fituation, it is an eligible opportunity for forming a terrace with the leaft expence and trouble, on account of its not requiring the addition of fo much earth and rubbifh, as when raifed entirely on a perfect level, wholly of made earth. Where there are any excavations of ground intended to form ha-has, pieces of water, &c. the excavated earth may be employed in forming terraces, &c.

In the bufinefs of forming a terrace, the bafe muft be ftaked out wider than the intended width at top for the walk, in order to admit of the afcent of flopes being moderate. And the whole of the made earth and rubbifh muft be well rammed and rolled down from time to time as it is applied, in order to render the whole equally firm, that it may not fettle irregularly after being finifhed. The flopes may either be laid with turf, or fown with grafs-feeds; but the firft is much the beft method, where it can be employed. See Grass *Ground*.

Terraces are now but little attended to, and, of courfe, but feldom employed in modern ornamental gardening, as they are moftly confidered as having a too ftiff and formal appearance, and as not conftituting that fort of neatnefs and tafteful elegance, which is fo much efteemed and admired at prefent in all forts of works of the garden kind.

Terrace, *Counter*, is a terrace raifed over another to join two grounds, or raife a parterre.

Terrace is alfo applied to the roofs of houfes that are flat, and on which one may walk; as alfo to balconies that project.

The terrace is properly the covering of a building which is in platform; as that of the periftyle of the Louvre, or that of the obfervatory, paved with flint and mortar. All the buildings of the Oriental nations are covered with terraces, to take the frefh air on, and even to lie on. See Pavement *of Terrace*.

Terrace, or *Terras*, ufed for mortar. See Tarrace.

TERRACINA, in *Geography*, a town of the Popedom, in the Campagna di Roma, fituated in a very fruitful but marfhy country, which makes the air unwholefome. This town was anciently the capital of the Volfci, and named Anxur. The Greeks called it Trachyna, corrupted into Terracina. In the year of Rome 348, it was taken and plundered by Fabius Ambuftus; and in 424 was made a Roman colony. Being built on a rock, in the reign of Tiberius 20,000 perfons were killed by the fall of a theatre. It is now a poor place. It had once a harbour: but that is choaked up; near Terracina are confiderable fragments of the Via Appia, made from Rome to Capua by Appius Claudius Coccus, and begun by him while cenfor, in the year of Rome 440: this road was paved with hard ftone of various fizes, but uniformly twelve inches in thicknefs; and was wide enough for two carriages; 47 miles S.E. of Rome. Near this place was a fountain of Neptune, the water of which was faid to be fatal.

TERRADEGLIAS, or Terradellas, Domenico, in *Biography*, a native of Barcelona, in Spain; but who went early into Italy, where he ftudied mufic at Naples under Durante, as an accomplifhment; but was reduced, by accidents in his family, to practife it as a profeffion.

He began to flourifh about 1739, when he compofed the opera of "Aftarto," and part of "Romolo," in conjunction with Latilla, for the Teatro delle Dame, at Rome.

In the latter end of the year 1746 he came to England, where he compofed two operas, "Mithridates" and "Bellerophon." But unfortunately for the compofer, none of the fingers of this time ftood high in the favour of the public. Yet his opera of "Mitridate," we well remember, received much applaufe, as mufic, diftinct from what was given to the performers. And his compofitions, when executed in Italy by fingers of the firft clafs, acquired him great reputation.

Befides the favourite fongs in the two operas juft mentioned, which are printed by Walfh, Terradellas himfelf, while he was in England, publifhed a collection of twelve Italian airs and duets in fcore, which he dedicated to lady Chefterfield. In thefe he feems lefs mafterly and original than in his other productions that have come to our knowledge. In the fongs he compofed for Reginelli, a very learned finger in ruin, we find boldnefs and force, as well as pathos. And fome *arie di bravura* of his compofition, for the celebrated tenor finger Babbi, at Rome, abound with fire and fpirit. If his productions are compared with thofe of his contemporaries, his writings, in general, muft be allowed to have great merit; though his paffages now feem old and common. This compofer having fpent his youth in Catalonia, was not regularly initiated into the myfteries of counterpoint in any Neapolitan converfatorio, having been placed under Durante, for a fhort time, only as a private fcholar; and we think we can fometimes difcover in his fcores, through all his genius and elegance of ftyle, a want of ftudy and harmonic erudition.

Terradellas was remarkable, not only for attending, in every fituation of the finger, to the fpirit of the drama which he had to compofe, but for giving good mufic to bad fingers, and not *under*-writing, as Mr. Bayes calls it, the inferior parts of his theatrical pieces. Indeed, it has always appeared to us, that an exquifite finger who can command attention

attention by the mere tone of his voice, and who requires only a *canevas*, or outline, to colour at his pleasure, is in less want of artificial and captivating composition, than an ordinary singer, who is neither possessed of voice nor taste sufficient to interest the audience. And Terradellas seems to have written all his songs for performers of abilities; for his airs are never made easy and trivial in order to spare the singer. Jomelli's pen always flowed with this spirit: for he never rejected a passage that presented itself, because it would be difficult and troublesome in the execution; but this freedom of style, twenty years ago, might be more safely practised than at present: for it is well known, that a company of singers is now reckoned good, in Italy, if the two first performers are excellent; and an opera is sure to please if two or three airs and a duet deserve attention; the audience neither expecting nor attending to any thing else. And the managers, who find this custom very convenient, take care not to interrupt play or conversation by the useless and impertinent talents of the under-singers; so that performers of the second or third class are generally below mediocrity.

He died at Rome in 1751, of grief and mortification, for the failure of an opera which he had composed with more care and hopes of success than usual.

TERRÆ *Ager*, *Amittere*, *Aratrum*, *Aratura*, *Denariatus*, *Legem*, *Lex*, *Librata*, *Obolata*, *Quadrantata*, *Quadrugata*, *Trinoda*, and *Uncia*. See the several articles.

TERRÆ *Filius*, *son of the earth*, a student in the university of Oxford, formerly appointed in public acts to make jesting and satirical speeches against the members of them, and to tax them with any growing corruption, &c.

TERRÆ *Oleum*. See OIL *of the Earth*.

TERRÆJEBIN. See TERENJABIN.

TERRAGE, or TERRAGIUM, anciently signified a service, in which a tenant or vassal was bound to his lord, to plough and reap the ground for him.

Others will have it to have been money paid for digging or breaking the ground in fairs and markets.

"Quieti sint de thelonio, pavagio, passagio, lastagio, tallagio, carvagio, prisagio, et terragio."

TERRAIGNOL, in the *Manege*, a horse that cleaves to the ground, that cannot be made light upon the hand, that cannot be put upon his haunches, that raises his fore-quarters with difficulty, that is charged with shoulders, and, in general, one whose motions are all short, and too near the ground.

TERRAIN, is the manege ground, upon which the horse makes his piste, or tread.

TERRANTONA, in *Geography*, a town of Spain, in Aragon; 8 miles S.E. of Ainsa.

TERRANUOVA, a town of Naples, in Calabria Citra; 9 miles N. of Bisignano.

TERRAON, or TORRAON, O, a town of Portugal, in Alentejo; 24 miles N.W. of Beja.

TERRAPOUR, a town of Hindoostan, in Baglana; 32 miles N. of Basseen.

TERRAQUEOUS, compounded of *terra* and *aqua*, *earth* and *water*, an epithet given to our globe or earth, considered as consisting of land and water, which together constitute one mass.

Some philosophers, particularly Dr. Burnet, charge the frame and fashion of the terraqueous globe as rude, unartful, and disorderly, and conclude it highly absurd to suppose it came thus out of the hands of the Creator; and, therefore, have recourse to the deluge for making it thus.

But others can perceive much art and conveniency, even in this apparent disorder: Dr. Derham particularly observes, that the distribution of land and water is admirable; the one being laid over the other so skilfully through all the world, that there is a just equipoise or balance of the whole globe. Thus the Northern ocean balances the Southern, and the American continent is a counterpoise to the European, African, and Asiatic.

And what some may object, that the waters occupy too great a part of the globe, which they imagine would be of more use if it were dry land, he obviates, by shewing that this would deprive the world of a due quantity of vapours and rain; for if the cavities which contain the sea and other waters were deeper, though the quantity of water were the same, and only the surface less and narrower, the evaporations would be so much the less, inasmuch as they are made from the surface, and consequently are in proportion to it.

TERRAR. See TERRIER.

TERRAS. See TERRACE and PAVEMENT.

TERRAS, *Marble*. See MARBLE.

TERRASSE, LA, in *Geography*, a town of France, in the department of the Isere; 13 miles N.N.E. of Grenoble.

TERRASSON, JOHN, *Abbé*, in *Biography*, a man of letters, was born at Lyons in 1670, and sent by his father, who was a very religious man, to the house of the Oratory in Paris; but the son, quitting this congregation, and disappointing his father's views, incurred his resentment, so that he was left with a very moderate pittance. However, the abbé Bignon procured him admission into the Academy of Sciences in 1707: he soon became a member; and in 1721, professor of Greek and Latin in the Royal College. Under the famous system of Law, he acquired temporary opulence, but was soon again reduced to penurious circumstances. He then retired from the world, studying and exercising that philosophy which raised him above it. He died at Paris in 1750, at the age of 80 years. His works are, "A Critical Dissertation on Homer's Iliad;" "Reflections in favour of Law's System;" "Sethos," a moral romance; "A Translation of Diodorus Siculus," 7 vols. 12mo. with preface, notes, and fragments. It was one of Terrasson's sayings, "What is the most credulous of all things? Ignorance. What is the most incredulous? Ignorance."

Andrew Terrasson, the elder brother of the former, a priest of the Oratory, was a celebrated preacher, and died at Paris in 1723. His "Sermons," in 4 vols. 12mo. were published in 1726, and reprinted in 1736.

Gaspard Terrasson, another brother, and priest of the Oratory, was more celebrated as a preacher than the former, and officiated at Paris during five years. Having incurred persecution, he quitted the pulpit and the congregation of the Oratory. He died at Paris in 1752. His "Sermons," in 4 vols. 12mo. appeared in 1749. His anonymous work, entitled "Lettres sur la Justice Chretienne," was censured by the Sorbonne.

Another person of the same family, *viz.* *Matthew Terrasson*, was born at Lyons in 1669, studied the law, and pleaded causes with great reputation. He was for some time an associate in the "Journal des Sçavans," and also censor royal. He died, much esteemed, at Paris, in 1734. A "Collection of his Pleadings, &c." was published in 4to.

The son of the preceding, *Anthony Terrasson*, was born at Paris in 1705, brought up to the bar, and excelled in jurisprudence. By order of chancellor d'Aguesseau, he composed a "History of Roman Jurisprudence," with a collection of Ancient Contracts, &c. in fol. 1750. In 1760 he was promoted to the chancellorship of Dombes, and died in 1782. He was the author of "Melanges d'Histoire, de Liter-

Literature, de Jurisprudence, de Critique, &c." 1768; and of other works. Moreri. Nouv. Dict. Hist. Gen. Biog.

Terrasson, in *Geography*, a town of France, and seat of a tribunal, in the department of the Dordogne; 18 miles N.E. of Montignac. N. lat. 45° 7'. E. long. 1° 23'.

TERRAUBE, a town of France, in the department of the Gers; 4 miles S.W. of Lectoure.

TERREBONNE, a town of Canada; 12 miles N.N.W. of Montreal.

TERREGLES, a town of Scotland, in the county of Dumfries; 2 miles W. of Dumfries.

TERREL, a town of North Carolina; 30 miles N. of Greeneville.

TERRELLA, μικρογη, *little earth*, is a magnet turned of a just spherical figure, and placed so as that its poles, equator, &c. do exactly correspond with those of the world.

It was thus first called by Gilbert, as being a just representation of the great magnetic globe we inhabit.

Such a terrella, if nicely poised, and placed in a meridian like a globe, it was supposed, would be turned round like the earth in twenty-four hours by the magnetic particles pervading it; but experience has shewn this to be a mistake.

TERRE-PLEIN, in *Fortification*, the top, platform, or horizontal surface of the rampart, on which the cannon are placed, and the defenders perform their office.

It is thus called as lying level, having only a little slope outwardly to bear the recoil of the cannon.

It is terminated by the parapet on that side towards the champaign; and by the inner talus on that side towards the place. Its breadth is from 24 to 30 feet.

TERRESCHOW, in *Geography*, a town of Bohemia, in the circle of Pilsen; 16 miles N.E. of Pilsen.

TERRESSA, one of the Nicobar islands, about fifteen miles long, and from two to five broad, of an oval form. N. lat. 8° 20'. E. long. 93° 36'.

TERRESTRIAL Birds. See Birds.

Terrestrial *Globe*. See Globe.

Terrestrial *Line*. See Line, *Terrestrial*.

Terrestrial *Paradise*. See Paradise.

Terrestrial *Roads*. See Road.

TERRE-TENANT, is he who has the actual possession of the land, otherwise called the occupant. See Tenant and Occupant.

Thus a lord of a manor having a freeholder, who letteth out his freehold to another to be occupied, this occupier who has the actual possession is called the *terre-tenant*.

TERRE-VERTE, in the *Colour-Trade*, the name of a green earth much used by painters, both singly for a good standing green, and in mixture with other colours.

The name is French, and signifies *green earth*.

It is an indurated clay, of a deep blueish-green colour, and is found in the earth, not in continued strata or beds, as most of the other earths are, but in large flat masses of different sizes, imbedded in other strata; these break irregularly in the cutting, and the earth is generally brought out of the pit in lumps of different sizes. It is of a fine, regular, and even structure, and very hard. It is of an even and glossy surface, very smooth to the touch, and in some degree resembling the morochthus, or French chalk, but adhering firmly to the tongue. It does not stain the hands in touching it; but being drawn along a rough surface, it leaves an even white line, with a greenish cast.

It does not ferment with acids, and is burnt to a dusky brown colour.

It is dug in the island of Cyprus, and in many parts of France and Italy. That from the neighbourhood of Verona has been used to be esteemed the best in the world; but of late there has been some dug in France that equals it. There is also an earth dug on the Mendip hills, in the sinking for coals, which, though wholly unobserved, is nearly, if not wholly, of equal value.

When scraped, and the finer parts separated, it is ready to be made up with oil for the use of the painters, and makes the most true and lasting green of any simple body they use. Hill and Da Costa. See Berg-*Gruen* and Verditer.

TERRIAGULLY, in *Geography*, a town of Bengal; 20 miles N.W. of Rajemal.

TERRIAH, a town of Hindoostan, in Rohilcund; 7 miles S. of Bereilly.

TERRIER, or Terrar, in our *Ancient Customs*, a collection of acknowledgments of the vassals or tenants of a lordship, containing the rents, services, &c. they owe their lord, and serving as a title or claim for demanding and executing the payment of them.

At present, by terrier we mean no more than a book or roll, in which the several lands, either of a private person, or of a town, college, church, &c. are described. The terrier should contain the number of acres, and the site, boundaries, tenants' names, &c. of each piece or parcel. See Domes-*Day*.

Terrier also denotes the lodge or hole which foxes, badgers, rabbits, &c. dig themselves under ground, and in which they save themselves from the pursuit of the hunters. Hence,

Terrier, *Terrarius*, is also used for a kind of little hound to hunt those animals, which, like a ferret, creeps into the ground, and by that means affrights and bites them; either tearing them with his teeth, or else haling them by force out of their holes. See Dog and Hound.

Terrier, in *Geography*, a town of Africa, on the Senegal; 25 miles S. of Cayar.

Terrier *Rouge*, a town of the island of St. Domingo; 15 miles E.S.E. of Cape Français.

TERRIFICATIO, a word used by some chemical writers to express the coalition of the earthy particles of some bodies after fermentation, or during the time of it.

TERRILS or Tyrrells *Pass*, in *Geography*, a post-town of the county of Westmeath, Ireland; 40 miles W. from Dublin.

TERRIMUNGALUM, a town of Hindoostan, in the Carnatic; 25 miles N. of Tritchinopoli.

TERRIORE, a town and fortress of Hindoostan, in the Carnatic; 24 miles N. of Tritchinopoli. N. lat. 11° 12'. E. long. 78° 45'.

TERRIS *Bonis et Catallis*, *Rehabendis post Purgationem*, in *Law*, a writ for a person to recover his lands, goods, or chattels formerly seized, after having cleared himself of a felony, upon suspicion of which he was convicted, and delivered to his ordinary to be purged.

Terris *et Catallis Tentis ultra debitum levatum*, a writ judicial for the restoring lands or goods to a debtor, who is distrained beyond the quantity of the debt. See Distress.

Terris *Liberandis*, a writ lying for a man convicted by attaint, to bring the record and process before the king, and take a fine for his imprisonment, and deliver him his lands and tenements again, and release him of the strip and waste.

It is also a writ for the delivery of lands to the heir after homage and relief performed; or upon security taken that he shall perform them.

TERRITORY, District, the extent or compass of land within the bounds, or belonging to the jurisdiction of any state, city, or other division. See District.

It is a maxim, that the church has no territory, *i. e.* it has no no temporal jurifdiction; and therefore an ecclefiaftical judge cannot arreft any body, not even a prieft. It is much in this fenfe that Cujas fays, the church has an auditory, but no territory.

Territory or *Diftrict of Columbia*, in *Geography*, a diftrict of America, ceded to the United States by thofe of Maryland and Virginia, and eftablifhed in the year 1800 as the feat of general government. It is beautifully fituated on both fides of the Potowmack river, between 38° 48′ and 38° 59′ N. lat., and 7′ E. and 7′ W. long. from Wafhington, the capital. The *capital* is about 77° 0′ 22″ W. from London. It is bounded on the N.E., S.E., and partly N.W., by Maryland; and on the S.W., and partly N.W., by Virginia: in extent it is ten miles fquare, and contains an area of 6400 fquare miles. The face of the country is elegantly variegated, and affords a great number of beautiful profpects, of which the Potowmack river is the leading feature. This diftrict affords a variety of ftreams and fprings for watering the city, and for other purpofes: its rivers are the Potowmack or Potomac, the Tiber creek, Reedy creek, Rock creek, and Four-mile Run. The foil is thin and fandy, but fufceptible of improvement: and the climate is difcriminated by a variable fpring, a pretty warm fummer, an agreeable autumn, and a variable, often very cold, winter.

Territory, *Illinois*, a territory of America, and likely to become foon one of the moft important ftates in the Union, is fituated between 37° and 41° 45′ N. lat., and 10° 15′ and 14° 15′ W. long. from Wafhington city; and is bounded on the N. by the North-weft territory, on the S. by Kentucky and Miffouri territory, on the E. by Indiana territory, and on the W. by Miffouri territory. Its extent from N. to S. is 306 miles, and from E. to W. 210 miles: its area contains 50,000 fquare miles, or 32,000,000 acres. The afpect of the country is level in the fouth, and to the north elevated and hilly, but not mountainous. The foil is generally fertile, and produces grain, grafs, fruit, flax, and hemp; and in the fouthern part, cotton. The climate is temperate and agreeable.

Territory, *Indiana*, an interefting country of America, lately diftinguifhed by this appellation, and now confidered as a *nineteenth ftate*, is fituated between 37° 45′ and 41° 52′ N. lat., and 7° 40′ and 10° 47′ W. long. from Wafhington city; and bounded on the N. by Michigan territory, lake Michigan, and North-weft territory, on the S. by Kentucky, on the E. by Ohio, and on the W. by Illinois territory. Its extent from N. to S. is 240 miles, and from E. to W. 138 miles. Its area contains 34,000 fquare miles, or 21,760,000 acres. The afpect of the country is hilly, but not mountainous; its fcenery rich and variegated; and it abounds with plains and large prairies. Its rivers are the Ohio, Wabafh, White-water, Tippecanoe, Illinois, and St. Jofeph's: its minerals are coal, lime-ftone, free-ftone, falt, and filver. The foil is generally rich and fertile; and its produce grain, grafs, and fruit, and in the fouth, cotton. Its climate is temperate, pleafant, and falubrious. Its legiflature confifts of a houfe of reprefentatives and fenate; the former elected annually, and the latter every three years: they muft hold no office of profit when elected. The executive confifts of a governor and lieutenant-governor; both elected for three years, and capable of being re-elected once: the former has a compenfation of 1000 dollars *per annum*, and the latter two dollars *per* day, while the legiflature is in feffion. Its judiciary adminiftration is compofed of a fupreme and circuit court: the former compofed of three judges, appointed by the governor and fenate for feven years; with a falary not exceeding 800 dollars *per annum:* the latter confifts of a prefiding judge and two affociates, who hold courts in each county: the prefiding judge appointed by the joint ballot of the legiflature for feven years, and the affociates elected by the people for feven years: fheriffs, clerks, and juftices, are elected by the people; the fheriff for three years, the clerks and juftices for feven years. The militia officers are elected by thofe who are fubject to military duty; and all above colonel, by the commiffioned officers. A ftate bank is to be eftablifhed at the feat of government, with one branch for every three counties; and the branch banks muft have 30,000 dollars in fpecie each, before they begin to act. Involuntary flavery is for ever excluded. The conftitution may be amended in 12 years: Corydon is to be the feat of government for nine years. The congrefs, in erecting the Indiana territory into a ftate, appropriated, in addition to the fchool fection, an entire townfhip of land for the fupport of a feminary of learning, and four fections for fixing the feat of the ftate governor.

Territory, *Michigan*, a diftrict in America, which, in 1796, was denominated Wayne county, has lately been erected into a territorial government, and organized with the ufual offices and powers. It is fituated between 41° 45′ and 45° 35′ N. lat., and 5° 5′ and 8° 18′ W. long. from Wafhington; and is bounded on the N. by the ftraits of Michilimackinac, on the S. by Ohio and Indiana, on the E. by lakes Huron and St. Clair, and Upper Canada, and on on the W. by lake Michigan. Its extent from N. to S. is 234 miles, and from E. to W. 138 miles. Its area contains 27,000 ſquare miles, or 17,280,000 acres. The central part of this territory is high, and from this is a deſcent in all directions.

The rivers are St. Mary's, Huron, Detroit, Black, Maramee, Grand, Carrion, Raiſin, &c. The ſoil is generally rich and fertile, and produces wheat, oats, barley, rye, corn, potatoes, fruit, &c. The climate is temperate and ſalubrious; winter laſting from the middle of November to the middle of March.

TERRITORY, *Miſſiſſippi*, an improving country of America, which, it is preſumed, will be divided into two ſtates, the Tombigby being the boundary. It is ſituated between 30° 15′ and 35° N. lat., and 8° and 14° 32′ W. long. from Waſhington city; and bounded on the N. by Tenneſſee, on the S. by Louiſiana, Weſt Florida, and the gulf of Mexico, on the E. by Georgia, and on the W. by Louiſiana and Miſſouri territory. Its extent from N. to S. is 312 miles, and from E. to W. 324 miles; and its area comprehends 89,000 ſquare miles, or 56,960,000 acres. Its general aſpect is, towards the ſouth, level, to the north, elevated and beautifully diverſified, and on the north-eaſt are ſome ſpurs of the Alleghany mountains. The ſoil, generally good, and in many places excellent, produces cotton, corn, rice, wheat, rye, oats, ſome ſugar, and indigo. The climate is much commended; the winters being mild, and the ſummers not warmer than ſeveral degrees to the northward.

TERRITORY, *Miſſouri*, an improving country of America, which may probably be ſubdivided into diſtinct ſtates, is ſituated between 26° and 49° 37′ N. lat., and 12° and 49° 30′ W. long.; and bounded on the N. by an unſettled country, on the S. by Louiſiana and the gulf of Mexico, on the E. by Upper Canada, the North-weſt territory, Illinois territory, Kentucky, Tenneſſee, Miſſiſſippi territory, and Louiſiana, on the W. by the Pacific ocean, and on the S.W. by the Spaniſh internal provinces. Its extent from N. to S. is about 1380 miles, and from E. to W. about 1680 miles; and its area contains 1,580,000 ſquare miles, or 1,011,200,000 acres. The aſpect of the country, ſouthward, is level, in many places overflowed by rivers; to the north, elevated, ſwelling out into large hills; and to the north-weſt and weſt, very lofty mountains. The rivers of the territory are the Miſſiſſippi, Miſſouri, Kanſes, Grand, Oſage, Maramee, St. Francis, White, Arkanſaw, Wachitta, Red, Sabine, Moines, Rio Colorado, Rio Bravos de Dios, Rio Guadalupe, Rio del Norte, &c. Its minerals are abundant, particularly lead, the mines of which near St. Genevieve are extenſive and valuable. The ſoil is various in quality, but much of it is rich and fertile; and produces grain, graſs, fruit, cotton, and ſome ſugar and indigo. The climate is, in the ſouth, warm, in the middle temperate, to the north and weſt cold; on the Pacific ocean temperate.

TERRITORY, *North-Weſt*, an extenſive territory of America, not yet organiſed into a regular government, is ſituated between 41° 45′ and 49° 37′ N. lat., and 7° and 18° 50′ W. long. from Waſhington city; and bounded on the N. by Upper Canada and lake Superior, on the S. by Indiana and Illinois territory, on the E. by Upper Canada and lake Michigan, on the W. and S.W. by Miſſiſſippi river, which divides it from the Miſſouri territory. Its extent from N. to S. is about 360 miles, and from E. to W. 456 miles; and its area contains about 147,000 ſquare miles, or 94,080,000 acres. The face of the country is generally undulating, in ſome places hilly, but not mountainous. Its rivers are the Miſſiſſippi, Ouiſconſin, Fox, Monomonie, Chippeway, &c. The ſoil is moſtly excellent; and the climate, towards the ſouth, is pleaſant, and to the north, cold. Few ſettlements have yet been made in this extenſive region, and the inhabitants were not included in the laſt cenſus. Meliſh.

TERRITORY *of Orleans*. See LOUISIANA, ORLEANS, and UNITED STATES.

TERROR. The effect of terror, or of ſudden frights, in diſeaſes, is often very great.

It is generally obſerved, that people who are moſt afraid of the plague in time of contagion, catch the infection ſooneſt; and that thoſe who are moſt terrified and diſheartened at firſt in the diſeaſe, generally die of it. It is indeed uncertain, whether this be attributed to the terror, or whether the terror itſelf, as a conſequence of dejection of ſpirits, be not merely a ſymptom of the diſeaſe. Kerkring, Spicileg. Anat.

Sudden frights, in acute diſeaſes, have evidently killed many,

many, by the agitation into which they have thrown the ſpirits, already too much diſorderd. We have alſo accounts of perſons abſolutely killed by terrors, when in perfect health at the time of receiving the ſhock from them: people ordered to be executed, but with private orders for a reprieve, have expired at the block without a wound.

The general effects of terror are a contraction of the ſmall veſſels, and a repulſion of the blood in the large and internal ones; hence proceed the ſuppreſſion of perſpiration, the general oppreſſion, trembling, and anguiſh of heart and lungs overcharged with blood, &c.

When a perſon is affected with terror, the principal endeavour ſhould be to reſtore the circulation to its due order, to promote perſpiration, and to allay the agitation of the patient. For theſe purpoſes he may drink a little warm liquor, as chamomile tea, &c.; the feet and legs may be put into warm water, the legs rubbed, and the chamomile tea repeated every ſix or eight minutes; and when the ſkin is warm, and there is a tendency to perſpiration, ſleep may be promoted by a gentle opiate.

TERRYA, in *Geography*, a town of Bengal; 30 miles S. of Beyhar.

TERSA, a ſmall river of Ruſſia, which runs into the Medveditza, in the country of the Coſſacs. N. lat. 50° 30'. E. long. 44° 34'.

TERSCHUEREN, a town of Guelderland; 7 miles E. of Amersfort.

TERSEKAN, a river of Ruſſia, which runs into the Iſchim, N. lat. 52° 50'. E. long. 67° 34'.

TERSHIZ. See TURSHISH.

TERSION, TERSIO, formed of *tero*, *I wear*, the act of wiping or rubbing a thing. See ABRASION.

TERTA, in *Ancient Geography*, a town ſituated, according to Ptolemy, in the interior of Thrace, between Sardica and Philippolis.

TERTHRON, a word properly ſignifying the extreme part of the ſail-yard in ſhipping. Hippocrates uſes it in a metaphorical ſenſe, to expreſs the extremity of a diſeaſe.

TERTIAN, in *Medicine*, a ſpecies of intermitting fever, of which the ſimilar paroxyſms occur at an interval of about forty-eight hours. See FEVER.

TERTIAN is alſo an old meaſure, containing eighty-four gallons, ſo called becauſe it is the third part of a tun. 1 R. III. c. 13. 2 H. VI. c. 11.

TERTIANARIA, in *Botany*, a name given by ſome authors to the ſcutellaria, or hooded willow-herb. J. Bauhin, vol. iii. p. 435.

TERTIARY CANONS. See CANONS.

TERTIAS, a word uſed very frequently in the writings of phyſicians, with the addition of *ad*; but it is capable of a double ſignification. *Ad tertias* is often uſed to expreſs how far the liquor is to be boiled away in the medical decoctions; yet it may in this caſe ſignify either the boiling to two-thirds, or to one-third part, of the whole. The more uſual ſenſe, however, is to boil away one-third part of the original liquor; and in the ſame manner to fill a veſſel *ad tertias*, does not ſignify to fill a veſſel one-third part full, but two-thirds, leaving only one empty.

TERTIATE, in *Gunnery*. *To tertiate* a great gun, is to examine the thickneſs of the metal at the muzzle, whereby to judge of the ſtrength of the piece, and whether it be ſufficiently fortified or not.

This is uſually done with a pair of calliper compaſſes.

The term is alſo applied to any piece of ordnance for finding whether it has its due thickneſs at the vent, trunnions, and neck; if the trunnions and neck are in their due order, and the chaſe ſtraight, &c.

TERTII *internodii pollicis extenſor*, in *Anatomy*. See EXTENSOR.

TERTIO *adjacente*, *Propoſitio de*. See PROPOSITION.

TERTIVERI, in *Geography*, a town of Naples, in Capitanata; 7 miles N.W. of Troja.

TERTIUM SAL, a *third ſalt*, a term uſed in *Chemiſtry* to expreſs a ſalt reſulting from the mixture of an acid and an alkali, which partakes ſo of the nature of both, as to be itſelf neither acid nor alkali, but neutral.

TERTRE, JOHN BAPTIST DU, in *Biography*, a miſſionary and writer of hiſtory, was born at Calais in 1610: and having ſerved in the army in early life, he joined the Dominicans at Paris, and made his profeſſion in 1635, aſſuming the name of John-Baptiſt inſtead of James. About five years afterwards, he was ſent as a miſſionary to the French American iſlands, where he collected materials for the work which engaged his attention after his return to France in 1658: that was his "Hiſtoire Generale des Antilles habitées par les François;" 4 vols. 4to. 1667—71. After having filled various poſts in the houſes of his order, he died at Paris in 1687. Moreri.

TERTUA, in *Geography*, a town of Hindooſtan, in Bahar; 34 miles E. of Bahar.

TERTULLIAN, QUINTUS SEPTIMIUS FLORENS TERTULLIANUS, in *Biography*, generally reckoned the moſt ancient Latin father extant, was born at Carthage, not long after the middle of the ſecond century. He was the ſon of a proconſular centurion, or military officer under the proconſul of Africa, and well acquainted with the Roman laws, though he does not ſeem to have practiſed the law as a profeſſion. He was alſo intimately converſant with the Greek and Roman poets, hiſtorians, orators, and philoſophers, and other heathen writers of every deſcription. His ſkill in Greek was ſo conſiderable, that he wrote ſeveral books in that language. It has been inferred from his parentage, and from ſome expreſſions in his works, that he was once a Heathen; but the time and circumſtances of his converſion to Chriſtianity are not known. Cave ſuppoſes that he embraced Chriſtianity about the year 185, and was made a preſbyter of the church of Carthage about the year 192. According to Du Pin, he flouriſhed chiefly from about the year 194 to 216. Tillemont is of opinion that he was born in 160, and that he died about the year 245, when he was between 80 and 90 years of age, having lived, as St. Jerom ſays, to an extreme, or decrepit, old age. Cave conjectures that he died about the year 220. It is ſaid that he was married, probably after his converſion to Chriſtianity. Having been a member of the Catholic church for many years, he ſeparated from it and became a Montaniſt, as Cave ſays, about the year 199, but about 205, according to Tillemont. Different accounts have been given of this change; but the moſt probable ſeems to be, that the ſpecious pretences of the Montaniſts to greater mortification in faſts and continence had an influence on his temper, which was ſevere. But whatever might have been his reaſons for adopting the principles of Montaniſm, they ſeem to have made ſo little alteration in him as an author, that there are ſeveral of his pieces, concerning which it is not eaſy to determine, whether they were written by Tertullian a Montaniſt, or Tertullian ſtill a Catholic. Although, in conſequence of this change, his reputation ſunk in the church, yet it produced no ſeparation between him and other Chriſtians, except in point of diſcipline, which, agreeably to his temper, he wiſhed to be harſh and rigorous. His doctrine remained the ſame with that of the Catholics. In proceſs of time, however, he believed the divine inſpiration of Montanus and his two propheteſſes, Priſcilla and Maximilla, and that they were thus enabled to make further diſcoveries than had before been made, for the greater perfection of Chriftians. He approved of the longer, more ftrict, and more freqnent fafts of the Montanifts; he condemned all fecond marriages; and denied that the church was authorifed to receive again into communion any who were chargeable with fornication, adultery, or any fuch offences, after baptifm. He often arrogantly calls his own people fpiritual, and the Catholics, as contemptuoufly, animal or carnal. We have already obferved that his knowledge was extenfive; his fancy alfo was lively; and though his temper was fevere, and his mode of expreffion vehement and pofitive, yet his writings frequently manifeft unaffected humility and modefty. The character given of his ftyle by Lactantius muft be univerfally allowed; that it is "rugged and unpolifhed, and very obfcure;" and yet, as Cave obferves, "it is lofty and mafculine, and carries a kind of majeftic eloquence along with it, that gives a pleafant relifh to the judicious and inquifitive reader." His books ftill extant, though many are loft, are numerous, fome of which were written before and others after he embraced the errors of Montanifm. Of thefe, the Apology is reckoned his principal work; and has been highly commended both by ancient and modern writers; whilft his other performances are written with wit and force, and are edifying and inftructive. The time when his "Apology" was written has been differently ftated by various authors: fome refer it to the year 200, others to 203 and 205; but Mofheim, after laborious examination, concludes that it was compofed in the year 198. All allow that it was written before he joined the Montanifts. Learned men generally agree, that it was not addreffed to the fenate of Rome, but to the governors of provinces, or perhaps to the proconful of Africa, and the chief magiftrates refiding at Carthage, where it was written, according to Lardner; though others are of opinion that it was written at Rome. From this Apology, it appears that Chriftians underwent a variety of grievous fufferings; they were, as he fays, "crucified, hung upon ftakes, burnt alive, thrown to wild beafts, condemned to the mines, and banifhed into defert iflands." That this was the cafe, appears alfo from Tertullian's book to the proconful Scapula, not written before the year 211 or 212. The "Apology" is written for the purpofe of fhewing the injuftice of the perfecutions inflicted upon Chriftians, and the falfehood of the charges brought againft them; and likewife to difplay the excellence of the Chriftian religion, and the folly and abfurdity of that of the Heathens. His two books "Ad Nationes" are connected with his Apology, and indicate his characteriftic vehemence. His addrefs to Scapula, already mentioned, was written under the emperor Caracalla, and contains an avowal of admirable principles. "It ought," he fays, "to be left to the free choice of men, to embrace that religion which feems to them moft agreeable to truth. No one is injured or benefited by another man's religion; it is not an act of religion to force religion, which ought to be adopted fpontaneoufly, not by compulfion." He proceeds to vindicate the conduct of Chriftians, and to fhew that their religious principles induced them to pay entire obedience to the emperors, and that therefore they did not deferve to incur the penalties of treafon. Another work of Tertullian has been often cited, *viz.* "De Præfcriptionibus adverfus Hæreticos." In this work he treats of herefy in general, and then difcuffes particular herefies in his five books againft Marcion, in others againft Praxeas, in defence of the Trinity, and againft Hermogenes, and the Valentinians. In his book "On the Soul," he inquires into the nature of the foul and its properties. In his treatife "On Baptifm," he abfurdly maintains that the moral ftain of the foul is effaced by the external wafhing of the body, and that punifhment is likewife remitted; a doctrine which fome late divines have zealoufly fupported. Baptifm by heretics he confiders as no baptifm, and contends that it ought to be repeated. In cafes of neceffity, he thinks infant-baptifm to be allowable, but he recommends deferring rather than haftening the adminiftration of this facrament. His book "On Penance" refutes the opinion advanced by the Montanifts, that fins committed after baptifm cannot be abfolved by the church. In his treatife "On Idolatry," he extends this crime to practices that are almoft unavoidable in fociety; fuch as bearing arms for the defence of the empire, adorning houfes in honour of the prince, and ufing cuftomary expreffions that have any reference to Heathen mythology. In his work "De Corona Militis," he applauds a Chriftian foldier who refufed to place a crown or garland on his head. In another work he confiders "flight in time of perfecution" as prohibited, and alfo giving money to efcape it. In his treatife "De Spectaculis," he diffuades Chriftians from attending public fhows. In his moral tracts is an exhortation to "patience," in which, as well as in a difcourfe addreffed to martyrs or confeffors, he dwells in an eloquent ftrain on the motives which fhould bind a Chriftian to the practice of that virtue. After his union with the Montanifts, Tertullian wrote four books in oppofition to the difcipline of the Catholic church; *viz.* "On Modefty;" "On Monogamy:" "An Exhortation to Charity;" and "A Treatife on Faith."

Tertullian, in his various writings, has afforded plain teftimonies to all the books of the New Teftament, commonly received by Chriftians at this time, except the Epiftle of James, the 2d of Peter, the 2d and 3d of John. The Epiftle to the Hebrews he afcribes to Barnabas. This ancient father has been much admired: Cyprian calls him "my mafter." Some perfons, however, have doubted whether he has done more good or harm in the Chriftian church. His character is judicioufly appreciated by one of his biographers (Gen. Biog.) in the following manner. Tertullian "was certainly a man of lively parts and large acquirements, of copious invention, and warm feelings. In his reafonings, however, he difplayed more fancy and fubtilty than found judgment; and the ardour of his temper inclines him to violence and exaggeration, while a propenfity to fuperftition renders him weakly credulous and gloomily auftere." His works have been frequently printed both feparately and collectively. Of his whole works, the editions of Rigaltius, fol. Paris, 1641, and of Semler, Hal. Magd. 6 vols. 1770—76, are moft efteemed. Dupin. Lardner. Mofheim.

TERVEERE, in *Geography*. See VEERE.

TERUEL, a town of Spain, in the kingdom of Aragon, at the conflux of the Guadalavir and the Alhambra; the fee of a bifhop, fuffragan of Saragoffa: it is defended by a citadel. This town was deftroyed by the Moors, and lay a long time abandoned, but was rebuilt and repeopled by Alphonfo II. in the year 1171. In the year 1365, on the 25th of April, it was taken and pillaged by Peter, king of Caftile; in memorial of which, the inhabitants keep the day a ftrict faft; 72 miles S. of Saragoffa. N. lat. 40° 32′. W. long. 1°.

TERVIS, a town of Iftria; 8 miles W. of Mitterburg.

TERUM, a town of Arabia, in Yemen; 35 miles W.S.W. of Schibam.

TERUNCIUS, in *Antiquity*, a very fmall brafs coin in ufe among the Romans.

The inconvenience of fuch very fmall pieces being foon found, the teruncius became difufed, but its name is ftill retained in reckoning, and thus it became a money of account.

The teruncius at firft was a quarter of the *as*, or libra; hence,

hence, as the *as* contained twelve ounces, the teruncius contained three, whence the name, which is formed of the Latin *tres unciæ*.

Teruncius was alfo ufed for the quarter of the denarius, fo that when the denarius was at ten affes, the teruncius was worth two and a half; and when the denarius was rifen to fixteen, the teruncius was worth four. See DENARIUS.

TERVOLA, in *Geography*, a town of Sweden, in the Lapmark of Kemi; 116 miles N. of Kemi.

TERWALDE, a town of Holland, in the department of Guelderland; 12 miles S. of Hattem.

TERZA, LA, a town of Naples, in the province of Otranto; 13 miles S.E. of Matera.

TERZA, Ital. the 3d in *Mufic*. The *terza maggiore*, or major 3d, is four femitones, or half notes, above the bafe; the *terza minore*, or minor 3d, is three. See CONCORDS and INTERVALS.

TERZETTO, in the *Italian Mufic*, a little tune or air in three parts. See TRIO.

TERZINI, Ital. implies, in the language of practical muficians, triplets, or three notes in the time of two.

TERZO SUONO, Ital. the third found, difcovered by Tartini to be produced in the medium by two founds that can be fuftained, and which third found is the true fundamental bafe. Upon this harmonic phenomenon Tartini has founded his fyftem; and Mr. Stillingfleet, in his "Principles and Power of Harmony," defcribes the *terzo fuono* in the following manner.

"Two founds being given on any mufical inftrument, which will admit of being held out for any time, and of being ftrengthened at pleafure, as in the trumpet, the German horn, the violin, hautbois, &c. a third found will be heard. On the violin, let the notes C E, C✻ E, B E, B G, B♭ G, be founded with a ftrong bow, the third founds will be heard in the following manner.

Tartini has added the above, and even given us a 3d found to difcords.

"The fame thing will happen if the fame intervals are founded by two players on the violin, diftant from one another about twenty-nine or thirty feet; always ufing a ftrong bow, and holding out the notes. The auditor will hear the third found much better, if placed in the middle between them, than if nearer to one than the other. Two hautbois produce the fame effect placed at a much greater diftance, and even when the hearer is not in the middle, and ftill more if he is."

Tartini has been unfairly treated by d'Alembert, M. Serre, and other French writers, who not only difpute his fyftem built on the *terzo fuono*, his own difcovery, but give the difcovery itfelf to another.

D'Alembert accufes him of writing in a manner fo obfcure, that it is impoffible to form any judgment of his intentions; yet he is obliged to own that the fubject itfelf is obfcure, metaphyfical, and uncertain. As to the obfcurity in the phenomenon itfelf, we deny it; the third found, produced by two other founds, we have always found, from innumerable experiments with two voices, two inftruments, two founds on one inftrument, as double ftops on a violin, violoncello, and on an organ, that the third found thus produced in the medium was the true fundamental bafe, fuch as Tartini himfelf has expreffed by mufical notes.

D'Alembert and all the French writers on the fubject, have ftated the cafe (except Rouffeau) in a difingenuous manner. Even when difputing Rameau's principles, they wifh to keep him above Tartini and all foreign claimants to original difcovery or improvement in mufic. Rouffeau is envied for being the firft to abufe the old French mufic, even by thofe who thought and allowed it to be bad in their other writings. See the Abbé Arnauld and M. Suard's critique upon his Dictionnaire de la Mufique, with thofe of the Abbé Rouffier, M. Laborde, &c. &c.

TERZO, in *Geography*, a town of France, in the department of the Tanaro; 2 miles S.W. of Acqui.

TERZOLA, in *Botany*, a name by which fome authors have called the eupatorium cannabinum, or water hemp-agrimony.

TERZOWITZ, in *Geography*, a town of Bohemia, in the circle of Rakonitz; 7 miles S.S.E. of Rakonitz.

TESA, in *Ancient Geography*, a town of Afia, in Carmania, upon the gulf Paragon. Ptolemy.

TESAKON, in *Geography*, a town of Africa, in the country of Nalus, on the Nuno Triftao.

TESCAPHE, in *Ancient Geography*, a town of Afia, in Mefopotamia, on the banks of the Tigris, near Seleucia. Ptol.

TESCHAR, in *Geography*, a town of Hindooftan, in Lahore; 42 miles E.S.E. of Bullaufpour.

TESCHEN, a principality of Silefia, bounded on the N. by the principality of Ratibor, on the E. by Poland, on the S. by Hungary, and on the W. by Moravia. It is for the moft part hilly, the Moravian chain terminating near Jablunkau, in the fouthern part, where alfo begin the Carpathian mountains. On the other hand, the north part is very fwampy, and overrun with lakes and meres; notwithftanding which, there are feveral fertile fpots. Befides which, it abounds likewife in wood. In the whole principality are five towns, part of the inhabitants of which fpeak German, and the others Polifh. The mountains are inhabited by Walachians, who make good heyducks, or footfoldiers. The excellent fire-arms here, called *Tefchins*, receive their name from this country, and more particularly from its capital, where they are made in great quantities.

TESCHEN, or *Teiffin*, a town of Silefia, which gives name to a principality, fituated on the Elfa, partly in a valley, and partly on a hill, and furrounded by a morafs. It contains a Roman Catholic and a Lutheran church, a college, and four convents. The inhabitants carry on fome commerce in leather, wool, and wine: here is a manufacture of fire-arms, and a particular kind of fufil, called, from the town, *Tefchins*; 26 miles S.E. of Ratibor. N. lat. 49° 43′. E. long. 18° 41′.

TESCHENAU, or TESCHNA, a town of Bohemia, in the circle of Bechin; 8 miles E. of Sobieflaw.

TESCHONOVITZ, a town of Pruffia, in Oberland; 18 miles E.S.E. of Ortelfberg.

TESCUCO. See TEZCUCO.

TESCYLETIUM, in *Ancient Geography*, a town of Italy, on the coaft of Magna Græcia, between the temple of of the Lacinian Juno and the town of Locri, according to Diodorus Siculus.

TESE, in *Geography*. See Test.

TESEGDELT, a town of Morocco, situated on a sharp rock, supposed to be impregnable; 80 miles W.N.W. of Morocco.

TESENI, a town of Asiatic Turkey, in Natolia; 34 miles S.E. of Degnizlu.

TESEREN, a town of Africa, in the country of Tafilet; 50 miles N.N.W. of Tafilet.

TESHOO-LOOMBOO, or Lubrong, the residence of the Teshoo Lama, and the capital of that part of Thibet immediately subject to his authority, is situated in N. lat. 29° 4′ 20″. E. long. 89° 7′. It is a large monastery, consisting of three or four hundred houses, the habitations of the Gylongs, or priests, besides temples, mausoleums, and the palace of the sovereign pontiff; in which is comprised also the residence of the regent, and of all the subordinate officers, both ecclesiastical and civil, belonging to the court. It is included within the hollow form of a high rock, and has a southern aspect. Its buildings are all of stone, none less than two stories high, flat-roofed, and crowned with a parapet rising considerably above the roof, composed of heath and brush-wood, inserted between frames of timber, which form a ledge below, and are fashioned above into a cornice, capped with masonry. The building is stained of a deep garnet-colour; a custom universally adopted in these regions, for distinguishing places of religious establishment, and which, when contrasted with the white walls, produces, in the appearance of their town, a very pleasing effect. All the houses have windows, the centre, or principal one, projecting beyond the walls, and forming a balcony: they are closed with black mohair curtains instead of shutters. The principal apartment in the upper story has an opening over it, covered with a moveable shed, which serves the purpose of sometimes admitting light and air, and in the winter season, occasionally, the grateful warmth of the sun. The tops of the walls are adorned with cylindrical monuments; some of which are plain, covered with black cloth, crossed by a white fillet; while others are made of copper, burnished with gold: as the palace and mausoleums are thus adorned with profusion, the view of the monastery, on approaching it from the plain, is brilliant and splendid. The plain of Teshoo-Loomboo, which is perfectly level, is encompassed by rocky hills: its length is about fifteen miles, and its southern extremity, from E. to W., is five or six miles broad. The rock, upon the southern face of which the monastery is situated, nearly occupies the whole width of the valley, and approaches so near to the hills, as to form a narrow defile, leaving room only for a road, and the bed of the river Painom-tchieu, which runs through it, and at a small distance joins the Burhampooter. A fortress commands the pass. The rock of Teshoo-Loomboo is the loftiest of all that are in its vicinity; and the monastery near its base is thus guarded from the violence of the N.W. winds. From the summit of this rock the eye commands a very extensive prospect, and the most interesting object in view is the celebrated river Burhampooter, called in the language of Thibet Erechoomboo. Here it receives the tributary waters of the Painom-tchieu. Turner's Tibet.

TESI TRAMONTINI, Vittoria, in *Biography*, one of the most renowned female singers that Italy has produced. She was born at Florence in 1690; began her vocal studies under the maestro di cappella Francesco Redi; then went to Bologna, and became a pupil of Campeggi; and received her last polish from Bernacchi. But she was no less admired for the dignity, grace, and propriety of her action, than her vocal powers.

Quantz, who heard her at Dresden in 1719, in the famous opera that was performed on occasion of the nuptials of the prince royal of Poland, sing with Senesino, the Berselli, wife of Lotti, Durestante, and the Faustina, characterizes her in the following masterly manner.

"Vittoria Tesi had by nature a masculine, strong, contralto voice. In 1719 she generally sung, at Dresden *all' ottava*, such airs as are made for base voices; but afterwards, besides the majestic and serious style, she had occasionally something coquettish in her manner, which was very pleasing. The compass of her voice was so extraordinary, that neither to sing high nor low gave her trouble. She was not remarkable for her performance of rapid and difficult passages; but she seemed born to captivate every spectator by her action, principally in male parts, which she performed in a most natural and intelligent manner." Life of Quantz, written by himself.

She sung at Naples in 1725, and at Vienna in 1748, where she remained till the time of her decease, in 1775, at 85 years of age.

She was the mistress of the Teuberinn and the De Amicis, both as justly famed for their acting as singing.

We were told at Vienna in 1772, that she had long quitted the stage, though the remembrance of her talents was so deeply impressed in the minds of many excellent judges, that whenever she was mentioned, it was to the disadvantage of all subsequent female singers. She had been very sprightly in her day, and yet was in high favour with the empress-queen in her latter years. Her story is somewbat singular. She was connected with a certain count, a man of great quality and distinction, whose fondness increased by possession to such a degree as to determine him to marry her: a much more uncommon resolution in a person of high birth on the continent, than in England. She tried to dissuade him: enumerated all the bad consequences of such an alliance; but he would listen to no reasoning, nor take any denial. Finding all remonstrances vain, she left him one morning, went into a neighbouring street, and addressing herself to a poor labouring man, a journeyman baker, said she would give him fifty ducats if he would marry her; not with a view to their cohabiting together, but to serve a present purpose. The poor man readily consented to become her nominal husband: accordingly they were formally married; and when the count renewed his solicitations, she told him it was now utterly impossible to grant his request, for she was already the wife of another; a sacrifice she had made to his fame and family.

Since that time she had lived many years with a man of great rank at Vienna, of nearly her own age; probably in a very chaste and innocent manner.

TESIA, in *Geography*, a town of New Mexico, in the province of Mayo; 45 miles E.S.E. of Santa Cruz.

TESIN, a town of Syria, celebrated for its olive oil; 18 miles N.E. of Antioch.

TESINO, a department of Italy, formed of the Pavese. It contains 156,471 inhabitants, who elect twelve deputies. Pavia is the capital.—Also, a river of Italy, which rises in mount St. Gothard, and passing through lake Maggiora, empties itself into the Po, at Pavia.

Tesino, or *Tessin*, a town of the county of Tyrol; 24 miles N.E. of Trent.

TESKELA, a town of Finland; 70 miles E. of Biorneborg.

TESKOWA, a town of Poland, in Volhynia; 40 miles E. of Lucko.

TESORO, a ſmall iſland in the Spaniſh Main, near the coaſt of South America. N. lat. 10° 8′. W. long. 75° 46′.

TESPIS, in *Ancient Geography*, a town of Aſia, in the interior of Carmania, and near Carmana. Ptolemy.

TESS, in *Geography*, a river of Moravia, which runs into the Marſch, 8 miles N. of Muglitz.

TESSAILAH, a town of Algiers; 20 miles S. of Oran.

TESSALON. See Thessalon.

TESSARACONTA, τεσσαρακοντα, among the Athenians, were forty men who went their circuits round the ſeveral boroughs, and had cognizance of all controverſies about money, if not above ten drachms; as alſo of actions of aſſault and battery. Potter, Archæol. Græc.

TESSARACONTERIS, in the *Naval Architecture of the Ancients*, a word uſed to expreſs a ſort of galley, in which there were no leſs than forty tiers of rowers one above another. Se Enneris and Polycrota.

TESSARA-COSTA, in our *Ancient Writers*. See Quadragesima.

TESSARACOSTON, τεσσαρακοςον, in *Antiquity*, a ſolemnity kept by women on the fortieth day after child-birth, when they went to the temple, and paid ſome grateful acknowledgments for their ſafe delivery. Pott. Archæol. Græc. tom. i. p. 432. and tom ii. p. 335.

TESSARINI, Carlo, in *Biography*, firſt violin, and leader of the band in the metropolitan church at Urbino, was born at Rimini in 1690; he was a ſpirited performer on his inſtrument, and a very voluminous compoſer. His ſtyle was light and flimſy, compared with that of Corelli and Geminiani; but his concertos not being very difficult, were much played in country concerts in our own memory, with thoſe of Alberti, Albinoni, and Vivaldi.

Teſſarini's firſt publication at Amſterdam has a title-page of great promiſe; but whether the promiſe was ever performed, ſceptics in theſe incredulous days will be much inclined to doubt. The title is in French, but literally tranſlated, is the following: "A new Method for learning theoretically, in a Month's Time, to play on the Violin, divided into three Claſſes, with progreſſive Leſſons for two Violins." Then twelve violin concertos; twelve flute ſolos; the maſter and ſcholars; divertimenti for two violins; twelve violin ſolos; ſix divertimenti for two violins, in canon, &c. &c. He lived till the year 1672, in the perpetual labour of publication; but his productions would now be as difficult to find as thoſe of Timotheus and Olympus.

TESSE, in *Geography*, a town of France, in the department of the Sarte; 15 miles S.W. of Le Mans.

TESSELÆ, a word uſed in *Pharmacy*, to expreſs lozenges cut into regular figures.

TESSELARII, among the Romans, artificers of chequered or moſaic work.

TESSELATED Pavement, *pavimentum teſſelatum*, a rich pavement of moſaic work, made of curious ſmall ſquare marbles, bricks, or tiles, called *teſſellæ*, from the form of dies.

Teſſelated pavements were much uſed in the tents of the Roman generals.

TESSERA, in *Roman Antiquity*, denoted in its primary ſenſe a cube or dye; ſo called from the Greek word τεσσαρα, or τεσσερα, *four*; reſpect being had to its number of ſides, diſtinct from the two horizontal planes, above and below. And it was thus diſtinguiſhed from the *talus*, which, being round at each end, contained only four planes or faces on which it could ſtand: and therefore, when thrown, had no more than two ſide faces in view. Hence *ludere talis et ludere teſſeris* are ſpoken of by Roman writers as two different games. The ſyllable *tes*. occurs often in Roman inſcriptions.

The word *teſſera* was applied to many other things, not ſo much from a ſimilitude in the figure, as from the relation they bore to ſome other thing of which they were the ſign or token; as the points on the upper plane of the dye denoted the good or ill ſucceſs of the caſt.

The *teſſera hoſpitalis* was either public or private. As to the former, we find among the inſcriptions publiſhed by Gruter, inſtances of two municipal towns which put themſelves under the patronage of the Roman governor; and the reciprocal engagements between them, engraved on two copper-plates in the form of an oblong ſquare, with a pediment at the top, is called in both *teſſera hoſpitalis*.

The deſign of the latter was to cultivate or maintain a laſting friendſhip between private perſons and their families; and gave a mutual claim to the contracting parties, and their deſcendants, of a reception and kind treatment at each other's houſes, as occaſion offered. For which end thoſe teſſeræ were ſo contrived, as beſt to preſerve the memory of that tranſaction to poſterity. And one method of doing this was by dividing one of them lengthwiſe into two equal parts, upon each of which one of the parties wrote his name, and interchanged it with the other. From this cuſtom came the prevailing expreſſion *teſſeram hoſpitalem confringere*, applied to perſons who violated their engagements.

The *teſſeræ frumentariæ* were ſmall tallies given by the emperors to the populace of Rome, entitling them to the reception of a quantity of corn from the public at ſtated ſeaſons. The perſon who had the inſpection of theſe was called *teſſerarius*. They were made of wood and of ſtone.

There was another kind of teſſera which intitled perſons to a ſight of the public games and other diverſions, uſually made in the form of an oblong ſquare.

The *teſſera militaris* was a ſignal given by the general, or chief commander of an army, as a direction to the ſoldiers for executing any duty or ſervice required of them.

This, upon urgent occaſions, was only vocal; but, in ordinary caſes, it was written on a tablet, commonly made of wood. Beſide the civil and military teſſeræ, there are others which related to religious affairs, and may be called ſacred. Phil. Tranſ. vol. xlv. art. 12.

TESSERMUIT, in *Geography*, an iſland near the S.W. coaſt of Eaſt Greenland. N. lat. 59° 59′. W. long. 44° 20′.

TESSET, a town and diſtrict of Africa, in the country of Sahara; 170 miles S. of Morocco. N. lat. 15° 24′. W. long. 7°.

TESSIN, Charles Gustavus, in *Biography*, a Swediſh count and conſiderable ſtateſman, was born at Stockholm in 1695, and received the rudiments of his education under his father. In 1714 he ſet out on his travels, and continued them through various countries of Europe for five years, availing himſelf of every opportunity that occurred of acquainting himſelf with their reſpective conſtitution and laws. At the age of twenty-five he was deputed to the courts of Great Britain, Denmark, and France, and alſo to the States of Holland, to announce the acceſſion of Frederic I. to the Swediſh throne; and in 1725 he was ſent to Vienna, to ſolicit the attention of that court to the new treaty of alliance between Sweden and Ruſſia. On the death of his father, in 1728, he ſucceeded him as principal intendant of the court, and in order to qualify himſelf for the office, he undertook a new tour at his own expence. In 1735 he was again diſpatched

to

to the court of Vienna, where he remained two years. He was chosen by the nobility speaker at the famous diet of 1738, on which occasion he obtained, in recompence of his conduct, a gold medal, bearing on one side his crest, and on the other the motto "Conscius Recti." He was appointed in 1739 to conduct an embassy from this diet to France, and resided at Paris till the year 1742, concluding during this interval an advantageous treaty of commerce with the king of the Two Sicilies, and terminating a subsidiary treaty of alliance with France, by which Sweden was to receive in the course of three years 27 tons of gold. In 1743 he was sent to Denmark, and in the following year to Berlin, on business of great importance. At Berlin he was honoured with the Prussian order of the Black Eagle. He occupied several other stations of dignity and trust, the duties of which he discharged with singular wisdom and fidelity. But the most important office assigned him, was that of preceptor to the crown prince, Gustavus III., to which he was appointed in 1747. On this occasion he wrote his "Letters addressed to a Young Prince," for the use of his royal pupil, which were afterwards translated into most of the languages of Europe. Retiring from public business in 1761, he lived on his estate till the time of his death, which happened in January 1770. Count Tessin was a zealous patriot and enlightened citizen, and a distinguished patron of letters. With a view of encouraging the arts and sciences, he made a great collection of books, pictures, drawings, coins, and other curiosities. But notwithstanding his various excellent qualities, his enemies were assiduous in fruitless attempts to throw a shade over his character, as may be seen in a work entitled, "An Historical Account of the State of Sweden under Frederic I." Gen. Biog.

Tessin, in *Geography*, a town of the duchy of Mecklenburg; 18 miles S.E. of Rostock.

TESSIURSAK, an island near the W. coast of West Greenland. N. lat. 61° 10′. W. long. 47° 30′.

TESSOUA, a considerable town of Africa, in the country of Fezzan; 100 miles E.S.E. of Mourzouk. Near this town, a river, now overwhelmed by the moving sands, but formerly a deep and rapid stream, had its course.

TESSOUELLE, a town of France, in the department of the Mayne and Loire; 5 miles S. of Chollet.

TESSUA, a town of Hindoostan, in Rohilcund; 18 miles S.S.E. of Bereilly.

TESSUE, a town of Persia, in the province of Adirbeitzan; 50 miles W. of Tauris.

TESSUNTEE, a town of the state of Georgia; 80 miles W. of Tugeloo.

TESSUT. See Teceut.

TESSY, a town of France, in the department of the Channel; 9 miles S. of St. Lo.

TEST, in *Metallurgy*, is a vessel of the nature of a coppel, used for large quantities of metals at once, and formed of the same materials.

The coppels, or small vessels, serve for operations of this kind, when small quantities only are concerned; but when larger are worked on, vessels of a larger size and coarser texture are employed, which are distinguished by the name of *tests*.

These are usually a foot and half broad, and are made of wood-ashes, not prepared with so much care as for coppel-making, and mixed with finely powdered brick-dust; these are made into the proper shape, either by means of a shallow vessel, made of crucible earth, or cast-iron, of proper dimensions, or only an iron ring, or hoop, with three bars arched downwards across the bottom, about two inches deep, and of different widths, from three or four inches to fifteen or more, according to the quantity of metal to be tested at once.

To make them in the first manner, an earthen vessel is to be procured, not glazed within, and by its depth and breadth proportioned to the quantity of metal to be worked; the inside of this vessel is to be well moistened with fair water, that the ashes to be put into it may adhere the better. Put into this vessel, thus prepared, the ashes and brick-dust before-mentioned, and first moistened either with water alone, or with water with a little white of an egg mixed in it; let the quantity of this be so much as will half fill the vessel, then press the mass with a wooden indented pestle, or, if not for a very large test, with a wooden cylinder, only of an inch thick: when thus pressed down add fresh ashes, and press them a second time, as in the making of coppels, and repeat this addition of fresh ashes till the earthen vessel be nearly full; then remove the superfluous ashes with an iron ruler, and let the inequalities remaining at the border be smoothed with a wooden or glass ball rolled round about. This done, you are to cut the cavity with a bowed iron, that you may have a broad spherical segment, not very deep; and lastly, by means of a sieve, strew this cavity carefully and regularly over with dry ashes of bones of animals, ground extremely fine, and squeeze these hard in, by the rotation of the wooden or glass ball. Thus you have a test finished, which, together with its earthen pot, must be set in a dry warm place.

To make the tests in the other manner, or by means of an iron ring; let a ring of that metal be filled with ashes mixed with brick-dust, and moistened as before mentioned, in such manner that they may rise considerably above the ring; then press them strongly either with your hands, or with an indented pestle, and afterwards, with gentle blows of a rammer, press the ashes from the circumference toward the centre, in a spiral line, and that in such manner, that, after having been sufficiently pressed, they may be a small matter higher than the brink of the ring. If there are now any vacancies in the mass, empty the ring, and fill it again with more ashes; for if you should attempt to fill up these by adding, were it but ever so little, ashes, the second, or additional quantities, will never cohere so firmly with the first, but that they may probably separate in the operation.

This done, turn the ring upside down, and on the other side, or bottom, take out the ashes to the quantity of one-third part of the depth of the ring, and again fill the vacuity with the same ashes, in such a manner that there may remain no sensible cavity,

When the mass is thus prepared, cut out a cavity in the larger surface of the ring, with a bowed iron, as in the former method.

The Germans have, beside these, another kind of tests, which they call *treibscherben*. These are a sort of vessels which resist the most violent fire, and are so extremely compact, that they sometimes will retain not only melted metals, but even the glass of lead itself.

The figure and size of these vessels may be the same with that of the coppel, but they are usually made larger; and the great difference of these tests from coppels, and from the ordinary tests, which are indeed only a kind of large and coarse coppels, is, that the matter of these is more compact and coherent.

The matter for making these tests is thus prepared: take of the purest and finest clay a sufficient quantity, make it into balls, and dry them either in the air, or on the fire; when dried, beat them to powder in a mortar, and pour on the powder a great quantity of warm water; let this mixture rest a while, and when the clay has subsided, pour off the

the water which ſwims at top; and let this waſhing be ſo often repeated, that all the moſt minute lumps of the clay be broken, and whatever ſalt it contains perfectly waſhed out: then add to this fine clay, of the pureſt ſand, of powder of calcined flints, ground, and well waſhed, of faulty but clean Heſſian crucibles, or of any incombuſtible ſtones ground very fine, ſuch a quantity as will render the maſs thick, and hardly adhering to the hands in kneading it, or pliant when rolled into a thin lamina.

This is the matter for making this ſort of teſts; but, before any quantity of the veſſels be made of this earth, it will be prudent firſt to finiſh a ſingle one, and try it, by putting on it a quantity of glaſs of lead, and expoſing it for an hour or more to the ſtrongeſt fire; by this trial you will be certain whether or not the maſs is capable of making veſſels that will reſiſt both the fire and the glaſs of lead; and by no other means but this trial is it poſſible to determine the due proportion of the mixture of the ingredients for this uſe, on account of the variety of the clays. Nature in ſome places affords a clay ſo well tempered, that it is extremely proper for the making of teſts without any preparation, or without the admixture of any other matter. Sometimes this only requires a ſimple waſhing, but commonly it is neceſſary to make it into balls, and powder or waſh them as before directed.

On the trial of a teſt made of this, or the former mixed clay, if it runs into glaſs, you muſt add to it of the powder of ſtones, eſpecially ſuch as beſt reſiſts the fire. Great care is to be taken not to add too much powdered chalk to theſe compoſitions, ſince if the matter is tempered with that alone, the teſts will indeed reſiſt the fire very well, but being too porous, they will yield a paſſage to litharge, which will ſoften them to ſuch a degree, that they will either fall aſunder of themſelves, or be totally cruſhed when taken hold of with the tongs.

Theſe veſſels are to be made in the following manner: rub over the ſides and bottom of a ſmall mortar, and alſo its peſtle, with oil, or with the fat of bacon; fill it two-thirds full of prepared clay, then make a ſlight impreſſion with your fingers in the middle of the clay; then place the bottom of the peſtle there, and force it down with blows of a hammer, the ſtronger the better. When thus properly hollowed, take it out of the mortar, and pare its edges, and dry it, as the coppels are dried, in the air, in a dry warm place.

Teſts thus prepared may be uſed as ſoon as dry, unleſs for ſalts or litharge; but theſe bodies, when melted in veſſels not firſt baked or hardened in the fire, always make their way through them.

Some of the German writers alſo recommend, both for teſts and coppels, a ſort of friable opaque ſtone, called white ſpath, which appears to be a ſpecies of gypſum, or of the ſtones from which plaſter of Paris is prepared. The ſpath is directed to be calcined with a gentle fire, in a covered veſſel, till the ſlight crackling, which happens at firſt, has ceaſed, and the ſtone has fallen in part into powder; the whole is then reduced into ſubtle powder, which is paſſed through a fine ſieve, and moiſtened with ſo much of a weak ſolution of green vitriol, as is ſufficient for making it hold together. Gellert, however, finds, that if the ſtone is of the proper kind, which can be known only by trials, calcination is not neceſſary. Theſe teſts are liable to ſoften or fall aſunder in the fire, which inconvenience may be remedied, according to Scheffer, by mixing with the uncalcined ſtones ſomewhat leſs than equal its weight, as eight-ninths of ſuch as had been already uſed and penetrated by the ſcoria of the lead, taking that part of the old teſt which appears of a green-grey colour, and rejecting the red cruſt on the top. But from his account it appears, that theſe teſts are leſs durable than thoſe made of the aſhes of bones, though much ſuperior to thoſe of wood-aſhes. Vegetable aſhes, which ſtand pretty well the teſting of ſilver, can ſcarcely bear any great quantity of gold, which requires a conſiderably ſtronger fire than the other; but bone-aſhes, ſays Dr. Lewis, anſwer ſo effectually, and are among us ſo eaſily procured, that it is unneceſſary for the refiner to ſearch for any other materials. Cramer's Art of Aſſaying, p. 60. 62. Lewis's Com. Ph. Tech. p. 144.

Test-*Liquor*, a term uſed by our dealers in brandies, &c. for a liquor which they uſe as a teſt of brandy, &c. to prove whether they be genuine, or mixed with home ſpirit. The people who uſe this, place great confidence in it, but it is really a very vague and uncertain thing. They pretend that this liquor will ſhew, by the colour which it makes on its being poured into brandy, whether it be genuine or adulterated; or if not genuine, in what proportion the adulterating ſpirit is mixed with it.

The whole fact is this: if a little common green or white vitriol be diſſolved in ſome fair water, it makes a teſt-liquor, a few drops of which being let fall into a glaſs of old French brandy, will turn the whole to a purple or fine violet-colour; and by the ſtrength or paleneſs of this colour, the dealers judge the brandy to be genuine or mixed in different proportions, with home ſpirits.

Old French brandy, having long lain in the caſk, takes a dilute tincture of the wood of the caſk, that is, of oak; and this being of the ſame nature with a ſolution or tincture of galls, naturally turns blueiſh or blackiſh with vitriol. A new diſtilled brandy, though wholly foreign, would not give this teſt; and a common malt ſpirit, with oak chips infuſed in it, will turn as dark as the fineſt brandy. While our diſtillers, indeed, had nothing in uſe for the colouring of their ſpirits but burnt ſugar, it was poſſible to make ſome gueſs at an adulteration with them, becauſe the brandy, in this caſe, would not become blackiſh in proportion to its former colour; the ſugar colour not turning to ink with the vitriol, like the other: but our diſtillers have ſince found a way of uſing an extract of oak for the colouring of their ſpirits, and ſince that, this teſt-liquor is of very little uſe, our common ſpirits, of any kind, turning as deep with it as the foreign brandies.

The very beſt way of making this teſt-liquor, is with a calcined vitriol of iron, diſſolved in a dilute or aqueous mineral acid. The liquor, when well made in this manner, is of a fine yellow colour, and will give, for a time, the fineſt blue to any ſpirituous tincture of oak.

The Engliſh were, at one time, very fond of high-coloured brandies, and it was then that the uſe of this teſt-liquor was moſt eſteemed; afterwards we, as well as other nations, finding that this colour was only owing to the caſk, began to diſlike, and to favour the pale brandies: at length we fell into the uſe of ſuch as were wholly limpid and colourleſs, and the re-diſtilling of all the old brandies of which people were poſſeſſed, took place; on this the teſt-liquor was found to be of no uſe at all, and accordingly rejected; but as we are of late again come into the eſteem of coloured brandies, and that with great juſtice, as the colour, when genuine, is a certain mark of the age of the liquor, this teſt-liquor is again got into more credit than it deſerves.

The famous Helvetian ſtyptic depended wholly on this accident for its colour; and it was no ſmall mortification to our chemiſts, when, ſome years ago, it was introduced into uſe among us, that they could not make it with our own ſpirits, but muſt be at the expence of true French brandy

brandy for it; our own spirits, though equally coloured, would never make that violet tincture, because their colour was owing to burnt sugar, not a tincture of oak. At length this mystery was explained, and a little scrapings of galls made all those quantities of this styptic, which had been set by as good for nothing, perfectly fine and well-coloured. Shaw's Essay on Distillery.

TEST-*Act*, in *Law*, is the statute 25 Car. II. cap. 2. (1673) which directs all officers, civil and military, to take the oaths, and make the declaration against transubstantiation, in the court of king's bench or chancery, the next term, or at the next quarter sessions, or (by subsequent statutes) within six months after their admission; and also within the same time to receive the sacrament of the Lord's supper, according to the usage of the church of England, in some public church, immediately after divine service or sermon, and to deliver into court a certificate thereof, signed by the minister and churchwarden, and also to prove the same by two credible witnesses, upon forfeiture of 500*l.* and disability to hold the same office. Besides this penalty, if, without taking the sacramental qualification within the time prescribed by the act, a person continues to occupy a civil office, or to hold a military commission, and is lawfully convicted, then he is disabled from thenceforth, for ever, from bringing any action in course of law, from prosecuting any suit in any court of equity, from being guardian of any child, or executor or administrator of any person, as well as from receiving any legacy. For an account of the nature and operation of the CORPORATION *Act*, we refer to that article.

The word *test* signifies *proof* or *trial*, being formed of *testis*, *witness*; this act being established with a view to exclude Roman Catholics from any share in the government, though it has operated to the exclusion of Protestant dissenters in general. The Corporation act, enacted in the year 1661, the 13th of Charles II., was principally, but not wholly, designed against Protestant Non-conformists. It was passed in a period of great heat and violence, the year after the Restoration; and it paved the way for the act of uniformity, which soon after passed. The king, with his ministers, and the majority in both houses, hated the Presbyterians, whom they considered, whether justly or not, as the authors of the late rebellion. Great power still remained in their hands, for, during the Protectorate, they had been appointed magistrates in all the country towns. To leave authority in such hands seemed dangerous: it was therefore judged expedient to regulate the corporations, and to expel those magistrates, whose principles were inimical to the constitution, civil and ecclesiastical. This gave rise to the Corporation act. The sacramental clause, however, in the Corporation act was intended against the Catholics; for, as the other provisions of the statute, by dispossessing the enemies of the court, had established the influence of the crown in all the corporations of the kingdom, the parliament was apprehensive that in the *next* reign, under a *Catholic* king, all corporation offices would be filled with *Catholics*. Besides, before the passing of the act of uniformity, those that were afterwards called dissenters, were within the inclosure of the church, and consequently participated in her sacraments, so that the sacramental clause must therefore have been intended as a guard against the Catholics, to whom it effectually applied, and not as a guard against those who were afterwards called dissenters, on whom, at that period, it could not operate.

It must also be allowed, that the original design of the test was not so much to exclude the Protestant dissenters, as the papists, as the Catholics were then called. It was brought in by the patriots, in the reign of Charles II., under their apprehension of popery, and a popish successor; and when, during the debate in the house of commons, it was observed, that it was drawn in such a manner as to comprehend the Protestant dissenters, the court greatly endeavoured to avail themselves of that circumstance in order to defeat the bill. But the dissenting members disappointed them, by declaring, that they had rather confide in the justice and generosity of parliament, to pass some future bill in their favour, than be the occasion of retarding or defeating the security, which the present bill was calculated to afford to the liberties of their country. Their patriotism produced, soon afterwards, a bill for their relief from the penal laws; but the parliament was prorogued, through the resentment of the court, to prevent its passing: and when, notwithstanding this, a bill in favour of the dissenters did afterwards pass both houses, *viz.* in the year 1680, and lay ready for the royal assent, the court ventured upon a very extraordinary expedient: the clerk of the crown was ordered to convey away the bill, and, accordingly, it was never afterwards to be found. The particular test of receiving the sacrament according to the rites of the church of England, was calculated to exclude the papists rather than the Protestant dissenters; as it was no uncommon thing for the latter, at that time, to receive the sacrament occasionally in the church of England, in order to express their charity towards it, as a part of the church of Christ. If it had been the design of the legislature to exclude all from civil offices but those who have a real affection for the constitution and worship of the church, it is apprehended they would have appointed the test to be, not merely once taking the sacrament at church, but a stated and constant conformity to its religious services.

It has been alleged, however, that though the Test act was designed against the Catholics, yet that few, even then, of the number, merited a treatment so severe. They, it is said by their advocates, had no concern in the views of Charles or his brother, in the schemes of wild ministers, or in the machinations of bad politicians. They had suffered much in the royal cause, and were pining in penury and distress, under the additional pressure of cruel laws. But whatever might be the reasons, real or pretended, for passing an act, of which Catholics were the principal ostensible objects, the case is now very much altered, and Catholics have assumed a new character, which entitles them, in the judgment of many, not merely to protection, but to a participation of the privileges of their fellow-subjects.

As the question concerning the repeal of the disqualifying laws which we have already mentioned, has been, and is likely soon again to become a subject of public discussion, and as it is a subject, generally considered, of great importance and interest, it may not be thought improper to state the arguments for and against the repeal of those excluding statutes, comprehending both Protestant dissenters and Catholics, in as concise a manner as possible. The general principles upon which the equitable decision of this question depends, are such as follow:—Every man has an undoubted right to judge for himself in matters of religion; nor should any mark of infamy, or any civil penalty, be attached to the exercise of this right:—Every man has a right to the common privileges of the society in which he lives; and among these common privileges, a capacity in law for serving his sovereign and country is one of the most valuable, distinguishing a *legal capacity* of service, from a *right* to an actual appointment, which depends upon the choice of his sovereign, or of his fellow citizens; and this capacity of serving the state is a right of such high estimation, and of such transcendent value, that exclusion from it is is deemed a proper punishment for some of the greatest crimes:—Actions, and not opinions, political or religious, are the proper objects of human authority and cognizance:—No man, who does not forfeit that *capacity* of serving his sovereign and country, which is his natural right, as well as the honour and emoluments that may happen to be connected with it, by overt-acts, ought to be deprived of them; and disabilities that are not thus incurred are unjust penalties, implying both disgrace and privation:—Punishment, without the previous proof of guilt, cannot be denied to be an injury; and injuries inflicted on account of religion are undoubtedly persecutions:—The ends of civil society can never justify any abridgment of natural rights that is not essential to these ends:—The institutions of religion, and the ordinances of civil government, are distinct in their origin and their objects, in the sanctions that enforce them, and the mode in which they are administered:—The institution of the Lord's supper, being wholly of a religious nature, and appointed merely as a memorial of his death, is improperly applied to the secular ends of civil society; and if it be so applied, it is not only an improper, but in many cases an insufficient, test of the principles and character of those to whom it is administered. Such are some of the leading principles, which have been the subjects of discussion in the debates that have occurred, both among writers and among our legislators, in considering the expediency of repealing the test laws. The case of the Catholics and of the Protestant dissenters has been repeatedly argued in both houses of parliament, and may probably again become the subject of public discussion. Many (indeed most) of the same arguments apply to both descriptions of persons; but we shall chiefly restrict ourselves to the pleas of the dissenters. They have urged, that being well-affected to his majesty and the established government, and ready to take the oaths required by law, and to give the fullest proof of their loyalty, they think their scruple to receive the sacrament after the manner of the church of England, or after the manner of any church, as a qualification for an office, ought not to render them incapable of holding public employments, civil or military: they also allege, that the occasional receiving of the Lord's supper as a qualification for a place, cannot, in the nature of things, imply that those who thus receive it, mean to declare their full and entire approbation of the whole constitution and frame of the established church; some men may be compelled by their necessities, or under the allurement of secular advantages, to do what they would not do, if they were left to their free choice. Others, perhaps, may comply with the sacramental test who are not even Christians, and who therefore cannot be supposed to wish well to Christianity itself, or to any national establishment of it whatsoever. Hence they are led to think, that such a test can be no real or effectual security to the church of England. Conceiving that they have a right, as *men*, to think for themselves in matters of religion, and that this right is prescribed and sanctioned by the Author of Christianity; and that they have a right, as *citizens*, to a common chance with their fellow-subjects for offices of civil and military trust, if their sovereign or fellow-citizens should think them worthy of confidence; they cannot be of opinion that any of the ends or objects of civil society require that these rights should be superseded, and that they should be excluded from the service of the state. Their advocates plead on their behalf, that the continuance of those acts which invade their rights is so far from being necessary to the well-being of the state, or to the establishment of the national church, that they are actually pernicious both to the state and church, and ought to be repealed. Their inutility is shewn by referring to the higher trust of legislative authority, to which the dissenters are admitted without hesitation or reserve, and without submitting to any such test. An exciseman surely, it is said, does not sustain a more important office, neither is it necessary that he should make a profession of his Christian faith more than a member of the house of commons or the house of peers. The principles of the dissenters, their attachment to the constitution, and their zeal in support of it, have been sufficiently manifested in a variety of instances, from the Revolution to the present day; and yet can it be asserted, that their exclusion from the service of the public is necessary or beneficial to the state? Can it be said that the continuance of the disabilities to which their profession subjects them, is necessary for the safety or honour of the church? The establishment of a church requires a legal provision for its ministers; but it does not require for its laity an exclusive right to civil and military trusts. The establishment of the church of England consists in her tithes, her prebendaries, her canonries, her archdeaconries, her deaneries, and her bishoprics. These constituted her establishment before the Corporation and Test acts had any existence: and they will equally constitute her establishment if these acts should be repealed. In Scotland they have had no such acts; and yet Scotland has an established church. In Ireland these acts have been repealed; and yet the established church of Ireland remains. In Holland, Russia, Prussia, Germany, &c. they have no such acts. As to the intimate and beneficial connection between church and state, on which some have grounded the supposed propriety and necessity of these laws, it would be sufficient to refer to the authority of archdeacon Paley, who has stated what ought to be the single end of church establishments. (See Religion.) Upon an appeal to history, it has been argued that the civil government maintained itself in former times, when *unconnected* with the church; and the disturbances which terminated in the ruin of both church and state, are said to have originated in the intolerant spirit and arbitrary proceedings of some ecclesiastics, who had themselves exercised powers, and had instigated their unhappy sovereign to actions and claims at least as contrary to, and subversive of, the true spirit of the constitution, as any of those violences of the times immediately succeeding, which have been so justly reprobated. In this connection, we may refer to the speech of an able advocate for the repeal of the disabling statutes: who maintains that no human government has a right to inquire into men's private opinions, to presume that it knows them, or to act on that presumption. Men should be tried by their actions, not by their opinions. This, if true with respect to *political*, was more peculiarly so with regard to *religious* opinions. In the position, said Mr. Fox, that the actions of men, and not their opinions, were the proper objects of legislation, he was supported by the general tenor of the laws of the land. History, however, afforded one glaring exception in the case of the Roman Catholics. The Roman Catholics, or rather the Papists, as they were then properly denominated, had been supposed by our ancestors to entertain opinions that might lead to mischief in the state. But it was not their religious opinions that were feared. Their acknowledging a foreign authority paramount to that of the legislature; their acknowledging a title to the crown superior to that conferred by the voice of the people; their political opinions, which they were supposed to attach to their religious creed, were dreaded, and justly dreaded, as inimical to the constitution. Laws therefore were enacted to guard against the pernicious tendency of their political, not of their religious, opinions; and the principle thus adopted, if not founded on justice, was at leaſt followed up with conſiſtency. Their influence in the ſtate was feared, and they were not only reſtricted from holding offices of power or truſt, but rendered incapable of purchaſing lands, or acquiring influence of any kind. But if the Roman Catholics of thoſe times were Papiſts in the ſtricteſt ſenſe of the word, and not the Roman Catholics of the preſent day, ſtill he would ſay, that the legiſlature ought not to have acted againſt them, till they put in practice ſome of the dangerous doctrines which they were thought to entertain. Diſability and puniſhment ought to have followed, not to have anticipated, offence. Thoſe who attempted to juſtify the diſabilities impoſed on the diſſenters, muſt contend, if they argued fairly on their own ground, not that their religious opinions were inimical to the eſtabliſhed church, but that their political opinions were inimical to the conſtitution. If they failed to prove this, to deprive the diſſenters of any civil or political advantage, was a manifeſt injuſtice; for it was not ſufficient to ſay to any ſet of men, we apprehend certain dangers from your opinions, we have wiſely provided a remedy againſt them, and you, who feel yourſelves aggrieved, calumniated, and proſcribed, by this remedy, muſt prove that our apprehenſions are ill-founded. The *onus probandi* lay on the other ſide; for whoever demanded that any other perſon ſhould be laid under a reſtriction, it was incumbent on him firſt to prove that the reſtriction was neceſſary to his ſafety, by ſome overt act, and that the danger he apprehended was not imaginary but real. Was it ſeriouſly to be contended, that religion depends upon political opinions; that it can ſubſiſt only under this or that form of government? It was an irreverend and impious opinion to maintain, that the church muſt depend for ſupport, on its being an engine, or ally, of the ſtate, and not on the evidence of its doctrines, to be found by ſearching the ſcriptures, and the moral effects it produced on the minds of thoſe whom it was its duty to inſtruct. See Toleration.

Mr. Pitt agreed with Mr. Fox in admitting, as a general principle, that the religious opinions of any ſet of men were not to be reſtrained or limited, unleſs they ſhould be found likely to prove the ſource of inconvenience to the ſtate: nor ought the civil magiſtrate, in any other point of view, to interfere with them; but he maintained, that when religious opinions are ſuch as *may* produce a civil inconvenience, the government has a right to guard againſt the probability of the civil inconvenience being produced; nor ought they to wait till, by being carried into action, the inconvenience has actually ariſen. It was not therefore on the ground that the diſſenters *would* do any thing to affect the civil government of the country, that they had been excluded from civil offices, but that if they had any additional degree of power in their hands, they *might*. On the other hand it has been pleaded, that to reſtrain men's civil rights from the ſuppoſed *tendency* of their opinions, is a very dangerous principle, as it muſt render their condition precarious and wholly dependent on the prejudices and will of the magiſtrate, and warranted unlimited reſtraint, and almoſt every ſpecies of perſecution.

Mr. Pitt, premiſing that the eſtabliſhment of a ſettled form of church and of its miniſters is neceſſary to the civil government of the country, ſuggeſts the impropriety of diſtributing the emolumenſs and offices of the eſtabliſhed church among perſons who, however reſpectable their characters might be, were not members of the ſame communion; but others ſay, that the emoluments and offices of the eſtabliſhed church are not the objects contended for, but thoſe of the ſtate, unleſs the church and ſtate be abſolutely identified. He alſo ſays, that theſe offices may be conſidered as matter of favour, becauſe it is conſiſtent with the government of this country, that all offices ſhould be given at its diſcretion; and here, he ſays, from the delicate nature of the caſe, the legiſlature had thought proper to interpoſe, and to reſtrain the ſupreme magiſtrate, the head of the executive authority, and limit him in his appointment to theſe offices; but ſurely, as he contends, this differed eſſentially from any degradation, diſgrace, or puniſhment of the diſſenters. Others, however, have conſidered this kind of reaſoning as fallacious, both in its principle, and in the inference deduced from it.

Mr. Fox concurred with lord North, who, though an advocate for the continuance of theſe diſqualifying laws, bore teſtimony to the principles and character of the diſſenters, in his avowal of their ſteady attachment to government; and he added, that their religious opinions were favourable to civil liberty, and that the true principles of the conſtitution had been remembered and affirmed by them, at times when they were forgotten, perhaps betrayed, by the church. See Dissenters.

Mr. Fox maintained, that the Teſt act was altogether inadequate to the end it had in view. The purport of it was, to protect the eſtabliſhed church, by excluding from office every man who did not profeſs himſelf well affected to that church. But a profeſſed enemy to the hierarchy might go to the communion table, and afterwards ſay, that in complying with a form, enjoined by law, he had not changed his opinion, nor, as he conceived, incurred any religious obligation whatever. There were many men, not of the eſtabliſhed church, to whoſe ſervices their country had a claim. Ought any ſuch man to be examined, before he came into office, touching his private opinions? Was it not ſufficient that he did his duty as a good citizen? Might he not ſay, without incurring any diſablility, "I am not a friend to the church of England, but I am a friend to the conſtitution, and on religious ſubjects muſt be permitted to think and act as I pleaſe." Ought their country to be deprived of the benefit ſhe might derive from the talents of ſuch men, and his majeſty prevented from diſpenſing the favours of the crown, except to one deſcription of his ſubjects? But whom did the teſt exclude, the irreligious man, the man of profligate principles, or the man of no principle at all? Quite the contrary; to ſuch men the road to power was open; the teſt excluded *only* the man of tender conſcience; the man who thought religion ſo diſtinct from all temporal affairs, that he held it improper to profeſs any religious opinion whatever, for the ſake of a civil office. Was a tender conſcience inconſiſtent with the character of an honeſt man? or did a high ſenſe of religion ſhew that he was unfit to be truſted? Allowing that the eſtabliſhed church ought to be protected, it was natural to inquire what was the eſtabliſhed church? Was the church of England the eſtabliſhed church of Great Britain? Certainly not: it was only the eſtabliſhed church of a part of it; for, in Scotland, the kirk was as much eſtabliſhed by law as the church was in England. The religion of the kirk was wiſely ſecured, as the eſtabliſhed religion of Scotland, by the articles of Union; and it was ſurely abſurd to ſay, that a member of the kirk of Scotland, accepting an office under government, not for the ſervice of England excluſively, but for the ſervice of the united kingdom, ſhould be obliged to conform, not to the religious eſtabliſhment of Scotland, in which he had been bred, but to the religious eſtabliſhment of England.

To the argument urged in favour of the Corporation and Teſt acts, founded on the apprehenſion that if they were repealed, the diſſenters might become a majority of the people, Mr. Fox gives a brief reply, *viz.* that if the majority of the people of England ſhould ever be for the abolition of the eſtabliſhed church, then it ought to be aboliſhed. It has been ſaid, that by manifeſting indulgence to other ſects, a candid a candid respect for their opinions, and a desire to promote mutual charity and good-will, the established church will be most likely to secure its stability and its honour. Whilst the grievances of persons of a different profession are redressed, and they are admitted to a participation of their civil rights, the church need not fear any combination for sapping its foundation, or for depriving it of its peculiar and distinguishing honours or emoluments. Men who are aggrieved, under a sense of what they conceive to be an indignity and injury, are the most likely to manifest hostility against an ecclesiastical establishment that engrosses all civil and secular advantages to itself.

It has been said, that it would conduce to the honour of the rulers and dignitaries of the church, if they would concur in abolishing laws which perpetuate the perversion and profanation of a religious institution :—an institution which certainly was not intended by its divine founder for the attainment and promotion of any selfish and secular purposes. *Here*, it is maintained, if any where, a line of separation should be drawn between religious and civil policy ; nor should the performance of a Christian duty be made an indispensible qualification for a secular office. The dissenters, says a well-informed member of the legislature (Mr. W. Smith), who, being himself one of them, is thoroughly acquainted with their principles and character, would equally object to receiving the sacrament *as a test* in their own places of worship, though many of them would not scruple to partake of it with their brethren of the establishment, and according to their form, when considered only in its true light, as a religious duty, and an expression of Christian charity. The writer of this article is acquainted with several conscientious and avowed members of the established church, who lament this abuse of a Christian ordinance, and who wish, for the purity and honour of the church to which they are attached, that the laws imposing this test were repealed. It would likewise contribute to the satisfaction of scrupulous ministers of the established church, to be released from the obligation of administering the sacrament, as a qualification for office abstractedly considered, and more especially to persons of known licentiousness of principles and conduct. By the duties of his function, by the positive precepts of his religion, and by the rubrick or canons of the church, the minister is enjoined to warn from the sacred table all blasphemers of God, all slanderers of his word, all adulterers, and all persons of a profligate life ; and yet to these very persons, if they demand it as a qualification, he is compelled, by the Test act, to administer the sacrament ; and if he refuses, a ruinous prosecution for damages is the obvious and inevitable consequence. On the other hand it has been said, that if the minister's conviction of profligacy of conduct is supported by all the circumstances which constitute legal proof, he may lawfully refuse the sacrament. The truth of this opinion is doubtful ; but it is certain, that if he should fail in that proof, his ruin is inevitable : and if he should succeed, it is almost equally certain ; for the expences of his suit will devour his scanty means, and probably consign him to a prison for his life. Allowing that any notorious evil-doer, offering himself to receive the sacrament, might be rejected by the minister, without becoming liable to any punishment, let it be considered what is the situation in which A or B, or the person who upon application to a minister had been refused the sacrament, was placed : from that moment he had incurred the penalties of the act, and was punished in a manner perfectly new, unexampled, and unauthorized by the laws of the land ; he was convicted without a trial by jury, and was disabled from enjoying an office which his majesty, in the legal exercise of his prerogative, had thought proper to confer on him ; and a person was thereby absolutely put into the hands of the clergy, who were to be the great arbitrators of qualification or disqualification for offices, and places of power and emolument. Some have attempted to justify the legal establishment of the profanation of a religious institution, by comparing it with those provisions of our law which enjoin the sanction of an oath ; but this argument has been considered as inapplicable to the present case, and altogether unavailing ; for though it be indeed true that the legislature, by compelling every petty officer of the revenue, and every collector of a turnpike toll, to swear deeply on his admission into office, has made the crime of perjury more common, at this time, in England, than it ever appears to have been in any other age or country : yet how does the frequent commission of this crime *against* law, justify the establishment of a religious profanation *by* law ? But, without any comment on the folly of pleading for a legislative debasement of religion in one way, by shewing that the legislature has contributed to its debasement in another, let it be asked, what resemblance the sacrament of the Lord's supper, which is merely a religious institution, bears to the ceremony of an oath, which is an institution so entirely political, that it answers none of the purposes of religion, promotes none of her interests, forms no part of her establishment, and belongs as much to the Jew, the Mahometan, and the idolater, as it does to the Christian. The difference, says Mr. W. Smith, between the sacrament, used as a test for office, and an oath, as a test of truth, is too obvious to escape the most careless observer. An oath was neither primarily, nor at all, an act of worship ; nor, though it necessarily supposed a belief in a supreme moral governor, was it ever used as a test of particular religious opinions : the sole object to which it was directed was the attainment of truth, (with respect either to the past or the future,) where other means were insufficient, —an appeal to a Being who, by the supposition, must be acquainted with all the circumstances, and must also be both able and inclined to punish falsehood in such cases, as an insult added to a crime, was perfectly well calculated to attain the proposed end, and inapplicable to any other purpose.

If, says Mr. Fox, in concurrence with some previous observations of Mr. Beaufoy, when a man is seen going to take the sacrament, it should be asked, " is this man going to make his peace with God, and to repent him of his sins ?" the answer should be, " No ; he is only going there, because he has lately received the appointment of first lord of the treasury ;" can any circumstance afford a greater proof of the indecency resulting from the practice of so qualifying ?

Some have contended, that to grant a remission in favour of Scotland of the Test and Corporation acts, would be a breach of the union ; an opinion which supposes, that because, by the articles of union, nothing can be *taken* from Scotland but what was then stipulated, therefore nothing can be *given*. Others say, that as the Test and Corporation acts are among the statutes which secure the doctrines, discipline, worship, and government of the established church of England, they are therefore by the act of union declared to be unalterable. In reply to this mode of arguing it has been observed, that the government and discipline, the doctrines and the worship of the English church, were the same before the statutes were enacted, and would continue the same if those statutes were repealed ; and consequently do not derive their security from them : whereas the act which relates to the patronage of the church of Scotland, and which *did* seem to affect its discipline, was held to be no breach of the articles of union ; neither was that union understood to be weakened by the subsequent act, which gave a complete toleration in Scotland to episcopal dissenters.

When the articles of union were under the consideration of parliament, a proposal was made in the house of lords, that

that the perpetual continuance of the Teſt act; and in the houſe of commons, that the perpetual continuance of the Corporation act, ſhould be declared a fundamental condition of the intended union: but the motions were both rejected; a proof that the legiſlature did not mean to give to them the ſame perpetual exiſtence as to the act of uniformity, and to the ſtatute that was paſſed in the thirteenth of Elizabeth, both of which were ſpecifically named, as conditions of the compact, and expreſsly declared irrevocable.

If the teſt and corporation laws are deemed unalterable parts of the articles of union, it follows, of courſe, that every alteration in thoſe laws muſt be deemed a breach of the union, and that every ſuſpenſion of thoſe laws muſt be conſidered as a ſuſpenſion of the union. Now both theſe acts are altered, and in part repealed, by ſubſequent ſtatutes, and for ſix months in almoſt every year are wholly ſuſpended. But who will aſſert that the articles of union are diſſolved, or that their obligation on the two countries is ſuſpended for ſix months in every year? or who will deny that the ſame power which alters a part may alter the whole of thoſe laws? Who will deny that the ſame authority which ſuſpends a law for ſix months, may aboliſh it for ever?

In favour of the continuance of theſe laws it has been urged, that they have exiſted for many years with great advantage; but many attempts have been made to diſprove the advantage of them, and they have repeatedly been complained of as both uſeleſs and unjuſt. Beſides, this argument for their exiſtence is abſurd, as it tends to perpetuate every enormity that can plead the ſanction of age. The horror of innovation may be felt or feigned as a bar to every improvement. It may be neverthеleſs aſked, how have theſe laws ſubſiſted? By repeated ſuſpenſions; for the indemnity bills are, with few exceptions, annual acts: and where would be the impropriety of ſuſpending them for ever, by an act of perpetual operation. In order to ſilence complaints of theſe partial and injurious laws, it has been ſaid that the act of indemnity, annually paſſed, protects from the penalties of the teſt and corporation laws all ſuch perſons as have offended againſt them. If it afford ſuch protection, what inconvenience can ariſe from a repeal of the ſtatutes themſelves? Is not the conſtant and invariable practice of paſſing ſuch a bill annually, a tacit acknowledgment that the teſt acts are improper or unneceſſary; that the penalties, if incurred, ought not to be enforced; and therefore no man could be blamed for reſorting to an indemnity, held out as a protection againſt puniſhments inflicted by laws which the legiſlature itſelf continually treated with a kind of diſreſpect, and which were already almoſt repealed in practice, though they were ſtill preſerved in the ſtatute-book by a ſpecies of ſuperſtitious regard? The only juſtification for evading a ſtatute, that can be for a moment maintained, is, when that ſtatute notoriouſly ought not to remain in force; and when to evade it, on account of its nature and tendency, is meritorious. But it has been ſaid, that the Indemnity act does not protect the diſſenters from the teſt and corporation laws; for its only effect is, that of allowing farther time to thoſe treſpaſſers on the law, againſt whom final judgment has not been awarded. Should, for example, a proſecution have been commenced, but not concluded, the Indemnity act does not diſcharge the proceedings; it merely ſuſpends them for ſix months; ſo that if the party accuſed does not take the ſacrament before the ſix months allowed by the Indemnity act ſhall expire, the proceedings will go on, and, long before the next indemnity act will come to his relief, final judgment will be awarded againſt him. Thus it appears, that the Indemnity act gives no effectual protection to the diſſenter, who accepts a civil office or military command; for he who cannot take the ſacrament at all, cannot take it within the time required by that act. After all, indemnity ſuppoſes criminality, and an obnoxiouſneſs to puniſhment: the office and penalty are created by theſe ſtatutes: repeal the laws, and indemnity becomes needleſs. No man would wiſh, if it were always practicable, to ſhelter himſelf under an act of indemnity for omitting to do what, independently of theſe laws, he ought not to do; or chuſe to have it thought that he is leſs fit and able to ſerve his king and country than his neighbour, who does not feel the reſtraint of his conſcientious ſcruples. In corporate towns and many public offices, the obligation to qualify is conſidered as a kind of dead letter, and an informer would be very generally thought an odious character.

As to the Corporation act, it is ſaid to have been *forced* from the legiſlature as an act of ſelf-defence; and this is the proper deſcription of an act, which, after the lapſe of much more than a century, when the grounds and reaſons for paſſing it no longer exiſted, ought to be repealed. The queſtion that forms the ſubject of this article is, in our opinion, intimately connected with the honour of the church and the proſperity of the ſtate, as well as with the general intereſts of religion and liberty; and with theſe views of its importance, we refer the deciſion of it to the impartial judgment of the reader.

Test, or *Teſe*, in *Geography*, a river of England, which riſes in the north-weſt part of Hampſhire, bordering on Wiltſhire, and runs into Southampton Water. Sir Henry Englefield ſeems inclined to think the original name was *Ant*.

TESTA, in *Antiquity*, the ſame with *oſtracon*. See Ostracism.

Testa, in *Italian Singing*. When a performer ſings through the noſe, the throat, or the teeth, the voice is called *voce da teſta*, to diſtinguiſh it from *voce di petto*. Toſi ſays: "let the maſter attend with great care to the voice of his ſcholar, which, whether it be *di petto*, or *di teſta*, ſhould always come forth neat and clear, without paſſing through the noſe, or being choaked in the throat; which are two of the moſt horrible defects in a ſinger, and paſt all remedy if once grown into a habit." Galliard's Tranſl. of Toſi on florid Song.

Testa, Pietro, in *Biography*, called Il Luccheſino, from having been born at Lucca. His birth took place in 1611, and he was firſt inſtructed in painting by Pietro Paolini; afterwards he ſtudied at Rome, under Domenichino and Pietro da Cortona. The principal objects of his ſtudy were antique marbles, and the remains of ancient architecture; in which employment ſuch was his aſſiduity, that few veſtiges of antiquity were known which had eſcaped his pencil. His extreme poverty made him moroſe and melancholy; and he made himſelf many enemies, by the freedom with which he ſpoke of the productions of other painters. From this ſtate of trouble he was relieved by Sandrart, who found him among the ruins, and compaſſionating his diſtreſs, took him to his houſe, where he clothed and entertained him, and introduced him to the prince Juſtiniani, who employed him. After this he ſucceeded; and the great freedom and eaſe of his pencil procured him many patrons. Several of the churches and palaces at Rome are adorned with his productions: the beſt are eſteemed to be thoſe of the Death of St. Angelo, in the church of St. Martino à Monti, and of the Death of Iphigenia, in the Palazzo Spada. His works, however, are more frequently to be met with at Lucca. As a deſigner, Pietro Teſta was unequal: he frequently tacked to antique torſos ignoble heads, and extremities copied from vulgar models. Of female beauty he appears to have been ignorant,

rant, though he adopted a character and form which are peculiar to himself. Of his compositions, generally perplexed and crowded, the best known and most correct is that of Achilles dragging Hector from the walls of Troy to the Grecian fleet. He delighted in allegoric subjects, and produced many of picturesque effect and attitudes: but, in their meaning, as obscure as the occasions to which they allude. Of expression, he only knew the extremes, grimace, or loathsomeness and horror. As a colourist, he was frequently rich and effective, harmonious and warm: and his execution bears the stamp of incredible freedom: while his chiaro-scuro is managed with great breadth and depth. His just character is that of a powerful machinist. He was drowned in the Tyber, in 1650, endeavouring to recover his hat, which the wind had blown into the water; though some suspect that he threw himself in, in a fit of despondency, to which he was prone.

He was an eminent engraver as well as a painter, and the number of his works in both arts attest his industry and ingenuity, considering the short period of his life.

Testa, in *Botany* and *Vegetable Physiology*, is the skin of a seed or kernel, which enfolds the embryo, cotyledons, and, if present, the albumen, giving them their due shape; for this integument is perfectly formed, before they have attained any solidity or distinct organization. The skin is generally double, as may be seen in the peach, apricot, and walnut, that glutinous coat of the latter, which stains our fingers in peeling the kernel, being lined with a much finer, white and smooth membrane, technically called *membrana* by Gærtner. In true pulpy seeds, like those of *Jasminum*, a quantity of pulp is lodged between the *membrana* and the outer skin. Both these integuments burst irregularly, merely from the swelling of their contents in germination.

Testa *di Moro*, in *Geography*, a small island near the E. coast of Sardinia. N. lat. 40° 45′. E. long. 9° 53′.

Testa *di Saori*, a town of the island of Corsica; 7 miles N. of Bastia.

Testa *Nevilli*, or *Testa de Nevil*, an ancient record kept by the king's remembrancer in the exchequer, containing the king's fees throughout the greatest part of England, with inquisitions of land escheated, and sergeanties.

It was denominated from its compiler Johan. de Nevil, one of the itinerant justices under king Henry III.

Testa *Sepiæ*. See Cuttle-*Fish Bone*.

TESTACEOLOGY, the science of testaceous vermes, or, in other words, of those soft and simple worms, which have a shelly or testaceous covering; whether, as in some kinds, it be sufficient to envelope and conceal the whole body, or only to cover a portion of it, as in others. The term is derived from *testa*, a shell; or we should rather wish, in order to support our definition, from *Testacea*, the name of the order of those vermes which have a shelly covering, and which, in the Gmelinian system, are thus defined: Testacea. Animalia Mollusca simplicia, domo sæpius calcarea propria, obtecta.

Under this idea of its derivation, the word testaceology must be considered preferable to that of conchology, in designating the science of those bodies which have a shelly covering; because it may imply, or be understood to imply, not only the science of the shells which form the covering or habitation, but the animal also by which it is inhabited, while that of conchology might be confined to the shells alone. It must however be confessed, that, strictly speaking, the terms testaceology and conchology are synonimous, and that their application in the manner we propose, must rather be determined by the taste of the future naturalist than any positive rule we might lay down. The science itself is but a branch of vermeology; and either the term conchology or testaceology may be applied with much propriety, at the discretion of the writer.

The term testaceology is certainly of late invention, and may in some degree be regarded rather as an innovation than amendment; for even with the definition we might be inclined to assign it, in order that it may be retained, there is still no actual difference in its meaning from the term conchology, a term which, to use the words of a writer of the last century, "comprehends the study of all animals that are testaceous, or have shelly coverings; not only those of the sea, but also those of the rivers and land;" and it has moreover an evident claim to priority, having been in use for at least the last forty years among the best English authors. Da Costa, a writer of no ordinary information, indeed appears to have assumed to himself the establishment, if not the actual invention of the term; for in his "Elements of Conchology," published in 1776, he expressly observes, "this peculiar branch of the history of nature, I shall call conchology." Many authors call it conchyliology; and this we find to be true in compliance both with the French and the Latin, the "Conchyliologie" of D'Argenville, and "Historia Conchyliorum" of Lister, two works of great celebrity, that had appeared some time before his "Elements" were published. We have thus endeavoured to prove that the terms testaceology and conchology are purely synonimous; and if any doubt remained, we might finally quote one further passage from the Elements before alluded to, in which we are distinctly told, that "the term of Conchology, applied to this branch of natural history by all authors, is quite applicable to its arrangement by the shells, and not by the fish." As we have already endeavoured to exemplify the rise, progress, and present state of the science of testaceous bodies in a very ample manner under the article Conchology, and may be allowed to presume, with some little confidence, that we have therein concentrated much useful information upon this truly pleasing and very favourite science, it might be esteemed a waste of words to enter into any very considerable digression upon the same subject again; we shall therefore merely recommend a careful perusal of that article to the attention of the reader, and trust the result will be considered satisfactory.

It was indeed our wish, and we had made some general promise to that effect, that under the present article we would resume this subject, and submit the outlines of what we were induced to think an improvement upon the present prevailing arrangement; and upon this point it is now incumbent to offer a few remarks.

The most ardent admirer of the great Linnæus will readily concede to us, that the science of conchology was not one of those within the province of his deep research, or the decided contemplation of his active mind. Its introduction as a science, was necessary to complete the series of the vast chain of animated nature, the classification of which he had undertaken in his "Systema Naturæ," and it was therefore one he could not omit. But for this, it is believed, and with tolerable certainty, that he would have willingly avoided the subject altogether in the latter editions of that work, as it was in the early ones. We have already shewn, under our article Conchology, the actual state in which Linnæus found the science, as handed down to him by his predecessors; and the various purposes to which he applied their labours and assistance. From a general view of the whole, there can no doubt remain that there is yet much to amend in the classification of shells, and that the subdivision of many of the genera already established into natural genera, appears desirable. It was under this persuasion that we had

had intended, when writing the article Testaceology, to have ſubmitted our ideas as to a new and more comprehenſive claſſification of the genera; to have pointed out the very eſſential diſtinctions that exiſt in ſhells of the ſame Linnæan genera; and have thence endeavoured to deduce an arrangement congenial with the characters of the reſpective natural genera which his artificial genera preſent. This we believe would have been regarded as an improvement in the claſſical diſtribution of the ſhell-tribe, but ſuch an illuſtration does not appear, upon more mature reflection, to be admiſſible here. It muſt be apparent that no words, unaccompanied by figures, could poſſibly convey to the reader any adequate conception of the minute, ambiguous, and intricate eſſential characters, which many among the various tribes of ſhells preſent; and that ſuch a ſeries of plates as it would demand to illuſtrate a ſubject ſo very copious and diffuſe, however deſirable in the opinion of the naturaliſt, could not be appropriated, with any degree of propriety, in addition to the very coſtly ſeries of plates already devoted by the Cyclopædia to this ſcience in particular.

The ſeries of plates which have already appeared, elucidate the whole of the Linnæan genera, and under each of thoſe genera, a number of the more ſtriking natural genera which appertain to them reſpectively. Theſe plates are numerous, and the ſubjects for them have been ſelected with every poſſible attention; nor can we heſitate to think upon the whole they will be conſidered, without any further addition, as amply ſufficient for every uſeful purpoſe of general information.

TESTACEOUS, in *Natural Hiſtory*, an epithet given to thoſe fiſh, which are covered with a ſtrong, thick ſhell; as oyſters, pearl-fiſh, &c.

In ſtrictneſs, however, teſtaceous is only applied to fiſh whoſe ſtrong and thick ſhells are entire; thoſe which are ſoft, thin, and conſiſt of ſeveral pieces jointed, as the lobſter, &c. being called *cruſtaceous*.

In medicine, all preparations of ſhells, and ſubſtances of the like kind, are called teſtaceous.—Such are powders of crab's claws and eyes, pearl, &c.

Dr. Quincy, and others, ſuppoſe the virtue of all teſtaceous medicines to be alike; that they ſeldom or never enter the lacteals, but that the chief of their action is in the firſt paſſages; in which however they are of great uſe in abſorbing acidities.

Hence they become of uſe in fevers, and eſpecially in rectifying the many diſtempers in children, which generally owe their origin to ſuch acidities.

TESTAMENT, Testamentum, in *Law*, a ſolemn and authentic act, by which a perſon declares his will, as to the diſpoſal of his eſtate, effects, burial, &c.

Teſtaments, according to Juſtinian, and ſir Edward Coke, are ſo called, becauſe they are *teſtatio mentis*: an etymon, ſays judge Blackſtone, which ſeems to favour too much of the conceit, it being plainly a ſubſtantive derived from the verb *teſtari*. The definition of the old Roman lawyers is much better than their etymology; *voluntatis noſtræ juſta ſententia de eo, quod quis poſt mortem ſuam fieri velit; i. e.* the legal declaration of a man's intentions, which he wills to be performed after his death. It is called *ſententia*, to denote the circumſpection and prudence with which it is ſuppoſed to be made; it is *voluntatis noſtræ ſententia*, becauſe its efficacy depends on its declaring the teſtator's intention, whence in England it is emphatically ſtyled his *will*: it is *juſta ſententia*, that is, drawn, atteſted, and publiſhed with all due ſolemnities and forms of law: it is *de eo, quod quis poſt mortem ſuam fieri velit*, becauſe a teſtament is of no force till after the death of the teſtator. Blackſtone's Com. vol. ii.

A teſtament has no effect till after death, and is always revocable till then. As teſtaments are acts, of all others, the moſt ſubject to deceits, ſurprize, &c. it was found neceſſary to uſe all kinds of precautions to prevent the wills of the deceaſed from being eluded, and the weakneſs of dying perſons from being abuſed. See Will.

The moſt ancient teſtaments among the Romans were made *viva voce*, the teſtator declaring his will in the preſence of ſeven witneſſes; theſe they called *nuncupative* teſtaments; but the danger of truſting the will of the dead to the memory of the living ſoon aboliſhed theſe: and all teſtaments were ordered to be in writing.

The French legiſlators thought *holographic* teſtaments, *i. e.* teſtaments written wholly with the teſtator's hand, an abundant ſecurity; but the Roman law, more ſevere, did not admit of teſtaments without farther ſolemnity.

The eaſieſt, and moſt favourable, is the twenty-firſt law in the *code de teſtamentis*, which permits ſuch as are unwilling to truſt the ſecret of their teſtaments to others, to write it with their own hand, and to cloſe it in the preſence of ſeven witneſſes, declaring to them, that it is their teſtament; after which it is to be ſigned by all the ſeven witneſſes.

Otherwiſe, to make a ſolemn teſtament, it was required to be atteſted by ſeven witneſſes, and ſealed with their ſeals.

Yet the *military* teſtament was not ſubject to ſo many formalities: the ſoldier was ſuppoſed too much employed in defending the laws, to be ſubject to the trouble of knowing them. His tumultuary profeſſion excuſed him from obſerving all the rules. See Military.

Teſtaments, wherein fathers diſpoſed of their eſtates among their children, had particular privileges, and were diſpenſed from moſt of the ordinary formalities.

Testament, *Probate of a*. See Probate and Will.

Testament, *Old* and *New*, in *Sacred Hiſtory*. The moſt common and general diviſion of the canonical books of ſcripture, is that of the Old and New Teſtament. (See Canon.) The Hebrew word *Berith*, from which it is tranſlated, properly ſignifies "Covenant." Accordingly St. Paul (2 Cor. iii. 6—18.), when he is ſhewing the ſuperior excellence of the goſpel covenant, or the diſpenſation by Chriſt above the legal covenant, or the diſpenſation by Moſes, uſes the word teſtament, not only for the covenant itſelf, but likewiſe for the books in which it is contained. The Hebrew term ברית, *berith*, invariably rendered covenant by our tranſlators in the Old Teſtament, is uniformly tranſlated Διαθηκη in the Septuagint; and in the writings of the apoſtles and evangeliſts, the words ἡ καινη διαθηκη are almoſt always rendered by our tranſlators the New Teſtament. It is obſerved, that the Hebrew term correſponds much better to the Engliſh word "Covenant," though not in every caſe perfectly equivalent, than to "Teſtament;" and yet the word διαθηκη, in claſſical uſe, is more frequently rendered *Teſtament*. Our tranſlators, ancient and modern, have probably been led to render it Teſtament, by the manner in which the author of the epiſtle to the Hebrews argues (ch. ix. 16, 17.), in alluſion to the claſſical acceptation of the term. The term *New* is added to diſtinguiſh the religious inſtitution of Jeſus Chriſt from the *Old Covenant*, that is, the diſpenſation of Moſes. Accordingly the two covenants are always in ſcripture the two diſpenſations, or religious inſtitutions; that under Moſes is the *Old*, and that under the Meſſiah is the *New*. Hence, from ſignifying the two religious diſpenſations, they came ſoon to denote the books in which what related to theſe diſpenſations was contained; the ſeveral writings of the

Jews being called ἡ παλαια διαθηκη, and the writings ſuper-added by the apoſtles and evangeliſts, ἡ καινη διαθηκη.

The New Teſtament conſiſted very anciently of two codes or collections, called goſpels and epiſtles. This was the caſe in the time of Ignatius, and alſo in the time of Tertullian, who diſtinguiſhes the goſpels by the names of the writers, and calls them our "Digeſta," or digeſts, in alluſion, as it ſeems, to ſome collection of the Roman laws digeſted into order. As to the order of the ſeveral goſpels, it appears, that in Tertullian's time they were diſpoſed, at leaſt in the African churches, according to the quality of the writers; thoſe two occurring firſt which were written by apoſtles, and then the other two written by apoſtolical men. In ſome of the moſt ancient MSS. now extant, the order of the ſeveral evangeliſts is thus; Matthew, John, Luke, Mark. The order of the four goſpels has been generally this: Matthew, Mark, Luke, John; then follow the Acts, St. Paul's epiſtles, the Catholic epiſtles, and the Revelation. It ſufficiently appears, from a variety of conſiderations ſuggeſted by the excellent Dr. Lardner, that the books of the New Teſtament, conſiſting of a collection of ſacred writings, in two parts, one called Goſpel or Goſpels, or Evangelicon; the other Epiſtles, or Apoſtle or Apoſtles, or Apoſtolicon, were only known, read, and made uſe of by Chriſtians. (See Canon.) It has been a ſubject of ſome diſpute, whether any ſacred books of the New Teſtament have been loſt; but there are many conſiderations, tending to ſatisfy us, that no ſacred writings of the apoſtles of Chriſt are loſt.

The four goſpels, in our poſſeſſion, were written for the benefit of thoſe who would undoubtedly receive them with reſpect, keep them with care, and recommend them to others; and if any other ſuch authentic hiſtories of Jeſus Chriſt had been written by apoſtles, or apoſtolical men, they would have been received, and preſerved in like manner. The book of the Acts, which we ſtill have, was the only authentic hiſtory of the preaching of the apoſtles after our Lord's aſcenſion, which they had in their hands, or had heard of; conſequently there was no other ſuch hiſtory to be loſt. The epiſtles of Paul, James, Peter, John, Jude, were ſent to churches, people, or particular perſons, who would ſhew them great regard when received, would carefully preſerve them, and readily communicate them to others, that they might take copies of them, and uſe them for their eſtabliſhment in religion and virtue; and if other ſuch epiſtles had been written, the caſe would have been much the ſame, nor could any of them have been eaſily loſt. Beſides, the apoſtles and evangeliſts, who drew up any writings for the inſtruction or confirmation of Chriſtian people, muſt have been careful of them. Upon the whole, we have no ſufficient reaſons for believing, that any ſacred writings of the New Teſtament have been loſt. All the books of the New Teſtament were written in Greek, except the goſpel of St. Matthew, who, according to St. Jerom, firſt wrote in Judea in the Hebrew language. Tertullian, as well as many other ancient writers, afford us various teſtimonies to the integrity and genuineneſs of the goſpels and other books of the New Teſtament in his time, as well as to their divine inſpiration. See Bible.

Although the New Teſtament was written in Greek, an acquaintance with the Greek claſſics will not be found ſo conducive to the interpretation of it, as an acquaintance with the ancient Hebrew ſcriptures. The propriety of its being written in the Greek language will appear from the following hiſtorical fact. After the Macedonian conqueſts, and the diviſion which the Grecian empire underwent among the commanders on the death of their chief, Greek ſoon became the language of the people of rank through all the extenſive dominions which had been ſubdued by Alexander. The perſecutions with which the Jews were haraſſed under Antiochus Epiphanes, concurring with ſeveral other cauſes, occaſioned the diſperſion of a great part of their nation throughout the provinces of Aſia Minor, Aſſyria, Phœnicia, Perſia, Arabia, Libya, and Egypt; which diſperſion was in proceſs of time extended to Achaia, Macedonia, and Italy. The unavoidable conſequence of this was in a few ages, to all thoſe who ſettled in diſtant lands, the total loſs of that dialect, which their fathers had brought out of Babylon into Paleſtine, excepting only amongſt the learned. At length a complete verſion of the ſcriptures of the Old Teſtament was made into Greek; a language which was then, and continued for many ages afterwards, in far more general uſe than any other. (See Septuagint.) The Jews, who inhabited Grecian cities, where the oriental tongue was unknown, would be naturally anxious to obtain copies of this tranſlation. Wherever Greek was the mother-tongue, this verſion would be gradually adopted into uſe not only in private in Jewiſh houſes, but alſo in public in their ſchools and ſynagogues, for the explanation of the weekly leſſons from the law and the prophets. The ſtyle of it would conſequently ſoon become the ſtandard of language to them with regard to religious ſubjects. Hence would ariſe a certain uniformity in phraſeology and idiom among the Grecian Jews, whereſoever diſperſed, in reſpect of their religion and ſacred rites, whatever might be the particular dialects which prevailed in the places of their reſidence, and were uſed by them in converſing on ordinary matters. From the conformity and peculiarity in language now noticed, ſome critics, in order to diſtinguiſh the idioms of the LXX and New Teſtament from that of common Greek, have termed it *Helleniſtic;* which ſee. Under that article we have intimated, that the habit which the apoſtles and evangeliſts had of reading the ſcriptures, and hearing them read, whether in the original or in the ancient verſion; would, by infecting their ſtyle, co-operate with the tendency which, as natives of Paleſtine, they would derive from converſation, to intermix Hebraiſms and Chaldaiſms in their writings. Some modern writers, whilſt they have adverted to this circumſtance, have defended the diction of the ſacred penmen of the New Teſtament, and extolled it as altogether pure and elegant. Among theſe we may reckon Pſochenius and Blackwall, who, with this view, have made diligent reſearches among the writings of the ancient Greeks, for the diſcovery of words and phraſes, which might appear to reſemble what has been accounted Hebraiſm or Syriaſm in the New Teſtament. Whereas the writings of the New Teſtament carry, in the very expreſſion and idiom, an intrinſic and irreſiſtible evidence of their authenticity. They are ſuch as, in reſpect of ſtyle, could not but have been written by Jews, and hardly even by Jews ſuperior in rank and education to thoſe whoſe names they bear; and yet, under this homely garb, we find the moſt exalted ſentiments, the cloſeſt reaſoning, the pureſt morality, and the ſublimeſt doctrine.

Abſtracting from that loweſt kind of beauty in language, which reſults from its ſoftneſs and harmony, conſidered as an object to the ear, every excellency of ſtyle is relative, ariſing ſolely from its fitneſs for producing, in the mind of the hearer, the end intended by the writer. Now in this view it is evident, that a ſtyle and manner may, to readers of one denomination, convey the writer's ſentiments with energy as well as perſpicuity, which, to thoſe of a different denomination, would convey them feebly, darkly, and, when judged by their rules of propriety, improperly. This ſeems to have been actually the caſe with the writers of the

New Teftament. The language of Matthew, Mark, Luke, and John, is better adapted to the readers, for whofe ufe the Gofpels and Acts were at firft compofed, than the language of Plato or Demofthenes would have been.

If we would enter thoroughly into the idiom of the New Teftament, we muft familiarife ourfelves to that of the Septuagint; and if we would enter thoroughly into the idiom of the Septuagint, we muft accuftom ourfelves to the ftudy, not only of the original of the Old Teftament, but of the dialect fpoken in Paleftine between the return of the Jews from the Babylonifh captivity, and the deftruction of Jerufalem by the Romans; for this laft, as well as the Hebrew, has affected the language both of the old Greek tranflation and of the New Teftament.

Such is the origin and the character of the idiom, which prevails in the writings of the apoftles and evangelifts, and the remarkable conformity of the new revelation we have by them, though written in a different language, to the idiom of the old. It has been diftinguifhed in the former by the name Helleniftic, not with critical accuracy, if regard be had to the derivation of the word, but with fufficient exactnefs, if attention be given to the application which the Hebrews made of the term Hellenift, by which they diftinguifhed their Jewifh brethren, who lived in Grecian cities and fpoke Greek. It has been by fome of late, after father Simon of the Oratory, more properly termed the Greek of the fynagogue. It is acknowledged, that it cannot ftrictly be denominated a feparate language, or even dialect, when the term dialect is conceived to imply peculiarities in declenfion and conjugation. But, with the greateft juftice, it is denominated a peculiar idiom, being not only Hebrew and Chaldaic phrafes put in Greek words, but even fingle Greek words ufed in fenfes in which they never occur in the writings of profane authors, and which can be learnt only from the extent of fignification given to fome Hebrew or Chaldaic word, correfponding to the Greek in its primitive and moft ordinary fenfe. This difference in idiom conftitutes a difficulty of another kind from that which is created by a difference in dialect; a difficulty much harder to be furmounted, as it does not affect the form of the words, but the meaning.

It is pertinent, however, to obferve, that the above remarks on the Greek of the New Teftament, do not imply that there was any thing which could be called idiomatical or vulgar in the language of our Lord himfelf, who taught always in his mother tongue. His apoftles and evangelifts, on the contrary, who wrote in Greek, were, in writing, obliged to tranflate the inftructions received from him into a foreign language of a very different ftructure, and for the ufe of people accuftomed to a peculiar idiom. The apparently refpectful manner in which our Saviour was accofted by all ranks of his countrymen, and in which they fpoke of his teaching, fhews that he was univerfally confidered as a perfon of eminent knowledge and abilities. It was the amazing fuccefs of his difcourfes to the people, in commanding the attention and reverence of all who heard him, which firft awakened the jealoufy of the fcribes and pharifees.

Although all the writers of the New Teftament wrote in the idiom of the fynagogue, we are not to conclude from hence, that there is no difcernible diverfity in their ftyles. As the fame language admits of a variety of dialects, and even of provincial and foreign idioms, fo the fame dialect and the fame idiom are fufceptible of a variety of ftyles. The ftyle of Paul has fomething peculiar, by which, in our opinion, there would be no difficulty in diftinguifhing him from any other writer. A difcerning reader would not readily confound the ftyle of Luke with that of either of the evangelifts who preceded him, Matthew or Mark; and ftill lefs would he miftake the apoftle John's diction for that of any other penman of the New Teftament. The fame differences of ftyle will be difcovered by one who is but moderately converfant in Hebrew in the writers of the Old Teftament. In it we have ftill greater variety than in the New. Some of the books are written in profe and fome in verfe: and in each, the differences between one book and another are confiderable. In the book of Job, for inftance, the character of the ftyle is remarkably peculiar. What can be more diffimilar in this refpect, though both are excellent in their kind, than the towering flights of the fublime Ifaiah, and the plaintive ftrains of the pathetic Jeremiah? In the books of Scripture we can fpecify the concife ftyle and the copious, the elevated and the fimple, the aphoriftic and the diffufe.

How this diverfity of ftyle is reconcileable with the idea of infpiration, we have attempted to fhew under the article Inspiration. See Campbell's Prelim. Diff.

TESTAMENTARY Adoption. See Adoption.

Testamentary *Caufes*, in *Law*, are thofe that relate to teftaments, which were originally cognizable in the king's courts of common law, *viz.* the county-courts; and afterwards transferred to the jurifdiction of the church, by the favour of the crown, as a natural confequence of granting to the bifhops the adminiftration of inteftates' effects. This fpiritual jurifdiction of teftamentary caufes is a peculiar conftitution of this ifland; for in almoft all other (even in popifh) countries, all matters teftamentary are of the jurifdiction of the civil magiftrate. And that this privilege is enjoyed by the clergy in England not as a matter of ecclefiaftical right, but by the fpecial favour and indulgence of the municipal law, and as it fhould feem by fome public act of the great council, is freely acknowledged by Lindewode, the ableft canonift of the fifteenth century; and about a century before, in a canon of archbifhop Stratford; alfo by the conftitutions of cardinal Othobon; and likewife by archbifhop Parker, in the time of queen Elizabeth. At what period of time the ecclefiaftical jurifdiction of teftaments and inteftacies began in England, is not afcertained by any ancient writer. It appears the foreign clergy were early ambitious of this power, though they were curbed by the edict of the emperor Juftin, which reftrained the infinuation or probate of teftaments (as formerly) to the office of the *magifter cenfus*: but afterwards by the canon law it was allowed, that the bifhop might compel, by ecclefiaftical cenfures, the performance of a bequeft to pious ufes. And therefore it fell within the jurifdiction of the fpiritual courts, by the exprefs words of the charter of king William I. which feparated thofe courts from the temporal. And afterwards, when king Henry I. by his coronation-charter, directed that the goods of an inteftate fhould be divided for the good of his foul, this made all inteftacies immediately fpiritual caufes, as much as a legacy to pious ufes had been before. This therefore, fays judge Blackftone, we may poffibly conjecture, was the era referred to by Stratford and Othobon, when the king, by the advice of the prelates, and with the confent of his barons, invefted the church with this privilege.

This jurifdiction is principally exercifed with us in the confiftory courts of every diocefan bifhop, or in the prerogative court of the metropolitan originally; and in the arches court, and courts of delegates by appeal. It is divifible into three branches; the probate of wills, the granting of adminiftrations, and the fuing for legacies. The two former

former of which, when no oppofition is made, are granted merely *ex officio et debito juftitiæ*, and are then the object of what is called the voluntary, and not the contentious jurifdiction. But when a caveat is entered againft proving the will or granting adminiftration, and a fuit thereupon follows, in order to determine either the validity of the teftament, or who hath a right to the adminiftration, this claim and obftruction are remedied by the fentence of the fpiritual court, either by eftablifhing the will, or granting the adminiftration. Blackftone's Com. vol. ii. See SUBTRACTION *of Legacies*.

TESTAMENTARY *Guardian*, *Succeffion*, and *Tutorage*. See the fubftantives.

TESTAMENTO *Annexo*, *Adminiftration cum*. If a teftator makes his will, without naming any executors, or if he names incapable perfons, or if the executors named refufe to act; in any of thefe cafes, the ordinary muft grant adminiftration *cum teftamento annexo*, to fome other perfon.

TESTAMENTS *of the Twelve Patriarchs*, in *Ecclefiaftical Hiftory*, a kind of apocryphal or fuppofititious book, in which thofe patriarchs are introduced, fpeaking their laft dying words, containing predictions of things future, and rules of virtue and piety; which they deliver to their fons as a choice treafure, to be carefully preferved, and to be delivered by them to their children. We have feveral editions of thefe in Latin; they were firft publifhed in Greek, by Grabe, and from his edition republifhed by Fabricius; and tranflated into Englifh by Mr. Whifton. Cave places the anonymous author of this book in the year 192, or nearer the beginning of the fecond century. They are cited by Origen, and, therefore, were probably written before his time. Grabe thinks they were written before the time of our Saviour, and afterwards interpolated by a Chriftian. But Mr. Whifton afferts, that they are really genuine, and one of the facred apocryphal, or concealed books of the Old Teftament. Cave fuppofes that this book was written by a judaizing Chriftian; Grabe apprehends that it was written in Hebrew: Beaufobre is of opinion that it was forged at the end of the firft, or beginning of the fecond century, by fome Chriftian converted from Judaifm, and he fufpects that the author was an Ebionite, and that he believed Jefus to be the fon of Jofeph and Mary. Dr. Lardner is pofitive that thefe teftaments are not the real laft words of the twelve patriarchs; but the clear knowledge of Chriftian affairs and principles fhews this book to have been written, or elfe very much interpolated, after the publication of the Chriftian religion. He fays, there is nothing in this work that might not have been written by a learned Jew of the fecond century or later, though he thinks that the author was a Chriftian, and well verfed in the Jewifh learning: and moreover he is of opinion, that he is placed early enough by Cave, at the year 192. Lardner's Works, vol. ii.

TESTATOR, or TESTATRIX, the perfon who makes his or her will and teftament.

M. Gillet fhews, that a perfon incapable of a legacy cannot demand any fum which the teftator in his teftament declares himfelf indebted to him in; in regard fuch a declaration of debt is prefumed a fraud againft the intention of the law.

TESTATUM, in *Law*, a writ in perfonal actions; where, if the defendant cannot be arrefted on a *capias* in the county where the action is laid, but is returned *non eft inventus* by the fheriff, this writ fhall be fent into any other county, where fuch perfon is thought to be, or to have wherewithal to fatisfy the demand.

It is called *teftatum*, becaufe the fheriff has before teftified, that the defendant was not to be found in his bailiwick.

TESTE, a term commonly ufed in the clofe of a writ, where the date is contained, which begins with *Tefte meipfo*, if it be an original writ; or, if judicial, *Tefte*, the *lord chief juftice*, &c. according to the court whence it comes. In fome ancient formulas, we read *Tefte cuftode Angliæ*. There muft be at leaft fifteen days between the tefte and return of every procefs awarded from the king's bench into any foreign county. See WRIT.

TESTENICH, in *Geography*, a fmall ifland in the gulf of Venice. N. lat. 44° 54′. E. long. 14° 47′.

TESTER. See TESTON.

TESTES, TESTICULI, in *Anatomy*; quia virilitatem teftantur; glandular bodies, peculiar to the male fex of animals, ferving the office of fecreting the fecundating fluid: hence their removal deprives an animal of the power of propagating its kind. See GENERATION, *Male Organs of*.

The teftes are wanting in moft of the fifh kind. The fpinofe fifhes in general have neither teftes nor paraftatæ; but all the cetaceous fifhes have them, and not a few of the cartilaginous kinds. Thofe fifh that have them, have always two, as in land-animals; but they differ much in figure and fituation in the feveral kinds, particularly in the whale and flat-fifh. See *Anatomy of* FISH.

TESTES *of the Brain*, two fmall hemifperical eminences, fituated at the pofterior and inferior afpect of the optic thalami, and now more generally known, together with two very fimilar ones immediately above them, by the name of tubercula quadrigemina. See BRAIN.

TESTES *Synodales*. See SYNODALES.

TESTI, FULVIO, *Count*, in *Biography*, an Italian poet, was born in 1593, at Ferrara, and fettling, when young, at Modena, he rofe to the higheft offices and honours of the ftate. Neverthelefs, alternate profperity and adverfity vifited him: inconftant and ambitious, he fell into difgrace with Francis I. who imprifoned him in the citadel of Modena, where he died in 1646. His poems are chiefly of the lyric clafs. The productions of his maturer judgment are diftinguifhed above thofe of his contemporaries for vigour and poetical fpirit; and fome of them, with refpect to elevation of fentiment and beauty of imagery, will bear comparifon with the productions of the beft Italian poets. He alfo attempted tragedy in two compofitions, intitled "Arfinda," and "L'Ifola d'Alcina;" but their ftyle is lyric rather than dramatic compofition. Tirabofchi. Gen. Biog.

TESTIBUS HIIS. See HIIS.

TESTICLE, TESTIS, in *Anatomy*. See GENERATION.

TESTICLE, *Difeafed*, in *Surgery*. See SARCOCELE, HYDROCELE, FUNGUS *of the Tefticle*, FUNGUS *Hæmatodes*, HERNIA *Humoralis*, &c.

TESTICLE, *Operation of removing*. See CASTRATION.

TESTIGOS, LOS, in *Geography*, a clufter of fmall iflands, about ten leagues from the continent of South America, and the fame diftance from the ifland of Grenada. N. lat. 11° 25′. W. long. 62° 5′.

TESTIMON, a town of Pruffia, in the province of Ermeland; 16 miles S.S.E. of Hilfberg.

TESTIMONIAL, a kind of certificate, figned either by the mafter and fellows of the college, where a perfon laft refided, or by three, at leaft, reverend divines, who knew him well for three years laft paft; giving an account of the conduct and learning of the perfon.

Such a teftimonial is always required before holy orders are conferred; and the bifhop even ordinarily demands one of a prieft before he admits him to a benefice.

TESTIMONIAL is alfo a certificate under the hand of a juftice of peace, teftifying the time and place when and where a foldier a foldier or mariner landed, and the place of his dwelling, and whither he is to pafs.

TESTIMONY. See Evidence.

Teftimony is a ferious intimation from another of any fact or obfervation, as being what he remembers to have feen, heard, or experienced. The evidence of teftimony is either oral or written. Some have unreafonably fuppofed, that this kind of evidence is folely and originally derived from experience. With regard to this it may be obferved, that the evidence of teftimony is to be confidered as ftrictly logical, no farther than human veracity, in general, or the veracity of witneffes of fuch a character, and in fuch circumftances in particular, is fupported, or hath not been refuted by experience. But that teftimony, antecedently to experience, hath a natural influence on belief, is undeniable, in which refpect it refembles memory. And in what regards fingle facts, it is a more adequate evidence than any conclufions from experience. When experience is applied to the difcovery of the truth in a particular incident, the evidence is called *prefumptive;* whereas ample teftimony is accounted a pofitive proof of the fact. Teftimony is capable of giving us abfolute certainty even of the moft miraculous fact, or of what is contrary to uniform experience. To this, when we have no pofitive reafons of miftruft or doubt, we are, by an original principle of our nature (analogous to that which compels our faith in memory), led to give an unlimited affent. As on memory alone is founded the merely perfonal experience of the individual, fo on teftimony, in concurrence with memory, is founded the much more extenfive experience, which is not originally our own, but derived from others. See on this fubject Campbell's Philof. of Rhet. vol. i. book i. chap. 5. and Differtation on Miracles, part i. fect. i. and i. See Faith.

For the credibility of human teftimony, fee Certitude.

TESTINA, in *Ancient Geography*, a town of Italy, belonging to the Sabines, placed by D'Anville S.W. of Amiternum.

TESTING, in *Metallurgy*, denotes the operation of refining large quantities of gold and filver, by means of lead, in the veffel called a *teft*. This operation is performed by the deftruction, vitrification, and fcorification of all the extraneous and deftructible metallic fubftances with which thofe noble metals are alloyed. It confifts in adding to the alloyed gold and filver, a certain quantity of lead, and in expofing afterwards this mafs to the action of the fire. The lead, by increafing the proportion of imperfect metals, prevents them from being fo well covered and protected by the perfect metals; by uniting with thefe, it communicates to them a property it has of lofing very eafily a great part of its inflammable principle; and laftly, by its vitrifying and fufing property, which it exercifes with all its force upon the calcined and naturally refractory parts of the other metals, it facilitates and accelerates the fufion, the fcorification, and feparation of thefe metals. The lead, which in this operation is purified, and fcorifies along with it the imperfect metals, feparates from the metallic mafs with which it is then incapable of remaining united: it floats upon the furface of the melted mafs; becaufe by lofing part of its phlogifton, (according to the former language of chemifts,) it lofes alfo part of its fpecific gravity, and laftly it vitrifies. The removal of the vitrified matter in the procefs is procured either by the nature of the veffel in which the melted matter is contained, and which, being porous, abforbs and imbibes the fcorified matter as faft as it is formed; or by a channel cut in the edge of the veffel through which the matter flows out.

The procefs of tefting is generally performed in the fame manner as that of cupellation. See Assaying and Copelling.

But when great quantities of bafe metal are to be worked off from a little gold, recourfe is had to a more expeditious method, that of tefting before the bellows. An oval teft is placed in a cavity, made in a hearth of a convenient height, and fome moiftened fand or afhes preffed round it to keep it fteady: the nofe of a bellows is directed along its furface, in fuch a manner, that if afhes are fprinkled in the cavity of the teft, the bellows may blow them completely out: fome have an iron plate fixed before the bellows, to direct the blaft downwards. To keep the furface of the teft from being injured in putting in the metal, fome cloths or pieces of paper are interpofed. The fuel confifts of billets of barked oak, laid on the fides of the teft, with others laid crofs-wife on thefe: the bellows impels the flame on the metal, clears the furface of afhes or fparks of coal, haftens the fcorification of the lead, and blows off the fcoria, as faft as it is formed, to one end of the teft, where it runs out through a notch made for that purpofe. About two-thirds of the fcorified lead may be thus collected; the reft being partly abforbed by the teft, and partly diffipated by the action of the bellows. Care muft be taken not to urge the blaft too ftrongly, left fome portion of the gold fhould be carried away by the fumes impetuoufly forced off from the lead, and fome minute particles of it entangled and blown off with the fcoriæ. Macquer's Chem. Dict. Art. *Refining*. Lewis's Ph. Techn. p. 146.

TESTO, Ital. literally *teft*. In *Mufic* it implies a fubject, or words of a fong, or other vocal compofition, to which fome air, melody, or harmony, is to be compofed.

It is a matter of great concern to underftand well how to appropriate or adapt the mufic to the words of a fong, to exprefs the fenfe, and make a juft application of the long and fhort fyllables to the notes and time with which they are to be connected.

But this branch of the fcience, which depends greatly on the knowledge of poetry, has lain a long time almoft unregarded; and even at prefent, very little care is taken in this point in the modern mufic, which is fomewhat wonderful, fince it was to this that the ancients attributed the extraordinary effects of their mufic; for by them this branch was moft accurately obferved, and by this they regulated and governed their meafures, fo that they might produce the defired effects; and fome philofophers fay, the human paffions and affections. Voffius de Poem. Cantu, &c.

TESTON, Tester, the name of a coin ftruck in France by Louis XII. in 1513, and in Scotland in the time of Francis II. and Mary queen of Scotland, fo called from the head of the king, (*tefte* or *tête*,) which was engraved upon it. The filver it contained was 11 deniers 18 grains; its weight, 7 deniers $11\frac{1}{2}$ grains; and its value 10 fols. The coinage of it was prohibited by Henry III. in 1575, when the value of it was augmented to 14 fols 6 deniers. Encycl.

A remarkable Scottifh medal of this kind was that inaugurative of Francis II. of France with Mary of Scotland, though it is more properly indeed French, being, as it is thought, ftruck upon their coronation, as being a queen of that country. It prefents bufts of Francis and Mary, face to face, with three legends around them, the outermoft of which contains their titles, the middle one this fingular fentence,

"Which wonders how the devil it got there:"

HORA NONA DOMINUS IHS EXPIRAVIT HELI CLAMANS, a moft ominous motto, one would imagine, to a fuperftitious ear. The innermoft legend is only the name of the city of Paris. There are fine French teftoons of Francis and Mary, likewife prefenting them face to face, with the arms of France

France and Scotland upon the reverſe, as is alſo the caſe of the medal juſt mentioned. Theſe pieces are ſo fine and rare, that Dr. Hunter gave ten guineas for the one in his cabinet, which contains as vaſt and well-choſen a private collection, of all ſorts of coins and medals, as any in the world.

Teſtoons, or ſhillings, were firſt coined in Scotland about the year 1553, and they bore the buſt of the queen and the arms of France and Scotland on the reverſe: they were of the ſame intrinſic value with thoſe of England, and were worth four ſhillings; the half-teſtoon two, Scottiſh money. The ſilver teſtoon of Mary, chiefly of 1553 or 1562, with her buſt, are rare, worth about 30*s.*; half ſtill more rare, valued at 3*l.* Pinkerton on Medals.

The teſton, teſtoon, or teſter, among us, ſucceeded the groat, which was introduced by Edward III. in 1354. It was alſo called ſhilling, and firſt coined by Henry VII. in 1503: and was rated at 12*d.* in the reign of Henry VIII. and afterwards reduced to 6*d.* The teſtoon of the firſt year of Edward VI. is extremely rare.

TESTOON, or Testone, a ſilver coin in Italy, and alſo in Portugal. At Florence, the teſtoon, or teſtone, as a money of account and a ſilver coin, is worth two lire, or three paoli. The teſtoon is a money of account at Liſbon, and is valued at 100 rees. And of the gold coins ſtruck ſince 1722, there are the Dezeſeis teſtoon of 1600 rees, and the Oito teſtoon of 800 rees. The ſilver coins are teſtoons of 100 and halves of 50 rees.

At Rome the ſcudo, as a money of account, is divided into $3\frac{1}{3}$ teſtoni; and among the ſilver coins, the teſtoni are valued at 3 paoli, the paoli being worth $5\frac{1}{4}$*d.* ſterling nearly. See Coin.

TESTORE, Carlo Giovanni, in *Biography*, a violiniſt and muſic-maſter, reſident at Verſeilles in 1770. In 1767 he publiſhed a treatiſe on muſic, entitled, "Muſica ragionata," in 4to. This author was perhaps the firſt Italian who adopted Rameau's principles. He ſimplified his rules, and made his treatiſe more intelligible to *principiante* than Rameau himſelf, or his ſcientific commentator d'Alembert. The full title of his book is "La Muſica ragionata eſpreſſa familiarmente in dodeci Paſſeggiate a Dialogo, ornati 140 eſſempi Muſicali in rami."

TESTOURE, in *Geography*, a town of Africa, in the country of Tunis, on the Mejerdah; 40 miles S.W. of Tunis.

TESTUDO, in *Antiquity*, was particularly uſed among the poets, &c. for the ancient lyre, or lyre of Amphion; becauſe it was ſaid to have been originally made, by its inventor Mercury, of the back or hollow ſhell of a teſtudo aquatica, or ſea-tortoiſe, which he accidentally found on the banks of the river Nile.

Mr. Molyneux has an expreſs diſcourſe, in the Philoſophical Tranſactions, to ſhew that the tortoiſe-ſhell was the baſis of the ancient lyre, and that the whole inſtrument had thence the denomination teſtudo; which account throws ſome light on an obſcure paſſage in Horace, ode iii. lib. 4. miſtaken by all the commentators:

"O, teſtudinis aureæ
  Dulcem quæ ſtrepitum, Pieri, temperas!
O mutis quoque piſcibus
  Donatura cygni, ſi libeat, ſonum!"

Testudo, *Tortoiſe*, in the *Military Art of the Ancients*, was a kind of cover, or ſcreen, which the ſoldiers, *e. gr.* a whole company, made themſelves of their targets, by holding them up over their heads, and ſtanding cloſe to each other.

Thus, if we ſuppoſe the firſt rank to have ſtood upright on their feet, and the reſt to have ſtooped lower and lower by degrees, till the laſt rank kneeled down on their knees, ſo that every rank covering with their targets the heads of all in the rank before them, they repreſented a tortoiſe-ſhell, or a ſort of ſloping roof.

This expedient ſerved to ſhelter them from darts, ſtones, &c. thrown upon them, eſpecially thoſe thrown from above when they went to the aſſault. It was alſo uſed in field-battles as well as in ſieges.

Testudo was alſo a kind of large defenſive engine, of an oval figure, compoſed of boards, and wattled up at the ſides with wicker, which moved on ſeveral wheels, ſerving to ſhelter the ſoldiers when they approached the walls to mine them, or to batter them with rams.

Testudo, in *Medicine*, denotes a ſoft broad tumour, or gathering of impure humours between the ſkull and the ſkin, called alſo *talpa*, as reſembling the ſubterraneous windings of the tortoiſe or mole.

Testudo, *Tortoiſe*, in *Zoology*, a genus of animals of the claſs of Amphibia and order of Reptiles; the generic characters of which are, that the body is furniſhed with a tail, and defended by a bony or coriaceous integument above and below, or above by ſcales; and that the upper mandible of the mouth cloſes over the lower; without diſtinct or proper teeth, the teeth, as they are called in the generality of tortoiſes, being no other than the ſerratures of the mandibles.

Gmelin enumerates thirty-three ſpecies, which are diſtributed into the three claſſes of *marine*, *fluviatile*, and *land* tortoiſes.

A. *Marine Tortoiſes, or Turtles with pinniform Feet, the former being longer.*

The animals of this claſs are diſtinguiſhed from the land tortoiſes by their very large and long fin-ſhaped feet, in which are incloſed the bones of the toes, the firſt and ſecond on each foot being furniſhed with viſible or projecting claws, the others not appearing beyond the edge. The ſhield, as in the land tortoiſes, conſiſts of a ſtrong bony covering, in which are imbedded the ribs, and which is coated externally by hard horny plates, in one or two ſpecies much thicker and ſtronger than thoſe of the land tortoiſes. Mr. Schœpf, cited by Dr. Shaw, obſerves, that the apparent number of claws or projecting extremities on the feet of the marine tortoiſes, appears to be no certain criterion of the ſpecies; but, on the contrary, is found to vary ſo as to contradict the Linnæan ſpecific characters.

Species.

Coriacea; Coriaceous Tortoiſe. Striated lengthwiſe; or brown turtle, paler beneath, with coriaceous ſhell, marked by five longitudinal tuberculated ribs. This is the largeſt of the marine tortoiſes, being found eight feet long, and one thouſand pounds in weight. It is larger than others of its tribe, and its external covering differs by not being horny, but reſembling ſtrong leather, marked over the ſurface into ſmall, obſcurely ſubhexagonal and pentagonal diviſions, without deſtroying its general ſmoothneſs. The longitudinal ribs or ridges are five; and comprehending thoſe that border the ſides, the number is ſeven. It has no under or thoracic ſhell; the head is large, and the upper mandible notched at the tip, ſo as to exhibit the appearance of two large teeth, between which, when the mouth is cloſed, is received the tip of the lower mandibles; the fins are large and long, and covered with a tough leathery ſkin; the tail is rather ſhort and ſharp-pointed. This ſpecies is a native of the Mediterranean, and has occaſionally been taken on the coaſts both of France and England. It is alſo found, not only in the European

ropean feas, but in thofe of South America, and about fome of the African coafts. The Greeks, according to Cépéde, were well acquainted with this fpecimen, and ufed it in the conftruction of the lyre or harp. (See TESTUDO, in *Antiquity*.) Pennant fays, that this fpecies is extremely fat, but the flefh coarfe and bad; but the Carthufians will eat no other fpecies. The fmall fea tortoife defcribed by Pennant in the Phil. Tranf. for 1771, is faid to be the young of this animal. Gmelin mentions this and another as varieties.

IMBRICATA. The imbricated or variegated turtle with thirteen imbricated fcales on the difk; thefe lap over each other at the extremities like tiles on the roof of a building. The head is fmaller than in other turtles; the neck longer; and the beak narrower, fharper, and more curved, fo as confiderably to refemble the bill of a hawk, and from this circumftance the animal derives its popular name of the "hawkfbill turtle." This turtle is a native of the Afiatic and American feas, and is fometimes found in the Mediterranean. It has been often known to meafure five feet in length, and to weigh 500 or 600 pounds. In the Indian ocean it attains a prodigious fize. Its fhell was anciently ufed for a fhield, and ftill ferves for that purpofe among barbarous nations. The flefh is not efteemed as a food; the lamellæ or plates of the fhell, being much ftronger, thicker, and clearer than thofe of any other kind, conftitute its fole value. See TORTOISE-*Shell*.

MYDAS. Brownifh turtle, with thirteen fcales on the difk; the green turtle of fome writers, with two nails on the fore-feet, and fingle ones on the hind-feet. This common green turtle (efculent turtle), is fo named from the green tinge, derived from the vegetable fubftances on which it feeds, often exhibited by its fat, when the animal is in its higheft perfection. It is one of the largeft of this genus, often meafuring above five feet in length (fometimes more than fix), and weighing more than 500 or 600 pounds. Its colour is a dull palifh brown, variegated with deeper undulations, but not exhibiting the beautiful colours which diftinguifh the T. imbricata. Its flefh, however, is in fuch eftimation, that the inhabitants of the Weft Indian iflands have long confidered it as one of the moft excellent articles of food, and have introduced a fimilar tafte into fome of the European nations. In our own country it is much efteemed, and confiderable quantities of it are imported to fupply the luxury of the metropolis. Its introduction, however, cannot be traced farther than about 50 or 60 years backward. Sir Hans Sloane informs us, in his Hiftory of Jamaica, that forty floops were employed by the inhabitants of Port Royal, in Jamaica, for catching them, and that the markets there are fupplied with turtle as ours are with butcher's meat. The method of taking them at the Bahama iflands is by ftriking them with a fmall iron peg two inches long, put in a focket at the end of a ftaff twelve feet long. Two men ufually fet out for this work in a little light boat or canoe, one to row and gently fteer the boat, while the other ftands at the head of it with his ftriker. The turtle are fometimes difcovered by their fwimming with their head and back out of the water, but they are ofteneft difcovered lying at the bottom, a fathom or more deep. If a turtle perceives he is difcovered, he ftarts up to make his efcape, the men in the boat purfuing him, endeavour to keep fight of him, which they often lofe, and recover again by the turtle putting his nofe out of the water to breathe: thus they purfue him, one paddling or rowing, while the other ftands ready with his ftriker. It is fometimes half an hour before he is tired; then he finks at once to the bottom, which gives them an opportunity of ftriking him, which is by piercing him with an iron peg, which flips out of the focket, but is faftened with a ftring to the pole. If he is fpent and tired by being long purfued, he tamely fubmits, when ftruck, to be taken into the boat or hauled afhore. There are men who by diving will get on their backs, and by preffing down their hind parts, and raifing the fore-part of them by force, bring them to the top of the water, while another flips a noofe about their necks.

The fea tortoifes, or turtles, fays Catefby, never go on fhore but to lay their eggs, which they do in April: they then crawl up from the fea above the flowing of high water, and dig a hole above two feet deep in the fand, into which they drop in one night above an hundred eggs, at which time they are fo intent on Nature's work, that they regard none that approach them; but will drop their eggs into a hat, if held under them; but if they are difturbed before they begin to lay, they will forfake the place, and feek another. They lay their eggs at three, and fometimes at four different times; there being fourteen days between every time; fo that they hatch and creep from their holes into the fea at different times alfo. When they have laid their complement of eggs, they fill the hole with fand, and leave them to be hatched by the heat of the fun, which is ufually performed in about three weeks. It may be proper to add, that the eggs are about the fize of tennis-balls, round, white, and covered with a fmooth parchment-like fkin. Gmelin mentions feveral varieties of this fpecies.

CARETTA. The variegated turtle, with fifteen dorfal fcales, thofe of the middle range gibbous towards their tips. This fpecies is larger than any yet difcovered, except perhaps the *coriacea*. It is called the "loggerhead turtle;" and though it refembles the laft fpecies, or green turtle, it is diftinguifhed by the fuperior fize of the head, the proportional breadth of the fhell, and by its deeper and more variegated colours: but the principal diftinction confifts in the number of dorfal fegments or fcutella of the fhell, which amount conftantly to fifteen. The fore-feet are very large and long; the hind-feet much fhorter, though broad. In a commercial view, this fpecies is of little importance; its flefh being rank and coarfe, and the laminæ of the fhell too thin for general ufe. It is faid, however, to afford a good quantity of oil, which may be ufed for lamps, &c. This turtle is very ftrong and fierce, and even dangerous. It is an inhabitant of the fame feas with the green turtle, but has been found in remote latitudes, even in the Mediterranean, and particularly about the coafts of Italy and Sicily.

MACROPUS. With an ovate, carinate, emarginate fhield, and the feet very large and bifarioufly unguiculated.

B. *Fluviatile, with palmated feet, fhell joined with the fternum by a membrane, and fupported in the middle on both fides by two proceffes of the fternum.*

ORBICULARIS. The T. europea of Schneider, with oval, flattifh, fmooth, dark brown fhell, marked with very numerous yellowifh fpecks and ftreaks. This fpeckled tortoife of the "Naturalift's Mifcellany," or T. meleagris, is of fmall fize, the fhell meafuring about four or five inches in length, and its difk compofed of thirteen, and the margin of twenty-five pieces; the under fhell whitifh-yellow, tinged towards the joints with brown; the head ovate, fomewhat convex above, and flattifh on each fide and beneath; the fkin of the neck lax and wrinkly; the legs fhort and fcaly, feet webbed, fore-feet having five toes and hinder only four; the claws on all the feet fharp-pointed, and crooked; the tail nearly half as long as the body, thin, attenuated, compreffed and fcaly, and alfo fpotted like the body.

This elegant fpecies is a native of many parts of Europe, being

being found in Italy, Sardinia, France, Hungary, Pruffia, &c. inhabiting lakes and muddy waters, and feeding on aquatic plants, infects, fnails, and fmall fifh. The flefh is faid to be good as food, for which purpofe it is fold in the markets, and occafionally kept in ponds, and fed or fattened with lettuce-leaves, bread, &c. &c. It may be conveniently kept in a cellar and fed with oats, fcattered on the floor, which it greedily eats when they begin to germinate. It depofits its eggs in fandy and funny places in the beginning of fpring, which are not hatched, as it is pretended, till the fucceeding fpring.

Membranacea. With three claws on the feet, and fhell ftriated on the back, membranaceous, ovate and grey. Found in the fea that wafhes Guiana. See T. Ferox.

Triunguis. With three claws on the feet, the difk of the back rugofe and orbiculated, the lower border fmooth, and noftrils in a cylinder elevated above and projecting beyond the head. Found rarely in the Nile, and fuppofed to be the fame with the former.

Cartilaginea. Shell orbicular, membranaceous, ftriated on the back; three claws on the feet, and nofe cylindric and prolongated. This is the T. Boddaerti and a rare fpecies. See the next article.

Ferox; Fierce Tortoife. With ovate, cartilaginous fhell; three claws on the feet, and tubular, prominent noftrils. Dr. Shaw queries whether the T. roftrata of Schœpf, the T. with palmated feet, &c. of Thunberg, the T. cartilaginea of Boddaert, the T. Boddaerti of Schneider, the T. triunguis of Forfkal, and the T. membranacea of Blumenberg, do not belong to this fpecies. This is a remarkable fpecies, and diftinguifhed by the unufual nature of its fhield, which is hard and offeous only in the middle part, while the edges gradually degenerate into a flexible coriaceous verge; obfcurely marked with five or fix tranfverfe bands, and granulated with fmall warts or prominences, gradually enlarging as they approach the flexible edge; the head rather fmall, fomewhat trigonal, with the fnout much lengthened, and the upper part drawn out into a fub-cylindric form, terminated by the noftrils, and projecting much beyond the lower mandible; the neck, when retracted, thick, and furrounded with many folds of fkin, but when exferted, equal in length to that of the whole fhell; the legs fhort, thick, and covered with a wreathed fkin; the feet furnifhed with ftrong and broad webs, connecting the three laft toes of each; the three firft on each foot furnifhed with ftrong claws, and the remaining ones unarmed; having, befides the proper toes, two fpurious ones on the hind and one on the fore feet, ftrengthening and expanding the web; the tail fhort, pointed, and curving inwards; the eyes very fmall and round; the colour above deep brownifh-olive, and below white; the fhell marked beneath in a very elegant manner, with ramifications of veffels.

This fpecies is found in Pennfylvania, Carolina, &c. &c.; and is poffeffed, differently from moft others of the tribe, of confiderable vigour and fwiftnefs of motion, fpringing towards its affailant, when attacked, with great alacrity and fiercenefs; about a foot and half long, and fifteen inches broad. It was firft defcribed by Dr. Garden. Its flefh is faid to be extremely delicate, being equal, if not fuperior, even to that of the green turtle. The great foft-billed turtle, defcribed by Mr. Bartram in his Travels, appears to be the fame with this. Found in all the rivers, lakes, and pools of Eaft Florida, weighing from 30 to 40 pounds. The T. roftrata of Thunberg feems to be the young of the fpecies above defcribed; and the T. triunguis of Forfkall is allied to the fame fpecies. Shaw.

Scabra. With fmooth difcoloured head, and fhield oval, convex, carinated and rough. The *fcabra* of Linnæus is defcribed as having palmated feet and flattifh fhell, with all the intermediate fcutella elevated on the back. The fhell of this fpecies is figured by Seba; it meafures about two inches and a half in length, and nearly two inches in breadth; being of a cordated figure, or fomewhat pointed at the bottom. Its colour is light-reddifh, variegated on the head and fhell with white lines and fpots; the feet marked with red fpecks, and having each five toes with fharp claws; the head prominent, and eyes fmall. Shaw.

Squamata; Scaly Tortoife. With ovate body, fmooth beneath, but covered above, together with the neck, feet, and tail, with numerous fcales. According to Bontius, in his Hiftory of Java, this fingular fpecies is an inhabitant of frefh waters, where it burrows under the banks, in order perhaps to depofit its eggs. The Javanefe call it *taunah*, or the digger, and the Chinefe *lary*, or the runner, a burlefque title given to it on account of its flow pace. Its flefh is faid to be extremely delicate; and the Chinefe ufe the pulverized fcales diffolved in water, as a remedy in dyfenteric cafes and againft the colic. It is faid to prey on fmall fifh. This fpecies feems to connect the lizard and tortoife tribes. Shaw.

Lutaria; Mud or Brown Tortoife. With flattifh fhell, and tail half the length of the body; carinated, fays Gmelin, behind with three fcutella. This fpecies is faid to be common in many parts of Europe, as well as Afia, being found in India, Japan, &c. According to Cépéde, it is not more than feven or eight inches from the tip of the nofe to that of the tail, and about three or four inches in breadth; the difk confifts of thirteen pieces, ftriated and flightly punctated in the centre, and along the middle range runs a longitudinal carina; the margin confifts of twenty-three pieces, bordered with flight ftriæ; the colour of the fhell is blackifh and alfo of the fkin; the feet are webbed, with five toes before, and four behind; the exterior toe of each foot is unarmed; the tail is ftretched out in walking, from which circumftance the animal has been called "Mus aquatilis." Like other tortoifes, it fometimes utters a kind of broken hifs. This animal is common in France, and particularly in Languedoc and many parts of Provence; and in a lake, fituated in the plain of Durance, fuch numbers were found as to fupply the neighbouring peafantry for more than three months. Although this fpecies be aquatic, it always lays its eggs on land, digging a hollow and covering them with mould. This animal is ufeful in a garden, which it frees from noxious animals, without doing any mifchief itfelf. It may be domefticated, and kept in a bafon or receptacle of water, fo contrived on the edges as to give it a ready egrefs, when it wifhes to wander about for prey. In fifh-ponds it is deftructive. Shaw. Gmelin mentions two varieties, *viz.* T. tabulata and T. campanulata.

Scorpioides. See T. Fimbriata.

Hermanni. With four claws on the feet, and the tip of the tail unguiculated. See T. Tricarinata.

Gmelin mentions feveral varieties of this fpecies.

Carolina. With digitated feet, gibbous fhell, and no tail. This is the T. claufa, or clofe tortoife, of Linnæus and other writers, with blackifh fhell, irregularly fpotted with yellow, with obtufe dorfal carina, and bivalve under-fhell completely clofing the upper, whence it obtains its name. The under part of the fhell is fo continued round the margin, that when the animal withdraws its head and legs, it is able accurately to clofe all parts of the fhell together, fo as to be perfectly fecure. The defence of this little animal, which rarely exceeds four or five inches in length, is fuch, that it is uninjured by a weight of 500 or 600 pounds, and

and able to walk under this heavy load. It is a native of many parts of North America, found chiefly in marſhy ſituations, and occaſionally in the drieſt and hotteſt places. It is principally ſought for on account of its eggs, which are reckoned a delicacy. It feeds on ſmall animals, as beetles, mice, and even ſerpents, which it draws into its ſhell, and cruſhes to death; and alſo on various vegetable ſubſtances.

Palustris. With depreſſed ſhell, five claws on the fore-feet, and four on the hind-feet; found in the ſtagnant waters of Jamaica, and ſeeking food in the adjoining meadows. This is the T. terrapin of Schœpf, and the T. concentrica of other writers, with ſub-depreſſed, ſub-carinated, oval yellow ſhell, with the ſcutella marked by concentric brown zones. The ſhell meaſures from four to ſix inches, or more. It is a native of North America, and ſold in the markets at Philadelphia, and elſewhere, under the name of "Terrapin," which name is indiſcriminately applied in America to ſeveral other ſpecies. It is common, as we have already ſaid, in Jamaica, and firſt deſcribed by Dr. Browne, in his "Hiſtory of Jamaica," who ſays it is a wholeſome and even delicate food. In the Leverian Muſeum there is a large and beautiful ſpecimen of the ſhell of this ſpecies. Shaw.

Caspica. With orbicular ſhell, ſcaly head, five claws on the fore-feet, four on the hind, and naked tail. Gmelin repreſents it as a native of Hircania, inhabiting freſh waters, and ſometimes growing to a vaſt ſize. The pieces compoſing the diſk are ſub-quadrate; thoſe of the border parallelogrammic; the colour variegated with black and green; the lower ſhell blackiſh, ſpotted with white.

Clausa. See T. Carolina, ſupra.

Pensylvanica. Tortoiſe, according to Schœpf, with ſmooth, elliptic, brown ſhell, with flattiſh back, the middle range of ſcutella ſub-rhomboid and ſub-imbricated, the firſt ſub-triangular; and according to Gmelin, with five claws on the fore-feet and four on the hind, and the apex of the tail horny and acute. This is the ſmall mud tortoiſe of Edwards; the ſhell meaſuring three or four inches in length. The head on the parts ſurrounding the jaws and eyes is of a reddiſh-yellow colour; the upper part, as well as the neck, legs, and tail, duſky; feet webbed; the tail ſmall. It is a native of North America, and is found in Pennſylvania, &c. inhabiting muddy waters. When living, it is ſaid to exhale a ſtrong muſky odour. Mr. Schœpf mentions a variety, and another occurs in the Leverian Muſeum Shaw.

Serpentina. The ſnake tortoiſe, characteriſed by Schœpf as having an ovate, depreſſed, triply carinated, ſharp-ſcaled ſhell, rounded and acutely ſerrated at the poſterior margin; and by Gmelin as having digitated feet, ſub-carinated ſhell, behind obtuſe, and acutely quindentated. This is the ſerrated tortoiſe of Pennant. It is a native of North America, inhabiting ſtagnant waters, growing to the weight of fifteen or twenty pounds, or more, preying on fiſh, ducklings, &c. ſeizing its prey with great force, and at the ſame time ſtretching out its neck, and hiſſing at the ſame time. The head is large, depreſſed, triangular, and covered with a ſcaly and warty ſkin: the orbits of the eyes are oblique; the mouth wide; the mandibles ſharp; the neck covered by ſcaly warts; the toes diſtinct; the tail ſtraight, and about two-thirds the length of the ſhell; and the under part of the body covered by a looſe, wrinkled ſkin, beſet with ſmalliſh ſoft ſcales and granules. This animal conceals itſelf in muddy water, leaving out only a part of its back, and thus appearing to be a ſtone or other inanimate object, more eaſily obtains its prey. In New York it is known by the title of the "ſnapping tortoiſe."

Spengleri. See T. Serrata, infra.

Fimbriata. Tortoiſe, according to Bruguiere, with oval, ſub-convex, triply carinated ſhell, ſub-digitated feet, cylindric ſnout, and neck fimbriated on each ſide. This is an animal of very ſingular and diſagreeable appearance. The ſhell is about fifteen inches or more in length, and its breadth eleven; but the whole animal, from the noſe to the end of the tail, is two feet three inches. The head is large and flat, rounded in front, and edged on the ſides with warty and wrinkled membranaceous appendages, about five inches wide, and covered behind by a three-lobed prominence; the noſe reſembles a proboſcis, cylindric, ten lines long, truncated, pierced by the noſtrils, at the tip, where they are ſeparated by a cartilaginous diviſion; the eyes are round, ſeated at the baſe of the proboſcis, and ten lines diſtant from each other; the mandibles are equal in length, and entire; the gape of the mouth is wide; the neck ſeven inches long, and four and a half broad; above flat and warted, and furniſhed on each ſide with ſix fimbriated membranaceous appendages diſpoſed lengthwiſe, and alternately larger and ſmaller; the under part of the neck is beſet with four ſimilar appendages, placed oppoſite to the two on the head, and increaſed by two longitudinal wrinkles: the fore-feet are ſcaly and warty, having five indiſtinct toes, with as many longiſh ſharp claws, convex above and flat beneath; the hind-feet are alſo ſcaly, with leſs diſtinct toes, having four claws, the fifth toe being unarmed, and very ſhort: the tail is an inch long, bent ſlightly, and covered with a granulated ſkin; all the thirteen ſemicircular pieces, of which the ſhell conſiſts, are wrinkled and irregularly notched at the hind part; the twenty-five marginal pieces are almoſt ſquare, radiated on the ſurface with oblique wrinkles, and toothed in the interior edge. The colour of the whole is brown, ſomewhat paler beneath. This animal is ſaid to be a native of Guiana, but is now rare in the rivers of Cayenne, as it has been plentifully taken by fiſhermen, it being conſidered as excellent food. It feeds on aquatic plants, and wanders by night to ſome diſtance in ſearch of paſture. It has been ſuggeſted, but without certainty, that this is the T. ſcorpioides of Linnæus. Shaw.

Picta. Tortoiſe with plane ſhell, marked on both ſides with a double ſpot of a black-blueiſh colour; ſcutella ſurrounded with a yellow margin, and neck ſtriated longitudinally with yellow and black; or tortoiſe with oblong, ſlightly convex, ſmooth, brown ſhell, with the ſcutella bordered with yellow. This is the cinereous tortoiſe of Brown's Zoology, and ſufficiently diſtinguiſhed from all others by the remarkable colours of the ſhield. This is a freſh-water ſpecies, and inhabits ſlow and deep rivers in North America, and ſhould have been referred by Gmelin to his ſecond claſs. In clear ſunny weather theſe animals are ſaid to aſſemble in multitudes, ſitting on the fallen trunks of trees, ſtones, &c. and immediately plunging into the water on the leaſt diſturbance. They are ſaid to ſwim very ſwiftly, but to walk ſlowly; to be able to continue many hours entirely beneath the water, but not to ſurvive many days if kept out of their favourite element. They are very voracious, deſtroying ducklings, &c. which they ſeize by the feet, and drag under water. They are ſometimes uſed as a food. The colour, as has been above obſerved, varies; being ſometimes of a blackiſh-brown, at other times of a reddiſh-cheſnut: the yellow markings are alſo either pale or deep in different individuals, and ſometimes whitiſh; the inferior, or under edges of the upper ſhell, as well as the upper edges, or commiſſures of the lower, are elegantly ſtreaked with black, as if artificially painted, and this variegation is continued over the ſkin of the ſides of the body. Shaw.

Guttata. Tortoiſe ſpotted, with oblong, moderately convex,

convex, ſmooth, brown ſhell, with ſcattered yellow ſpots. This is T. punctata of Schœpf. It is a rather ſmall ſpecies, and a native of North America, inhabiting rivers and lakes. The young are ſcarcely larger than pigeon's eggs, and are very black, beautifully ſpotted with gold colour.

Longicollis; Long-necked Tortoiſe. Smooth, ovate, with extremely long neck. This ſpecies is a native of New Holland, and is of the river or freſh-water kind. The colour of the whole animal above is deep olive-brown; beneath paler, and inclining to whitiſh. Shaw.

C. *Land tortoiſes, with clavated unguiculated feet, convex ſhell, and bony commiſſures joined with the ſternum.*

Denticulata. Tortoiſe with ſub-digitated feet, and orbicularly-cordated ſhell, with denticulated marginal ſegments. The ſhell is of a pale yellowiſh-brown colour, about four inches long and three broad, covered on the diſk by broad hexagonal and pentagonal ſcutella, of a flattened form, with a large diſtinct middle ſpace, granulated by ſmall tubercles, and the remainder marked by five lines or furrows. The edge of the ſhell conſiſts of twenty-three pieces, projecting in a ſerrated manner round the outline. It is ſuppoſed to be a native of North America. The feet, in Gmelin's edition of the Syſtema Naturæ, are ſaid to be without diſtinct toes; and the tail ſhort.

Græca. The common land tortoiſe, with ſub-digitated feet, hinder part of the ſhell gibbous, lateral margin very obtuſe, and ſcutella flattiſh. Gmelin.

It is deſcribed by others as the tortoiſe with hemiſpheric black and yellow ſhell, gibbous behind; the pieces compoſing the diſk convex, and the ſides obtuſe. This tortoiſe is ſuppoſed to be a native of almoſt all the countries bordering on the Mediterranean ſea, and to be more frequent in Greece than in other regions. It is found in the European Archipelago iſlands, and in Corſica and Sardinia, and alſo in many parts of Africa. In Greece it is an article of food; the eggs are eaten boiled, and the blood is often ſwallowed recent. In September the animal hides itſelf under ground, and emerges in February: it lays its eggs in June, in a ſmall hole on a ſunny ſpot, out of which, after the firſt rains of September, the young are hatched. In England it retires about the end of October, and re-appears about the middle of April; but theſe ſeaſons vary with the climate and weather, &c. The males often fight, butting at each other with a noiſe that may be heard at a conſiderable diſtance. This animal lives to a moſt extraordinary age, exceeding the period of even a century.

One of the moſt remarkable inſtances is that of a tortoiſe introduced into the archiepiſcopal garden at Lambeth, in the time of archbiſhop Laud, and as near as can be collected from its hiſtory, about the year 1633, which continued to live there till the year 1753, when it was ſuppoſed to have periſhed rather from accidental neglect on the part of the gardener, than from the mere effect of age. This tortoiſe has had the honour of being commemorated by Derham, and many other writers, and its ſhell is preſerved in the library of the palace at Lambeth.

The general manners of the tortoiſe, in a ſtate of domeſtication in this country, are very agreeably detailed by Mr. White, in his Hiſtory of Selbourn. "A land tortoiſe," ſays Mr. White, "which has been kept thirty years in a little walled court, retires under ground about the middle of November, and comes forth again about the middle of April. When it firſt appears in the ſpring, it diſcovers very little inclination for food, but in the height of ſummer grows voracious; and then, as the ſummer declines, its appetite alſo declines; ſo that for the laſt weeks in autumn it hardly eats at all. Milky plants, ſuch as lettuces, dandelions, ſow-thiſtles, &c. are its principal food.

"The tortoiſe is totally a diurnal animal, and never ſtirs after it becomes dark. The tortoiſe," adds Mr. White, "like other reptiles, has an arbitrary ſtomach, as well as lungs, and can refrain from eating, as well as breathing, for a great part of the year. I was much taken with its ſagacity, in diſcerning thoſe that do it kind offices; for as ſoon as the good old lady comes in ſight who has waited on it for more than thirty years, it hobbles towards its benefactreſs with awkward alacrity; but remains inattentive to ſtrangers. Thus, not only 'the ox knoweth his owner, and the aſs his maſter's crib,' but the moſt abject and torpid of beings diſtinguiſhes the hand that feeds it, and is touched with the feelings of gratitude. This creature not only goes under the earth from the middle of November to the middle of April, but ſleeps great part of the ſummer; for it goes to bed in the longeſt days at four in the afternoon, and often does not ſtir in the morning till late. Beſides, it retires to reſt for every ſhower, and does not move at all in wet days. When one reflects on the ſtate of this ſtrange being, it is a matter of wonder that Providence ſhould beſtow ſuch a ſeeming waſte of longevity on a reptile that appears to reliſh it ſo little as to ſquander away more than two-thirds of its exiſtence in a joyleſs ſtupor, and be loſt to all ſenſation for months together in the profoundeſt of all ſlumbers! Though he loves warm weather, he avoids the hot ſun; becauſe his thick ſhell, when once heated, would, as the poet ſays of ſolid armour, 'ſcald with ſafety.' He therefore ſpends the more ſultry hours under the umbrella of a large cabbage leaf, or amid the waving foreſts of an aſparagus bed. But as he avoids heat in the ſummer, ſo in the decline of the year he improves the faint autumnal beams, by getting within the reflection of a fruit-tree wall; and though he has never read that planes inclining to the horizon receive a greater ſhare of warmth, he inclines his ſhell by tilting it againſt the wall, to collect and admit every feeble ray."

The tortoiſe is ſaid to be more tenacious of life than any other of the amphibia; many experiments performed upon them by Redi, of a cruel nature, ſuch as opening their ſhells, taking out the brain, cutting off the head, evince their tenaciouſneſs of life, and that the vital principle is very ſlowly diſcharged from theſe animals. Shaw.

Carinata. Tortoiſe with digitated feet, and gibbous ſhell, with the four firſt dorſal ſcutella carinated, and entire ſternum: found in warm regions, but very little known.

Geometrica. Shell ovated, with all the elevated ſcutella above plane, marked with yellow ſtriæ iſſuing from the centre in form of a ſtar: or, according to others, this is the tortoiſe with ovate black ſhell, and elevated ſcutella radiated with yellow; the T. teſſelata minor of Ray. The pieces of which the diſk of the ſhell conſiſts are very prominent, ſtriated, or furrowed pretty diſtinctly with numerous lines on their ſides, and terminated above by a yellowiſh, flat, ſquare, or rather hexagonal roughened ſpace or centre, from which proceed, in a radiated direction, ſeveral well-defined yellow ſtreaks towards the edge; thus conſtituting a beautiful kind of geometrical appearance on the black ground colour on which they are diſpoſed: the marginal pieces, which are commonly twenty-four, ſometimes twenty-ſix, in number, are alſo ſtreaked with yellow, but in a ſomewhat different ſtyle.

The native country of this beautiful tortoiſe is perhaps not truly aſcertained; though the ſhell is more frequently ſeen in Europe than that of almoſt any other kind. It is ſaid, however, to inhabit Aſia and Africa, and even to be found in America. According to Mr. Thunberg it is particularly common in ſhrubby places about the Cape of Good Hope. It is ſaid to lay about twelve or fifteen eggs at a time.

time. The count de Cépedé fuppofes this fpecies to be the Terrapin of Dampier, which that navigator reprefents as very beautifully variegated, and as delighting in moift and marfhy places; adding, that its flefh is efteemed as a food, and that it is found in plenty on the coafts of the Pine iflands, between the continent of America and Cuba: they are found in the forefts, where they are eafily taken: the hunters mark them on the fhield, and let them wander about the woods; being fure to find them again at no great diftance, every one eafily recognizing his own property, and afterwards carrying them to Cuba. Shaw.

Pusilla; Little Tortoife. With fub-digitated feet, and hemifpheric fhell, with convex, trapezial fcutella, ftriated on the margin, and punctated on the difk. This is the African land tortoife of Edwards, and thus defcribed by him from a fpecimen obtained from Weft Barbary. "The iris of the eye is of a reddifh hazel colour; the lips hard, like the bill of a bird; the head covered with fcales of a yellowifh colour; the neck, hind legs, and tail, covered with a flexible fkin of a dirty flefh-colour; the fore-legs covered with yellow fcales on their outfides, which are partly expofed when the legs are drawn in; the fhell round, and pretty much rifing on its upper fide, and flat beneath; the pieces or compartments are of a yellowifh colour, clouded and fpotted with large and fmall irregular dufky or blackifh fpots, and are alfo furrowed or creafed, the creafes leffening, one within the other, till they reach the top or middle part of each: the tail is thick, fcaly, and about an inch in length; and the vent is fituated within the tail itfelf near the bafe: there are five claws on the fore-feet, and four on the hind, all ftrong, black, rather bowed, and fharp-pointed." This fpecies is found at the Cape of Good Hope, and much refembles the T. græca.

Indica. Tortoife with brown fhell, reflected above the neck, and marked with a tubercle on the three upper fcutella. This is the great Indian tortoife, firft defcribed by Perrault in the "Hiftory of Animals," publifhed by the Royal Academy of France; and confounded by M. Cépéde with the T. græca. It is found in India, on the coaft of Coromandel, &c. Of this there are two varieties, one brought from the Cape of Good Hope, and another from the Southern iflands.

Sulcata. Tortoife with a tail, digitated feet, gibbofe fhell, and fcutella lineated and circumfcribed with a furrow; or tortoife with brown ovate fhell, with furrowed fcutella yellow on each fide. This is one of the larger fpecies of land tortoife, being about a foot or more in length from the nofe to the tip of the tail. The fhell is very convex, and has the general habit of the *græca* and *geometrica* as to fhape. This fpecies is faid to be a native of the Weft Indies, and perhaps may be the "Hicatee" of Brown, defcribed in his Hiftory of Jamaica. Dr. Shaw fuggefts that this fpecies may be the fame with T. tabulata.

Planairia. Tortoife with digitated feet, and fhell oval, convex, and fmooth. Found at Surinam.

Americana Terrestris. Tortoife with oval, gibbofe fhell; fcutella yellow in the middle of the difk; the margin marked with fhining, black, furrowed, lateral polygons. This is conjectured by Gmelin to be the Jaboti of the Brafilians, and the cagado of the Portuguefe. Found in South America.

Tabulata. Tortoife with oblong, gibbofe, brown fhell, with the fcutella of the difk rectangular and furrowed; with yellowifh centres. This was firft defcribed and figured in Seba's "Thefaurus," and there faid to be a native of Brafil, though it is believed to be rather an African fpecies. The general length of the fhell is about five or fix inches: fufpected to be the fame fpecies with T. fulcata, fupra. Shaw.

Marginata. Tortoife with blackifh-brown, oblong, gibbofe fhell, variegated with yellow, widened and depreffed on the hind part. The true native country of this fpecies is not very diftinctly known. Mr. Schœpf inclines to think that it is an American fpecies. Cépéde has confounded it with the T. græca. Shaw.

Radiata. Tortoife with ovate black fhell, and flattifh fcutella radiated with yellow. This is the great chequered tortoife-fhell of Grew's Muf. Reg. It has been concluded by fome perfons, from a general refemblance in the pattern of the fhell, and a fimilarity in colours, that this is the fame fpecies with T. geometrica, or a variety of it. But Dr. Shaw has pointed out a variety of differences between them and fuch as warrant our ftating that the two fhells are perfectly diftinct. Grew, who has defcribed this fpecies, fays that its native country is Madagafcar; but Dr. Shaw fuggefts that it is alfo a native of Jamaica, and that in characters and fize it agrees with the "Hicatee" tortoife mentioned in Brown's Zoology. Shaw.

Rugosa. Tortoife wrinkled, with black wrinkled fhell, mottled and variegated with yellow; with the middle dorfal pieces fubpanduriform or fiddle-fhaped. In the Leverian mufeum there is a variety, or perhaps a fexual difference of this fpecies.

Elegans. Tortoife with orbicular, convex, yellow fhell, with tranfverfe, oval, brown fpots. Seba has defcribed it under the name of the T. terreftris Ceilonica elegans minor. Shaw.

Areolata. Tortoife with moderately convex fhell, with fubquadrangular, elevated, deeply furrowed fcutella, and depreffed rough areolæ. This is defcribed by Seba under the appellation of T. terreftris Brafilienfis.

Serrata. Tortoife with depreffed yellowifh fhell, minutely freckled with dufky fpecks; all the fcutella of the difk carinated, and the hinder margin of the fhell ferrated. This is fuppofed by Dr. Shaw to be the T. fpengleri of Gmelin's Linnean Syftem.

Tricarinata. Tortoife with oval, flightly convex, fhell, with entire margin, and all the fcutella of the difk carinated. This fpecies agrees, in fhape and other particulars, with Linnæus's defcription of his T. orbicularis. Shaw.

Scripta. Tortoife with orbicular depreffed fhell, with all the fcutella marked by varioufly-formed characters, and the marginal pieces fpotted beneath. This is the T. fcabra of Thunberg. Its native place is not afcertained. Shaw.

Galeata. Tortoife with depreffed oval fhell, with the three middle fcutella fharply carinated, and twenty-four marginal pieces. The native place of this fpecies is not known; but it was brought to Mr. Retzius from India, and lived two years kept in frefh water: it fubfifted on bread, &c. and fometimes on flies. From the beginning of October to the middle of May it remained without food, fcarcely elevating its head above the water. It delighted in funfhine, and endeavoured to climb up the fides of the veffel occafionally, in order to enjoy its influence. It is doubtful, whether this be the T. fcabra of Linnæus. It is called *galeata* by Retzius, from the armed or cataphracted covering of the head. Shaw.

Granulata; Chagrin Tortoife. With orbicular, flattifh, granulated fhell, with cartilaginous border. This fpecies feems to be allied to the T. ferox, having the fhield furnifhed with a cartilaginous and flexible border. It is defcribed by M. Cépéde, and was brought from India by M. Sonnerat. Shaw.

Dr. Shaw, among the fea-tortoifes or turtles, has defcribed the

the turtle with green variegated fhell, fo named by the count de Cépéde. Thefe turtles are faid to be found in great numbers in the Southern ocean, and about Cape Blanco, in New Spain. They alfo occur in the gulf of Mexico, and many of the large American rivers, both above and below the line; but they have never been difcovered in the feas of the Old Continent. The flefh is faid to be very delicate; and is even preferred in fome places to that of the common turtle. M. Bomare is faid by Cépéde to have firft defcribed this fpecies.

The "trunk turtle" is mentioned by Catefby, who fays, without ever having feen it, from the report of others, that thefe turtles grow to a very large fize, of a narrow form, but very deep, the upper fhell being more convex than in other kinds of turtle. Their flefh is rank, but affords a large quantity of oil, which conftitutes their value.

The "rhinoceros turtle," or *la tortue nafìcorne*, has not been accurately defcribed. Count de Cépéde fays, that it is a native of the American feas, and bears a general refemblance to the common or green turtle; but is diftinguifhed by having a large foft tubercle on the tip of the fnout, in which are fituated the noftrils. It is eaten in the fame manner as the green turtle, and is chiefly found in the equatorial regions. Shaw's General Zoology, vol. iii. pt. 1.

TESTUDO *Veliformis Quadrabilis*, an hemifpherical vault, or cieling of a church, &c. in which four windows are fo contrived, as that the reft of the vault is quadrable, or may be fquared.

The determination of thefe windows was a problem propofed to the great mathematicians of Europe, particularly the cultivators of the new calculus differentialis, in the Acta Eruditorum Lipfiæ, by fig. Viviani, under the fictitious name of A. D. Piollfei pufillo-geometra, which was the anagram of poftremo Galilæi difcipulo.

It was folved by feveral perfons, particularly M. Leibnitz, the very day he faw it: and he gave it in the Leipfic Acts in a variety of ways; as alfo did M. Bernouilli, the marquis de l'Hofpital, Dr. Wallis, and Dr. Gregory.

TESTWOOD, in *Biography*, a finging man in the choir of Windfor, was burnt for his intemperate zeal in the caufe of Proteftantifm, 1544, when Marbeck was likewife condemned, but afterwards pardoned.

TESZERSKEY, in *Geography*, a town of Croatia; 6 miles S.W. of Nevi.

TET, a river of France, which rifes in the Pyrenées, a little above Mont Louis, and runs into the Mediterranean, 7 miles E. of Perpignan.

TETANUS, in *Medicine*, a difeafe confifting in a fpafmodic contraction of feveral of the mufcles of voluntary motion, and more particularly of thofe which fhut the lower jaw: and this being a conftant and prominent fymptom, the affection is commonly known by the name of *locked jaw*. The fpafm of the mufcles is of the *tonic* kind; or that in which the exceffive contraction continues for a confiderable time, without any interval of complete relaxation: in which refpect it is oppofed to *clonic* fpafms, or convulfions, where the contractions and relaxations alternate in rapid fucceffion. (See CONVULSION and SPASM.) The powers of fenfation and of intellect remain unimpaired in tetanus; in which refpect alfo it is contrafted with epilepfy.

Tetanus admits of many varieties and modifications, on which the older nofologifts had founded different fpecies of the difeafe. A rigidity of the mufcles of the lower jaw was denominated *trifmus*. When the mufcles of the back were chiefly affected, the difeafe was termed *opifthotonos*: when thofe of the fore-part of the trunk, with the flexors of the extremities, were the feat of fpafm, it was called *emprofthotonos*. Sometimes, though very rarely, the fpafms are confined to one fide of the body only, bending it ftrongly to that fide; a form of the difeafe which has been named by Sauvages *tetanus lateralis*, and by later writers, the *pleurofthotonos*, or *pleurotonos*. It was only when the fpafm was almoft univerfal, that it was confidered as entitled to the appellation of *tetanus*. Of late years, however, thefe names have very properly been confidered as expreffing only varieties of one and the fame affection, differing merely in feverity, but arifing from the fame caufes, and requiring the fame mode of treatment. Thefe various forms of fpafm often follow one another in fucceffion in the fame cafe, and mark the progrefs of the difeafe through its different ftages. Thus the trifmus, or locked jaw, is only a part or prelude of opifthotonos and tetanus; and though it may prove fatal at this early period, the imperfect form in which the fymptoms of a difeafe, which has been thus arrefted in its courfe, may appear, is by no means fufficient to eftablifh a generic difference in the difeafe itfelf. There appears, however, to be fome foundation for a divifion of cafes, according to their duration, into the acute and the protracted: the former being very little under the controul of medicine, and in almoft every inftance fatal; the latter being milder in its character, and often yielding, if proper means are employed for its fubjugation.

Another ground of diftinction among the different cafes of this formidable diforder, is derived from the nature of the caufes from which they have originated. The moft ufual caufes are certain mechanical injuries to the body, more efpecially fuch as are attended with a puncture or laceration of a nerve: on other occafions, it may be the effect of the fudden application of cold, when the body has been previoufly overheated: and, in a few inftances, it has appeared to arife fpontaneoufly; that is, when it could not be traced to any external exciting caufe whatever. Tetanus arifing from wounds is, in general, flower in its progrefs than that which proceeds from cold; but is attended with more danger to life.

On fome occafions the difeafe comes on fuddenly, and with great violence; but more commonly the attack is gradual. It is often eight or ten days, and fometimes much longer, after the infliction of a wound, before the firft fymptoms of tetanus make their appearance: and this frequently happens when the effects of the injury on the part itfelf appear to have fubfided; when the wound has healed, and no pain or uneafinefs has remained. Thofe cafes in which the difeafe is more flow in its approach, afford the beft opportunity of tracing the natural fucceffion of fymptoms: and the firft uneafy fenfation which is then obferved, is that of a flight ftiffnefs in the back part of the neck and about the fhoulders, which, gradually increafing, impede the rotatory motions of the head, and alfo its flexion forwards: fo that the patient cannot look downwards, or to either fide, without turning his whole body. This uneafy feeling, being chiefly felt on motion, very much refembles what occurs from rheumatifm, but it is accompanied with a fenfe of general laffitude and debility. The rigidity now extends from the back of the neck to the mufcles of the jaw, and of the root of the tongue, fo that both maftication and fwallowing become difficult and painful; and at length impoffible. The attempt at deglutition is attended with convulfive efforts; efpecially when liquids are endeavoured to be fwallowed. So great is the diftrefs which accompanies thefe convulfions, that the patient becomes very reluctant to renew the trials, and refufes all nourifhment; and it fometimes infpires him with even a dread of the fight of water.

As the difeafe advances, another fet of fymptoms appears, bringing

bringing with them a confiderable increafe to the fufferings of the patient. A fudden and violent pain is felt fhooting from the lower extremity of the fternum to the fpine, in the fituation of the diaphragm. Thefe fpafms recur from time to time, at fhort intervals; and at each recurrence, give the fignal for an immediate aggravation of all the other fpafms. The mufcles of the neck and jaw are immediately called into violent action; the head is pulled ftrongly backwards; and the jaw becomes firmly clenched. Thefe periodical acceffions of fpafm become more fevere, and their effects more durable; fo that the head continues to be in a ftate of retraction, and the jaw is permanently clofed, the teeth being fo firmly fet together, as not to admit of the fmalleft opening. Such conftitutes what may be regarded as the firft ftage of the difeafe; which fometimes takes up three or four days. At other times the difeafe eftablifhes itfelf, with its whole train of dreadful fymptoms, in a few hours; in which cafe the danger is imminent; as death generally takes place in from twenty-four to forty-eight hours, and the patient very rarely paffes over the third day.

The continuance of the difeafe, if the patient furvive the immediate attack, is marked by the increafing fpafm of the diaphragm, which now returns every ten or fifteen minutes, and is inftantly fucceeded by a ftronger retraction of the head, and rigidity of the mufcles extending down the back, along the fpine, and affecting even thofe of the lower extremities. Their contractions increafing in force, the body is frequently raifed in the form of a bow, refting upon the head and feet alone: a ftate which is more particularly denominated *opifthotonos*. The countenance, as is obferved by Dr. Chalmers, is pale and contracted; the maftoid, coracohyoid, and fterno-hyoid mufcles, together with the others concerned in deglutition, and the deltoid and pectoral mufcles, are moft violently contracted, fo that the fhoulders are ftrongly raifed forwards, and the arms are ftretched out, or drawn acrofs the body; but the wrifts and fingers feem not to be affected. In a few feconds, a remiffion takes place; the fhoulders and arms recline, and the inferior extremities relax; yet not fo entirely, but that generally fuch a degree of rigidity continues, as to prevent their being bent, even when this is attempted by another perfon. The mufcles on the fides and fore part of the neck continue ftill contracted, although not fo ftrongly; but their action is overcome by the number and ftrength of the pofterior ones; fo that the contraction of the head conftantly remains. The patient breathes quick for fome minutes, as if he had been exceffively exercifed, and the pulfe is fmall, fluttering, and irregular, but both become more calm and flow. The face is fometimes pale in the intervals, but oftener flufhed; and the whole countenance expreffes ftrong appearances of the moft melancholy diftrefs; as well on account of the terror the patient feels at the approaching paroxyfm, as from the torture he has fuffered from the laft, of which the painful contractions he ftill feels perpetually remind him. He, for the moft part, defires to lie ftill as much as poffible, and to avoid all attempts at drinking, fpeaking, or any kind of motion; all of which are apt to occafion a return of the fpafm in all its horrors. Some, indeed, are folicitous to try a change of pofition, in hopes of obtaining one of greater eafe; but the act of turning the patient never fails to bring on an attack of the convulfion, by which the head is drawn back to the fpine: and it is at length found, that the beft means of avoiding this is for him to lie perfectly ftill on the back.

It may, in general, be obferved, that the extenfor mufcles are affected with fpafm before the flexors. In the lower extremities, indeed, both the flexor and extenfor mufcles are commonly at the fame time affected, and keep the limbs rigidly extended. The flexors of the head, and the mufcles that pull down the lower jaw, become affected in the progrefs of the difeafe, together with the abdominal mufcles; fo that the belly is ftrongly retracted, and feels hard, like a piece of board. The fpafm of thefe and the other flexor mufcles, becoming fo powerful as to balance the action of the extenfors, is a circumftance that marks the advance of the difeafe, and may be regarded as conftituting the commencement of a third ftage. In this fituation the body and limbs are perfectly ftraight and rigid, and incapable of being moved in any way; and it is to this condition that the term *tetanus* has been more efpecially applied. It is a ftate of the moft exquifite fuffering: the patient is on the rack from the continual recurrence of the fpafm, which has fcarcely any remiffion. The recti mufcles of the abdomen often contract unequally, producing the appearance of hard balls in particular parts. The whole belly is drawn inwards, and does not yield in the leaft to the defcent of the diaphragm in infpiration. Although the lower extremities are always rigid at this period, yet their action is fo violent during the height of the paroxyfms, that were it not for the ftanders-by, the patient would be projected feet foremoft off the bed; or would, at other times, be pufhed upwards with fuch an impetus, as to ftrike the head with great force againft whatever might happen to be in the way. Occafionally, the flexor mufcles acquire the preponderance over the extenfors, and the trunk of the body is bent forwards, the chin being fixed to the breaft. This is what has been called *emprofthotonos*, and occurs only in the moft violent, and of courfe the leaft frequent form of the difeafe. It would appear from fome cafes reported by Sauvages, that thefe oppofite ftates are difpofed to alternate with one another.

In extreme cafes, there are hardly any of the voluntary mufcles that remain in their natural ftate. The face and eyes are diftorted; the tongue is fuddenly darted out between the teeth, and often miferably lacerated from their clofing at the fame moment. Even the fmall mufcles of the ear partake of the fpafmodic action, which fo univerfally prevails in the fyftem. While the tongue is thruft out, the mufcular flefh, which is fituated between the arch of the lower jaw, and the upper part of the trachea, is drawn upwards within the throat. The countenance is much contracted; a general fweat breaks out; the eyes are watery and languid; and a pale or bloody froth bubbles out from between the lips. Tetanus, in thefe violent forms, is, perhaps, the moft painful difeafe that can affect the human frame. So exquifite a degree of pain would fcarcely be compatible with life, were it not occafionally affuaged by the fhort and imperfect remiffions of fpafm which occur. A more continued and fevere fpafm, or a general convulfion, generally finifhes the tragedy, and releafes the unhappy victim from all his mifery: or, if already too exhaufted by the feverity of pain to admit of this mode of termination, delirium often enfues, protects the patient by a happy infenfibility to further fuffering, and fmooths the avenue to death, which is then preceded by a general relaxation of the fpafms.

Such are the fymptoms which peculiarly belong to tetanus: and it is, perhaps, the moft remarkable circumftance attending the difeafe, that hardly any function is primarily affected, except that of mufcular action. The fenfes and appetites are perfect and entire; the intellectual functions are undifturbed; and the natural functions proceed in their ufual courfe. Fever is neither an effential nor a common attendant on the difeafe. In the firft ftage, when the fpafm is confined to a few mufcles, the pulfe is not affected: it becomes accelerated only when the fpafmodic actions are general,

general, and this merely in confequence, as it would appear, of the mechanical effect produced on the blood-veffels by the contractions of the mufcles, which will hurry on the circulation, and throw the blood upon the heart in larger quantity than ufual, rendering the pulfe contracted, frequent, and irregular. The refpiration is hurried from the fame caufe, and the temperature of the body, as might be expected, is increafed in the fame proportion. That thefe fymptoms are not the effect of fever, appears from the ftate of the blood, which is ftated to be of a loofer texture than natural, and never exhibits the buffy coat, as in inflammatory difeafes. This circumftance is particularly noticed by Dr. Clephane, and alfo by Dr. Chalmers; and the remark has often been verified by fubfequent obfervers. On fome occafions, indeed, when the diforder is very violent, the arterial actions are increafed, and a febrile ftate prevails; and this appears to take place more frequently when the difeafe has originated from cold, than when it has been excited by wounds. The fkin is at firft natural, but, as the difeafe advances, is covered with a cold fweat. The tongue is always moift. Vomiting fometimes takes place early in the complaint, but it commonly fubfides in the progrefs of it: it is even ufual for the appetite of hunger to remain through the whole courfe of the difeafe; and what food can be got down appears to be fufficiently well digefted. Some local effects feem to be attributable to the contractions of the abdominal mufcles. The fphincter of the bladder is occafionally affected with fpafm, fo as to impede the difcharge of urine, which is voided with pain and difficulty: at other times, its fecretion is fuppreffed. When it can be obferved, it is ftated as being high-coloured, and fomewhat turbid. The bowels are found to be, in every inftance, obftinately coftive, a ftate which may partly be accounted for by the effect of opiates, which are fo generally adminiftered for the cure: but which, independently of this caufe, appears to be inherent in the difeafe itfelf. The bowels require the moft draftic purgatives; and there is a great fenfe of uneafinefs about the precordia. In the latter ftages of this diforder, indeed, when the powers of life begin to decline from the vaft expenditure of energy occafioned by the violent mufcular actions, every function in the fyftem partakes of the general diforder; the intellect gives way, and the patient finks from exhauftion alone, if a general convulfion does not occur to haften his end. It is mentioned by Dr. Cullen, that, in feveral cafes, a miliary eruption has appeared upon the fkin; but he expreffes a doubt whether this was a fymptom of the difeafe, or the effect of a certain treatment of it. It has not been obferved, he adds, to denote either fafety or danger, or to have any effect in changing the courfe of the diftemper.

From the more violent forms of the difeafe, hardly any inftance of recovery has been known to take place. On the other hand, the mere protraction of the fymptoms is an indication of the comparative mildnefs of the difeafe. Few patients fall a facrifice after the ninth or tenth days, which period they never could have attained, unlefs the violence of the complaint had in a great meafure fubfided. In this milder form, however, it may be prolonged feveral weeks; and fometimes the fpafmodic difpofition remains, even for months, before health is completely reftored. The pulfe, in thefe cafes, continues flow and hard, and the belly bound: but if blood b drawn, it does not exhibit any difference from its ufual ftate. Under every circumftance of recovery, indeed, the convalefcent labours long under general debility, and cannot, for months, raife himfelf from a fupine or recumbent pofture without affiftance, nor without pain.

Occafional deviations from the courfe above defcribed are met with in different cafes; but they are not of fufficient importance to lay the foundation of any diftinct variety. The moft fingular of thefe anomalies is the one recorded by Dr. (now fir Gilbert) Blane, of a cafe in which tetanus prevailed to a very confiderable extent, without affecting the patient with the leaft degree of pain. The fpafms were, in this inftance, accompanied with a tingling fenfation, which was even rather agreeable than diftreffing. The cafe, however, terminated fatally: but to the laft, no pain was experienced. In two cafes mentioned by the fame author, the fpafms affected only the fide of the body in which the wound was fituated.

The refult of diffections of patients who have died of tetanus, has thrown no light whatever on the nature of this terrible affection. Sometimes there are found flight effufions within the cranium: but, in general, no morbid appearance whatever can be detected in the head. There appears to be always more or lefs of an inflammatory appearance in the villous coat about the œfophagus and ftomach in the neighbourhood of the cardia. But thofe who are converfant with diffections, muft be well aware that thefe appearances are common to a great number of difeafes, and are uniformly met with in every cafe of rapid or violent death. Befides the rednefs and increafed vafcularity of thefe parts, M. Larrey ftates that he found the pharynx and œfophagus much contracted, and covered with a vifcid reddifh mucus. Dr. M'Arthur found, in feveral cafes, the inteftines much inflamed; and in two of them a yellow waxy fluid, of a peculiar offenfive fmell, covering their internal furface: but whether the inflammation was primary, or only a confequence of the preffure of the abdominal mufcles, which contract fo violently in this difeafe, he is unable to decide. See Medico-Chirurgical Tranfactions, vol. vii. p. 475.

Tetanus is a difeafe much more prevalent in hot than in cold climates. It is comparatively a rare difeafe in this ifland; but even here, the effect of warmth in giving a predifpofition to it is fufficiently obfervable. It is more common in the fouth than in the north of England, and is much more feldom met with in Scotland than in England. It is fenfibly more frequent in warm than in cold feafons. In warm, and efpecially in tropical climates, it may be regarded as an endemic difeafe, appearing at all feafons, but efpecially during the prevalence of the greateft heats. Warmth operates by increafing the mobility of the fyftem, while at the fame time it tends to diminifh the pofitive ftrength of the fibre. The fenfibility to all impreffions is greater in hot climates, while the power of refifting the caufes of injury is leffened: hence the greater predifpofition to fpafmodic difeafes in general. The natives of hot climates do not enjoy a greater exemption from tetanus than European fettlers. Negro flaves are peculiarly liable to its attacks. It affects all ages, fexes, conftitutions, and complexions: but, *cæteris paribus*, is more apt to feize upon thofe in whom the largeft fhare of vital power has been beftowed upon the mufcles of voluntary motion. Hence it attacks more readily the robuft, and thofe who are accuftomed to much bodily labour. Partly on this account, and partly from their being more expofed to the occafional caufes of the difeafe, men are much more frequently the fubjects of tetanus than women.

In the torrid zone, the moft frequent exciting caufe of tetanus is the application of cold when the body is heated. It is often induced by the alternate expofure to the fcorching heat of the fun, and to the heavy fhowers which frequently occur in tropical regions, and produce great and fudden viciffitudes of temperature. Sleeping out of doors after a hot day, efpecially on damp ground, or in a fituation where a ftream of cool air is admitted to the body, is often followed by tetanus in hot climates. Dr. Chalmers relates that a young man chofe to cut off his hair and fhave his head on a

warm

warm day in March, and went to bed without a cap: but the weather changing and becoming cold in the night, he was feized with tetanus, and the next morning was found rigid with the difeafe. The imprudent ufe of the cold bath, or even a draught of cold water, when the body has been warm by exercife, has frequently brought on tetanus.

In temperate climates, on the other hand, the difeafe feldom arifes from the application of cold; although there is one well-attefted inftance mentioned by Dr. Gregory in his lectures, of its occurring from this caufe in Scotland: but it is more frequently the confequence of lacerated or punctured wounds, and is particularly incident to injuries of nerves, and of tendinous parts. It fometimes follows the amputation of a limb; and it would appear that wounds of the joints, particularly thofe of the hands or feet, are more peculiarly liable to produce tetanus. In warm countries, the flighteft cut or bruife is in danger of being fucceeded by this formidable malady. Hence few of thofe that are wounded in battle recover: and few furvive any confiderable operation. It has been fuppofed by many, that tetanus arofe from the partial divifion of fome nervous fibres, in confequence of which the undivided filaments were unequally and violently ftretched: a ftate which would be remedied by their complete divifion. Experience, however, the ftubborn enemy to fo many hypothefes, has by no means proved favourable to this opinion. It has alfo been ftated to be more frequently the refult of wounds, which remain in a ftate of great irritability, without proceeding to fuppuration; it does not, however, appear that this pofition is fupported on any extenfive obfervation. It very often happens, indeed, that tetanus fhews itfelf when the wound was almoft healed, and the dreffings have been laid afide.

In the late campaigns of our armies in the peninfula of Spain and Portugal, according to the report of fir James Macgrigor, tetanus occurred in every defcription, and in every ftage of wounds, from the flighteft to the moft formidable, from the healthy and the floughing, from the incifed and lacerated, from the moft fimple and moft complicated. It occurred at uncertain periods; but it was remarked, that if it did not commence before twenty-two days from the date of the wound, the patient was fafe. It terminated in the fecond, third, and fourth days, and even as late as the feventeenth and twentieth days, though ufually it was not protracted beyond the eighth. The moft rapidly fatal cafe that has ever been recorded, is one that we have on the authority of the late profeffor Robifon of Edinburgh. It occurred in a negro, who was a waiter at a tavern, and who happened to fcratch his thumb with the broken edge of a china plate, and who died of tetanus a quarter of an hour after this apparently flight accident.

As the acute form of traumatic tetanus, obferves Dr. Dickfon, is fo uniformly fatal, it is of the greateft confequence to attend to whatever may affift in detecting the difeafe early, or in warding it off. Richerand ftates, that in wounds threatening convulfions and tetanus, a perfevering extenfion of the limbs during fleep often manifefts itfelf before any affection of the lower jaw; and we fhould naturally pay more attention to any admonition of this kind in punctured or extenfive lacerated wounds, particularly of tendinous or ligamentous parts, efpecially in injuries of the feet, hands, knee-joint, back, &c. in which the difeafe moft frequently fupervenes. Some prelufive indications of danger may often be derived from the increafe of pain, irritation, and reftleffnefs, nervous twitchings, pain and difficulty in deglutition, or in turning the head; fpafms, or partial rigidity of fome of the voluntary mufcles; pain at the fcrobiculus cordis; a fuppreffed or vitiated ftate of the difcharge, &c. which mark the flower approaches of the difeafe. M. Larrey adduces feveral inftances of tetanus, in which the wound was either dry, or afforded only a fcanty ferous exudation, and where the fymptoms were relieved on fuppuration being re-eftablifhed; and Dr. Reid, in the Edinburgh Medical and Surgical Journal for July 1815, remarks, that on removing the dreffing, inftead of healthy pus, the furface of the wound was coverd with a darkifh unhealthy looking matter, which he had in two former inftances noticed as the forerunner of tetanus. A torpor of the inteftines has generally been obferved to precede as well as to accompany the difeafe. Mr. Abernethy obferves, that in four cafes where he inquired into the ftate of the bowels, the evacuations were not like fæces; and he propofes as a queftion in inveftigating the caufe, what is the ftate of the bowels between the infliction of the injury and the appearance of this dreadful malady? Dr. Parry has adduced the velocity of the circulation as an ufeful criterion of the danger of the difeafe; and obferves, that if the pulfe be not above 100 or 110, by the fourth or fifth day the patient almoft always recovers; but if it be quickened early, that it proves fatal; and yet there are a few inftances of recovery where the pulfe has rifen to 120 on the firft day. M. Larrey remarks, that when the perfpiration, which fo often attends the difeafe, is fymptomatic, it begins upon the head and extremities; and when it is critical, it occurs over the cheft and abdomen: but in many cafes, perfpiration flows very freely without bringing relief.

We have already ftated, that in fome inftances the fource of irritation producing the difeafe is not obvious. Such cafes of fpontaneous tetanus are very rare. Dr. Willan, in his Reports, p. 289, mentions having met with an inftance in a female, 32 years of age, where there had not been any previous accident or local injury whatever; and where the only circumftance, which was likely to have contributed to its production, was fevere diftrefs of mind, occurring in a frame previoufly debilitated.

When we reflect upon the obfcurity which involves both the *ratio fymptomatum* and the proximate caufe of tetanic affections, we need not wonder that the practice in thefe diforders fhould ftill be entirely empirical. The indication of cure which is generally applicable in all difeafes, namely, the removal of the exciting caufes, has but little place in a morbid condition, which is the confequence of caufes that in general have ceafed to act, or which it is not in our power either to remove or controul. In thofe cafes where we could fuppofe local irritation to be ftill operating, the moft effectual method of counteracting its effects on the fyftem, would obvioufly be to intercept all communication between the feat of the irritation and the fenforium. If, however, the difeafe has already eftablifhed itfelf, and the fevere fymptoms have come on, it does not appear that this would fucceed in arrefting the courfe of the diforder. Experience has but too fully fhewn, that the amputation of the limb from the injury of which the tetanus had arifen, will very feldom procure even a mitigation of the fymptoms, if performed after a certain period from their firft appearance. This plan was fully tried in our army at Touloufe, and totally failed. In fome inftances, however, it is faid that a favourable change has enfued, and that patients have even recovered by the facrifice of the wounded limb: and it has been remarked, that the fpafms relaxed immediately on the divifion of the foft parts by the knife, and before the faw was applied to the bone, in order to complete the operation. It is, therefore, highly probable, that the free divifion of the parts above the wound, or ftill more certainly the amputation of the limb, would, at a certain ftage of the affection,

fecure

fecure the patient from the approach of tetanus. But the difficulty is here to eftimate the probability of the patient's having the difeafe, as nothing fhort of the certainty of its being at hand, could well juftify the operation.

As it is matter of experience that an early and highly irritable and painful condition of the wound has a tendency to excite tetanus, as well as a ftate in which the difcharge is of a peculiar unhealthy character, or is fuppreffed altogether, our immediate objects fhould be to allay as much as poffible the local irritation, and to re-eftablifh a healthy fecretion of pus. Mechanical caufes of irritation fhould as much as poffible be obviated, by early attention to remove fplinters of bone, balls, or other foreign bodies, that may be lodged in the wound. Poultices and foothing applications will anfwer the double purpofe of quieting local inflammation, and bringing on healthy fuppuration. The irritability of the furface may fometimes be moft effectually deftroyed by lunar cauftic, after which, an emollient poultice may be applied. An oppofite plan of treatment has been recommended by Dr. Rufh, namely, that of exciting confiderable inflammation in the wounded part, by epithems of turpentine, and other highly ftimulating applications; which, though it may in certain cafes have fucceeded in preventing tetanus, does not appear to be generally applicable, and feems accordingly to have been abandoned. On the contrary, it has of late been the univerfal practice in the navy, to add tincture of opium to the dreffings applied to wounds, with a view of preventing tetanus. With the intention of re-exciting fuppuration where there is no difcharge, M. Larrey recommends the application of blifters as near as poffible to the wound, and adduces inftances of fuccefs from this mode of treatment.

But the cure of tetanus, when once it has commenced, is to be fought for more by the ufe of general, than of topical remedies. The feat of the diforder has been transferred to the brain and nervous fyftem, and our efforts muft be directed to allay their inordinate actions. The plan from which theory would lead us to expect moft fuccefs, is that of exciting fome new action in thefe organs, by which their energies would be directed into fome different channel, and the exifting morbid action would be fufpended and fuperfeded. The remedies which exert the moft powerful immediate effects in the nervous fyftem, are accordingly found to be the moft efficacious in the cure of tetanus. Opium, wine, and other highly diffufible ftimuli, digitalis and other narcotics, the fudden affufion of cold water, bleeding, purging, impregnating the fyftem with mercury, the exhibition of arfenic, of oil of turpentine, of alkalies, and of ipecacuanha, have refpectively been reforted to, and with very various, and in general but limited fuccefs. The fame methods from which cures have been obtained in the milder cafes, generally fail to make the leaft impreffion on the difeafe in its feverer forms. We learn from the valuable report of fir James Macgrigor, already alluded to, that there were very few, out of feveral hundred cafes that occurred in the Britifh armies during the late campaigns on the Peninfula, where this difeafe had made any progrefs, in which it terminated fuccefsfully, or in which remedies, however varied, feemed to have any beneficial influence.

Opium is the remedy on which reliance has moft generally been placed in combating this formidable difeafe; and there is no doubt that in mild cafes it is competent to its complete folution. But for this purpofe, it is abfolutely neceffary that its ufe be begun from the earlieft appearance of the fymptoms; that it be given in very large dofes; and that the dofes be repeated at fhort intervals: fo that the fyftem be kept conftantly under the influence of the remedy. It is, indeed, aftonifhing how the fyftem, when poffeffed by a ftrong difpofition to fpafm, will refift the operation of this and other remedies, which in its ordinary ftate would have been more than fufficient to overpower and deftroy it. Patients labouring under tetanus will bear with impunity quantities of opium, that at any other time would have been certainly fatal. Inftances are upon record of five, ten, and even twenty grains, being taken every two or three hours for many days, without its producing any extraordinary narcotic effects upon the fenforium. It is always, however, advifeable to begin with comparatively moderate dofes, fuch as forty or fixty drops of tincture of opium, which may be repeated at intervals of three or four hours, and increafed at each repetition, till fome fenfible effect is produced on the fpafms. It feems requifite to augment the dofe rapidly, as the difeafe preffes upon us every hour, and no time is to be loft in refifting its advances, while there is yet a chance of controuling its fury. The circumftance of the clofing of the jaw, and the difficulty of deglutition, the increafe of which may foon render it hardly poffible to introduce medicines into the ftomach, is an additional motive urging us to pufh our remedies before thofe obftacles arife. Glyfters are our only refource, when it is impoffible to overcome the fpafm of the fauces. Opium has alfo been applied externally and topically to the jaws; and relief has fometimes been obtained from an opiate plafter on the maffeter mufcles, or behind the ears; but thefe are comparatively very trifling in their efficacy, and applicable only to the flighteft cafes, or to thofe in which convalefcents are ftill affected with a recurrence of one or two local fymptoms.

It is of the greateft importance in all cafes of tetanus, and more efpecially where opium is given, to excite a proper action of the bowels, fo as to allow of no ftagnation of their contents. The teftimony of the army phyficians, as appears from the report of fir James Macgrigor, is highly in favour of a rigid perfeverance in the ufe of purgatives, given in dofes to produce a full effect daily. Dr. Forbes ftates, that a folution of fulphate of magnefia, in infufion of fenna, was found to anfwer better than any other purgative, and it was daily given in a fufficient quantity to procure a copious evacuation, which was always dark-coloured, and highly offenfive: and to this practice he chiefly attributes, in one fevere cafe, the removal of the difeafe. The infrequency of locked jaw in the Weft Indies, in the public fervice, of late years, is chiefly afcribed by Dr. Dickfon, to the greater freedom with which purgatives have been employed, particularly fince the publication of Dr. Hamilton's work on the operation of this clafs of remedies; an opinion which is corroborated by the teftimony of various authors, as to the ftate of obftinate coftivenefs which prevails in this difeafe, and the offenfive nature of the contents of the inteftines.

For the introduction of the ftimulant and tonic plan of treatment, we are chiefly indebted to Dr. Rufh, who was led to adopt it from fome theoretical views he entertained on the nature of tetanus, which he conceived to be effentially a difeafe of debility. There can be no doubt that in many cafes the exhibition of wine or fpirits has been attended with very good effects. Dr. Hoffack, in vol. iii. of the American Medical Repofitory, relates feveral cafes which were cured by large quantities of wine.

A free allowance of wine and porter after gun-fhot wounds has appeared alfo, according to the ftatement of Dr. M'Arthur, to have contributed to the very fmall number of cafes of tetanus which occurred under his care in the hofpital at Barbadoes, during nearly fix years of the moft active period of the war. Of the numerous cafes of gun-fhot wounds received into the hofpital, and of operations performed, during the whole

whole of that period, only two inftances of tetanus occurred. Bark has been given in conjunction with wine and opium; and the muriated tincture of iron has alfo been ufed with apparent advantage. The fuccefs of the tonic plan of treatment refts alfo on the teftimonies of Dr. Wright of Jamaica, Dr. Cochrane of Nevis, and feveral other Weft Indian practitioners; and alfo on that of Dr. Currie of Liverpool.

The prefence of an inflammatory diathefis, which occafionally accompanies the fpafmodic ftate, prefents, however, a material obftacle to the employment of the above-mentioned remedies. So much is this the cafe, that many phyficians have recommended the free ufe of the lancet, particularly in the early ftages of tetanus. Dr. Dickfon ftates it as his opinion, that in a full habit, where the wound is fwelled, inflamed, and painful, venefection, with free purging, and fuch other means as are calculated to allay the general and local irritation, afford the faireft chance of averting the danger. (See the 7th volume of the Medico-Chirurgical Tranfactions, part 2.) In the 6th volume of the fame work, a cafe is detailed by Mr. Earle, in which, though it terminated fatally, bleeding was beneficial, and leffened the patient's fufferings; and in the fame volume, it is alfo mentioned with approbation by the medical officers in the Peninfula. Dr. M'Arthur confiders that he ufed blood-letting with evident relief in one cafe, in the naval hofpital at Barbadoes; that the fpafms were ameliorated, the difeafe protracted, and the morbid appearances after death were lefs marked in confequence. M. Larrey alfo adduces fome examples where it produced a good effect. Mr. Guthrie gives three cafes which occurred in the hofpitals of St. Andero, out of many which were recorded, where venefection was the principal remedy. In the firft, in which tetanus from a wound in the hand was advancing with rapidity, the patient was bled *ad deliquium* feveral times with good effect, calomel and diaphoretics being given at the fame time, and he recovered. In the fecond cafe, the patient was bled in the fame manner, with an evident amendment of the fymptoms; fo much fo, indeed, that he fuffered but little from fpafm, and could open his mouth very well, when he was feized with diarrhœa, which, in the debilitated ftate he was in, carried him off. In the third cafe, of a man of a fanguine temperament, and fuffering from acute tetanus, venefection pufhed to the utmoft totally failed.

Digitalis has been tried in the Peninfula in feveral cafes, occafionally with good effect, though it never appears to have effected a cure. Ether, camphor, mufk, and other antifpafmodics, as likewife the alkalies, were alfo tried, and found equally unfuccefsful. Caftor is ftrongly recommended by Aratæus, but is too feeble a remedy to have any decifive influence in fo violent a diforder.

The affufion of cold water has in general been attended with great benefit. It is a practice particularly recommended by Dr. Wright, in the London Medical Obfervations, and is fanctioned by the concurring teftimonies of Dr. Cochrane, in the Medical Commentaries, and of Dr. Currie, in his Medical Reports, &c. as well as by many other practitioners. A large pailful of cold water fhould be thrown upon the patient every two or three hours; he is to be immediately wiped dry, and laid in bed after each affufion, and an opiate draught adminiftered. Some remiffion of the fpafms will in this way be generally obtained; and many inftances are upon record, of complete cures being effected by perfeverance in this plan. Before the introduction of this practice, the warm bath was very commonly employed; the patient, after ufing it, being placed in bed, without being dried, between two blankets, with a view to bring out a fweat. It does not appear, however, that this plan was attended with any general or permanent advantage; and is certainly inferior in efficacy to the cold affufion. The cold bath, fays fir James Macgrigor, in acute tetanus, is worfe than ufelefs. The ufe of a hot bath impregnated with potafs, and a few ounces of quick-lime, has been much recommended by Dr. Stutz of Suabia in traumatic tetanus. See Medical and Phyfical Journal, vol. iii.

The powerful relaxing effects of tobacco given in glyfter in cafes of hernia and enteritis, have fuggefted its employment in tetanus. Mr. Earle tried it in one very acute cafe, in which, although it afforded a temporary alleviation from fpafm, fo much agitation was produced by it, that it was not perfevered in. He is, however, induced to recommend the trial of a fuppofitory made of the extract of nicotiana, and paffed up into the rectum. But, according to the report of fir James Macgrigor, tobacco glyfters, tried in the advanced ftage of the difeafe, feemed to have no effect. He reprefents, however, the tobacco fume as deferving of further trial. A remarkable cafe is recorded by Dr. Phillips, in the 6th volume of the Medico-Chirurgical Tranfactions, in which the jaw fuddenly fell, upon the exhibition of an enema with oil of turpentine.

It has been fuppofed that mercury thrown quickly into the fyftem, fo as to excite falivation, would prove highly ferviceable in relieving the fpafms, and particularly thofe of the mufcles of the jaw. This practice was firft introduced by the practitioners in the Weft Indies, and in particular by Drs. D. and A. Monro, and appears to have fucceeded in many cafes. Dr. Rufh conceives that its falutary effect is connected with its inducing in the fyftem a ftate of inflammatory diathefis incompatible with the fpafmodic action, which it would therefore fuperfede. Whatever benefit, however, may have been experienced from this plan in mild cafes, it completely fails in the more fevere of making any impreffion on the difeafe. Dr. Emery, Mr. Guthrie, and other medical officers attached to our army in the Peninfula, after the battle of Salamanca, tried inunction of the whole body three times a day, with ftrong mercurial ointment, in unlimited quantity, with no degree of fuccefs. Mr. Guthrie reports, that after the battle of Touloufe, a fatal cafe occurred in a man ftrongly under the influence of mercury, which he had ufed previous to the action for the cure of the itch. The combination of calomel with ipecacuanha, which has been much recommended, is equally inefficacious with the other remedies, in the acute and fully formed difeafe. In the mild tetanus, benefit has been derived from calomel: and its operation on the bowels is always ufeful, and fingularly fo in the mild difeafe diftinguifhed by the fpafms coming on flowly, and continuing of the fame violence; inftead of their fudden acceffion, and their continuing with increafing violence, as happens in the acute fully formed tetanus. In this, calomel cannot be depended upon, as the patient is carried off before the medicine can have any effect.

Several remedies were formerly in vogue, of which it is hardly neceffary to give any account, as they have now loft all the credit they once enjoyed. It may be fufficient to mention the Barbadoes tar, alluded to by Dr. Cullen; the colchicum autumnale, or meadow faffron, recommended by Dufrefnoy; bliftering, electricity, unctuous applications, partial fomentations, &c. moft of which appear either to be inert, or at beft very weak auxiliaries to the remedies already defcribed.

Of late years, tetanus has been much lefs frequent in the Weft Indies, when compared with former wars. This is attributed, apparently with great reafon, by Dr. Dickfon, to the improvements in the medical and furgical treatment of wounds; to greater cleanlinefs, and more perfect ventilation; and in general to fuperior comforts, diet, and accom-

 modation;

TET

modation; but particularly to the greater attention paid to the ftate of the bowels. See Medico-Chirurgical Tranfactions, vol. vii.

TETARBOLION, in *Ancient Coinage*, the quarter-obolus, which is the moft minute coin yet found, being of $2\frac{1}{4}$ grains, and its current worth a farthing and a half.

TETARIUM, in *Ancient Geography*, a town of Afia, fituated in that part of Lycaonia, which Ptolemy comprehends in Galatia.

TETARTEMORION, among the *Ancients*, denotes the fourth part of the zodiac.

TETARTO-CHRUSOS, τεταρτο-χρυσος, in *Ancient Coinage*, a gold coin of Philip, Alexander, and Lyfimachus, which was a quarter of the Philippus or χρυσος; it weighs 33 grains, and paffed for 5 drachmæ of filver, 3*s.* 9*d.*, now worth intrinfically 5*s.*

TETAVI, in *Geography*, a town of the principality of Georgia, in the province of Caket.

TETBURY, or Tedbury, anciently *Teteberie*, a large and refpectable market-town in the hundred of Longtree, and county of Gloucefter, England, is fituated 20 miles S. by E. from Gloucefter, and 99 miles W. by N. from London. Its name evidently determines it to have been a military ftation. On the S.E. fide, within the memory of many living, were traces of a ftrong camp, now completely deftroyed, where arrows and javelin-heads have been found, with various Englifh coins of high antiquity. Roman coins of the Lower Empire have likewife been met with in and near the town. Tetbury confifts principally of four ftreets, croffing in the centre, and contains many good ftone buildings. The governing officer is a bailiff, who is annually chofen. The population of the parifh, including four hamlets, in the year 1811, was 2533, the number of houfes 522. A weekly market is held on Wednefday, and four fairs annually. The wool-combing and wool-ftapling branches are carried on here, but to no great extent. The clothing manufacture was formerly attempted, but the want of a continual fupply of water prevented its being brought to perfection. Even for domeftic ufes, water has, till within a few years, been fcarce; but in 1749, a well was funk to the depth of 104 feet, fince which time other wells have been opened, and the inconvenience in a great degree removed. The parifh church confifts of an ancient tower, and a modern body; the former is terminated by a fpire, the latter is built in imitation of the pointed ftyle, appearing externally as a fingle nave with cloifters, but withinfide divided into aifles, by a very flight arcade and cluftered columns, on the principle on which the roof of the theatre at Oxford was conftructed. The old church, which was built foon after the Conqueft, having become from length of time very ruinous, was taken down (excepting the tower and fpire), and rebuilt at the expence of 5000*l.*; and opened for divine fervice in 1784. Two turnpike roads lead through the town in crofs directions; one to London and Bath, the other to Gloucefter and Southampton. A deep hollow, in the nature of a moat, at the weft end, made the entrance into the town inconvenient, till the commiffioners of the roads built a high bridge of four arches acrofs it in 1775. Rudge's Hiftory of Gloucefterfhire, vol. i. 1803. Beauties of England and Wales, vol. v. Gloucefterfhire; by J. Britton and E. W. Brayley, 1803.

TETCHA, a fmall river of Ruffia, which runs into the Ifet, near Dolmatov, in the province of Ekaterinburg.

TE-TCHUEN, a town of Corea; 60 miles E.N.E. of Han-tcheou.

TETE, a fort belonging to the Portuguefe, in the country of Mocaranga, on the Zambefe.

Tete *de Buch, La*, a town of France, in the department of the Gironde, fituated on the S. fide of a large bay, called "The Harbour of Arcachon," the entrance of which is dangerous on account of the fand-banks; 30 miles S.W. of Bourdeaux.

TETEROA, a harbour on the W. coaft of the ifland of Ulietea.

TETEROW, a town of the duchy of Mecklenburg; 18 miles S.W. of Guftro.

TETERSKOI, a town of Ruffia, on the Podkamenfkaia Tungufka. N. lat. 59° 54′. E. long 101° 14′.

TETHALASSOMENOS, a term ufed by the old medical writers, to exprefs wine mixed with fea-water.

TETHER. See Tedder.

TETHERING, the practice of confining animals to a certain range of feeding, by means of ropes, chains, or other contrivances.

TETHRONIUM, in *Ancient Geography*, a town of Greece, in the Phocide; being one of thofe which Herodotus refers to the vicinity of the river Cephifus.

TETHUROA, in *Geography*, a fmall ifland in the South Pacific ocean, fubject to Otaheite, compofed of fix or feven low iflets near each other, not many feet above the level of the fea; abounding in cocoa-nut trees, but not in bread-fruit, which the inhabitants are not allowed to cultivate. The inhabitants are about 3000, chiefly employed in catching of fifh, which they bring to Otaheite, and exchange for bread-fruit; 24 miles N.W. of Point Venus. S. lat. 17° 4′. W. long. 149° 30′.

TETHYS, in *Mythology*, the daughter of Cœlum and Terra, and wife of Oceanus. Her chariot, which is reprefented as gliding over the furface of the waters, was a fhell of an extraordinary figure, and whiter than ivory.

Tethys, in *Zoology*, a genus of the Mollufca order of Vermes, or worms; the characters of which are, that the body is free, fomewhat oblong, flefhy, and having no peduncles; the mouth terminating in a cylindric probofcis, under the lip; and two foramina on the left fide of the neck. It has two fpecies.

Leporius. With a ciliated lip; found in the Mediterranean fea.

Fimbrica. With a crenulated lip; found in the Adriatic fea.

TETIMIXIRA, in *Ichthyology*, the name of an American fifh, more ufually known by the name of the *pudiano*.

TETIN, in *Geography*, a town of Bohemia, in the circle of Beraun; 3 miles S. of Beraun.

TETITLAN, a town of Mexico, in the province of Xalifco; 18 miles S.E. of Compoftello.

TETIUS, in *Ancient Geography*, a river of the ifle of Cyprus, which ran from the N.W. to the S.E. and difcharged itfelf into the fea, near the promontory of Dades, after having watered Citium.

TETIUSCHI, in *Geography*, a town of Ruffia, in the government of Kazan, on the Volga; 52 miles S. of Kazan.

TETOBE, a town of the ftate of Georgia; 5 miles W. of Tugeloo.

TETRACERA, in *Botany*, received that name from Linnæus, in allufion to the four horn-like points of the capfules of the original fpecies, the word being compounded of τετρας, *four-fold*, and κερας, *a horn*. The genus however has fubfequently received an acceffion of feveral fpecies with folitary capfules and ftyles, which invalidate the ftrict propriety of its name, and render its fituation in the artificial fyftem of Linnæus ambiguous.—Linn. Schreb. 367. Juff. 280. See EURYANDRA.)—Clafs and order, *Polyandria Tetragynia*, Linn. Willd. Rather *Icofandria Monogynia*; or *Pentagynia*, according to the principles laid down in Sm. Introd. to Bot. ed. 3. 325. Nat. Ord. *Senticofæ*, Linn. *Rofaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five or fix deep, rounded, unequal fegments, permanent. *Cor.* Petals from three to five, roundifh, concave, inferted into the calyx, and longer than its fegments. *Stam.* Filaments numerous, inferted into the calyx, fhorter than the petals; anthers of two round lobes. *Pift.* Germens fuperior, from one to three or four, ovate, quite diftinct; ftyles vertical, awl-fhaped; ftigmas obtufe. *Peric.* Capfules from one to three or four, ovate, divaricated, each of one valve, burfting along the upper edge, of one cell. *Seeds* folitary, roundifh, attached to the bottom of the capfule, and clothed with a jagged tunic from the bafe.

Eff. Ch. Calyx in five or fix deep unequal fegments. Petals four or five. Capfules burfting at their upper edge. Seeds folitary, tunicated.

Obf. The capfules refemble follicles, but the feed is attached to their bafe.

Section 1. *Flowers with a folitary germen and ftyle.*

1. T. *farmentofa.* Trailing Tetracera. "Vahl Symb. v. 3. 70." Willd. n. 1. (Delima farmentofa; Linn. Sp. Pl. 736. Burm. Ind. 122. t. 37. f. 1. Piripu; Rheede Hort. Malab. v. 7. 101. t. 54. Frutex indicus farmentofus, foliis hifpidis rigidis, &c.; Burm. Zeyl. 101.)—Leaves elliptic-oblong, ferrated, rough. Style folitary. Follicle ovate, polifhed, briftly.—Native of Ceylon.—The *ftem* is fhrubby, with trailing, round, leafy *branches*, rough with minute briftly hairs. *Leaves* alternate, ftalked, very rough on the upper fide with minute fcales, furnifhed with one rib, and many ftraight, parallel, tranfverfe, oblique veins, which latter are hairy beneath. *Panicles* terminal, compound, many-flowered, hairy. *Calyx* of the fruit reflexed, reddifh, fringed. *Follicle* pointed, the fize of a fmall pea, brown, highly polifhed, clothed with erect briftly hairs. *Seed* black, ftanding on a toothed cup-like tunic.

2. T. *tomentofa.* Downy Tetracera. Willd. n. 2. (Tigarea dentata; Aubl. Guian. 920. t. 351.)—Leaves elliptical, pointed, with tooth-like ferratures; fmooth above; downy beneath. Flowers dioecious. Style folitary.—Native of woods in Cayenne, flowering in January, and ripening its feed in March. The trailing fhrubby branched *ftem* climbs to the tops of the higheft trees, from whence its pendulous *branches* reach almoft to the ground. The young *fhoots* are downy. *Leaves* alternate, ftalked, four or five inches long, and two or more in breadth; their upper furface fmooth and green; the under filky and hoary. The *flowers* and *fruit* agree with the following.

3. T. *afpera.* Harfh Tetracera. Willd. n. 3. (Tigarea afpera; Aubl. Guian. 918. t. 350.)—Leaves roundifh, fomewhat undulated, rough. Flowers dioecious. Style folitary.—Frequent in the woods of Cayenne, bearing flowers and fruit in January. Aublet fays it is fometimes fo abundant as to render the forefts impaffable, from the entanglement of its *ftems* and *branches*, which climb to the tops of trees, and hang from thence to the ground. Their roughnefs, like that of the *leaves*, renders them the more troublefome and dangerous. The French call this fhrub *Liane rouge*, or red climber, from the colour of its decoction, which the natives of the country confider as a remedy for venereal diforders. The *leaves* are alternate, ftalked, of a broad elliptical, or roundifh, figure, obtufe, flightly wavy at the margin, rough on both fides with rigid, crooked, hoary hairs. Their ribs and veins like thofe of the firft fpecies. The largeft *leaves* are three inches and a half long, and three broad. *Flowers* in axillary panicles, male on one plant, female on another. *Calyx* in four or five concave, pointed fegments. *Petals* four or five, white. *Stamens* numerous, fhort. *Anthers* yellow, their two lobes feparated by a furrow. *Piftil* abortive in the male flowers, as the *ftamens* are without *anthers* in the female, whofe *germen* is roundifh, with one *ftyle*, and a broad blunt *ftigma*. *Capfule* folitary, reddifh, rough to the touch, containing one feed. *Aublet.*

4. T. *nitida.* Polifhed Tetracera. "Vahl Symb. v. 3. 70." Willd. n. 8.—"Leaves lanceolate-oblong, rough, entire. Style folitary."—Suppofed to be a native of Trinidad. *Willd.*

Willdenow has four more fpecies in this fection, of which his *T. Doliocarpus*, *ftricta*, and *Calinea*, will be found under our article DOLIOCARPUS; and his *T. obovata* is our MAPPIA.

Sect. 2. *Flowers with three or four germens and ftyles.*

5. T. *Euryandra.* New-Caledonian Tetracera. "Vahl Symb. v. 3. 71." Willd. n. 9. (Euryandra fcandens; Forft. Prod. 41.)—Leaves oblong, obtufe, fmooth, entire. Styles three.—Native of New Caledonia. *Stem* fhrubby, climbing. *Leaves* ftalked, two inches or more in length; paler beneath.

6. T. *volubilis.* Serrated Rough Tetracera. Linn. Sp. Pl. 751. Hort. Cliff. 214. Willd. n. 10. (Arbor americana convolvulacea, Broad leaf, *i. e.* platyphyllos barbadenfibus dicta, foliis ferratis; Pluk. Phyt. t. 146. f. 1.)—Leaves obovate-oblong, ferrated, very harfh. Styles four. Calyx filky within.—Native of the Weft Indies. The *branches* are round, with a rough, dotted, membranous, deciduous bark. *Leaves* alternate, ftalked, five or fix inches long, and two and a half or three wide, obtufe, very rough, like a file, with minute fcales, efpecially beneath; each lateral rib, at leaft in the upper half of the leaf, terminating in a fharp but fhallow ferrature. *Panicles* terminal, compound, rough with ftarry hairs. *Calyx* harfh and hoary externally; briftly and filky within. *Capfules* unequal, ovate, tumid, beaked, brown, fmooth and highly polifhed; rounded, not depreffed or keeled, at the fides. *Seed* fmall, black, in a pale, finely laciniated, tunic.

7. T. *rotundifolia.* Round-leaved Tetracera.—Leaves roundifh-elliptical, entire, very harfh on both fides. Styles four. Calyx fmooth within.—Native of Guiana. We have received fpecimens of this new fpecies from Mr. Rudge and Mr. Forfter, under the name of *Tigarea afpera* of Aublet, our *Tetracera afpera*, fee n. 3, which, unlefs that author has made feveral great miftakes, muft be a very different plant. The prefent has always three or four *ftyles*, and as many *capfules*; and the *leaves*, though like Aublet's t. 350. in fhape, are quite entire, not undulated. They are harfh on both fides, like a very fine file, as is the *branch* in a lefs degree. The *panicles* are terminal. The *calyx* has a fhort, inverfely conical, tube, and is hoary externally, fmooth and naked within. The *ftamens* appear to be perfect in the fame flower with the four *piftils*. *Capfules* three or four, oval, brown, fmooth and fhining; keeled and depreffed at the fides, lefs tumid than the foregoing. *Seed* entirely enveloped in its jagged tunic.

8. T. *lævis.* Smooth Tetracera. "Vahl Symb. v. 3. 71." Willd. n. 11.—"Leaves oblong, fmooth, pointed, nearly entire. Flowers terminal. Capfules four."—Native of the Eaft Indies. *Stem* fhrubby. *Leaves* alternate, two or three inches

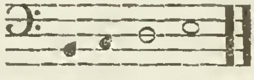
inches long, veiny, smooth on both sides; tapering at the base; serrated with a few slight teeth towards the point. *Footstalks* very short. *Flower-stalks* solitary or in pairs, terminal, an inch long. *Flowers* somewhat racemose, one or two on each partial stalk. *Calyx* with six roundish segments. *Capsules* four, as long as the finger-nail, roundish, tumid, pointed, very smooth and polished. *Seed* small, black, polished, covered in its lower half with a whitish tunic, whose margin is toothed. *Vahl.*

9. T. *alnifolia.* Alder-leaved Tetracera. Willd. n. 12.—"Leaves oblong, acute, nearly entire; roughish beneath. Panicle terminal."—Native of Guinea. *Branches* woody, round, smooth. *Leaves* coriaceous, tapering at the base, rounded at the extremity, with somewhat of a point; mostly entire, but occasionally furnished with an obsolete tooth or two near the end; veiny; shining and smooth above. *Calyx* with four deep segments. *Petals* apparently five. *Filaments* a little dilated at the end, with an anther (or lobe) at each side. *Capsules* four. *Seed* black, entirely covered by its whitish tunic. *Panicle* simple. *Stalks* three-flowered. *Willd.*

Willdenow suspects the *Assa indica*, of Houttuyn's Dutch edition of the Vegetable System of Linnæus, v. 4, 40. t. 26. f. 1, may be another species of the genus before us. The same author is also inclined to refer Thunberg's WAHLBOMIA, see that article hereafter, to *Tetracera.*

TETRACHORD, TETRACHORDON, formed of τετρα, of τετράκις, *four times*, and χορδη, *a chord*, or *string*, in the *Ancient Music*, was a series of four sounds, of which the extremes, or first and last, constituted a fourth. These extremes were fixed and immutable; the two middle sounds were changeable according to the genera, and called *mobiles.* There were three genera or ways of tuning each tetrachord; the *diatonic*, *chromatic*, and *enharmonic.* The character of the diatonic was the tone; of the chromatic, the semitone; and of the enharmonic, the quarter-tone.

A tetrachord in the diatonic genus consisted of one major semitone and two tones.



In the chromatic genus, of two semitones and a minor third.

In the enharmonic genus, of a quarter tone, a semitone, and a major third.

The general system or scale of the Greeks consisted of tetrachords repeated, as the scale of Guido does of octaves. See GREEK *Music.*

The tetrachord of Mercury contained four strings or chords, in the proportion of twelve, nine, eight, and six; so as to give the fourth, fifth, and octave of the lowest chord. This is the opinion of Boethius, and after him of Zarlino. Vide Wallis's Append. Ptolem. Harm. p. 178.

TETRACTIS, in *Natural History*, a name given by Linkius, and other authors, to a kind of star-fish, composed only of four rays, the more common kinds having five.

TETRACTYC ARITHMETIC. See ARITHMETIC.

TETRACTYS, in the *Ancient Geometry.* The Pythagoric tetractys is a point, a line, a surface, and a solid.

TETRADECARHOMBIS, in *Natural History*, the name of a genus of fossils, of the class of the selenitæ.

The word is derived from the Greek τετρα, *four*, δεκας, *ten*, and ῥομβος, *a rhomboidal figure*, and expresses a rhomboidal body consisting of fourteen planes.

The characters of this genus are, that the bodies of it are exactly of the same form with the common selenitæ; but that in these, each of the end planes is divided into two; and there are by this means eight of these planes, instead of four. See SELENITES.

TETRADIAPASON, *Quadruple Diapason*, a musical chord, otherwise called a quadruple eighth, or nine-and-twentieth. See DIAPASON.

TETRADITÆ, TETRADITES, in *Antiquity*, a name given to several different sects of heretics, out of some particular respect they bore to the number four, called in Greek τετρα. Thus the Sabbatians were called tetraditæ, from their fasting on Easter-day, as on the fourth day, or on Wednesday.

The Manichees, and others, who admitted of a quaternity instead of a Trinity in the Godhead, or four persons in lieu of three, were also called tetraditæ.

The followers of Petrus Fullensis bore the same appellation of tetraditæ, by reason of the addition they made to the Trisagion, to countenance an error they held, that in our Saviour's passion it was not any particular person of the Godhead, *e. gr.* the Son that suffered, but the whole Deity.

The ancients also gave the name tetraditæ to children born under the fourth moon, and these they believed unhappy.

TETRADIUM, in *Botany*, from τετραδιον, *a party of four*, as a file of four soldiers, &c. alluding to the prevalence of the number four in its parts of fructification.—Loureir. Cochinch. 91.—Class and order, *Tetrandria Tetragynia.* Nat. Ord. *Terebintaceæ*, Juss.? or perhaps *Rutaceæ.*

Gen. Ch. *Cal.* Perianth inferior, minute, permanent, of four spreading acute leaves. *Cor.* Petals four, ovate, incurved, or nearly erect, longer than the calyx. *Stam.* Filaments four, thick, awl-shaped, hairy, equal to the corolla in length; anthers ovate, erect, of two cells. *Pist.* Germen roundish, four-lobed; style none; stigmas four, awl-shaped, erect. *Peric.* Capsules four, roundish, bursting at the top. *Seeds* solitary, roundish, polished, tunicated.

Eff. Ch. Calyx inferior, of four leaves. Petals four. Capsules four. Seeds solitary, tunicated.

1. T. *trichotomum.* *Cây dâu deâu* of the Cochinchinese. Native of the hills of Cochinchina. A middle-sized tree, with ascending branches. *Leaves* pinnate, with an odd one; leaflets lanceolate, smooth, entire. *Flowers* whitish, in ample, nearly terminal, three-forked *clusters;* or rather, as we presume, *panicles.*

De Theis well remarks, that this genus appears to be allied to BRUCEA: we think also it is evidently very near FAGARA (see those articles). In deference to the weighty opinion of Jussieu, we have not, without doubt, referred it to his natural order of TEREBINTACEÆ; but it appears rather to belong to his imperfectly-defined one of RUTACEÆ, to both which articles we refer the reader.

Nothing is said by Loureiro respecting the qualities or uses of this tree.

TETRADRACHM, in *Ancient Coinage*, a silver coin worth four drachmas, or 3*s.* sterling, the drachma being valued at 9*d.* But if we estimate the value of the drachma at a higher rate, that of the tetradrachm will increase in due proportion. This is the largest form of Greek silver coins, excepting the tetradrachm of the Eginean standard, which is worth 5*s.* The largest tetradrachms weighed from 430 to 440 grains. See DRACHM and SHEKEL.

TETRADYNAMIA, in *Botany*, (from τετρα, *four*, and δυναμις, *power*, indicating a superiority of four stamens over the rest,) the fifteenth class of the Linnæan artificial system, which

which is in itſelf, with the exception of one genus, *Cleome*, a natural claſs, comprehending all the cruciform flowers. Its eſſential character conſiſts in having ſix ſtamens, four of which riſe above the reſt. This is indeed ſo naturally diſtinct a tribe of plants, that it is hard to trace any particular affinity between them and any others. The following is the character of the flowers.

Cal. Perianth oblong, of four ovate-oblong, concave, obtuſe, converging leaves, projecting downwards at their baſe, the oppoſite ones moſt ſimilar to each other, deciduous. The projection generally obſervable at the baſe is for the lodgment of honey, the calyx here being a nectary, ſo far at leaſt as containing the honey. *Cor.* termed cruciform, of four equal petals; their claws inverſely awl-ſhaped, or tapering downwards, flattened, erect, rather longer than the calyx; limb flat, or nearly ſo, the border of each petal being dilated outwards, obtuſe, its ſides ſcarcely touching its neighbour. The petals are inſerted into the ſame circle in which the ſtamens are placed. *Stam.* Filaments ſix, awl-ſhaped, erect, the two oppoſite ones the length of the calyx, the reſt rather longer, but not equal to the corolla; anthers ſomewhat oblong, pointed, thickeſt at the baſe, erect, their points recurved. Nectariferous glands, variouſly circumſtanced in the different genera, are ſeated at the baſe of the ſtamens, eſpecially between the ſhorter ones and the piſtil, thoſe ſtamens, to avoid preſſing upon ſuch glands, being moſtly curved, by which they become ſhorter than the four others. *Piſt.* Germen ſuperior, daily increaſing in height; ſtyle either the length of the longer ſtamens, or wanting; ſtigma obtuſe. *Peric.* Pod of two valves, and frequently as many cells, burſting from the baſe to the ſummit, the partition, if preſent, more or leſs extended beyond the valves, the prominent part being the original ſtyle. *Seeds* roundiſh, drooping or pendulous, ranged alternately, in a double row, along the partition, in which they make ſlight depreſſions. *Receptacle* linear, ſurrounding the edge of the partition, and embraced by the margins of the valves.

Linnæus obſerves, that all ſyſtematic botaniſts, even the moſt eminent, have unanimouſly conſidered this as a truly natural claſs of plants. Some of them have neverthelеſs admitted into it, here and there, a genus or two in oppoſition to nature, which fault he juſtly conceives himſelf to have avoided, except with regard to *Cleome*.

The plants of this claſs have univerſally been termed antiſcorbutic. Their flavour is generally acrid, though watery. Few vegetables yield leſs of an eſſential oil; yet this ſubſtance is to be obtained from them by cohobation, or repeated diſtillation, and its qualities are peculiarly acrid and fœtid, ſomewhat like volatile alkali. This oil gives the offenſive ſcent to water in which cabbage has been boiled, and it cauſes theſe vegetables to diſagree with ſome ſtomachs, though they are generally reputed wholeſome.

The claſs in queſtion is divided into two orders, 1. *Siliculoſa*, in which the pod is roundiſh, and for the moſt part hardly longer than its ſtyle. 2. *Siliquoſa*, with a very long pod, to which the ſcarcely perceptible ſtyle bears no proportion.

The genera of the firſt order are diſtributed into two ſections, one having the pod, here termed a *ſilicula*, or pouch, entire, and the other furniſhed with a notched, or emarginate, pouch. The genera here are characteriſed by the different ſhapes of their pouch, or its valves, and the comparative length of the ſtyle.

The order of *Siliquoſa* is divided into ſuch as have a cloſe calyx, whoſe leaves converge longitudinally, and ſuch as have a gaping, or ſpreading calyx. The genera here are partly defined by the form of the pod and its valves, and their mode of burſting, and partly by the ſituation of the nectariferous glands.

Theſe principles of generic diſtinction, laid down by Linnæus, have not proved ſo ſatisfactory in practice as could have been wiſhed, inſomuch that, not only Haller, but ſome leſs controverſial botaniſts, have differed from the learned Swede in their ideas of ſeveral of the cruciform genera. The beſt attempt to reform them has lately been made by Mr. R. Brown, in the ſecond edition of Mr. Aiton's *Hortus Kewenſis*. This able obſerver has recurred for aſſiſtance to the cotyledons, taking into conſideration their being either folded or flat, accumbent or incumbent. The latter difference we believe to have been firſt noticed by Gærtner, in his characters of *Eryſimum*. By *accumbent* is meant that the edges of the unexpanded cotyledons are applied, in a parallel manner, to the infant radicle; and by *incumbent*, that the flat ſide, or back, is preſented to that part. The latter is ſeen in *Eryſimum*, and is the moſt unuſual poſition. The number of ſeeds in each cell of the pouch is alſo adverted to by Mr. Brown, as well as ſeveral other incidental marks; by the aſſiſtance of all which the whole tribe appears much more ſatisfactorily arranged than heretofore, though we do not profeſs to agree, in every point, with our learned friend. His *Mathiola*, conſiſting of the hoary ſpecies of *Cheiranthus*, ſuch as *incanus*, *ſinuatus*, *tricuſpidatus*, &c. ſeems leſs happily ſeparated from the original genus, than his *Malcomia*, compoſed of *C. maritimus*, *Heſperis africana*, &c. In the latter caſe, the ſimple acute ſtigma, incumbent cotyledons, and the habit of the plants, afford a ſufficiently clear diſtinction. In the former, whatever difference there may be in habit, the characters ſeem to us not ſufficiently evident or important. It is alſo proper to remark, that whatever aſſiſtance ſuch a difference as that above deſcribed in the cotyledons may afford, towards forming a philoſophical idea of a genus, its great obſcurity renders it unfit for practical and daily uſe. On this ſubject we need not enlarge upon what Linnæus has ſo happily enforced, and generally practiſed.

TETRAEDRON, or TETRAHEDRON, formed of τετρα, *four*, and ἕδρα, *ſide*, in *Geometry*, one of the five regular or Platonic bodies of ſolids, comprehended under four equilateral and equal triangles.

The tetraedron may be conceived as a triangular pyramid of four equal faces. Such is that repreſented in *Plate* XV. *Geomet. fig.* 4.

It is demonſtrated by mathematicians, that the ſquare of the ſide of a tetraedron is to the ſquare of the diameter of a ſphere, in which it may be inſcribed, in a ſubſeſquialteral ratio: whence it follows, that the ſide of a tetraedron is to the diameter of a ſphere it is inſcribed in, as $\sqrt{2}$ to the $\sqrt{3}$: conſequently they are incommenſurable. See REGULAR *Body*.

TETRAETERIS, τετραετηρις, in the *Athenian Chronology*, a cycle of four years; for which ſee Potter, Archæol. Græc. lib. ii. cap. 26. tom. i. p. 459.

TETRAGASTRIS, in *Botany*, from τετρα and γαστηρ, *the ſtomach* or *belly*, becauſe of the four protuberant lobes of the ſeed-veſſel.—Gærtn. v. 2. 130. t. 109. f. 5.—Claſs and order, as well as Nat. Ord. unknown.

Nothing is known of this genus but its fruit, which Gærtner obtained from the collection at the botanic garden of Amſterdam. He deſcribes it as a depreſſed *berry*, of four lobes and four cells, with ſolitary ſeeds.

Its form is nearly globoſe, a little depreſſed, convex and pointed at the ſummit, marked with four longitudinal furrows, ſeparating the prominent, cuſhion-like lobes, into which

which it is divided below, and which form four ſingle-ſeeded cells. Its diameter is above an inch. The fleſh, in the old fruit at leaſt, is thin and rather leathery. The nuts, or cells, are large, hard, undivided, gibbous at the outſide, angular at the inner, moderately thick, or rather thin, whitiſh, not ſeparated from each other by any intermediate pulp. *Receptacle* central, ending in the ſummit of the berry, producing from its upper part four ſhort umbilical threads. *Seeds* ſolitary, pendulous, large, obovate, reddiſh-brown. *Skin* ſimple, thin, coriaceous. *Albumen* none. *Embryo* the ſhape of the ſeed, inverted, pale and whitiſh. *Cotyledons* thick, fleſhy, flat on one ſide, convex on the other, emarginate at the inſertion of the *radicle*, which is minute, ſeated within the notch of the cotyledons, at their upper end.

TETRAGON, τετραγονος, formed from τετρα, *four*, and γωνια, *angle*, in *Geometry*, a quadrangle, or a figure with four angles.

Thus a ſquare, parallelogram, rhombus, and trapezium, are tetragonal figures.

Tetragon, in *Aſtrology*, denotes an aſpect of two planets with regard to the earth, when they are diſtant from each other a fourth part of a circle, or 90°.

The tetragon is expreſſed by the character □.

TETRAGONIA, in *Botany*, ſo called by Linnæus, from τετρα and γωνια, *an angle*, alluding to the quadrangular figure of the fruit. The word is happily abbreviated from Boerhaave's *Tetragonocarpus*, which has the ſame meaning. —Linn. Gen. 252. Schreb. 340. Willd. Sp. Pl. v. 2. 1023. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 210. Juſſ. 317. Lamarck Illuſtr. t. 437. Gærtn. t. 127. and 179.—Claſs and order, *Icoſandria Pentagynia*. Nat. Ord. *Succulentæ*, Linn. *Ficoideæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, in four, occaſionally three or five, ovate, flat, rather deflexed, coloured, permanent, deep ſegments, revolute at the edges. *Cor.* none, unleſs the calyx be taken for ſuch. *Stam.* Filaments twenty, capillary, ſhorter than the calyx, into whoſe baſe they are inſerted; anthers oblong, incumbent. *Piſt.* Germen inferior, roundiſh, with four angles; ſtyles four, awl-ſhaped, recurved, the length of the ſtamens; ſtigmas downy, running along the ſtyles. *Peric.* Drupa coriaceous, quadrangular, with four prominent longitudinal wings, or points, the oppoſite ones narroweſt, not burſting. *Seed.* Nut ſolitary, bony, of two or more cells, with oblong ſolitary kernels.

Eſſ. Ch. Calyx with from three to five deep permanent ſegments. Petals none. Drupa inferior, angular. Nut with ſeveral cells.

Obſ. Linnæus remarks that the primary flower is five-cleft, which led him to refer this genus to the order *Pentagynia*. But it only affords an inſtance, among many others, that his orders of *Icoſandria*, like thoſe of *Polyandria*, except *Monogynia* and *Polygynia*, are beſt reſolved into one, they being liable to frequent uncertainty, not only in the ſame genus or ſpecies, but the ſame individual plant. See Tetracera.

1. T. *fruticoſa*. Shrubby Tetragonia. Linn. Sp. Pl. 687. Willd. n. 1. Ait. n. 1. (T. foliis linearibus; Mill. Ic. t. 263. f. 2. Tetragonocarpus africana fruticans, foliis longis et anguſtis; Commel. Hort v. 2. 205. t. 103.)—Stem ſhrubby, erect. Leaves linear. Fruit winged.—Native of the Cape of Good Hope. A greenhouſe plant in England, ever ſince the time of biſhop Compton, flowering in the latter part of ſummer, and eaſily propagated by cuttings, but not endowed with much beauty, or any other quality to render it popular. The *ſtem* is ſhrubby, buſhy, with round, alternate, leafy *branches*. *Leaves* alternate, ſeſſile, linear-oblong, obtuſe, entire, revolute, downy and ſoft, an inch or more in length, with axillary tufts of ſmaller ones. *Flowers* yellow, in ſomewhat whorled leafy cluſters.

2. T. *decumbens*. Trailing Tetragonia. Ait. ed. 1. v. 2. 177. ed. 2. n. 2. Willd. n. 2. "Decand. Pl. Graſſes, t. 23. (T. foliis ovatis integerrimis, caule fruticoſo decumbente; Mill. Ic. t. 263. f. 1.)—Stem ſhrubby, downy, decumbent. Leaves obovate. Fruit winged.—Native of the Cape of Good Hope. A greenhouſe ſhrub, cultivated by Miller in 1758. It differs from the former in the larger ſize, and broad obtuſe form of its *leaves*, as well as in having a more gliſtening mealy ſurface, and more numerous axillary tufts of *flowers*. The *ſtem* is more or leſs decumbent, and clothed with very ſoft denſe hairs.

3. T. *herbacea*. Herbaceous Tetragonia. Linn. Sp. Pl. 687. Willd. n. 3. Ait. n. 3. (Tetragonocarpus africana, radice magnâ craſſâ et carnoſâ; Commel. Hort. v. 2. 203. t. 102.) Stem herbaceous, ſmooth, decumbent. Leaves ovate, ſtalked. Flowers ſomewhat corymboſe. Fruit winged. Native of the Cape, cultivated by Miller. The *root* is perennial, thick, fleſhy, and lobed. *Herb* ſmooth, ſucculent, with many decumbent, branched, annual, leafy *ſtems*, and ſcattered, ovate, more or leſs acute, entire *leaves*. *Flowers* yellow, generally five-cleft, larger, and more ſhowy, than in the two preceding, ſtalked, partly axillary, partly corymboſe. All our knowledge of this ſpecies is derived from Commelin's work, nor had Linnæus any ſpecimen in his herbarium. The laſt-deſcribed is ſometimes, in gardens, miſtaken for *T. herbacea*.

4. T. *hirſuta*. Hairy Tetragonia. Linn. Suppl. 258. Willd. n. 4. Thunb. Prodr. 87.—"Herbaceous, hairy, procumbent. Leaves ovate, villous. Flowers axillary, ſeſſile, three together."—Gathered by Thunberg, at the Cape of Good Hope.

5. T. *ſpicata*. Spiked Tetragonia. Linn. Suppl. 258. Willd. n. 5. Thunb. Prodr. 87.—"Herbaceous, ſmooth, erect. Lower leaves ovate; uppermoſt lanceolate. Flowers racemoſe."—From the ſame country as the laſt. *Thunberg*. We have ſeen no ſpecimens of theſe two ſpecies. It is remarkable that the younger Linnæus defines the *flowers* of *T. hirſuta* ſeſſile, whilſt Thunberg calls them ſtalked. Poſſibly the latter confounded with his *hirſuta*, our *decumbens*, of which there is a ſpecimen, apparently gathered by him, in the Linnæan collection.

6. T. *echinata*. Hedge-hog Tetragonia. Ait. ed. 1. v. 2. 177. ed. 2. n. 4. Willd. n. 6. "Decand. Pl. Graſſes, t. 113."—Stem herbaceous. Leaves rhombeo-ovate. Fruit prickly.—Native of the Cape, from whence Mr. Maſſon introduced it at Kew, in 1774. The *root* is annual or biennial. *Stem* herbaceous, divided from the baſe into ſeveral decumbent *branches*, hardly a foot long, angular, from the decurrent *footſtalks*, which are half the length of the ſpreading ſucculent *leaves*, each an inch long. *Flowers* pendulous, on very ſhort, axillary, ſolitary, thread-ſhaped, purple *ſtalks* clothed with cryſtalline globules. *Calyx* in three or four ſegments; cryſtalline without; greeniſh-yellow within. *Stamens* only three or four. *Germen* triangular, flat underneath, its angles beſet with numerous conical thorns. *Styles* three. *Nut* of three cells. *Willden.*

7. T. *expanſa*. Horned Tetragonia. Ait. ed. 1. v. 2. 178. ed. 2. n. 5. Willd. n. 7. "Decand. Pl. Graſſes, t. 114." Scop. Inſubr. v. 1. 32. t. 14. Thunb. Tr. of Linn. Soc. v. 2. 335. (T. halimifolia; Forſt. Prodr. 39. Pl. Eſcul. 67. T. japonica; Thunb. Jap. 208.)—Stem herbaceous. Leaves ovate-rhomboid; tapering at the baſe. Fruit with four horns.—Native of New Zealand, about the borders of woods, in buſhy ſandy places, as well as of the Friendly iſlands, and of Japan. Sir Joſeph Banks introduced

it

it to Kew garden, in 1772, and from thence the other gardens of Europe have been ſupplied. The plant is a rather tender biennial herb, flowering in Auguſt and September. Forſter tells us it proved a moſt valuable reſource to captain Cook's crew, as a pot-herb, while his ſhip lay at Tongatabu. The whole plant is ſucculent, covered with very minute cryſtalline dots, as if moiſt with dew. *Root* fibrous. *Stem* divided from the bottom into many irregular, round, leafy branches. *Leaves* alternate, ſtalked, ſomewhat deltoid, entire, rather heart-ſhaped at the baſe, but tapering down into the *footſtalk*. *Flowers* yellow, axillary, on ſhort, uſually ſolitary, ſtalks. *Fruit* turbinate, clumſy, the ſize of a filberd, with four or five ſharp horns. The cells are five or ſix, anſwering to the number of *ſtyles*.

8. T. *cryſtallina*. Diamond Tetragonia. Ait. ed. 1. v. 2. 178. ed. 2. n. 6. Willd. n. 8. L'Herit. Stirp. v. 1. 81. t. 39. "Decand. Pl. Graſſes, t. 34."—Stem herbaceous. Leaves ovate, ſeſſile, dotted with cryſtalline points. Fruit without thorns.—Native of Peru. *Dombey*. Sent to Kew, by M. Thouin, in 1788. It is annual, and flowers in the dry ſtove in June. *Herb* a ſpan high, covered with cryſtalline granules, like the Ice-plant. *Stem* nearly erect, branched from the bottom. *Leaves* acute, entire, about two inches long, bright green. *Flowers* of a dull orange, or tawny yellow, axillary, ſtalked, moſtly ſolitary. *Calyx* in four ſegments. *Stamens* about ſixteen. *Styles* four. *Drupa* turbinate, quadrangular. *Nut* four-lobed, with four cells.

For *Tetragonia ivæfolia*, Linn. Suppl. 257, ſee HALORAGIS, n. 1.

TETRAGONIA, in *Gardening*, contains plants of the ſhrubby and herbaceous, ſucculent, perennial kinds, among which the ſpecies moſt uſually cultivated are the following; the ſhrubby tetragonia (T. fruticoſa); the trailing tetragonia (T. decumbens); the herbaceous tetragonia (T. herbacea); and the hedge-hog tetragonia (T. echinata). All theſe plants are natives of the Cape, and, of courſe, of the rather tender kind.

Method of Culture.—The firſt and laſt ſorts may be increaſed by cuttings, which ſhould be cut off from the plants a few days before they are planted, that the part where they are cut may be healed, ſetting them out in July, that they may have time to make good roots before winter, on a bed of freſh earth, ſhading them from the ſun in the heat of the day. They ſhould afterwards be frequently refreſhed with water in ſmall quantities. In a few weeks, when well rooted, they ſhould be taken up, and planted into pots filled with light freſh undunged earth, and be placed in a ſhady ſituation until they have taken new root, after which they may be placed with other hardy exotic plants in a ſheltered ſituation, where they may remain till the middle or latter end of October, at which time they ſhould be removed into the greenhouſe, and placed where they may enjoy as much air as poſſible in mild weather, as they only require to be protected from the froſt, being pretty hardy with reſpect to cold. As, when planted in the full ground in the ſummer ſeaſon, they are apt to grow rank and large, or even when permitted to root into the ground through the holes at the bottom of the pots, the pots ſhould be frequently removed to prevent it, as they are injured by it.

The firſt and ſecond ſorts are likewiſe capable of being raiſed by ſeeds, ſown in a gentle hot-bed, or in a warm border of light freſh earth, in the ſpring. When the plants are about four inches high, they may be planted out in pots, treating them in the ſame manner as the cuttings.

And the third ſort will grow from cuttings planted early in the ſpring, in the ſame manner as the others.

The ſhrubby ſorts are durable in their ſtems, roots, and branches; but the herbaceous kinds often die down in the ſtalks and branches towards the autumn, and ſend up new ones at the end of that ſeaſon, which retain their leaves during the winter months.

They afford ornament among other potted plants, and the firſt ſort has ſomething ſingular and curious about it.

TETRAGONIAS, a name given to a meteor whoſe head is of a quadrangular figure, and its tail or train long, thick, and uniform: this is not much different from the trabs or beam.

TETRAGONIS, in *Ancient Geography*, a town of Arachoſia, at the foot of mount Caucaſus, called more anciently Cartana. Pliny.

TETRAGONISM, τετραγωνισμος, a term which ſome authors uſe to expreſs the quadrature of the circle.

TETRAGONOPTERUS, in *Ichthyology*. See SALMO *Bimaculatus*.

TETRAGONOPTRUS. See ZEUS, CHÆTODON *Cornutus*, *Nigricans*, and *Capiſtratus*.

TETRAGONOTHECA, in *Botany*, from τετραγωνος, *quadrangular*, and θηκη, *a caſe*, or *cell*, a name firſt contrived by Dillenius, to expreſs the ſquare form of the common calyx, and now retained by L'Heritier and Willdenow for the original and only remaining ſpecies of the genus. See the others under DIDELTA, POLYMNIA, and WEDELIA.—Dill. Elth. 378. Linn. Gen. 438. L'Herit. Stirp. 177. Willd. Sp. Pl. v. 3. 2116. Ait. Hort. Kew. v. 5. 84. Purſh 563.—Claſs and order, *Syngeneſia Polygamia-ſuperflua*. Nat. Ord. *Compoſitæ oppoſitifoliæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common Calyx* ſimple, large, of one leaf, in four deep, flat, ſpreading, triangular-heartſhaped ſegments, permanent. *Cor.* compound, radiant. Florets of the diſk perfect, numerous, funnel-ſhaped, five-cleft, reflexed; thoſe of the radius ten or twelve, ligulate, dilated outwards, three-cleft, equal, bluntiſh. *Stam.* in the florets of the diſk. Filaments five, capillary, very ſhort; anthers united into a cylindrical tube. *Piſt.* in all the florets. Germen roundiſh; ſtyle thread-ſhaped, the length of the ſtamens; ſtigmas two, reflexed or revolute. *Peric.* none. *Seeds* ſolitary; in the diſk roundiſh; in the radius ſomewhat ovate. Down none. *Recept.* chaffy.

Eſſ. Ch. Receptacle chaffy. Seed-down none. Calyx ſimple, of one leaf, quadrangular, in four deep ſegments.

Obſ. The ſynonym of *Tetragonotheca*, Linn. Gen. 438, ſhould be eraſed from our article POLYMNIA.

1. T. *helianthoides*. Sun-flower Tetragonotheca. Linn. Sp. Pl. 1273. Willd. n. 1. Ait. n. 1. Purſh n. 1. (T. doronici maximi folio; Dill. Elth. 378. t. 283. Polymnia tetragonotheca; Linn. Syſt. Veg. ed. 13. 658. Sm. Inſ. of Georgia, v. 2. 137. t. 69.)—Native of North America, in a fertile ſoil, on the borders of woods, and along hedges, from Virginia to Florida, flowering from July to September. *Purſh*. The *root* is perennial, hardy in our gardens. *Stem* erect, round, leafy, hairy, branched, from four to ſix feet high. *Leaves* hairy, veiny, toothed or wavy; the lowermoſt ſtalked, ovate; upper ſeſſile; oppoſite acute. *Flowers* from the forks and ends of the branches, ſtalked, large, of a golden yellow, reſembling a ſun-flower.

TETRAGONUS, in *Anatomy*, a muſcle, called alſo *quadratus genæ*.

TETRAGRAMMATON, τετραγραμματον, a denomination given by the Greeks to the Hebrew name of God, יהוה *Jehovah*, becauſe in the Hebrew it conſiſts of four letters. See ADONAI.

TETRAGYNIA, in *Botany*, from τετρα, and γυνη, *a female*, the name of an order in ſeveral claſſes of the Linnæan artificial ſyſtem, characterized, as the word itſelf imports, by by the flowers having four ftyles, or piftils. This order is better founded, and more invariable, in fome claffes than others. With the TETRANDRIA, (fee that article,) it naturally correfponds, and is well exemplified in the genera *Potamogeton* and *Ruppia*. In *Octandria*, though of rare occurrence, it is no lefs certain. In *Icofandria* and *Polyandria* it is very fallible, of which we have lately given examples. (See TETRACERA and TETRAGONIA; alfo POLYANDRIA.) The order *Tetragynia* in the claffes *Pentandria* and *Dodecandria* is, however, fufficiently well-founded. In *Decandria* no example of it occurs, nor fcarcely in *Hexandria*.

TETRAHIT, an old name, fuppofed to allude to the four-cornered ftem. See GALEOPSIS.

TETRALOGIA, in the *Dramatic Poetry of the Ancients*, denoted four dramatic pieces of the fame author, of which the three firft were tragedies, and the laft of the fatyric kind. Their defign was to celebrate a victory in the literary contefts. Æfchylus and Euripides have written fome pieces of this kind. Encycl.

TETRAMETER, in the *Ancient Poetry*, an iambic verfe confifting of four feet.

The word is formed from τετρα, *four*, and μετρον, *meafure*; *q. d.* four metres.—We meet with none of thefe but in the comic poets, as Terence, &c.

TETRANDRIA, in *Botany*, the fourth clafs in the Linnæan artificial fyftem, is fo called from τετρα, and ανηρ, *a man*, becaufe it is characterized by having four ftamens, in the fame flower with the piftil or piftils. Thefe are of equal length, the flower being regular, by which this clafs is diftinguifhed from the 14th, whofe flowers are ringent, and two of their four ftamens, which ftand next each other, are longer than the reft. See DIDYNAMIA.

The orders of this fourth clafs are three, diftinguifhed by the number of their piftils. 1. *Monogynia*, a numerous and various order, comprifing the ample tribe of *Proteaceæ*; and the intricate family of the *Stellatæ*, to which *Galium* and *Rubia* belong. The large genera of *Scabiofa* and *Plantago* likewife range under the *Tetrandria Monogynia*; the former of which exhibits a curious example of aberration in number between the *corolla* and *ftamens*. Some of its fpecies have a four-cleft *corolla*, anfwering in that refpect to the *ftamens*, whilft others have five fegments in the former, though the number of the latter remains invariably but four. 2. *Digynia* is a fmall order, to which, amongft a few other genera, Linnæus has referred *Cufcuta*, but it rather belongs to *Pentandria Digynia*, the greater number of the fpecies having five-cleft pentandrous flowers. This order will, however, receive a very curious acceffion in TETRARRHENA. (See that article.) 3. *Tetragynia* contains *Ilex*, *Potamogeton*, and *Ruppia*, Britifh genera, all of which have four feffile ftigmas; with feveral others, not naturally related, but for the moft part feparated, by the artificial character of *number*, from their allies in other parts of the fyftem. That character however is fufficiently conftant in the prefent inftance.

TETRANDRIA is likewife the denomination of feveral orders in the Linnæan Syftem, as in *Gynandria*, if STYLIDIUM (fee that article) be judged to have four ftamens; and certainly in *Monoecia* and *Dioecia*, where there are feveral really tetrandrous genera.

TETRANGURIA, a name ufed by fome authors for the citrul, a plant of the gourd kind, whofe feeds are ufed in medicine.

TETRANTHERA, fo named by Jacquin, from τετρα, and ανθηρ, becaufe of the four feparate cells, which have the appearance of four diftinct anthers, on the dilated fummit of each filament, and were indeed confidered as fuch by the author. We greatly prefer this name to that of *Litfea*, ufed by Lamarck and Juffieu; becaufe the latter is of barbarous origin, and becaufe we are happy to follow the example of Mr. Brown, who juftly prefers, in this cafe, the claffical authority of Jacquin. To the learned Juffieu neverthelefs belongs the honour of having firft affembled under this genus feveral plants, which authors had either confidered as diftinct genera, or erroneoufly referred to others already eftablifhed, as will appear by the various fynonyms we are about to exhibit.—Jacq. Hort. Schoenbr. v. 1. 59. Dryandr. in Roxb. Coromand. v. 2. 25. Brown Prodr. Nov. Holl. v. 1. 408. (Litfea; Lamarck Dict. v. 3. 574. Juff. in Bull. des Sciences, v. 3. 73. Tomex; Thunb. Jap. 10. Nov. Gen. 65. Schreb. Gen. 315. Willd. Sp. Pl. v. 2. 839. Mart. Mill. Dict. v. 4. Juff. 440. Hexanthus; Loureir. Cochinch. 195. Sebifera; Loureir. ibid. 637. See TOMEX, HEXANTHUS, and SEBIFERA.)—Clafs and order, *Dodecandria Monogynia*. Nat. Ord. *Lauri*, Juff. *Laurinæ*, Brown.

Gen. Ch. *Cal.* Involucrum of four or five ovate, concave, deciduous leaves, containing feveral ftalked flowers. Perianth none, unlefs the corolla be taken for fuch. *Cor.* of one petal, tubular, more or lefs deeply divided into from four to fix elliptic-oblong equal fegments; fometimes abrupt and entire, the limb being deficient. Nectary of feveral ftalked glands or fcales intermixed with the ftamens. *Stam.* Filaments from twelve to eighteen, fometimes but fix, thread-fhaped, erect, the outer ones longeft; anthers with four lateral cells at their inner fide. *Pift.* Germen fuperior, ovate; ftyle thread-fhaped; ftigma notched. *Peric.* Berry ovate or globofe, of one cell. *Seed* folitary, the fhape of the berry.

Obf. The ftamens are ufually imperfect in the flowers of one tree, and the piftil in thofe of another; but this is hardly a fufficient reafon for placing this genus in the clafs *Dioecia*, the ftructure of the flowers being alike, and both organs, at leaft their rudiments, prefent in each. The four cells of the anthers, as Mr. Brown obferves, diftinguifh *Tetranthera* from *Laurus*.

Eff. Ch. Involucrum of four or five leaves, deciduous. Corolla with about five fegments. Nectary of feveral ftalked glands. Anthers of four lateral cells. Stigma fomewhat lobed. Berry fuperior, with one feed.

1. T. *japonica*. Japan Tetranthera. (Tomex japonica; Willd. n. 1. Thunb. Jap. 190.)—Stamens twelve. Leaves obtufe; downy beneath, as well as the involucrum. Flower-ftalks fimple.—Common at Kofido in Japan, flowering in October and November.—It is there known by the name of *Fiwa*. The *ftem* is arboreous, tall, branching, above two feet in diameter. *Branches* downy, knotty; angular when young. *Leaves* alternate, ftalked, oblong, obtufe, entire, erect, with parallel ribs; fmooth and green above; hoary and downy beneath; three or four inches long. *Footftalks* angular, ftriated, downy, an inch in length. *Flowers* axillary, capitate, dioecious, on folitary, angular, downy, bracteated ftalks, half an inch long. The *involucrum* confifts of five or fix leaves, the outer ones fmalleft, and contains the fame number of flowers. *Thunberg*.

2. T. *laurifolia*. Laurel-leaved Tetranthera. Jacq. Hort. Schoenbr. v. 1. 59. t. 113. (Tomex Tetranthera; Willd. n. 2.)—Stamens about fifteen. Leaves obtufe, fmooth, as well as the involucrum. Flower-ftalks fomewhat umbellate.—Native of China. Cultivated at the Mauritius by the name of Cerifier de la Chine, or Chinefe Cherry-tree. From thence it was brought to Schoenbrun gardens, where it bears the open air in fummer, and flowers in the hot-houfe in September and October.—It is there a *tree*, ten feet

feet high, with a head of round knotty *branches*, downy when young. *Leaves* about the ends of the branches, alternate, on downy ſtalks, an inch long, obovate, coriaceous, entire, light green, ſmooth and ſhining, except a ſlight pubeſcence on the rib and veins; their length about five inches. *Flower-ſtalks* lateral, ſcattered, below the leaves, umbellate, about two inches long, each bearing from two to five *flowers*, whoſe *involucrum* is pale green, *corolla* white; their ſhort partial ſtalks (within the involucrum) hairy, as well as the *ſtamens*. *Berries* red, globoſe, the ſize of a currant. Jacquin ſays nothing of the dioecious nature of the *flowers*, but he appears to deſcribe one with an imperfect *piſtil*. His *fruit* perhaps was of exotic growth.

3. T. *apetala*. Apetalous Tetranthera. Roxb. Coromand. v. 2. 25. t. 147. Brown n. 1. (Laurus involucrata; Retz. Obſ. faſc. 6. 27?)—Stamens about fifteen. Leaves elliptical, obtuſe, ſingle-ribbed, ſmooth. Corolla abrupt, undivided, bearing the ſtamens on its margin.—Native of the mountainous parts of the circars of Hindooſtan, flowering in June. *Roxburgh*. Mr. Brown met with the ſame in the tropical part of New Holland. This is ſaid to be a middle-ſized *tree*, with round ſmooth *branches*, leafy towards the ends. The *leaves* are ſtalked, three or four inches long, and two, or two and a half, wide, entire, bright green. *Flower-ſtalks* uſually three-flowered, much like thoſe of the laſt, to which this ſpecies is nearly akin; but the want of a limb to the *corolla*, and the oval violet-coloured *berry*, ſufficiently diſtinguiſh it.

4. T. *monopetala*. Monopetalous Tetranthera. Roxb. Corom. v. 2. 26. t. 148.—Stamens about nine. Leaves elliptic-oblong, acute, ſingle-ribbed; ſomewhat downy beneath. Flowers cluſtered. Limb of the corolla half five-cleft.—Native of the vallies of Hindooſtan, flowering in the hot ſeaſon. Dr. Roxburgh ſays the *wood* is white, tolerably hard; and that the bark is uſed by the inhabitants of the hills, to cure diarrhœas, being given in ſubſtance. Its taſte is mildly aſtringent, with much balſamic ſweetneſs. The *leaves* are longer, narrower, and more acute than in the former. *Flowers* in ſhort, axillary, denſe, partly umbellate, cluſters, with five leaves to the *involucrum*, and as many ſegments to the greeniſh tubular *corolla*. *Berries* ovate, of a violet black.

5. T. *ferruginea*. Ruſty Tetranthera. Brown n. 2. (Hexanthus umbellatus; Loureir. Cochinch. 196. Litſea hexantha; Juſſ. n. 4.)—Stamens about nine. Leaves elliptic-oblong, acute, ſingle-ribbed; downy beneath, as well as the branches. Corolla in ſix deep ſegments.—Native of Cochinchina, as well as of the tropical part of New Holland. A *tree* of a moderate ſize, whoſe timber is uſed in building. The *leaves* are large, entire, with many tranſverſe veins. *Flowers* pale green, in ſmall axillary umbels.

6. T. *dealbata*. White-leaved Tetranthera. Brown n. 3.—"Stamens ſix. Leaves broadly elliptical, pointed, triple-ribbed, ſmooth; whitened beneath. Footſtalks and branches downy. Corolla deeply four-cleft, hairy. Involucrum villous."—Native of the neighbourhood of Port Jackſon, New South Wales. Mr. Brown thinks *Laurus Myrrha*, Loureir. Cochinch. 251, which is perhaps not ſpecifically different from *Laurus involucrata*, Roxb. Coromand. v. 2. 46. t. 187, is very nearly related to the preſent ſpecies, though differing in having ſmaller *leaves*, a ſomewhat ſilky *involucrum* on a ſhort ſtalk, and nearly ſmooth *corolla*. We cannot but obſerve that Roxburgh's t. 187. by no means exhibits the peculiar *anthers* or *nectary* of a *Tetranthera*. His plant however ſhould ſeem to be the *Litſea trinervia* of Juſſieu, which the latter takes for *Laurus involucrata* of Retzius, but that ſhould have ſingle-ribbed *leaves*. See our third ſpecies.

7. T. *chinenſis*. Chineſe Tetranthera. (Litſea chinenſis; Lamarck Dict. v. 3. 574. Juſſ. n. 5.)—Stamens numerous, polyadelphous. Leaves elliptical, obtuſe, ſmooth. Footſtalks, branches, and involucrum downy. Corolla none.—Native of China; cultivated in the iſland of Mauritius, where its power of reſiſting the force of high winds, renders this tree valuable for making tall hedges. The *leaves* are four inches long, two broad; pale beneath. *Flowers* dioecious. *Involucrum* of four concave, ſpreading, downy leaves. *Stamens* united into from five to nine downy bundles. *Germen* ſurrounded with abortive ſtamens. *Berry* ſpherical, ſmooth, the ſize of a ſmall cherry, with a flavour of camphor and ivy, which renders it diſagreeable, and only fit food for birds. *Lamarck*. This ſpecies is ſaid to have been brought alive to Europe, and was in 1789 cultivated in the Pariſian garden; but we have neither heard nor ſeen any thing of it in England.

8. T. *ſebifera*. Tallow Tetranthera. (Tomex ſebifera; Willd. n. 3, excluding the ſynonym of Retzius. Sebifera glutinoſa; Loureir. Cochinch. 638.)—Stamens from twelve to fifteen. Leaves ovate-oblong, bluntiſh, ſingle-ribbed, ſmooth. Flower-ſtalks umbellate, downy as well as the involucrum. Corolla none.—For a further account of this ſpecies, ſee SEBIFERA, under which article Loureiro's faulty generic character, and eſpecially his deſcription of the ſtamens, prevented our recognizing the plant as already deſcribed by Willdenow.

9. T. *piperita*. Pepper Tetranthera. (Litſea piperita; Juſſ. n. 7. Laurus Cubeba; Loureir. Cochinch. 252.)—Stamens ſix. Leaves lanceolate, without rib or vein. Stalks ſingle-flowered. Corolla in ſix roundiſh unequal ſegments.—Native of Cochinchina, and perhaps alſo of China. In the former country it is frequently cultivated, for the ſake of the cordial and tonic qualities of its berries and bark. A decoction of one or the other, the latter being weakeſt, is given in hyſteric, paralytic, and melancholic diſorders. The recent fruit is uſed as a ſeaſoning for fiſh. The ſcent is fragrant; taſte aromatic and pungent. Each berry reſembles a grain of black pepper, with a long ſlender ſtalk. Loureiro ſuſpected it to be the true Cubeb, but erroneouſly. (See PIPER.) The *tree* is of a moderate ſize, much branched. *Leaves* alternate, ſtalked, two inches long, entire, flat, ſhining, and, we preſume, ſmooth. *Flowers* white, on crowded, lateral, ſimple ſtalks. *Involucrum* of four roundiſh, concave, coloured, deciduous leaves, containing five flowers. *Style* none. *Berry* globoſe, very ſmall, black.—Such is Loureiro's account, from which, having ſeen no ſpecimen, we have extracted the ſpecific character.

TETRANTHUS, ſo called by profeſſor Swartz, in his *Prodromus*, p. 115, from τετρα and ανθος, on account of the four flowers in one common calyx.—Schreb. Gen. 592. Willd. Sp. Pl. v. 3. 2402. Mart. Mill. Dict. v. 4. Swartz Ind. Occ. 1385. t. 27.—Claſs and order, *Syngeneſia Polygamia-ſegregata*. Nat. Ord. *Compoſitæ capitatæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common Calyx* of five ſmall, linear, fringed leaves, at firſt reflexed, then erect, containing four flowers: *partial* of one leaf, tubular, much longer than the former; tapering and ſomewhat compreſſed at the baſe; oblique, acute and fringed at the ſummit; containing one floret. *Cor.* of each floret tubular; its limb in five unequal ſegments, the three lowermoſt longeſt, and moſt reflexed. *Stam.* in each floret, Filaments five, capillary; anthers united into a cylindrical tube, rather ſhorter than the tube of the corolla. *Piſt.* Germen ſuperior, in the tube of the partial calyx, oblong; ſtyle

 thread-

thread-fhaped, divided, fpreading, longer than the corolla; ftigmas linear, downy, reflexed. *Peric.* none, except the permanent fheathing partial calyx. *Seeds* folitary, oblong, fomewhat ftriated, crowned with a membranous fringed border. *Recept.* minute, naked.

Eff. Ch. Common Calyx of five leaves, containing four flowers: partial of one oblique leaf. Seeds with a membranous fringed border. Receptacle naked.

1. T. *littoralis.* Shore Tetranthus. Willd. n. 1. Swartz Ind. Occ. 1386.—Found on the banks of rivers in Hifpaniola. A fmall annual herb, flowering in the fpring, and, as Swartz juftly obferves, very peculiar in its fructification. There certainly cannot be a better example of the order *Polygamia-fegregata.* Willdenow fays it has the afpect of MITCHELLA; fee that article. The *ftem* is flender, creeping, fmooth, fubdivided, a fpan long, attaching itfelf by little tufts of long white fibrous *radicles* from each joint. *Leaves* oppofite, ftalked, roundifh-ovate, entire, with a fhort obtufe point, three-ribbed, fmooth, half an inch long. *Footftalks* fmooth and flender, nearly an inch in length. *Flower-ftalks* axillary, folitary, erect, longer than the leaves, flender and downy. *Flowers* fmall, white.

TETRAO, in *Ornithology*, a genus of the Gallinæ order of birds; the characters of which are, that it has a fpot near the eyes naked, or papillofe, or rarely covered with feathers. It comprehends fixty-feven fpecies, claffed under feveral divifions and fubdivifions.

A. *With the naked Spot above the Eyes, and hairy Legs.* LAGOPODES.

a. *With four-toed Feet.*

UROGALLUS. With roundifh tail, and white axillæ. This is the cock of the wood of Ray and Willughby, and wood grous of Pennant and Latham. (See GROUSE.) It is found in the forefts and marfhes of the colder parts of Europe and Northern Afia.

PHASIANELLUS. With wedge-fhaped tail; head, neck, and body above, teftaceous, and black-banded. This is the long-tailed grous from Hudfon's Bay of Edwards, long-tailed grous of Latham, and fharp-tailed grous of Pennant. Found in Hudfon's Bay and the uncultivated parts of Virginia.

TETRIX. With bifurcated tail, fecondary quills white towards the bafe. This is the urogallus minor of Briffon and Gefner, and black cock, black game, or black grous of Ray, Willughby, Pennant, and Latham. Found in the woods, heaths, &c. of the cold parts of Europe and Siberia. (See GROUSE.) The varieties of this fpecies are the tetrix alba of Blum. Act. Stock. 1785, and the urogallus minor punctatus of Briffon, or tetrao hybridus of Sparrman, or fpurious grous of Pennant.

NEMESIANUS. With red tail, fpotted with black; black tip, and body varied with black and red: the Nemefian grous of Latham.

BETULINUS. With black tail, varied with black tranfverfe fpots; and rump whitifh, with black bands: the birch grous of Latham.

CANADENSIS. With black tail-feathers, yellow at the tip, and two white ftreaks at the eyes: the black and fpotted heath-cock of Edwards, and fpotted grous of Pennant, Forfter, and Latham; and gelinotte du Canada of Buffon.

CANACE. With entire tail, and white fpot near the ears and noftrils: the black and fpotted heath-cock of Edwards. Found at Hudfon's Bay.

LAGOPUS. Cinereous; hairy toes; white quills; black tail-feathers, tipped with white; the intermediate white: this is the white game of Willughby, and ptarmigan of Pennant and Latham. (See PTARMIGAN.) Of this fpecies there are feveral varieties; as the lagopus varia of Gefner and Willughby, the bonafia fcotica of Briffon, and the attagen of Briffon, or red game, moor-cock, or gor-cock of Ray and Willughby, and red grous of Pennant and Latham. (See GOR-COCK.) Found in Siberia and the northern parts of Europe.

ALBUS. Orange, varied with black bands and white ftreaks; hairy toes; tail-feathers black, tipped with white; the intermediate wholly white: this is the white partridge of Ellis and Edwards, and the white grous of Pennant and Latham. Found gregarious in the forefts of North America, Europe, and Afia.

RUPESTRIS. Orange, varied with black bands and white ftreaks; plumofe toes; black tail-feathers tipped with white; the intermediate wholly white with black lores: this is the rock grous of Pennant. Found at Hudfon's Bay.

LAPPONICUS. With naked fcaly legs; with a fuperciliary fcarlet line covered with a membrane of the fame colour; the primary quill-feathers and tail-feathers tipped with white: the rehufak of the Arctic Zoology. Found in the woods and mountains of Lapland.

CUPIDO. With fuccenturiate cervical wings: the attinga americana of Briffon, and pinnated grous of the Arctic Zoology and of Latham. Found gregarious in North America.

UMBELLUS. With the cervical umbo exftant: this is the attagen pennfylvanica of Briffon, the ruffed heath-cock of Edwards, and ruffed grous of the Arctic Zoology and of Latham. Found in North America.

TOGATUS. With the greater axillary feathers black-azure: this is the bonafia major canadenfis of Briffon, and fhoulder-knot grous of Forfter (Phil. Tranf. vol. lxii.) and of Latham. Found at Hudfon's Bay.

BONASIA. The tail-feathers cinereous, with black points and band; the two intermediate excepted: this is the bonafia of Briffon, the gallina corylorum of Gefner and Aldrovand, the gelinotte of Buffon, the hafelhuhn of Ray and Willughby, and hazel grous of the Arctic Zoology and of Latham. Found among the hazels of Europe and Weftern Siberia.

CANUS. Body grey, undulated with brown; the beak and legs black. Found in Sweden.

ALCHATA. Above varied; the two intermediate tail-feathers twice longer than the others, and fubulate: the ganga of Buffon, the partridge of Damafcus of Willughby and Ray, the kitiwiah or African lagopus of Shaw's Travels, the kara of Ruffel's Aleppo, the little pin-tailed grous of Edwards and Latham. Of this there are two varieties, *viz.* the tetrao fenegallus and gelinotte of Senegal of Buffon; and the tetrao caudatus of Gmelin's Travels. Found in Southern Europe, Africa, Arabia, Syria, and Perfia.

NAMAQUA. Above fpadiceous, with the two intermediate tail-feathers longer and fubulate: the Namaqua grous of Latham. Found in Africa amid the dry defarts inhabited by the Namaquis, flying gregarious to fountains.

INDICUS. Front white, furrounded by a wreath behind black; the body above yellowifh-red, varied with black lunules: the Indian grous of Latham. Found at Coromandel.

ARENARIUS. Ruff, abdomen, and vent black; tail-feathers with brown and grey bands, tipped white; the two intermediate yellowifh: the fand grous of Latham. Found about the Volga near Aftrachan.

b. *With three-toed Feet.*

PARADOXUS. With three-toed feet; toes hairy, almoft joined

joined at the apex: this is the heteroclitous grous of Latham. Found in the Southern Tartarian defart.

B. *With papillofe Skin about the Eyes; and naked Legs.*

c. *With the Feet of the Male fpurred.* PERDICES, *or Partridges.*

FRANCOLINUS. Abdomen and throat black, and wedge-formed tail: this is the tetrao orientalis of Haffelquift, and francolin of other authors. Found in the fouth of Afia and Europe, and in Africa, of the fize of the partridge, feeding on feeds, emitting a hiffing found, and flefh delicious.

MADAGASCARIENSIS. Abdomen black, varied with large red fpots; throat white; the two intermediate tail-feathers reddifh, with black bands; the pintado partridge of Latham. Found in Madagafcar.

RUFUS. Legs and beak fanguineous; throat white, furrounded with a band black, white pointed: this is the perdix græca of Briffon and Ray, the bartavelle of Buffon, the red partridge of Albin, the Greek or great red partridge of Willughby, and Greek partridge of Latham. Of this fpecies there are three varieties, *viz.* the tetrao rufus of Gmelin, or perdix rubra of Briffon, or perdix rufa major of Gefner and Jonfton, or red-legged partridge of Ray, Willughby, and Albin, or Guernfey partridge of Latham; the perdix rufa alba of Briffon; and the perdix rubra barbarica of Briffon, or the red-legged partridge from Barbary of Edwards, or Barbary partridge of Shaw's Travels. Found gregarious in the woody mountains of Europe, Afia, and Africa, much larger than the partridge.

PERDIX. With a naked fcarlet fpot under the eyes; tail ferruginous; breaft brown; and legs whitifh: this is the common *partridge*, (which fee.) Of this fpecies there are the following varieties; *viz.* perdix cinereo alba of Briffon; perdix tota alba; perdix torque albo; perdix brunnea; perdix mento gulaque, or chin and throat red. Found in flocks in the cultivated fields and paftures of Europe and Siberia.

DAMASCENUS. With a naked fcarlet fpot under the eyes; tail ferruginous; breaft brown; and legs yellow: the perdix damafcena of Briffon, and Damafcus partridge of Ray, Willughby, and Latham. This fpecies migrates in flocks through the middle of Europe, and is allied to the partridge, but lefs, with a longer beak.

MONTANUS. Legs and beak red; throat reddifh and dingy: the perdix montana of Briffon. Found in the mountains of Europe.

RUBRICOLLIS. Legs, beak, chin, and throat naked, all red: the red-necked partridge of Latham. Found in Africa.

PETROSUS. Beak and legs red; body brown, and ferruginous fpot on the breaft: the rufous-breafted partridge of Latham. Found amid the rocks and mountains near Gambia.

PERLATUS. Legs and eye-brows red; beak blackifh; throat white; and body varied with brown: the perdix chinenfis of Briffon, and pearled partridge of Latham. Found in China: and it has a variety with beak and legs brown, eye-brows fpotted with white and black, at the Cape of Good Hope.

BICALCARATUS. With double-fpurred feet, and black eye-brows: the Senegal partridge of Latham. Found near the Senegal.

ZEYLONNENSIS. With double-fpurred feet; beak and naked area of the eyes red; tail round and brown: the Ceylon partridge of Latham.

SPADICEUS. With two-fpurred feet red; beak yellow; and body fpadiceous or bright red-coloured; the brown African partridge of Latham. Found in Madagafcar.

NUDICOLLIS. With two-fpurred feet, and naked throat red; the bare-necked partridge of Latham.

GINGICUS. Bill black; rump and tail red, grey, and black mixed; and eye-brows white: the Gingi partridge of Latham. Found near Gingi, in Coromandel.

PONDICERIANUS. Bill black; two intermediate tail-feathers red, numerous angulated lines brown; and four bands ochre-coloured: the Pondicherry partridge of Latham. Found in Coromandel.

NÆVIUS. Legs and bill reddifh; body brown, variegated with yellow: the ococolin of Ray and Buffon, the Mexican partridge of Latham. Found in the temperate parts of New Spain.

d. *Coturnices, or Quails.* See QUAILS.

e. *With four Toes.*

FERRUGINEUS. Legs and beak brown; body beneath diluted light red, above ferruginous-brown; feathers of the neck longer and acutely tipped; the hackled partridge of Latham. Found in China.

JAVANICUS. Legs flefh-coloured; front, fpot on the hind head, and abdomen, orange; beak, breaft and tail cinereous, varied with black: Javan partridge of Latham. Found in the ifland of Java.

VIRIDIS. Green; legs and beak reddifh; area of the eyes red; wings fpadiceous: the green partridge of Latham.

VIRGINIANUS. With a black band above and below the eyes; vertical line yellow; the Virginian partridge of Latham. Found among the trees of America.

MARILANDUS. With white eye-brows; neck pointed with white and black: the New England partridge of various writers; the Maryland partridge of the Arctic Zoology and of Latham. Found in America.

KAKELIK. Bill, eye-lids and legs fcarlet; breaft cinereous; back undulated with white and cinereous. Found in Bucharia, &c.

CASPIUS. Cinereous, fpotted with light red; the noftrils, orbits, and temples dufky. Found near Aftrabad, in Perfia.

MEXICANUS. Legs and bill fanguineous; the fuperciliary line white: the coturnix ludoviciana of Briffon, colcuicuiltu of Ray and Willughby, the Louifiana quail of Latham. Found in Louifiana.

FALKLANDICUS. Variegated with brown fpots and curvated ftriæ; beneath white; bill lead-coloured; legs brown; temples fpotted with white: Malouine quail of Latham. Found in the Falkland iflands.

NOVÆ HISPANIÆ. Legs and bill black; crefted head and neck variegated with white and black; body and quill-feathers yellow, the latter tipped with white: this is the grand colin of Buffon, and Mexican quail of Latham. Found in New Spain.

COYOLCOS. With yellow legs; crown and neck fafciated with white and black; body above yellow, varied with white. This is the coturnix mexicana of Briffon; the coyolcozquo of Ray and Willughby, the coyolcos of Buffon, and leffer Mexican quail of Latham; the eyes are black.

SUSCITATOR. Variegated with yellowifh, red, black and grey; bill longer. This is the coturnix javenfis of Briffon, the coturnix indica Bontii of Ray and Willughby, the reveil-matin or caille de Java of Buffon, and noify quail of Latham. Found in the woods of Java.

STRIATUS. With reddifh legs; white eye-brows; tail, throat,

throat, lower breaſt and abdomen black, white-guttated: the Madagaſcar quail of Latham.

GRISEUS. With black legs and bill; body dilutely and ſordidly grey, black-banded: the grey-throated quail of Latham. Found in Madagaſcar.

COROMANDELICUS. Head black; vertex and ocular faſcia red and yellow; throat white, ſurrounded with a black ſtria; body ſtriated; quill-feathers brown: the Coromandel quail of Latham.

NOVÆ GUINEÆ. Brown; greyiſh legs; black quill-feathers, the covers of the wings obſoletely yellow: the New Guinea quail of Latham.

MANILLENSIS. Above black; legs and bill black; throat white; breaſt grey, ſpotted black; abdomen yellow, black-banded: the Manilla quail of Latham.

CRISTATUS. The dependent creſt and throat yellow: this is the quauhtzonecolin of Ray and Willughby, the zone-colin of Buffon, the creſted quail of Latham. Found in Guiana and New Spain.

SINENSIS. Body ſpotted grey; throat black, with a white bow: the coturnix philippenſis of Briſſon, and Chineſe quail of Edwards and Latham. Found in China and the Philippine iſles.

COTURNIX. Body ſpotted grey; eye-brows white; the margin and lunule of the tail-feathers ferruginous: the quail of Pennant and others. Of this there are two varieties, the coturnix major of Briſſon, and the coturnix wholly white.

f. *With three Toes.*

GIBRALTARICUS. With pale legs; black bill; quill-feathers and tail black: the Gibraltar quail of Latham.

ANDALUSICUS. Red, variegated with black; beneath reddiſh-white; legs and bill fleſh-coloured: the Andaluſian quail of Latham.

NIGRICOLLIS. Body above cinereous, variegated with red and black beneath; legs and bill cinereous; chin and throat black; quill-feathers brown: black-necked quail of Latham. Found in Madagaſcar.

LUZONNIENSIS. Head, neck, and throat variegated with white and black; throat and breaſt bay; abdomen yellowiſh; legs and bill dilutely grey: the Luzonian quail of Latham. Found in the Manilla iſlands.

C. *With the Area about the Eyes covered with Feathers, but naked and tetradactyle:* TINAMOU.

GUIANENSIS. With legs and bill brown; back variegated with cinereous brown and blackiſh ſtreaks; throat cinereous; abdomen palely orange and brown. This is the partridge of Guiana of Bancroft and Latham. Found in Cayenne and Guiana.

MAJOR. Legs yellowiſh and brown; bill black; vertex red; body olivaceous; ſpots on the back and tail black. This is the macucagua of Marcgrave, Ray, and Willughby, the magona of Buffon, the tinamou of Cayenne, the great tinamou of Latham. Found in South America, particularly in the woods of Cayenne and Guiana.

CINEREUS. Cinereous-brown: the cinereous tinamou of Latham.

VARIEGATUS. Legs and bill brown; head and neck black; body above variegated with tranſverſe lines, light red and black; beneath red; throat and middle of the abdomen white: the variegated tinamou of Latham. Found in Guiana.

SUVI. Legs and bill yellow; head and neck black; body above brown; beneath red: the little tinamou of Latham. Found in Guiana.

TETRAODON, in *Ichthyology*. See TETRODON.

TETRAPETALOUS, in *Botany*, an epithet given to the flowers that conſiſt of four ſingle petala, or leaves placed around the piſtil.

Theſe M. Juſſieu calls *polypetalous* flowers.

Mr. Ray, who calls them *tetrapetalous*, makes them conſtitute a diſtinct claſs, which he divides into, 1. Such as have an uniform tetrapetalous flower, and their ſeed-veſſels a little oblongiſh, which he therefore calls *ſiliquoſe*. 2. Such as have their ſeed-veſſels ſhorter, which therefore, for diſtinction ſake, he calls *capſulatæ* and *ſiliculoſæ*. 3. Such as have a ſeeming tetrapetalous flower, that is, a monopetalous one, divided deeply into four partitions, which he particularizes alſo as *anomalous*.

TETRAPHARMACUM, τετραφαρμακον, compounded of τέτρα, *four*, and φαρμακον, *drug*, or *remedy*, in the general denotes any remedy conſiſting of four ingredients.

TETRAPHIS, in *Botany*, a name contrived by Hedwig, to expreſs the four points by which the fringe of this moſs is peculiarly diſtinguiſhed. (See FRINGE.)—Hedw. Fund. v. 2. 87. t. 7. f. 32. Schreb. Gen. 758. Sm. Fl. Brit. 1179. Compend. 153.—Claſs and order, *Cryptogamia Muſci*. Nat. Ord. *Muſci*.

Eſſ. Ch. Capſule oblong. Fringe ſimple, of four pyramidal, erect, unconnected teeth.

1. T. *pellucida*. Tranſparent Four-toothed Moſs. Fl. Brit. n. 1. Compend. 163. Engl. Bot. t. 1020. Hedw. Sp. Muſc. 45. t. 7. f. 1. *a—f*. Sibth. Oxon. 275. Turn. Muſc. Hib. 13. (Mnium pellucidum; Linn. Sp. Pl. 1574. M. ſerpillifoliis tenuibus pellucidis; Dill. Muſc. 232. t. 31. f. 2.)—Capſule cylindrical. Leaves ovate, acute, ſingle-ribbed.—Not rare in moiſt ſhady places, about the roots of trees, in various parts of Europe. It is annual, flowering early in the ſpring, and ripening fruit in May. The whole moſs is of a bright tranſparent green. *Root* fibrous, matted. *Stems* moſtly ſimple, an inch high, clothed with alternate, ſeſſile, ovato-lanceolate, acute, entire, wavy, ſingle-ribbed *leaves*, and each terminated by a ſolitary *flower*. The male *flowers*, far more abundant than the female, are little, round, ſtalked, powdery heads, each enveloped in three broad ovate leaves. The *females*, on a different ſtem, are leſs elevated, and more minute, each with from four to ſix *ſtyles*, one of which only, as uſual, is prolific, and the cylindrical, ſmooth, nearly upright *capſule* becomes elevated on a bright orange or crimſon ſtalk, an inch long. The tawny *veil* is torn at the baſe. *Lid* conical, reddiſh, thin, not half ſo long as the capſule. *Fringe* remarkable for its four rigid, poliſhed, acute, pyramidal teeth, of a ſhining brown, by which the genus was well characterized, even when the preſent was the only known ſpecies. Hedwig obſerved the flowers to be ſometimes abortive, and replaced by buds. In the early ſpring he now and then met with *ſtamens* and *piſtils* in the ſame flower.

2. T. *ovata*. Ovate Four-toothed Moſs. Mohr Ind. Crypt. 3. Sm. Compend. 163. Grimmia Browniana; Engl. Bot. t. 1422. Bryum Brownianum; Dickſ. Crypt. faſc. 4. 7. t. 10. f. 16. Orthotrichum Brownianum; Fl. Brit. 1269.)—Capſule ovate. Radical leaves ligulate, obtuſe, without a rib.—Gathered by Mr. R. Brown, by the river ſide at Roſlin, near Edinburgh; and by the late Mr. William Brunton, on ſand-ſtone rocks at lord Grantley's lakes, near Ripon, Yorkſhire. The habit of the plant, and eſpecially the ribbed *veil*, cauſed us firſt to refer our imperfect ſpecimen to *Orthotrichum*, till Mr. Sowerby thought he found the *fringe* to be that of a *Grimmia*. Meanwhile Mr. Funk, a German botaniſt, aſcertained it to be formed of four teeth only, conſtituting a genuine *Tetraphis*, thus

thus adding a fecond fpecies to the curious genus before us. With refpect to habit, indeed, this has little refemblance to the original fpecies. It is a minute, brownifh, pellucid mofs, whofe foliage is all over dotted or reticulated. The *root* feems annual. *Stems* none. Radical *leaves* few, erect, linear, very narrow, a little dilated upwards, obtufe, entire, without rib or vein: thofe which form a *fheath*, at the bafe of the *fruitftalk*, fhort, ovate, acute, with a rib or keel. *Stalk* red, folitary, half an inch high. *Capfule* erect, fmooth, ovate, brown. *Lid* fhort, with an oblique point. *Fringe* red, certainly of only four fhort, acute, firm teeth.

TETRAPHOE, a name given by the people of Guinea to a plant, which they give in decoction as a cure for fluxes. This plant grows alfo in Malabar, where they ufe the roots boiled in whey for the piles; and in the colic they give the root in powder, about a fcruple for a dofe. It is called in this latter place *wellia cadavalli*, and by Petiver *xanthium Malabaricum capitulis lanuginofis*. The ftalks of it are woody and hoary, efpecially about the tops. Its leaves ftand by pairs on fhort footftalks, and while young they are hoary underneath, with a very foft and velvety down; the others are rough, like the fpotted lungwort, but feldom are fo large; the flowers grow in fpikes, and confift each of fine green leaves filled with fcarlet filaments; after thefe the fruit ripens, and is a fort of woolly bur, covered with foft and hooked prickles, very like the common Englifh burdock, but not of a third part of the fize. Phil. Tranf. N° 232.

TETRAPILUS, a genus of Loureiro's, in his Cochinch. 611, named from τετρα, and πιλος, *a hat*, or *hood*, becaufe the four fegments of the corolla end each in a hooded point. Every part of the defcription anfwers to the genus OLEA, fee that article; except that the flowers are dioecious (which indeed is of little confequence, fome of the known fpecies being fubject to have the ftamens and piftils occafionally in feparate flowers); and the berry is faid to have two cells, with feveral feeds. Though *Olea* therefore is known to have two cells in the young germen, there being here more than one feed, muft reduce Loureiro's plant to *Liguftrum;* and it may prove very near *L. japonicum*, Thunb. Jap. 17. t. 1, though fcarcely the fame fpecies.

TETRAPLA, formed from τετραπλος, *quadruplex*, *fourfold*, in *Church Hiftory*, a Bible difpofed by Origen, under four columns, in each of which was a different Greek verfion, *viz.* that of Aquila, that of Symmachus, that of the Seventy, and that of Theodotion.

Sixtus of Sienna confounds the tetrapla with the hexapla; but the tetrapla is a different work, compofed after the hexapla, and in favour of fuch as could not have the hexapla.

Some authors are of opinion, that the order in which the four verfions of the tetrapla were ranged, was different from that in which we have rehearfed them; and particularly, that the Septuagint was in the firft column; but St. Epiphanius fays exprefsly to the contrary, and places it in the third. He even gives us Origen's reafon for putting it there, which was, fays he, that the beft verfion might be in the middle, that the others might be the more eafily confronted with it, and corrected from it.

Baronius, however, in his Annals for the year 231, takes the Septuagint to have been in the third place in the hexapla, but in the firft in the tetrapla; but Epiphanius gives it the fame place in both. See HEXAPLA.

TETRAPOGON, in *Botany*, fo named by Desfontaines, from τετρα, and πωγων, *a beard*, becaufe of the four awns affembled in each calyx.—Desfont. Atlant. v. 2. 388. Willd. Sp. Pl. v. 4. 898.—Clafs and order, *Polygamia Monoecia*, Desfont. and Willd. rather *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume of two nearly equal, oblong, membranous, fhining, awnlefs valves, containing three florets. *Cor.* of two valves; the outer one keeled, abrupt, villous, with a long, ftraight, terminal, fpreading awn; inner fmaller, membranous, awnlefs. *Stam.* Filaments three, fhort, capillary, deflexed; anthers oblong, emarginate, pendulous. *Pift.* Germen fmall, roundifh, fuperior; ftyles two, fhort; ftigmas feathery, oblong. *Peric.* none, except the permanent corolla. *Seed* folitary, invefted with the corolla, but not united to it. The terminal *floret* is imperfect, but both valves are awned.

Eff. Ch. Calyx of two valves, three-flowered. Corolla of two unequal valves; the outermoft abrupt, awned. Central floret imperfect; both valves awned.

1. T. *villofus*. Villous Four-bearded Grafs. Willd. n. 1. Desfont. Atlant. v. 2. 389. t. 255.—Gathered by Desfontaines in fandy ground in Barbary, near Cafsa. The *ftem* is erect, about a foot high, knotty, leafy, a little compreffed, fmooth. *Leaves* linear, fmooth, narrower than their long fheaths, of which the uppermoft, in particular, is much inflated, embracing the bafe of the *fpike*, which refembles that of a POLYPOGON. (See that article.) The *flowers* are feffile, difpofed in four ranks, on a flender zigzag common ftalk, or *receptacle*, their copious yellowifh *awns* about half an inch in length, fpreading every way. The outer valve of the *corolla* is clothed with copious foft fpreading hairs.

TETRAPOLIS, in *Ancient Geography*. See CARPATHOS.

TETRAPOLIS, *Attica*, the name of a country of Greece, N. of Attica; in which, according to Strabo, were four towns built by Xanthus, when he reigned in this diftrict of Greece; whence its name, from τετρα, *four*, and πολις, *city*.

TETRAPOLIS, *Dorica*, a country of Greece, in the Doride, between the country of the Etolians and that of the Enianes, according to Strabo.

TETRAPOLIS *Syriæ*, a country of Afia, in Syria, according to Strabo; it contained four principal towns, which had the fame founder.

TETRAPTOTE, TETRAPTOTON, in *Grammar*, a name given to fuch defective nouns as have only four cafes; fuch are *aftus*, &c.

TETRAPYRAMIDIA, derived from τετρας, *four*, and πυραμις, *a pyramid*, in *Natural Hiftory*, the name of a genus of fpars.

The bodies of this genus are fpars influenced in their fhape by an admixture of particles of tin; and are found in form of broad-bottomed pyramids of four fides.

Of this genus there is only one known fpecies, which is ufually of a brownifh colour, and is found in Saxony; as alfo in Devonfhire, Cornwall, and other counties of England, where there is tin. Hill.

TETRAPYRGIA, in *Ancient Geography*, a town of Cappadocia, in Garfauria.—Alfo, a town of Africa, upon the coaft of Marmarica, before Portus-Phycus, according to Strabo.

TETRARCH, TETRARCHA, τετραρχης, formed of τετρα, *four*, and αρχη, *rule*, *dominion*, a prince who holds and governs the fourth part of a kingdom.

Such, originally, was the import of the title *tetrarch;* but it was afterwards applied to any petty king or fovereign; and became fynonimous with *ethnarch*, as appears from the follow-

following considerations: 1. That Pliny makes mention of six tetrarchies within the cities of Decapolis. 2. That Herod's kingdom was only divided into three parts, which yet were called tetrarchies, and the sovereigns of them (Luke, iii. 1.) tetrarchs. 3. Josephus Antiq. Jud. lib. xiv. c. 23. tells us, that, after the battle of Philippi, Antony, going into Syria, constituted Herod tetrarch; and on medals the same Herod is called *ethnarch*.

TETRARRHENA, in *Botany*, so named by Mr. R. Brown, from τετρα, and αῤῥην, *male*, on account of the very remarkable character in this tribe, the grasses, of the four stamens, which Mr. Brown says he has ascertained by repeated examination.—Brown Prodr. Nov. Holl. v. 1. 209.—Class and order, *Tetrandria Digynia*. Nat. Ord. *Gramina*.

Eff. Ch. Calyx of two-valves, single-flowered. Corolla double; each of two valves, naked at the base. Nectary of two scales, opposite, alternate with the valves of the corolla. Stigmas feathery.

The inflorescence is a simple, equal, somewhat racemose spike. Flowers awnless.

1. T. *distichophylla*. Two-ranked Tetrandrous Grass. Br. n. 1. (Ehrharta distichophylla; Labill. Nov. Holl. v. 1. 90. t. 117.)—Flowers downy. Corolla ribbed, obtuse; the outermost valve half the length of the rest. Leaves straight, hairy as well as their sheaths. Stem branched at the base.—Native of Cape Van Diemen. The *stem* is hardly a foot high, with many erect leafy branches. *Leaves* lanceolate, acute, about an inch long, moderately spreading in two ranks. *Spikes* solitary, stalked, terminal, erect, about an inch in length, simple, the *flowers* almost all sessile, spreading in two rows.

2. T. *acuminata*. Pointed Tetrandrous Grass. Br. n. 2.—"Flowers smooth. Corolla ribbed; the outer glumes acute; one valve rather shorter than the inner glumes; the other longer, with a taper point. Leaves and their stems smooth. Stem branched."—Found by Mr. Brown in the same country.

3. T. *juncea*. Rushy Tetrandrous Grass. Br. n. 3.—"Flowers smooth, imbricated. Calyx without ribs. Corolla ribbed, obtuse. Stem branched; straight and smooth like the leaves."—From the southern coast of New Holland. *Brown*.

4. T. *lævis*. Smooth Tetrandrous Grass. Br. n. 4.—"Flowers smooth, distinct. Calyx ribbed, rather acute. Corolla obtuse, smooth, without ribs. Stems simple. Leaves smooth, flat, rather lax."—Gathered by Mr. Brown in the same country with the last species.

TETRASARIUS, a word used by some of the medical writers, to express half an ounce.

TETRASPASTON, τετρασπαστον, in *Mechanics*, a machine in which are four pullies. See Pulley.

TETRASTATER, τετραστατηρ, in *Ancient Coinage*, a Grecian gold coin of Lysimachus, Antiochus III., and of some of the Egyptian monarchs. It was the quadruple chrusos (χρυσος), weighing about 530 grains, and current for 80 drachmas of silver, valued at about 3*l*., now worth 4*l*. sterling. Some weigh 540 grains, which may be owing to the gold of such being of more alloy; though it may well be questioned, says Pinkerton (Medals, vol. i.), if they were ever meant to relate to the Attic standard.

TETRASTICH, τετραστιχον, a stanza, epigram, or poem, consisting of four verses.

TETRASTŒCHON, in *Botany*, a term often used by the Greek writers, and generally misunderstood by those who copy their accounts. Pliny has made an error in the description of the euonymus, which has confounded two different shrubs together ever since, by mistaking the sense of this word, used by Theophrastus, in his account of it. He says, that the fruit is divided within into four orders or series of seeds; this he expresses by the word *tetrastœchon*, which Pliny, supposing to be the same with the word *tetragonon*, has translated into *granum quadrangulæ figura*.

But this is by no means the sense of the word which was used by the Greeks, to express that a thing had τετταρας ταξεις, four rows, orders, or series of seeds in it: nor does it at all express the seeds being square, much less its being single, for the original derivation of the word was from the term κατα στοιχον, used in dances. These were composed of several series of persons, called στοιχοι, *stæchi*; and every stœchon consisted of several persons, who all moved together. See Euonymus.

TETRASTYLE, formed from τετρα, *four*, and στυλος, *column*, in the *Ancient Architecture*, a building, and particularly a temple, with four columns in its front.

TETRASYLLABICAL, a word consisting of four syllables.

TETRATHECA, in *Botany*, received that name from the writer of the present article, in allusion to the four cells of its anthers, the word being compounded of τετρα, and θηκη, *a case*, or *cell*. Mr. Brown indeed, in his General Remarks on the Botany of Terra Australis, p. 12, offers some observations tending to invalidate this name and character. But it appears to us, that they both derive confirmation from the consideration, of which we are well aware, that most anthers have four cells when young, though, as they burst lengthwise, the partition of each cell is obliterated. Whereas the peculiarity of our *Tetratheca*, admitted by our intelligent friend, consists in the four cells remaining unaltered, because the pollen is discharged by a terminal tube or orifice; nor is it of any great consequence that he has found, in some species, the partition to be obliterated, in an advanced state of the anthers. *Ceratopetalum*, for example, is a good name and a well-marked genus, though there is a species destitute of petals. With respect to the natural order, and the situation of the singular appendage to the seed, in the genus before us, we gladly profit by Mr. Brown's correction, hoping to be pardoned, though we may have made several false steps, in the totally strange wilderness of New Holland plants, which we were among the first, without any guide, to attempt to lay open to botanists.—Sm. Bot. of New Holl. 5. Exot. Bot. v. 1. 37. Willd. Sp. Pl. v. 2. 321. Ait. Hort. Kew. v. 2. 347.—Class and order, *Octandria Monogynia*. Nat. Ord. akin to *Polygaleæ*, a new order to which *Polygala* is referred; but in Mr. Brown's opinion constituting, along with another genus, a still different order, which, from the name destined for that genus, he chooses to denominate Tremandreæ, of which we propose to treat in its proper place.

Gen. Ch. *Cal.* Perianth inferior, in four deep equal segments, deciduous. *Cor.* Petals four, obovate, equal, many times longer than the calyx. *Stam.* Filaments eight, inserted into the receptacle, very short, equal, erect, simple; anthers terminal; oblong, somewhat curved, much shorter than the corolla, with four longitudinal furrows, and as many cells, and terminating in a simple tubular beak, through which the pollen is discharged. *Pist.* Germen superior, very small, obovate, compressed; style vertical, cylindrical, simple, hardly so long as the anthers; stigma simple. *Peric.* Capsule obovate, compressed, of two cells and two valves, the partitions from the middle of each valve. *Seeds* one or two in each cell, oval, pendulous, with a naked scar, but crowned, at the opposite end, with a twisted crest.

Eff.

Eff. Ch. Calyx four-cleft, inferior. Petals four. Anthers beaked, with four cells. Capfule of two cells and two valves, with partitions from their middle. Seeds crefted, about two in each cell.

1. T. *juncea*. Rufhy Tetratheca. Willd. n. 1. Ait. n. 1. Sm. Bot. of New Holl. 5. t. 2.—Smooth. Leaves alternate, lanceolate. Stem with fharp angles. Branches elongated, and almoft naked.—Native of New South Wales, from whence we received drawings and fpecimens, through the hands of Dr. John White, foon after the fettlement of the colony there. This plant was fent to Kew, by Mr. Peter Good, in 1803, and it is marked as flowering in July and Auguft, being kept in the greenhoufe in winter. The *root* is woody, fmall, perennial. *Stems* fomewhat fhrubby, much branched even from the bafe; the branches long, flender, very acutely angular, fo as to be almoft winged, leafy, fmooth like every other part. *Leaves* generally few and fmall, acute, feffile, entire, with a ftrong mid-rib. *Stipulas* none. *Flowers* fcattered along the branches, on fimple folitary red ftalks, about an inch long, each from the bofom of a diminifhed leaf, and making a very elegant appearance. The *calyx* is red. *Petals* crimfon or rofe-coloured, three-fourths of an inch long. *Anthers* purplifh-brown, tipped with yellow. We have a variety with white *petals*, the *calyx* and *ftalks* of which preferve their ufual colour.

2. T. *ericifolia*. Heath-leaved Tetratheca. Sm. Exot. Bot. v. 1. 37. t. 20.—Leaves whorled, linear, revolute, minutely toothed. Stem rough with afcending briftles. Flower-ftalks and calyx very fmooth. From the fame country as the foregoing, and fent, with drawings, at the fame time. This is of more humble growth than *T. juncea*, and much more leafy. The *leaves* are four, five, or more, in each whorl from top to bottom of the ftem and branches, feffile, narrow, about half an inch long; their edges, and fometimes their upper furface, near the point, rough with minute teeth. *Flowers* rofe-coloured, drooping, about half the fize of the foregoing, on fimple, folitary, axillary ftalks, as long as the leaves. *Anthers* purple, with yellow tips, badly reprefented by the engraver, who miftook the original drawing of the fection of an anther, for the *germen*, and altered it accordingly. *Capfule* ovate, emarginate. *Seeds* with a fmall white creft, moftly two in each cell.

3. T. *glandulofa*. Glandular Tetratheca. Sm. Exot. Bot. v. 1. 39. t. 21.—Leaves imperfectly whorled, lanceolate, revolute, toothed with little fpines. Stem downy. Flower-ftalks and calyx rough with glands.—Sent intermixed with the laft, from New South Wales. The fpecimens of both appeared to have been burnt down to the ground, probably by fires made by the favages in the woods, and had grown up again; which proves them to be perennial plants, though fcarcely fhrubby. The fize of the prefent fpecies, and its general afpect, agree with *T. ericifolia*, but the *corolla* and *anthers* are of a darker tint. The *ftem* is clothed with very fhort clofe down, by no means briftly; while the *flower-ftalks* and *calyx*, inftead of being fmooth, are covered with glandular hairs. The *leaves* are rather broader, and lefs whorled, being often merely oppofite, or even difperfed.

4. T. *thymifolia*. Thyme-leaved Tetratheca. Sm. Exot. Bot. v. 1. 41. t. 22.—Leaves whorled, lanceolate, toothed with little fpines. Stem, flower-ftalks, and calyx rough with afcending briftles.—From the fame country. Rather larger than either of the two laft, and readily diftinguifhed, at firft fight, by its broader lefs revolute *leaves*. The briftly hairs clothing the *flower-ftalks* and *calyx* are its peculiarly diftinguifhing character. The *flowers* are of a fine crimfon, with violet *anthers*, whofe tips are yellow. Few genera are more peculiar, or more elegant, than *Tetratheca*, and the fpecies are all worthy of a place in our collections.

TETRATONON, is the Greek name of an interval of four tones; which in modern mufic is ufually called the fuperfluous or fharp fifth.

TETRAX, in *Ornithology*, the name of a bird of the *otis* or buftard kind, called by fome authors *anas campeftris*, or the field-duck, and alfo little buftard; and by fome others, the *canna*. See OTIS.

It is a very common bird in France, where it is called *canne patriere:* it is called *anas*, from its fitting on the ground, juft as the duck does on the water. It is of the fize of a pheafant, and has a beak like that of the common hen. It is taken with nets, as the partridge: it runs very fwiftly, and, like the buftard, has no hinder toes. Its belly is white, and its back is variegated with grey, red, and black. It feeds on vegetables, and on fmall infects.

TETREUMA, in *Botany*, a name given by the people of Guinea to a fpecies of fhrub, very common among them, and ufed to cure whitlows. They dry the leaves, and reduce them to powder; and, moiftening them with any liquor, apply them to the place. Petiver has called this *arbor Guineenfis lauruftini facie*, from its great likenefs to the common fhrub which we call the lauruftine. The leaves are opaque and ftiff, and are an inch and a quarter broad, and two inches and a half long. Thefe ftand alternately on all fides of the ftalk, and are fixed on fhort pedicles. The flowers grow out of the bofoms of the leaves, and ftand in clufters in the manner of thofe of the common lauruftine. Phil. Tranf. N° 232.

TETRICA, in *Ancient Geography*, a town of the Sabines, placed by Varro in the environs of mount Fifcellus, which lay northward. Servius on Virgil fays, that it belonged to Picenum, becaufe in his time, its limits had been changed. The Abbé Chaupé places it where we now find Leoneffa. There we find the terrible rocks, horrentes rupes, mentioned by Virgil.

TETRICUS MONS, a fcraggy mountain of Italy, in the country of the Sabines. Pliny.

TETRINA, in *Geography*, a town of Ruffia, in the government of Archangel, near the White fea; 100 miles N.N.W. of Archangel.

TETRIX, in *Ornithology*, a fpecies of *tetrao;* which fee.

TETRODON, in *Ichthyology*, a genus of the Branchioftegi order of fifhes, according to the arrangement of Gmelin; the characters of which are, that the jaws are long, divided at the tip; the branchiæ or gills have a linear aperture; the body is roughened beneath, and the ventral fins are wanting. The fifhes of this genus, like the Chiodon, have the power of inflating their bodies at pleafure, by means of an internal membrane, and during this time the fmall fpines of the fides and abdomen rife fo as to be a defence againft their enemies. They live principally on cruftaceous and teftaceous animals. Gmelin enumerates thirteen fpecies.

SCELERATUS; the Noxious Tetrodon. Tetragonal, with very large head; length two feet or more. Found in the American and Pacific oceans, and confidered as highly noxious, producing, when eaten, very fevere fymptoms.

TESTUDINEUS; a Tortoife-fhell Tetrodon. Abdomen plane, fmooth, and back with white curved futures; length two feet; colour rufous-brown above, marked by numerous round pale blue fpots; beneath bluifh or afh-coloured, beautifully varied by longitudinal brown ftreaks; fins and tail bright ferruginous; the whole abdomen is furnifhed with numerous fmall fpines, which, when the animal is undifturbed, are imbedded in correfponding cavities in the fkin,

but

but elevated, when the fiſh is alarmed and diſturbs its body. Found in the Indian ſeas.

Lagocephalus; Hare Tetrodon. Abdomen aculeated; ſmooth body, and prominent ſhoulders; length twelve inches; thick in front; hinder parts tapering ſuddenly towards the tail; colour above yellowiſh-brown, beneath whitiſh with a ſilvery caſt; acroſs the back marked with ſhort, black, or dark-brown bars, and over the ſides with many, ſcattered, round, blackiſh ſpots; ſides and abdomen beſet with radiated ſpines; fins ſmall, and tail ſlightly rounded. Found in the Indian and American ſeas; and ſtraying into northern latitudes, are taken about the Britiſh coaſts. This fiſh has the power of inflating the abdomen to a large ſize; and derives its name from the reſemblance of its head to that of a hare.

Lineatus. With brown and pale bands; length ten or twelve inches, ſquare ſhape; and when inflated, like the laſt; body beſet with ſmall ſpines; colour grey on the abdomen, with longitudinal, deep-brown ſtreaks; fins and tail as in the laſt ſpecies. Found in the Indian and American ſeas, and alſo in the river Nile.

Electricus. With red, green, and white ſpots; above brown, and beneath ſea-green; yellow at the ſides, and green fins; length ſeven or eight inches; eyes large, with red circles. Found in the Indian and American ſeas, among coral rocks; and when touched with the hand, affecting it with an electric or galvanic ſhock.

Ocellatus. Ocellated on the ſhoulder-band; length ſix or eight inches; thick, ovate ſhape, contracting towards the tail; colour deep green above, paler on the ſides and abdomen, which are whitiſh; acroſs the middle of the back, as far as each pectoral fin, a broad black creſcent, edged with yellow; dorſal fin ſituated on a round black ſpot with yellow edges; lateral line from beneath the eyes to the tail, which is ſmall and roundiſh; under parts beſet with many ſpines. Found in the Indian ſeas and adjoining rivers, particularly thoſe of China and Japan; very poiſonous in its nature, and it is prohibited to be eaten under very ſevere penalties by the emperor of Japan.

Spengleri. Head bearded with many cirri; lengthened ſhape; above brown-coloured, with roundiſh deep brown ſpots; abdomen tumid, whitiſh, and beſet with ſmall ſpines; with cirri or ſoft prominences diſperſed about the upper parts of the body. Found in the Indian ſeas, ten or twelve inches in length

Hankenii. With lower jaw longer than the upper; length eight or ten inches; like the former in general appearance; above brown-coloured, with ſmall whitiſh clouds or ſpots; beneath whitiſh, with ſmall ſpines. Found in the Indian ſeas.

Oblongus. Oblong, with equal jaws; length ſix inches; lengthened ſhape; colour whitiſh, with grey back, marked by many ſemi-decurrent brown bands; fins and tail cinereous; two lateral lines, one near the back, the other near the abdomen. Found in the Indian ſeas.

Rostratus; Snouted Tetrodon. Both jaws elongated to the beak; length a few inches; oblong-ovate ſhape, contracting towards the mouth and tail; ſnout lengthened and ſlightly tubular; colour blueiſh-brown, beneath whitiſh; fore-part of the abdomen beſet with ſpines, few over the back; fins brown. Found in the Indian ſeas.

Lævigatus; Smooth Tetrodon. With the abdomen aculeated in front; a large ſpecies; blueiſh above, with two white ſtripes on each ſide; under parts white; from the mouth to the end of the pectoral fins aculeated; the other parts being ſmooth. Found in the American ſeas.

Hispidus. Entirely hiſpid, with briſtly papillæ; length two feet; ſhape, when inflated, like that of T. lagocephalus; colour whitiſh; upper parts marked acroſs the back by three or four ſemi-decurrent brown bands; whole body beſet with ſmall ſpines. Found in the Mediterranean and Indian ſeas. Small remains of this ſpecies are ſaid to occur among the petrifactions of mount Bolca near Verona.

Mola. Unarmed, ſharp, compreſſed, rounded; a very ſhort rounded tail; dorſal fin annexed to the anal, with oval ſpiracles. (See Sun-*Fiſh.*) Dr. Shaw has made a diſtinct genus of the ſun-fiſh under the name of *cephalus*, the characters of which are, that the jaws are bony, and body terminating abruptly, ſo as to reſemble the head of a fiſh. This genus comprehends the mola, or ſhort ſun-fiſh; the oblong ſun-fiſh, with truncated body, or oblong diodon of Pennant (ſee Sun-*Fiſh*); the variegated, with whitiſh undulations and ſpots; and the Pallaſian C. or ſilvery ſun-fiſh, with browniſh back, and ſpiny carinated abdomen. The mola, or ſhort ſun-fiſh, is a native of the European ſeas. Its general colour is brown, with a ſilvery caſt on the ſides and abdomen; the ſkin rough; the pectoral fins ſmall, rounded, and placed horizontally; the dorſal and anal fins placed oppoſite, and of a lengthened ſhape, with rounded tips continued into the tail-fin. This fiſh is ſometimes ſeen lying on its ſide, on the ſurface of the water, when it may be eaſily taken. In the Northern ſeas it arrives at a vaſt ſize, of the length of eight or even ten feet, and 500 pounds in weight: it is ſuppoſed to feed principally on ſhell-fiſh, and in the night it is ſaid to exhibit a high degree of phoſphoric ſplendour.

Of this there is a variety, *viz.* the *truncatus*, unarmed, ſmooth, compreſſed, oblong, with a very ſhort tail, the dorſal and anal fins annexed, with lunated ſpiracles. This is the oblong ſun-fiſh of Pennant.

Stellatus; Spherical Grey Tetrodon. Whitiſh beneath, with the body beſet with radiated ſpines: the tetrodon etoilé of Cepede. Length twelve or fourteen inches; ſhape, when inflated, nearly ſpherical; colour greeniſh, deeper on the back, marked with duſky ſpecks; under parts whitiſh; vent ſurrounded by a black circle; whole body covered with ſmall ſtellated or radiated ſpines; dorſal fin rounded at the tip, and attached at the baſe by a kind of footſtalk; tail oval. Found in the Indian ſeas. Shaw.

Punctatus; Spherical Brown Tetrodon. With black ſpecks, whitiſh abdomen, and very narrow dorſal fin: the tetrodon pointellé of Cepede. Reſembling the former. Found in the Indian ſeas. Shaw.

Meleagris; Pintado Tetrodon. Brown, ſpeckled with white. Found in the Indian ſeas, and when taken, making a kind of grunting noiſe, like ſeveral others of this and neighbouring genera.

TETSCHIN, or Tetzin, or *Dietſchin*, in *Geography*, a town of Bohemia, in the circle of Leitmeritz, on the river Elbe; 15 miles N. of Leitmeritz. N. lat. 50° 46′. E. long. 14° 17′.

TETSI, a town of Thibet; 27 miles E. of Laſſa.

TETT, a place now in ruins, ſituated to the ſouth of Azamore, on the northern extremity of the bay of Mazagen, in the empire of Morocco; the name ſignifies in Arabic Titus, and is therefore ſuppoſed to denominate the ruins of Titus, founded by the Carthaginians.

TETTER, a diſeaſe among animals, which is of the ring-worm kind, and which runs or ſpreads itſelf upon the ſkin in different directions, whence probably it has received the name. It attacks different parts, but is moſt commonly met with on and about the rump, not unfrequently running down upon the joints of the tail for ſome diſtance.

It is of a ſcabby itchy nature and appearance, and when neglected,

neglected, is said to have sometimes become of the quality of canker, in some sorts of animals. In cases where it fixes upon the more fleshy parts of the bodies of the animals, it is often attended with such troublesome itchings, as to cause them to rub themselves against posts, walls, and other places, until they rub off and destroy the very hair and skin of the parts. Nay, the animals will, it is said, sometimes even tear off the flesh with their teeth, if they can come at the parts.

The cure of the disease may mostly be accomplished by the use of a ball composed of from half a drachm to a whole one of calomel, or more, according to circumstances, in union with some sort of cooling purgative powder: or a powder constituted of crude antimony, æthiops mineral, and cremor of tartar, of each about half an ounce; which should be given once or twice a day in a quart of oat-meal gruel. At the same time, washing the parts well with Goulard water, and afterwards applying a little of an ointment composed of sulphur, blue ointment, and hog's-lard to them.

The animals should be well taken care of while the cure is going on.

TETTIGES, τέττιγες, *grasshoppers*, in *Antiquity*, a title the Athenians assumed to themselves. See Gegenes.

TETTIGOMETRA, in *Entomology*, a name by which the ancients called the nymph of the cicada, or *tettyx*; and they named this nymph, from which they frequently saw that fly hatched, *tettigometra*, which signifies the *mother of the cicada*. See Harvest-*Fly*, Cicada, and Vegetable-*Fly*.

TETTIGONIA, a word used by the ancients to express the smaller species of cicada, with which they were acquainted. They called the larger *acheta*.

It is generally supposed, that the tettigonia was the same with our smallest kind, called by the French *cigalon*; but M. Reaumur observes, that as the ancients knew two kinds of the cicada, we know three; and that our middle one seems to have been their tettigonia or small cicada, and that they were not acquainted with our smallest kind, or cigalon, which is not larger than a hornet.

TETTIGONIÆ of Linnæus. See Gryllus.

Tettigoniæ of Fabricius. See Cicada.

TETTNANG, in *Geography*, a town of Germany, and principal place of a lordship of the same name, united with Montfort, ceded to Bavaria by the peace of Presburg; 8 miles N. of Lindau.

TETTOVA, a town of European Turkey, in Macedonia; 13 miles W. of Skopia.

TETTUA-MOTU, a cape on the E. coast of New Zealand, the N.E. point of Poverty bay. N. lat. 38° 36'. W. long. 181° 30'.

TETUAN, Tetawan, or *Tetteget*, a town of Africa, in the empire of Morocco and province of El Garb, situated near the river Busega, about a league and a half inland from the Mediterranean, and inhabited by Moors and Jews; who for the most part speak a corrupt Spanish, in which language their commercial negociations are transacted. They are genteel in their persons and polite in their manners. The environs of Tetuan are planted with vineyards and gardens, which are kept in good order, and which produce more excellent fruits than those in other parts of the empire. From the raisins and figs the Jews distil an ardent spirit (called Mahaya), which, at the age of a year, resembles the Irish usquebaugh, and it is preferred to English brandy and rum. Of this they drink immoderately, and generally take a glass before eating. Leo Africanus attributes the foundation of this town to the people of Africa. It was afterwards embellished, and the population increased, when the Moors were driven out of Spain. This was the place of residence for many of the consuls of the European powers, till the year 1770, when the reigning emperor, Seedy Mahomed, would no longer permit them to remain, nor again to establish themselves in the place. The port of this town has kept a trading communication with Gibraltar, whence the ships come to victual, when the wind is in the west, and does not allow them to make Tangiers. The shore of Tetuan is only safe when the wind is in the west, at which time ships ride securely; but when it veers to the east, they must remain here no longer. Our fleets often victual and water here, and this was the case with that of the immortal Nelson, previously to his victory in Aboukir bay. Tetuan is said to contain 16,000 people; 30 miles S.E. of Tangiers. N. lat. 35° 30'. W. long. 5° 20'.

TETYAN Head, a cape on the W. coast of the island of Mindanao; near which is a harbour that may be entered without danger. N. lat. 7° 20'. E. long. 124° 36'.

TEVAKUN, a town of Persia, in the province of Khorassan; 45 miles E.S.E. of Meschid.

TAVARA, a town of Naples, in Capitanata; 5 miles N.E. of Volturara.

TEUBER, or Teuberinn, Elisabeth, in *Biography*, a celebrated German opera singer, and élève of the famous Tesi. She was chiefly attached to the court of Vienna, where she resided in 1772. She had sung at Naples in 1769 with great applause; but was peremptorily ordered by her physicians never to sing again. Her health had been so much impaired in Russia, where she had remained three years, that the whole faculty was unanimous in pronouncing that the exercise of her profession would be fatal. However, in spite of this prediction, she afterwards recovered her health and voice sufficiently, in a journey to Italy, to appear again on the stage at Naples in 1785; where, finding that her voice had somewhat lowered its pitch, she performed the principal man's part in contralto, to the entire satisfaction of the public. She was the daughter of a famous violinist in the emperor's service; she had lessons in singing from Hasse, in acting from the Tesi, and often sung in the operas of Haydn at Esterhazi.

TEUCHERN, in *Geography*, a town of Saxony, in Thuringia; 18 miles S.W. of Leipsic.

TEUCHITES, in *Botany*, a name used by some for the *scœnanth* or *schœnanth*, camel's hay, which ought to be written *teuochitis*. There is a city *Teuochis* in Egypt, near the borders of Arabia, and the geographers all mention a lake in the neighbourhood of this city; in this lake it is probable the schœnanth might grow; and being gathered there, and sold in the adjoining city of Teuochis, the purchasers might distinguish it with an epithet formed of the name of the place where they bought it. See Scœnanth.

TEUCHTLACOT-ZANHQUI, in *Zoology*, a name by which the natives of some of the American nations call the rattle-snake.

TEUCRIUM, in *Botany*, an ancient name, whether applied to any species of this genus, or of any other, because the plant was discovered by Teucer the Trojan prince, or dedicated to him, or found in the country of Troy, sometimes called *Teucria*, we must humbly profess our inability to form any opinion or conjecture.—Linn. Gen. 287. Schreb. 384. Willd. Sp. Pl. v. 3. 13. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 606. Prodr. Fl. Græc. Sibth. v. 1. 390. Ait. Hort. Kew. v. 3. 365. Schreb. Unilab. 26. Pursh 405. Tourn. t. 98. Juss. 112. Lamarck Illustr. t. 501. (Polium; Tourn. t. 97. Chamædrys; Tourn. t. 97.)

t. 97.)—Clafs and order, *Didynamia Gymnofpermia.* Nat. Ord. *Verticillatæ*, Linn. *Labiatæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cloven half way down into five acute, nearly equal, fegments, gibbous on one fide at its bafe, permanent. *Cor.* of one petal, ringent. Tube cylindrical, fhort, ending in an incurved throat. Upper lip erect, acute, divided throughout into two diftant fegments, divaricated towards each fide: lower fpreading, three-cleft; its lateral fegments refembling the upper lip, nearly erect; the central one roundifh, and very large. *Stam.* Filaments four, awl-fhaped, longer than the upper lip of the corolla, afcending, curved, prominent between its divifions; anthers fmall, incumbent. *Pift.* Germen fuperior, deeply four-lobed; ftyle thread-fhaped, agreeing with the ftamens in fize and pofition; ftigmas two, flender, acute. *Peric.* none, the unchanged calyx containing the feeds in its concave bafe. *Seeds* four, roundifh, reticulated or wrinkled.

Eff. Ch. Upper lip of the corolla deeply divided, beyond its bafe, divaricated. Stamens prominent.

Obf. The upper lip of the corolla being fo deeply divided, even below its bafe, into the tube itfelf, and its fegments fo far afunder, there feems to be no upper lip at all. The latter however is more truly the cafe in *Ajuga*, to which, and not to *Teucrium*, belongs the *Chamæpitys* of Tournefort; its upper lip being, in a manner, cut away. *Teucrium* of Tournefort has a bell-fhaped calyx, and the middle fegment of the lower lip of its corolla concave. *Polium* of the fame author has its flowers collected into denfe terminal heads. His *Chamædrys* has axillary flowers, and a tubular *calyx*. *Marum* of Boerhaave has thyme-like leaves, and a peculiarly pungent fmell. *Scordium* of Ray and Rivinus has the odour of garlic. *Iva* of Dillenius has the calyx very protuberant at the lower part. All thefe neverthelefs form together a moft natural and well-defined genus, whofe qualities are more or lefs aromatic or bitter; its habit ufually herbaceous, moftly perennial, often fhrubby; leaves oppofite, fimple, though in fome inftances much divided; pubefcence various, but hardly ever abfent; flowers blue, red, yellow, or whitifh, axillary, folitary or whorled, panicled or capitate; their incurved ftamens and ftyle always very confpicuous between the divifions of the upper lip.

Thirty-five fpecies are enumerated in the fourteenth edition of Linn. Syft. Veg. from which *Chamæpitys*, *Iva* and *falicifolium* are to be removed to *Ajuga*. Willdenow, after making thefe deductions, has fixty-four. He follows Schreber and others, in making many more fpecies out of the allies of *Polium*, than Linnæus would ever allow to be more than varieties. Two new ones from Crete are added in the Prodr. Fl. Græc. The genus is generally European, but not entirely fo, and for the moft part inhabits warm funny climates. No attempt has been made to diftribute it into fections. We fhall indicate fome traces of fuch, as we felect the more curious or remarkable fpecies for illuftration, defcribing all the Britifh as well as the new ones.

T. *campanulatum.* Bell-fhaped Germander. Linn. Sp. Pl. 786. Willd. n. 1. Ait. n. 1. (T. fupinum, perenne, paluftre, apulum, glabrum, foliis laciniatis, flore albo; Till. Pif. 163. t. 49. f. 1.)—Leaves many-cleft, nearly fmooth. Flowers axillary, folitary. Calyx awned. Stem procumbent.—Native of moift fituations, in Italy and the Levant. Miller appears to have cultivated it in 1728, but the true plant is now fcarcely to be feen in our gardens, and is little known to botanifts. The fynonym of Tilli has no right to be marked as a variety, anfwering exactly to the Linnæan fpecimens and defcription, nor do we find any other figure of this fpecies. Schreber feems to have mifled Willdenow, to quote a fynonym of Rivinus, which has no exiftence. This we find tranfcribed into Hort. Kew. with a correction of t. 14 for 24; though nothing but *T. Botrys* is there to be feen. No lefs incorrectly is Rivinus, t. 19, cited by Willdenow, after Schreber, for *T. orientale;* as Dr. Sims has noticed in Curt. Mag. 1279. *T. campanulatum* is a very diftinct, perennial, herbaceous, nearly fmooth, fpecies, whofe *ftems* are fquare, leafy, more or lefs proftrate and creeping. *Leaves* an inch long, twice three-cleft, with bluntifh, notched, flightly revolute fegments. *Flowers* axillary, folitary, oppofite, ftalked, with a large, bell-fhaped, rather pungent-pointed, *calyx*. The *corolla* is faid to be white.

T. *lævigatum.* Smooth Yellow Germander. Vahl Symb. v. 1. 40. Willd. n. 2.—Quite fmooth. Lower leaves many-cleft; upper three-cleft, entire. Flowers axillary, folitary. Segments of the calyx oblong, without awns.—Gathered at Monte Video, by Commerfon, whofe fpecimen is before us. This fpecies is larger in all its parts than the foregoing, and appears to be herbaceous and erect, quite fmooth, except a flight downinefs, here and there, upon the young branches or ftalks. *Leaves* ftalked, an inch and half long, deeply divided into three wedge-fhaped, jagged, blunt, very fmooth and flat, lobes; the upper, or floral, ones much fmaller and narrower, fimply three-cleft. *Flowers* yellow. Segments of the *calyx* oblong-lanceolate, with one central rib and two marginal ones, acute, but not tipped with any awn or briftly point.

T. *orientale.* Great-flowered Germander. Linn. Sp. Pl. 786. Willd. n. 3. Ait. n. 2. Curt. Mag. t. 1279. (T. orientale anguftifolium laciniatum, flore magno fubcæruleo; Comm. Rar. 25. t. 25.)—Leaves deeply three-cleft, many-cleft, linear. Clufters terminal, compound. Flower-ftalks horizontal, longer than the floral leaves.—Native of the Levant. Cultivated by Miller, and recently reftored to our gardens by feeds obtained from Siberia, by Mr. Loddiges. The *root* is perennial. Several decumbent *branches* from the root bear *leaves* divided into many linear fegments; but the foliage of the erect panicled flowering *ftem* is doubly three-cleft below, fimply above. *Inflorefcence* terminal, racemofe, compound, with fmall bracteaceous leaves. *Flowers* numerous, almoft as large as thofe of *T. fruticans* hereafter defcribed, of a light purplifh-blue. All the herbage, and even the *corolla*, is hairy or downy. We have already mentioned, under our firft fpecies, that the citation of Rivinus by Willdenow is an error.

T. *Botrys.* Cut-leaved Annual Germander. Linn. Sp. Pl. 786. Willd. n. 5. Ait. n. 3. Mill. Ic. t. 264. f. 1. (Iva mofchata, folio multifido; Riv. Monop. t. 14. Chamæpitys fœmina; Ger. Em. 525.)—Leaves many-cleft. Flowers axillary, oppofite, in pairs, turned one way. Calyx tubular, inflated and gibbous at the bafe.—Native of Germany, Switzerland, France and Italy, in dry fields. *Root* annual, fibrous. *Herb* hairy, branched from the bottom, erect. *Leaves* deeply pinnatifid, fomewhat three-lobed. *Flowers* ftalked, crimfon, four together, making a fort of half whorl. The *calyx* becomes greatly enlarged after flowering, tubular, remarkably inflated below, and terminating in five triangular, awned, converging teeth.

T. *trifidum.* Trifid-leaved Germander. Retz. Obf. fafc. 1. 21. Willd. n. 7. Ait. n. 5. (T. capenfe; Thunb. Prodr. 95.)—Leaves hoary, in three deep linear fegments. Stalks axillary, three-flowered. Calyx hoary, without awns.—Gathered at the Cape of Good Hope, by Thunberg and Maffon. The latter fent feeds to Kew in 1791. The plant is fhrubby, flowering moft part of the fummer, and kept in the greenhoufe in winter. Its afpect is not unlike Winter Savory, but more hoary. The fegments of the

leaves

leaves are an inch long, revolute, entire. *Flower-ſtalks* half the length of the leaves. Segments of the *calyx* elongated, lanceolate, revolute, ſingle-ribbed, bluntly pointed, not awned. *Corolla* purpliſh. *Seeds* with a net-work of wrinkles over their ſurface.

T. *Pſeudo-chamæpitys*. Racemoſe Slender-leaved Germander. Linn. Sp. Pl. 787. Willd. n. 8; excluding the ſynonym of Cluſius. (Chamæpitys alia; Camer. Epit. 680. Chamæpityos ſpuriæ alterius altera icon; Dod. Pempt. 47.)—Leaves deeply once or twice three-cleft, linear, acute, revolute, hairy. Cluſter terminal, ſimple. Bracteas three-cleft. Calyx hoary, awned.—Native of Spain, Barbary, and the ſouth of France. The *ſtem* is ſhrubby, divided from the bottom into many aſcending, leafy, ſquare, moſtly hairy branches. *Leaves* in very narrow, ſomewhat awned, ſegments, more or leſs hairy. *Flowers* much like thoſe of *T. orientale*, but forming a ſimple terminal *cluſter* at the top of each branch, with deeply three-cleft linear *bracteas*, uſually as long as the *flower-ſtalks*. Lip of the *corolla* externally hairy. The *Pſeudochamæpitys* of Cluſ. Hiſt. v. 2. 185. Lob. Ic. 385. f. 1. Chamæpitys ſpuria altera; Ger. Em. 526; the left-hand figure in Dod. Pempt. 47; all from the ſame wooden block; appears to us a different ſpecies from the above-deſcribed, with which we are unacquainted. There can be no doubt that the *T. mauritanum*, Linn. Sp. Pl. 787, entirely adopted from Shaw's rude figure, n. 575 of his Phyt. Afric. Specimen, is exactly the ſame with the real *Pſeudo-chamæpitys* of Linnæus, which we have from Spain and Barbary, and which the cut of Camerarius, as well as the right-hand one of Dodonæus, clearly repreſents.

All the foregoing ſpecies, with a few more which may be found in Linnæus and Willdenow, apparently conſtitute a ſection of the genus before us, whoſe deeply-divided *foliage* gives them a peculiar and ſtriking character. Their *infloreſcence* nevertheleſs differs conſiderably, and on a more careful examination it will be found, that the racemoſe blue-flowered ones are moſt naturally akin to the *T. fruticans*, notwithſtanding its undivided entire *leaves;* while the others are more related to ſome cut-leaved red-flowered ſpecies, with which we ſhall meet hereafter; inſomuch that no natural ſubdiviſion of this genus could be founded on the above character.

T. *fruticans*. Blue Tree Germander. Linn. Sp. Pl. 787. Willd. n. 9. Ait. n. 6. Sm. Fl. Græc. Sibth. t. 527, unpubliſhed. (T. latifolium; Linn. Sp. Pl. 788. Curt. Mag. t. 245. T. fruticans bœticum; Cluſ. Hiſt. v. 1. 348. Dill. Elth. 379. t. 284. T. bœticum; Ger. Em. 659.)—Leaves ovato-lanceolate, entire; ſnow-white and cottony beneath. Flowers axillary, ſolitary. Segments of the calyx ovate, cottony at the back.—Native of the ſouth of Europe and north of Africa. A hardy and common greenhouſe plant in England, ſometimes bearing our milder winters in the open air, eſpecially near the ſea. The *ſtem* is ſhrubby, buſhy, three or four feet high, with ſtraight, divaricated *branches*, clothed, like the backs of the *leaves* and *calyx*, as well as all the *ſtalks*, with peculiarly white, ſoft, denſe down. The *leaves* vary in ſize and breadth, as may be ſeen in the plate of Dillenius, whoſe fig. 368. miſled Linnæus to make a ſpecies, by the name of *latifolium*, which is but a trifling variety. The upper ſurface of the *leaves*, and inſide of the *calyx*, are dark-green, uſually quite ſmooth. *Flowers* large and handſome, of a fine blue, coming out at all times of the year: the middle ſegment of their lower lip ſometimes deeply cloven.

T. *brevifolium*. Short Hyſſop-leaved Germander. Schreb. Vertic. Unilab. 27. Willd. n. 10. Sm. Fl. Græc. Sibth. t. 528, unpubliſhed. (Roſmarinum ſtœchadis facie; Alpin. Exot. 103. t. 102. Polio retto di Candia; Pon. Bald. 156.)—Leaves lanceolate, revolute, entire, obtuſe, hoary. Flowers ſolitary. Calyx without awns.—Native of rocks in Crete, near the ſea-ſhore. The *ſtem* is ſhrubby, with copious ſpreading, ſquare, leafy branches. *Leaves* about an inch long, of a hoary green on both ſides, veiny. *Flowers* on ſlender, ſolitary, ſimple ſtalks, from the boſoms of the upper leaves. *Corolla* bluſh-coloured, with purple veins. Segments of the *calyx* revolute and blunt. Schreber and Willdenow cite, under this ſpecies, T. frutefcens, ſtœchadis arabicæ folio et facie; Tourn. Cor. 14. Rivin. Monop. t. 20; which is correct as to Tournefort, but no ſuch thing occurs in Rivinus. If we had not conſulted, in ſir Joſeph Banks's library, the moſt perfect copy of his work known to exiſt, we ſhould not ſpeak ſo decidedly on this head.

T. *creticum*. Roſemary-leaved Germander. Linn. Sp. Pl. 788. Willd. n. 11. Sm. Fl. Græc. Sibth. t. 529, unpubliſhed. (T. hyſſopifolium; Schreb. Vertic. Unilab. 28.)—Leaves linear-lanceolate, revolute, entire, obtuſe; white and cottony beneath. Flowers often two or three together. Calyx cottony, ſpinous.—Native of Crete, Cyprus, and Egypt. A taller, larger *ſhrub* than the laſt, ſome of whoſe ſynonyms were confounded with it by Linnæus. Its habit and foliage much reſemble Roſemary. The *flowers* are light purple, or pink, and form long leafy *cluſters*, at the ends of the *branches*, being either ſolitary, or two or three together, on ſhort downy *ſtalks*, from the boſoms of the upper *leaves*. The *calyx* is cottony without; green within; and has ſhort ſpinous points.

T. *Marum*. Marum Germander, or Cat-thyme. Linn. Sp. Pl. 788. Willd. n. 12. Ait. n. 7. (Pſeudo-Marum; Rivin. Monop. Irr. t. 13, not t. 40, which is Thymus Maſtichina. Marum Cortuſi; Bauh. Hiſt. v. 3. 242.)—Leaves ovate, acute, entire, ſtalked, cottony beneath. Flowers racemoſe, in pairs, turned one way. Calyx woolly.—Native of Spain, and the iſles of Hyeres. Frequent in greenhouſes, where it is very hardy, being cultivated for the ſake of its peculiarly pungent ſcent, which powerfully induces ſneezing, and which renders it not leſs grateful to cats than Valerian. The *ſtem* is buſhy, of humble growth, with round hoary branches. *Leaves* a quarter of an inch long, of a hoary green on the upper ſide. *Flowers* crimſon.

T. *quadratulum*. Little Square-leaved Germander. Schreb. Vertic. Unilab. 36. Willd. n. 13. Sm. Fl. Græc. Sibth. t. 530, unpubliſhed. (T. ramoſiſſimum; Desfont. Atlant. v. 2. 4. t. 118.)—Leaves obovate-rhomboid, deeply toothed; cottony beneath. Flowers axillary, ſolitary, deflexed. Calyx woolly.—Native of fiſſures of rocks, in Spain, Barbary, and Crete. A ſmall, decumbent, branching *ſhrub*, whoſe *leaves* are not half an inch long; green above; white beneath. *Flowers* pink, their *calyx* bent down, ſo as to make a right angle with its *footſtalk*, and then recurved. Segments of the upper lip of the *corolla* advanced towards thoſe of the lower in a remarkable degree. *Style* reflexed.

T. *Laxmanni*. Laxmann's Germander. Linn. Syſt. Veg. ed. 13. 439. Willd. n. 16. Ait. n. 10. Marſch. von Bieberſt. Taur. v. 2. 35. "Waldſt. and Kitaib. Hung. v. 1. 71. t. 69."—Leaves elliptic-oblong, villous, ribbed, nearly entire. Flowers axillary, ſolitary, oppoſite, turned one way.—Native of Siberia, Hungary, &c. We notice this ſpecies here merely to expreſs our concurrence with the opinion of the able author of the Flora Taurico-Caucaſica above cited, that it certainly belongs to *Ajuga*, as well as the *T. ſalicifolium*, Linn. Mant. 80, already referred thither by Schreber and Willdenow. The two ſpecies are very nearly akin, and anſwer in character and habit entirely to *Ajuga*, and not to *Teucrium*.

T. *Arduini.* Arduino's Germander. Linn. Mant. 81. Willd. n. 20. Sm. Fl. Græc. Sibth. t. 531, unpubliſhed. (T. foliis ovato-crenatis, ſubhirſutis, petiolatis, caulibus ſpicâ flaveſcente piloſâ terminatis; Arduin. Spec. 1. 12. t. 3. Scutellaria cretica; Linn. Sp. Pl. 836. Willd. Sp. Pl. v. 3. 176. Ait. Hort. Kew. v. 3. 429. Caſſida cretica fruticoſa, catariæ folio, flore albo; Tourn. Cor. 11.)—Leaves ovate, ſerrated, hairy. Cluſters denſely imbricated, cylindrical, with linear bracteas, longer than the flowers. Upper ſegment of the calyx dilated, heart-ſhaped; two loweſt ſetaceous.—Native of Crete, and of the ſhady woods of the Bithynian Olympus. It appears to have been cultivated by Miller in 1729. Although Linnæus, in referring this plant, after Tournefort, to *Scutellaria*, perceived it to be a *Teucrium*, neither he nor any one elſe, till lately, ſuſpected it to be deſcribed twice over in his works. This we diſcovered by a compariſon of original ſpecimens. The *ſtem* is herbaceous, not ſhrubby, ſquare, croſs-branched, leafy, rough with ſpreading hairs. *Leaves* ſtalked, not unlike thoſe of Balm in ſize, form, and colour. *Cluſters* from one to four inches long, near an inch in diameter, ſolitary at the ends of the branches, erect, of innumerable crowded white *flowers*. The *calyx* is hairy, ſuddenly bent downwards at its taper baſe, then horizontal, its border very unequally five-cleft; the upper ſegment broad, as in *Scutellaria*, reflexed at the ſides, tipped with a briſtle; two next ſhort, triangular; two loweſt long, narrow, with pungent points.

T. *canadenſe.* Nettle-leaved Hoary Germander. Linn. Sp. Pl. 789. Willd. n. 21. Ait. n. 13. Purſh n. 1. (Chamædrys canadenſis, urticæ folio, ſubtùs incano; Tourn. Inſt. 205.)—Leaves ovato-lanceolate, ſtalked, ſharply ſerrated, downy on both ſides; hoary beneath. Cluſter terminal, denſe, ſomewhat whorled. Bracteas ovate, ſhorter than the flowers. Segments of the calyx nearly equal.—In low grounds, on the borders of ponds and lakes, from Canada to New York, perennial, flowering in July and Auguſt. The habit of the *leaves* and *infloreſcence* is like that of ſome ſpiked *Veronica*. At the inſertion of each pair of *footſtalks*, the *ſtem* is ſurrounded with a ring of prominent hairs. The *calyx* is bell-ſhaped, with five broad, nearly equal, ſegments. *Corolla* purple.

T. *virginicum.* Viginian Germander. Linn. Sp. Pl. 789. Willd. n. 22. Ait. n. 14. Purſh n. 2. "Schkuhr Handb. t. 160." (T. virginianum meliſſophyllon, floribus cæruleis; Pluk. Almag. 363. Phyt. t. 318. f. 1; with a very faulty repreſentation of the corolla.)—Leaves ovate-oblong, ſerrated, downy; the upper ones ſeſſile. Spikes crowded, whorled. Bracteas the length of the calyx.—In low grounds and bogs, from New York to Carolina, perennial, flowering from June to Auguſt. It very much reſembles the laſt. *Purſh.*—Miller is ſaid to have cultivated both theſe North American ſpecies in 1768. We have ſeen only the former.

T. *abutiloides.* Mulberry-leaved Germander. L'Herit. Stirp. v. 1. 84. Willd. n. 27. Ait. n. 17. Jacq. Hort. Schoenbr. v. 3. 58. t. 358.—Leaves heart-ſhaped, acute, crenate, downy. Cluſters axillary, not longer than the footſtalks.—Diſcovered by Mr. Maſſon in Madeira, from whence it was brought to Kew, in 1777. It flowers in the greenhouſe in April and May, and is conſpicuous for the large ſize of its *leaves*, four or five inches long, on denſely downy *footſtalks*, half that length. The *flowers* are no leſs remarkable for their golden hue, and their ſituation in denſe, ſolitary, lateral, ſtalked *cluſters*, which rarely equal the footſtalks in length.

T. *Scorodonia.* Wood Germander, or Wood Sage. Linn. Sp. Pl. 789. Willd. n. 28. Fl. Brit. n. 1. Engl. Bot. t. 1543. Curt. Lond. faſc. 5. t. 40. Fl. Dan. t. 485. (Scorodonia; Rivin. Monop. Irr. t. 12. S. ſive Salvia agreſtis; Ger. Em. 662.)—Leaves heart-ſhaped, ſerrated, ſtalked, hairy. Stem erect. Flowers leaning to one ſide, in lateral and terminal cluſters.—Very common in dry heathy ground, and ſandy woods, throughout Europe, from Norway to Greece, flowering in July and Auguſt. Linnæus ſeems to have recollected this plant with delight in the fields of Hartecamp, where the garden of his friend Cliffort had been to him a real paradiſe. The *root* is creeping and perennial. *Herb* a foot or two in height, dark green, hairy, bitter, with a ſtrong ſcent like hops, for which it is ſaid to be not a bad ſubſtitute in brewing. We wiſh nothing worſe had ever been uſed. The long aggregate cluſters of *flowers* are rendered conſpicuous by the contraſt of the pale yellow *corolla* and purple *ſtamens*. The upper ſegment of the *calyx* approaches in form and breadth to what we have pointed out as ſo remarkable in *T. Arduini.*

T. *betonicum.* Hoary Germander. Ait. ed. 1. v. 2. 279. ed. 2. n. 19. Willd. n. 30. L'Herit. Stirp. v. 1. 83. t. 40. Curt. Mag. t. 1114. (T. betonicæfolium; Jacq. Coll. v. 1. 145. t. 17. f. 2.)—Leaves ovato-lanceolate, bluntly ſerrated, ſtalked, ſoft and downy; hoary beneath. Stem ſhrubby. Cluſters aggregate, terminal. Bracteas lanceolate, entire. Native of Madeira. A very handſome greenhouſe ſhrub, introduced by ſir Joſeph Banks, in 1775, flowering moſt part of the ſummer, and eaſily propagated by cuttings. The crimſon *flowers* are elegantly contraſted with the hoarineſs of the herbage; the upper ſurface of the *leaves* being greener than the reſt. The ſegments of the upper lip of the *corolla* being broader and blunter than uſual, ſome doubts have been ſtarted whether this ſpecies belonged to *Teucrium* or to *Ajuga*, or whether theſe genera were really diſtinct. To this we would anſwer, that the habit of the latter is peculiar, and its eſſential character no leſs clear, conſiſting in a ſhort notched *upper lip*, inſtead of the remotely-lobed one of *Teucrium*. We believe moreover that the central lobe of the lower lip is always divided and divaricated in *Ajuga*.

T. *maſſilienſe.* Apple-ſcented Germander. Linn. Sp. Pl. 789. Willd. n. 32. Ait. n. 21. Jacq. Hort. Vind. v. 1. 41. t. 94. (T. n. 6; Gerard. Gallopr. 277. t. 11.)—Leaves ovate, rugged, hoary, ſtrongly crenate. Stem erect. Flowers turned to one ſide, in lateral and terminal, upright cluſters.—Native of the iſles of Hyeres, but ſcarcely known in any other country, nor is it often to be ſeen in gardens. The *ſtems* are a foot high. *Leaves* ſtalked, bluntiſh, hardly an inch long. *Flowers* ſmall, light crimſon. Upper ſegment of the *calyx* broad-ovate. The whole *herb* is clothed with a hoary, ſoft, velvet-like pubeſcence, and when touched exhales a very powerful and peculiar ſcent, like mellow apples, and therefore, to many people, not agreeable, though combined with a ſpicy fragrance. Gerard's plate, like the others in his book, is very finely executed.

T. *Scordium.* Water Germander. Linn. Sp. Pl. 790. Willd. n. 34. Fl. Brit. n. 2. Engl. Bot. t. 828. Woodv. Med. Bot. t. 57. Fl. Dan. t. 593. (Scordium; Rivin. Monop. Irr. t. 11. Ger. Em. 661.)—Leaves oblong, ſeſſile, with tooth-like ſerratures. Flowers axillary, ſtalked, in pairs. Stem procumbent.—Native of marſhy places in various parts of Europe, but rare in England, except in the Iſle of Ely. It appears to be the true σκορδιον of Dioſcorides, retaining a ſimilar appellation, among the modern Greeks, and occurring, as Dr. Sibthorp obſerved, in Crete, Zante, and Aſia Minor. The *root* is perennial and creeping. *Herb* decumbent or proſtrate, hairy, and ſomewhat hoary, very bitter, with a ſtrong, unpleaſant, garlic-like ſcent. *Flowers* pale purple, in oppoſite pairs, from the boſoms of moſt of the

the *leaves*. This herb has formerly been celebrated for its deobſtruent and tonic qualities, but is now out of medical uſe, except perhaps in the receſſes of the country.

T. *ſcordioides* of Schreber, Willd. n. 35, ſeems to us, without doubt, a variety of the laſt, as it is made in Prodr. Fl. Græc. v. 1. 393.

T. *Chamædrys*. Wall Germander. Linn. Sp. Pl. 790. Willd. n. 36. Fl. Brit. n. 3. Engl. Bot. t. 680. Woodv. Suppl. t. 243. (Chamædrys; Rivin. Monop. Irr. t. 10. f. 2. Tourn. Inſt. t. 97; a much better figure. C. major latifolia; Ger. Em. 656.)—Leaves nearly ovate, ſtalked, deeply crenate. Flowers axillary, three together, ſtalked. Stem round, hairy.—Found on dry rocks and old walls in the more temperate or warm countries of Europe. It is abundant on the old city wall, on the north ſide of Norwich, as well as here and there in other parts of England, but not univerſally. Dr. Sibthorp obſerved the plant in dry ſtony places, throughout Greece and the iſles of the Archipelago, where it ſtill retains nearly the ſame appellation of χαμαιδρυς, recorded in Dioſcorides. It flowers in July and Auguſt, and has a perennial creeping *root*. The *ſtem* is buſhy, rather diffuſe, and ſlightly ſhrubby, a ſpan high. *Leaves* of a full ſhining green, ſlightly hairy, deeply crenate and cut. *Flowers* crimſon, numerous, more handſome than thoſe of *T. Scordium*, with which ſpecies the preſent has been ſuppoſed nearly to agree in virtues. It is equally bitter, but more agreeably, though leſs powerfully, ſcented.

T. *lucidum*. Shining Germander. Linn. Sp. Pl. 790. Willd. n. 39. Ait. n. 25. Sm. Fl. Græc. Sibth. t. 532, unpubl. (Chamædrys alpina fruteſcens, folio ſplendente; Tourn. Inſt. 205. Magnol. Hort. 52. t. 9.)—Leaves ovate, ſtalked, deeply crenate, ſmooth and ſhining. Flowers axillary, three together, ſtalked. Stem ſquare, erect, nearly ſmooth. —Native of alpine vallies in Savoy and Provence. Found by Dr. Sibthorp on Parnaſſus, and other Grecian mountains, as well as in the iſland of Cyprus. The tall, erect, ſquare *ſtems*, often quite ſmooth; numerous whorls of large crimſon *flowers*; and ſhining *leaves*, of which the upper or floral ones are more numerouſly quite entire; all render this plant, at firſt ſight, decidedly different from the laſt, and yet they are very nearly related, ſo that an eſſential difference is difficult to ſeize, and perhaps none that has yet been indicated is invariably conſtant.

T. *flavum*. Yellow Shrubby Germander. Linn. Sp. Pl. 791. Willd. n. 41. Ait. n. 26. Sm. Fl. Græc. Sibth. t. 533, unpubl. (Teucrium; Rivin. Monop. Irr. t. 10. f. 1. Chamædrys fruteſcens major, floribus ochroleucis; Moriſ. ſect. 11. t. 22. f. 1.)—Leaves ovate, crenate, downy. Whorls ſix-flowered, compoſing terminal cluſters, with ovate, concave, entire bracteas. Stem ſhrubby, downy. —Native of rocks and old walls, in the ſouth of Europe, and north of Africa; abundant in the Archipelago, and on the walls of Rome. The *ſtem* is woody, branched, erect, about two feet high; its *branches* leafy, bluntly quadrangular, clothed with very ſoft, velvet-like, curved pubeſcence, as is the whole of the herbage. *Leaves* ſtalked, hardly an inch long; tapering and entire at the baſe. *Flowers* pale yellow, compoſing long, whorled, erect *cluſters*, with pale-green *bracteas*, about equal to the *calyx*. The teeth of the latter are nearly equal. Upper ſegments of the *corolla* edged with red.

T. *bicolor*. Two-coloured Chili Germander. (T. heterophyllum; Cavan. Ic. v. 6. 56. t. 577.)—Leaves wedge-ſhaped, obtuſe; undivided or cut. Flowers axillary, ſolitary. Calyx nearly regular, with ten ſtrong ribs.—Gathered by Louis Née, in the neighbourhood of Talcahuano, in Chili, flowering in November and December. We have a wild ſpecimen from the late abbé Cavanilles, whoſe ſpecific name we are obliged to change, there being already a *T. heterophyllum*, Willd. n. 37. The *ſtem* is ſhrubby, almoſt ſix feet high, with ſquare leafy *branches*, clothed, like the *calyx*, *ſtalks*, and under ſide of the foliage, with very ſhort denſe pubeſcence. The *leaves* are about an inch long, nearly ſmooth on the upper ſide, various in breadth; the broadeſt deeply and coarſely cut; the reſt undivided and entire; the lower ones on ſhort ſtalks; the upper ſeſſile. *Flowers* from the boſoms of the upper leaves, on ſhortiſh, round, finely downy ſtalks. *Calyx* cut almoſt half way down into five, nearly equal, acute, ovato-lanceolate ſegments, each with a ſtrong mid-rib; its tube having five intermediate ribs beſides. *Corolla* externally hairy, white, the middle of its lower lip of a violet red.

T. *montanum*. Dwarf Mountain Germander. Linn. Sp. Pl. 791. Willd. n. 42. Ait. n. 27. Sm. Fl. Græc. Sibth. t. 534, unpubliſhed. (Ajuga folio integro; Rivin. Monop. Irr. t. 15. Polium ſeptimum; Cluſ. Hiſt. v. 1. 363. f. 1, 2. P. lavandulæ folio; Ger. Em. 655. f. 2, 3.)

β. T. ſupinum. Linn. Sp. Pl. 791. Willd. n. 43. Ait. n. 28. Jacq. Auſtr. t. 417. (P. montanum octavum; Cluſ. Hiſt. v. 1. 363. P. montanum minimum; Ger. Em. 655.)

Corymbs terminal. Leaves linear-lanceolate, ſomewhat revolute, almoſt entire; cottony beneath. Calyx reticulated, ten-ribbed, ſlightly downy, with ſpinous teeth.—Native of dry mountainous or alpine ſituations, in Germany, Switzerland, France, Spain, and Greece; ſometimes, though rarely, preſerved in pots, under a frame, in our more curious gardens. A dwarf buſhy *ſhrub*, like Thyme, with a ſtrong woody *root*, and many diffuſe, downy, leafy *ſtems*. *Leaves* crowded, oppoſite, ſtalked, hardly an inch long, very rarely notched, various in breadth; green, convex, and nearly ſmooth, above; veiny, very white and cottony, beneath. *Flowers* in denſe, ſeſſile, ſolitary corymbs. *Calyx* tubular, pale, with equal, ſpreading, tapering, pungent teeth, from whoſe intermediate ſinuſes the veins ſpread ſtar-wiſe. *Corolla* pale buff-coloured, the ſegments of its upper lip veined with red.

Schreber has long ago united *T. montanum* and *ſupinum*; nor was Linnæus ignorant of their near affinity; though in this inſtance, as in every thing relative to alpine plants of the ſouth of Europe, which he had rarely examined alive, he was diſpoſed to give up his own opinion, to that of practical obſervers. Cluſius having repreſented *T. ſupinum* ſo different in ſize and habit from *montanum*, might help to miſlead following botaniſts; but in truth they hardly deſerve to be diſtinguiſhed as varieties, *ſupinum* being only rather leſs luxuriant, with narrower *leaves*, which indeed vary on the very ſame root. The ſpecies before us has lent a ſpecific name to ſome other plants, as *Andromeda polifolia* of Linnæus, and *Menzieſia polifolia* of Juſſieu, which have no ſimilitude to the true ancient *Polium* hereafter deſcribed, but greatly reſemble this.

T. *pyrenaicum*. Pyrenean Germander. Linn. Sp. Pl. 791. Willd. n. 45. Ait. n. 29.—Corymbs terminal. Leaves orbicular, crenate, hairy; entire and ſlightly wedge-ſhaped at the baſe. Calyx-teeth tapering, fringed.—Native of the Pyrenées. Cultivated by Miller in 1731, at Chelſea garden, where we have ſeen it a few years ſince, yet there ſeems to be no certain figure of this beautiful plant extant. Its habit is ſomewhat like the laſt, but the *leaves* totally different, being almoſt orbicular, and from half an inch to an inch in diameter, flat, green, veiny and hairy. *Flowers* in denſe convex tufts, variegated with pale yellow and purple; the ribs and teeth of the *calyx* fringed with long briſtly hairs.

Whether

Whether Schreber's *T. rotundifolium*, Willd. n. 46, to which the figures of Boccone and Barrelier, cited for the former, are faid to belong, be more than a variety, we have no means of determining.

T. *Polium.* White Poley Germander. Linn. Sp. Pl. 792. Willd. n. 52. Ait. n. 31, Sm. Fl. Græc. Sibth. t. 535, unpublifhed. (T. Teuthrion; Schreb. Unilab. 46. Polium montanum; Ger. Em. 653, 654. P. montanum album ferratum, &c.; Barrel. Ic. t. 1074.)—Heads roundifh, leafy. Leaves feffile, oblong, obtufe, convex, bluntly crenate, denfely woolly. Calyx very woolly, obtufe, pointlefs.—Native of mountains in Italy, Spain, and the fouth of France; very common in Greece, the Archipelago, and throughout the Levant; rarely feen in our gardens, being impatient of wet. The *root* is woody and very ftrong. *Stems* numerous, a fpan long, afcending, erect, or partly decumbent, round, clothed, like the reft of the herbage, with extremely foft, white, woolly down. *Leaves* numerous, oppofite, half an inch or an inch long, thick and woolly, their edges remarkably deflexed, with ftrong, round, recurved teeth; the bafe flightly wedge-fhaped, fcarcely ftalked. *Flowers* numerous, in denfe, feffile, terminal, often aggregate, heads, or fhort fpikes, intermixed with leaves; the lower heads ufually ftalked. *Calyx* very woolly and obtufe. *Corolla* white, with a yellow palate.

Schreber, who is followed by Willdenow, makes numerous fpecies out of the reputed varieties of this plant, of which we are unable, for want of fufficient means of examination, to form an opinion. The characters given do not fatisfy us, nor do the fpecimens we have feen afford better.

The moft ftriking of the whole is *T. aureum*, Schreb. Unilab. 43. Willd. n. 48. Ait. n. 30. Cavan. Ic. v. 2. 16. t. 17, remarkable for the golden tint on its heads and upper leaves. This has ufually a folitary head or fpike, and perhaps the *calyx-teeth* are more flender and acute than in the common *T. Polium*, which merits inquiry. On the other hand, *T. capitatum*, which we fhall next defcribe, approaches nearly to fome of the above-mentioned varieties, fo that perhaps they ought to be referred to it, rather than to *Polium*.

T. *capitatum.* Purple Poley Germander. Linn. Sp. Pl. 792. Willd. n. 56. Ait. n. 32. Cavan. Ic. v. 2. 17. t. 119. Sm. Fl. Græc. Sibth. t. 536, unpublifhed. (Polium monfpeffulanum; Bauh. Hift. v. 3. 299.)—Heads roundifh, leafy, lateral and terminal, ftalked. Stem crofs-branched. Leaves feffile, linear-oblong, obtufe, convex, crenate, hoary. Calyx woolly, oblong, obtufe, pointlefs.—Native of hills in Siberia, Spain, the fouth of France, Zante, Cyprus, and Greece. This is of a more flender habit than the laft, lefs woolly, and more hoary, with purple *flowers*, a more elongated tubular *calyx*, and narrower *leaves*. The tube of the *corolla* alfo is longer, and much lefs bell-fhaped, or inflated in the throat. It is nearly related to *T. Polium*, but furely a diftinct fpecies.

T. *cuneifolium.* Wedge-leaved Poley Germander. Sm. Prodr. Fl. Græc. Sibth. n. 1311. Fl. Græc. t. 537, unpublifhed.—Heads terminal, denfe. Leaves rounded, deeply crenate; wedge-fhaped at the bafe; woolly all over. Calyx blunt, pointlefs.—Gathered by Dr. Sibthorp, on the Sphaciote mountains of Crete. The general outline of the plant anfwers to *T. rotundifolium*, Willd. n. 46; but that is a far lefs woolly plant, with a pointed *calyx*, and not allied to the *Polium* tribe. The prefent has round, trailing, fhrubby, crofs-branched *ftems*, a foot or more in length. Every part of the herbage is covered with thick, white, foft, woolly or velvetty down. *Leaves*, with their ftalks, an inch long. *Flowers* fnow-white, in aggregate terminal heads. *Calyx* tubular, with fhort rounded teeth. Segments of the upper lip of the *corolla* large, as long as the *ftamens*, which they embrace, and partly conceal. *Anthers* red.

T. *alpeftre.* Sharp-toothed Alpine Poley Germander. Sm. Prodr. Fl. Græc. Sibth. n. 1312. Fl. Græc. t. 538, unpublifhed.—Flowers axillary, folitary. Leaves wedge-fhaped, rounded, deeply crenate, downy. Stem tufted, much branched.—Found by Dr. Sibthorp, upon the moft lofty fummits of the Spachiote mountains of Crete. The *root* is woody, dividing at the crown into innumerable ftrong, woody, depreffed *ftems*, which bear a denfe tuft of afcending, leafy, downy *branches*, hardly a finger's length. *Leaves* ftalked, greyifh, about half an inch long, obtufe. *Flowers* oppofite, on fhort ftalks, from the bofoms of two or three of the uppermoft pair of leaves. *Calyx* tubular, finely downy. Tube, throat, and upper lip of the *corolla*, pale yellow; lower lip white, its middle fegment deeply concave.

T. *pumilum.* Rofemary-leaved Poley Germander. Linn. Sp. Pl. 792. Willd. n. 61. (Polium montanum pumilum rubrum; Barrel. Ic. t. 1092, 1093.)—Heads terminal, folitary, feffile, leafy. Leaves crowded, feffile, linear, revolute, fmooth; downy beneath. Stems afcending, woolly. Calyx pointed.—Native of hills in Spain, flowering in July and Auguft.—From the woody perennial *root*, fpring feveral, more or lefs erect, fimple or branched, leafy *ftems*, three or four inches long, clothed with denfe, foft, white wool. The *leaves* are hardly an inch long, crowded and fomewhat imbricated, in four rows, narrow, ftrongly revolute, obtufe; convex, green and polifhed on the upper fide; concave, with a downy rib, juft vifible beneath. *Calyx* ribbed, downy, with fhort, thick, fpinous points. Tube of the *corolla* flender, downy, as well as the outfide of the limb.

We are quite unable to imagine how *T. Libanitis* of Schreber, Willd. n. 60. Cavan. Ic. v. 2. 17. t. 118, came to be diftinguifhed from *pumilum*, as there does not appear to be the leaft difference between them, except the *ftem* of *Libanitis* being more erect; but that circumftance is evidently variable. *T. verticillatum*, Cavan. t. 198. Willd. n. 59, feems alfo but a variety; though we prefume not to determine this without feeing a fpecimen.

T. *fpinofum.* Thorny Germander. Linn. Sp. Pl. 793. Willd. n. 64. Ait. n. 33. Sm. Fl. Græc. Sibth. t. 539, unpublifhed. (Chamædrys fpinofa; Bauh. Prodr. 117. Scordium fpinofum odoratum; Cornut. Canad. 123. t. 124. Barrel. Ic. t. 202. S. fpinofum; Cavan. Ic. v. 1. 19. t. 31.)—Stem and branches fpinous, hairy. Flowers axillary, oppofite. Upper fegment of the calyx ovate; the reft awl-fhaped, fpinous.—Native of fields and hilly places in Spain and Portugal. Dr. Sibthorp met with it in fields between Smyrna and Burfa. The *root* is annual. *Stem* branched copioufly from the very bottom, about a foot high, bufhy, the *branches* oppofite, croffing each other in pairs, fpreading, fquare, clothed with very foft prominent hairs, tipped with ftrong fpines, and furnifhed with fmaller lateral ones, particularly at the infertion of the leaves and flowers. *Leaves* feffile, deflexed, fmall, oblong, obtufe, notched, green, hairy. *Flowers* numerous, folitary or in pairs, from the bofoms of the diminifhed or upper leaves, each on a fhort, round, hairy *ftalk*. *Calyx* deflexed and bent at the bafe, then horizontal and fomewhat bell-fhaped; its upper fegment very broad, ribbed, fpinous-pointed, erect, or rather reflexed, the four others fhorter, prominent, afcending, pungent. *Corolla* white, with red ftripes on its upper lip; the middle fegment of the lower very large, flightly concave; the bafe of the tube globular.—The *flowers* are by no means reverfed, *refupinati*, in Sibthorp's figure of this fpecies, though

Lœfling

Lœfling fo defcribes them, and led Linnæus to adopt that character. His *T. mucronatum*, Sp. Pl. 793, differs in no refpect from the *fpinofum*, to which therefore we have transferred its fynonyms.

TEUCRIUM, in *Gardening*, furnifhes plants of the underfhrubby and herbaceous kinds, among the great number of which, the fpecies following are the moft generally cultivated: the yellow-flowered fhrubby germander (T. flavum); the fage-leaved germander, or wood-fage (T. fcorodonia); ths nettle-leaved germander (T. canadenfe); the dwarf mountain germander (T. montanum); the Pyrenean germander (T. pyrenaicum); the poley (T. polium); the round-headed germander (T. capitatum); the dwarf germander (T. pumilum); the narrow-leaved tree-germander (T. fruticans); the broad-leaved tree-germander (T. latifolium); the Cretan germander (T. creticum); and the common marum or cat-thyme (T. marum).

There is a variety in the firft fort which is hairy, with yellow flowers, with pale white flowers, and with purple flowers.

In the fourth fort there is likewife a variety with much fmaller leaves, which are hoary on their under fide.

Alfo in the fixth fort there are feveral varieties; as the common yellow poley, which has the ftalks rather herbaceous and trailing, about fix inches long, and hoary: leaves woolly, about half an inch long, fome wedge-fhaped, others oblong, ending in obtufe points, and crenate towards their ends: the flowers collected in oblong thick fpikes at the end of the branches, of a deep yellow colour, and appearing at the beginning of June. This grows naturally in Spain. The narrow-leaved yellow poley, which has woody ftalks, erect, branching, and covered with a hoary down, rifing fix or eight inches high; the leaves linear, woolly, about half an inch long, having fometimes two or three flight indentures on their edges; the flowers collected in roundifh fpikes at the end of the branches; they are bright yellow, have woolly calyces, and appear in June and July. It grows naturally in Spain and Portugal. The white poley, which has the ftems a foot long, and trailing: the leaves are a little cottony, entire on the fides, but toothed at the end: the flowers are pretty large, white, tinged a little with purple. It is a native of the fouth of France. There is alfo the purple poley.

And there is a variety in the feventh fort which has an erect branching ftalk, that rifes a foot high; the lower part becomes woody, but the upper is herbaceous: the leaves are linear-lanceolate, about an inch long, crenate, of a pretty thick confiftence, and a little woolly: the flowers collected in a corymb at the end of the branches, white, appearing in July and Auguft.

The ninth contains a variety which is a little more branched, and has fmaller fhorter leaves: the flowers are paler, the ftamens fomewhat longer, the anthers fmaller and brown; whereas in the larger fort they are violet: and another with variegated leaves.

Method of Culture.—All the herbaceous and ligneous kinds may be readily increafed by parting the roots, by flips of the young branches, and feeds: the roots may be divided in the autumn, or early fpring, and the flips of the branches be taken off in the fpring and fummer, being planted out in moift fhady fituations, and well rooted, they may be removed to where they are to remain, though it is beft to plant them at once where they are to grow: the feeds may be fown in a bed or border of common earth in the early fpring feafon.

But in the polium kinds, the feeds fhould be fown in a bed of light earth, and the plants be either put out in nurfery-rows, or fet where they are to remain, in the latter end of fummer.

The fhrubby forts may likewife be increafed by flips or cuttings of the young fhoots of the branches, which fhould be planted in pots filled with light mould, in the fpring and fummer months, in order to be removed under the protection of the greenhoufe in winter, being afterwards managed as other greenhoufe exotics.

Thefe plants are all of the perennial kind, and fome of them are durable in the ftems and branches for feveral years.

The firft forts afford variety in the borders, &c. and the latter in affemblage with greenhoufe plants.

TEUDERIUM, in *Ancient Geography*, a town of Germany, in the vicinity of Bogadium and Mediolanium. Ptolemy.

TEVENDEZ, in *Geography*, a mountain in the S.E. part of Fez; being part of the Atlas.

TEVERONE, a river of Italy, which joins the Tiber near Rome.

TEVESAR, a town on the W. coaft of the ifland of Celebes. S. lat. 2° 2′. E. long. 119° 21′.

TEUFFEL'S BRUCK, or *Devil's Bridge*, a bridge over the Reufs, formed of a fingle arch, about twenty-two feet radius, fupported by two rocky peaks, nearly perpendicular, between which the river runs at the depth of fome hundred feet; 3 miles from Urferen.

TEUFFEN, a town of Switzerland, in the canton of Appenzel; 6 miles N.N.W. of Appenzel.

TEUFING, or TAUZIM, a town of Bohemia, in the circle of Pilfen; 22 miles N.W. of Pilfen. N. lat. 50° 2′. E. long. 13° 5′.

TEUGA, in *Botany*, the name given in the Hortus Malabaricus to a genus of plants, called by Linnæus and others *coccus*.

TEUGLASSA, in *Ancient Geography*, an ifland which Thucydides feems to place on the coaft of Afia Minor, in the neighbourhood of the Doride.

TEVIN, in *Geography*, a town of Perfian Armenia, on a fmall river which runs into the Aras; 15 miles S.E. of Erivan.

TEUKE, a town of Perfia, in the province of Khoraffan; 32 miles E. of Tabas-kileki.

TEUMES, in *Ancient Geography*, a river of Greece, in Bœotia, which watered the town of Thebes, according to Hefychius.

TEUMESSUS, a borough of Bœotia, upon a mountain E. of Thebes, and near a fmall river called Thermodon. Here was a temple of Diana Telchinia. It was notorious for the fuperftitious credulity of its inhabitants.—Alfo, a mountain of Greece, in Bœotia.

TEVO, ZACCARIA, in *Biography*, author of an ample treatife on mufic, written in Italian, and publifhed at Venice, in fmall quarto, 1706, entitled "Il Mufico Teftore;" (*teftore* literally means a weaver; but metaphorically, a compofer, an author;) the mufician's *text*, or guide. The work is divided into four parts, twenty chapters in each, the titles of which are very promifing; but his ftyle is not very pleafant, nor are his definitions or inftructions very fatisfactory. The author had read much, but his digeftion was not fo good as his appetite. He fwallowed, without due maftication, all the old ftories about the invention and miraculous powers of mufic. He affigns to Orpheus, the fon of Apollo, the invention of the violin, and to Sappho that of the bow; affuring us that fhe was the firft who ufed it in the prefent manner! He not only finds the inventor of every species of instrument, but the time when and place where it was first constructed. There is little science, and still less ingenuity, in the examples of composition given in illustration of the rules of counterpoint: so that if the young student, who peruses this work for instruction, is not a conjurer before he begins the task, he will not be made one by the mysteries which it unfolds.

Yet with patient perseverance, a young student who has little leisure, and few books to read, may become superficially learned with little trouble by this book. Tevo quotes authority for all that he advances; but his authorities are not always good, nor does he distinguish good from bad. Several obscure and even contemptible authors are quoted in the same solemn manner as the best. But in citing so many writers indiscriminately, the chief part are now so scarce and difficult to be found, that in search of them all the great libraries of Europe may be visited in vain. To save the student's time, and form his taste in literature, as well as judgment in music, the author should have quoted none but writers of the first authority, or have told his young readers what stress was to be laid on the rest.

But since the time of Tevo, so many better authorities in composition and didactic works, both on the theory and practice of music, have appeared, that we can hardly recommend the "Musico Testore" to the perusal of any but those who have much time to spare, who read every thing, and are curious to know the history and state of the art at every period of time.

TEUOCHIS, in *Ancient Geography*, a lake and town of Egypt.

TEVOEN-SOUSON, in *Geography*, a town of Chinese Tartary; 12 miles N.W. of Teldom.

TEUPITZ, a town of Brandenburg, in the Middle Mark, on a lake; 20 miles S. of Berlin. N. lat. 52° 5′. E. long. 13° 30′.

TEURERT, or TEVRERT, a town of Fez, on the borders of Algiers; 40 miles E.N.E. of Teza. N. lat. 34° 2′. W. long. 3° 30′.

TEURISCI, in *Ancient Geography*, a people placed by Ptolemy in the northern part of Dacia, between the Anerti and the Cistoboci.

TEURISTÆ, a people of Germany, placed by Strabo in the vicinity of the Danube and the Alps.

TEURNIA, a town of Norica, S. of the Danube, between Virunum and Idunum. Ptol. and Plin.

TEURTEVILLE, in *Geography*, a town of France, in the department of the Channel; 6 miles N. of Valognes.

TEUSCHNITZ, a town of Bavaria, in the bishopric of Bamberg; 34 miles N.E. of Bamberg. N. lat. 50° 23′. E. long. 11° 30′.

TEUSHANUSHSOUGGOGHTA, an Indian town of Pennsylvania, on the Alleghany river.

TEUTATES, in *Mythology*, a name or attribute of the Supreme Being, which was worshipped by the Gauls and Britons as a particular divinity. It is evidently compounded of the two British words "Deu-tatt," which signify God the parent or creator, a name properly due only to the one true God, who was originally intended by that name. Thus Lucan, l. i. v. 445.

> "Et quibus immitis placetur sanguine divo
> Teutates; horransque feris altaribus Hesus."

When these ancient nations sunk into idolatry, they degraded Teutates into the sovereign of the infernal world, the same with the Dis and Pluto of the Greeks and Romans (or, as others think, with Mercury); and worshipped him in such a manner as could be agreeable to none but an infernal power.

TEUTHEA, in *Ancient Geography*, a considerable town of the Peloponnesus, in Achaia, W. of Tritæa.

TEUTHIS, a town of the Peloponnesus, in Arcadia, in which were a temple of Venus, and another of Diana.

TEUTHIS, in the Linnæan system of *Ichthyology*, a genus of the abdominal fishes; the characters of which are, that the head is a little truncated on the fore-part; that the branchiostege membrane has five rays; and that the teeth are equal, rigid, and near each other, and forming a regular chain. Linnæus and Gmelin mention two species; *viz. hepatus*, and *javus* or *java*. This genus is now annulled, and the species are transferred to Acanthurus and Chætodon.

HEPATUS; Acanthurus Teuthis; Blue Acanthurus. With the middle of the body paler, and a spine on each side of the tail. This is a native of the Indian and American seas, ten or twelve inches long, or more; resembling in shape the chætodons, the head sloping in front from the origin of the dorsal fin; the colour, when recent, a deep or blackish-blue; on each side of the body is a very large, oblong-ovate whitish patch or spot, surrounded by a border of a deeper cast; the skin is roughened by very small scales; the tail is slightly lunated, dusky on the upper and lower part, and marked towards the base by a whitish ovate spot; the teeth are crenated; and on each side of the base of the tail is a very strong spine, capable of elevation at the animal's pleasure, to an horizontal direction, from the channel in which it lies. The fish figured by Catesby in his Natural History of Carolina, under the name of *Teng*, is supposed to be this species.

JAVA or JAVUS; Chætodon Guttatus. Whitish-grey, with oblong body, sprinkled with very numerous, round, rufous spots; length about ten or twelve inches; colour grey, with a dusky tinge on the upper parts, and every where sprinkled, except on the head, pectoral, ventral, dorsal and anal fins, with numerous, small, round, rufous spots; scales small, none at the bases of the fins; gill-covers smooth; dorsal and anal fin of moderate breadth; tail slightly inclining to a forked, or rather lunated shape, and speckled like the body. Native of Java. This species is supposed by Bloch and Cepede to be the *teuthis javus* of Linnæus. But Dr. Shaw remarks, that Linnæus's description does not agree in the disposition of its colours with those of the C. guttatus, as it is expressly said to be marked with longitudinal streaks: so it is figured by Gronovius. See CHÆTODON *Guttatus*, changing Japan in the close of that article to Java.

TEUTHOPHACE, a word used by the ancients to express a sort of food made of beet-roots and lentils, often prescribed as a good diet for the sick.

TEUTHRANIA, in *Ancient Geography*, a town and small country of Mysia, situated towards the E., and near the source of the Caicus. Herodotus says that it was once a gulf, and it was gradually formed by the accumulation occasioned by the Caicus.

TEUTHRONA, a town of Laconia, in a small bay, on the Laconic gulf, N.E. of Pyrrhicus.

TEUTLAN, in *Geography*, a town of Mexico, in the province of Guadalajara; 50 miles N.N.W. of Guadalajara.

TEUTLEBEN, a town of Germany, in the principality of Gotha; 4 miles W. of Gotha.

TEUTONES, in *Ancient Geography*, a people of Germany, who at the time when the Romans became acquainted with them, were politically connected with the Cimbri, if they

they were not actually a tribe of the same people; and settled at no great distance from them. (See CIMBRI.) They are said to have worshipped a divinity called *Thaut*, who is supposed to have been one of their ancestors deified. The Teutones were known before the Cimbri, and uniting with them, overran the territories that were subject to the Romans; and it has been affirmed that they inhabited the banks of the *Codani Sinus*, and the island called *Codania Insula*, whence they assumed the appellation of "Codani." Pytheas of Marseilles, according to Pliny, is the first author who mentions the Teutones; and Pomponius Mela says, that their habitations were near the gulf *Codanus*. It is very probable that they extended themselves through the country that bordered on the Baltic sea; and that from thence they engaged in many warlike emigrations; transporting themselves with their arms and baggage, their wives and children, through other countries which they pillaged. It was in the year of Rome 640 that they first became known to the Romans; having advanced south of the Danube to the country called Noricum, where they were encountered by the consul C. Papirius Cursor, who obstructed their passage towards the borders of Italy. They then proceeded towards Gaul, and made their ingress among the Helvetians. Having arrived in Gallia Narbonnensis, the Cimbri were there defeated by the consul Aurelius; but the Teutones made an attempt to invade Italy by the Western Alps. They were, however, resisted by Marius, and in a desperate engagement, in which the latter proved victorious, the Teutones left upon the field an almost incredible number of slain; which, including the Gauls who had fallen in a combat which took place some days before, amounted, according to historians that have not been chargeable with exaggeration, to 100,000 persons. Marius also defeated the Cimbri in Italy.

TEUTONIC, something belonging to the *Teutones*, an ancient people of Germany, inhabiting chiefly along the coast of the German ocean. See GOTHIC.

TEUTONIC *Language*, is the ancient language of Germany, which is ranked among the mother-tongues.

The Teutonic is now called the *German*, or *Dutch*, and is distinguished into *upper* and *lower*.

The *upper* has two notable dialects; *viz.* 1. The Scandian, Danish, or perhaps Gothic; to which belong the languages spoken in Denmark, Norway, Sweden, and Iceland. 2. The Saxon, to which belong the several languages of the English, Scots, Frisian, and those on the north of the Elbe.

To the *lower* belong the Low Dutch, Flemish, &c. spoken through the Netherlands, &c.

The learned Mr. Whitaker has lately, in his History of Manchester, controverted the opinion of those who affirm the English language to be genuine and unmixed Teutonic, and asserted it to be of Celtic origin. Mr. Drake, in his Essay on the Origin of the English Language, Archæol. vol. 5. has endeavoured to support the former opinion, by comparing part of Ulphila's Gothic version of the gospel of St. John, executed above 1400 years ago, with the same in our present translation, and evincing the striking affinity between the two languages; notwithstanding the different mediums through which they have descended, and the many ages that have elapsed since they have been separated. Every circumstance, he observes, that constitutes the true genius of a language, is visibly derived to the English from the Goths and Saxons. The articles, flexure of the genitive case, prepositions and auxiliary verbs, are all absolutely Teutonic. The English, he says, is clearly the natural descendant of the Gothic or Teutonic; and he challenges the deepest enquirer into the Celtic to produce so decisive a proof of any affinity of that tongue with ours. The British, he adds, has little or no resemblance to the English. Many of their terms may have gained admission among us, as, from the vicinity and long intercourse we have had with that people, may necessarily be imagined, but their idioms and genius are as radically and essentially different as any two languages can possibly be.

TEUTONIC *Order*, a military religious order of knights, established towards the close of the twelfth century; and thus called, because it consisted principally of Germans, or Teutones.

The origin, &c. of this order were thus: the Christians, under Guy of Lusignan, laying siege to Acre, or Acon, a city of Syria, on the borders of the Holy Land; at which siege were present, Richard king of England, Philip Augustus of France, &c. some Germans of Bremen and Lubèc, touched with compassion for the sick and wounded of the army, who wanted common necessaries, set on foot a kind of hospital under a tent, which they made of a ship's sail; and here betook themselves to a charitable attendance on them.

This started a thought (about the year 1190) of establishing a third military order, in imitation of the Templars, and the Hospitalers.

The design was approved by the patriarch of Jerusalem, the archbishops and bishops of the neighbouring places, the king of Jerusalem, the masters of the Temple and the Hospital, and the German lords and prelates then in the Holy Land; and, by common consent, Frederic duke of Suabia, who was then at their head, sent ambassadors to his brother Henry, king of the Romans, to solicit the pope to confirm the new order.

Calixtus III. who then governed the church, granted it by a bull of the 23d of February, 1192, and the new order was called "The Order of Teutonic Knights of the House of St. Mary of Jerusalem."

The habit of this order was a white mantle, with a black cross.

The pope granted them all the privileges of the Templars, and the Hospitalers of St. John; excepting that they were to be subject to the patriarchs, and other prelates; and that they should pay tithe of what they possessed.

The first master of the Teutonic order, Henry Walpot, elected during the time of the siege of Acre, after the taking of that city, purchased a garden, in which he built a church, and an hospital, which was the first house of the Teutonic order.

Such is the account given by Peter of Duisbourg, a priest of this order.

Jaques de Vitty differs a little from this account; and relates, that the Teutonic order was established at Jerusalem before the city of Acre was besieged.

The order made no great progress under the three first grand-masters; but under the fourth, Herman de Salza, it became very powerful; insomuch that Conrade, duke of Mazovia and Cujavia, about the year 1230, sent an embassy to him, to solicit his friendship and assistance, offering him and his order the provinces of Culme and Livonia, with all the lands they could recover from the idolatrous Prussians, who harassed him exceedingly with their continual incursions, and against whom he intended this new militia; his own knights of the order of Christ, or of Dobrin, instituted for the like purpose, being found too weak.

De Salza accepted the donation, and Gregory IX. confirmed it; and, to aid the knights in reducing the Prussians,

 sians,

ſians, Innocent IV. publiſhed a croiſade. With this help, in a year's time, they ſubdued the provinces of Warmia, Natangia, and Barthia; the inhabitants of which renounced the worſhip of idols; and, in the courſe of fifty years more, they reduced all Pruſſia, Livonia, Samogitia, and Pomerania, &c.

In 1204, duke Albert had founded the order of Sword-bearers, Port-glaives, which now became united to the Teutonic knights, and the union was approved by pope Gregory IX.

The order, thus maſters of all Pruſſia, built the cities of Elbing, Marienburg, Thorn, Dantzick, Koningſberg, and ſome others: the emperor Frederic II. permitted them to add to the arms of their order, the imperial eagle; and St. Louis, in 1250, allowed them to quarter the fleur-de-lis.

After the city of Acre had been recovered by the infidels, the grand-maſter of the Teutonic order removed his ſeat from that city to Marienburg. As the order grew in power, the knights took more ſtate on them; and at length, inſtead of friars, brothers, as at firſt, would be called *lords*. And though the grand-maſter Conrade Zolnera, of Rotenſteine, oppoſed this innovation, his ſucceſſor Conrade Wallerod not only approved it, but even procured himſelf to be treated with honours only rendered to the greateſt princes.

Diviſions being got into the order, the kings of Poland made their advantage of them: the Pruſſians revolted to them: and after ſeveral wars between the knights and the Poles, the former yielded to king Caſimir the Upper Pruſſia, and did homage to him for the Lower.

At the time of the Reformation, Albert, marquis of Brandenburg, then grand-maſter, becoming a Lutheran, renounced the dignity of grand-maſter, diſſolved the commanderies, and drove the knights out of Pruſſia.

Moſt of the knights followed his example, and embraced the reformation: the reſt transferred the ſeat of their order to Margentheim, or Mariendahl, in Franconia, which they ſtill retain.

They there elected Walter of Cromberg their grand-maſter, formed a proceſs againſt Albert, and the emperor put him to the ban of the empire. The order, however, could never recover their domains; and are now little more than the ſhadow of what they formerly were, having only three or four commanderies, ſcarcely ſufficient for the ordinary ſubſiſtence of the grand-maſter and his knights.

The officers of the Teutonic order, when in its ſplendor, were the grand-maſter, who reſided at Marienburg: under him were the grand-commander; the grand-marſhal, who had his reſidence at Koningſberg; the grand-hoſpitaler, who reſided at Elbing; the draper, who took care to furniſh the habits; the treaſurer, who lived at the court of the grand-maſter; and ſeveral commanders, as thoſe of Thorne, Culme, Brandenburg, Koningſberg, Elbing, &c.

They had alſo their commanders of particular caſtles and fortreſſes; advocates, proveditors, intendants of mills, proviſions, &c.

Waiſſelius, in his Annals, ſays they had twenty-eight commanders of cities, forty-ſix of caſtles, eighty-one hoſpitalers, thirty-five maſters of convents, forty ſtewards, thirty-ſeven proveditors, ninety-three maſters of mills, ſeven hundred brothers or knights to take the field, one hundred and ſixty-two brothers of the choir, or prieſts, and ſix thouſand two hundred ſervitors or domeſtics.

TEUTSCH Leipsh, in *Geography*, a town of Hungary 5 miles E. of Roſenberg.

Teutsch *Pron*, a town of Hungary; 10 miles N.W. of Kremnitz.

TEUTSCHDORF, a town of Hungary; 5 miles N.W. of Caſchau.

TEUTSDORF, a town of Pruſſia, in the province of Oberland; 10 miles E.N.E. of Holland.

TEUVRENT, a town of Africa; 145 miles E.N.E. of Fez.

TEUW, a ſmall iſland in the Eaſt Indian ſea. S. lat. 7° 11′. E. long. 129° 20′.

TEUXUNTA, in *Ancient Geography*, a town of Sicily, which had been built by Micythus, king of Rhegium and Zancle, according to Diodorus Siculus.

TEWANTAPAGUE, in *Geography*, a town of Mexico, in the province of Guaxaca; 135 miles E.S.E. of Guaxaca.

TEWKESBURY, anciently *Teodechesberie*, a large and reſpectable borough and market-town, in the lower diviſion of the hundred of the ſame name, in Glouceſterſhire, England, is ſituated in the vale of Eveſham, on the eaſtern banks of the Avon, near its confluence with the Severn, at the diſtance of 8 miles N.N.E. from Glouceſter, and 104 miles W.N.W. from London. This town was rendered famous in hiſtory, from a battle fought near it, between the Yorkiſts and Lancaſtrians, wherein Edward IV. gave a total overthrow to Henry VI. Three thouſand of the Lancaſtrians were reported to have been ſlain in the field, and queen Margaret, with many others, was taken priſoner. The ſeveral circumſtances which occurred during the engagement, and the events ſubſequent to the victory, are very fully related in the hiſtories of England. Tewkeſbury was again the ſcene of another action in the civil wars of Charles I. It was at different periods in poſſeſſion of both parties; and the final capture of it by the parliamentary forces was of great conſequence as a frontier town, ſecuring that ſide of the county, and commanding great part of Worceſterſhire.

Tewkeſbury was firſt incorporated by charter in the 17th of Elizabeth, under the title of "bailiffs, burgeſſes, and community of the borough of Tewkeſbury." Other charters were granted by James I. and James II.; the latter, in the ſecond year of his reign, re-incorporated them by the name of "mayor, aldermen, and common council;" but this charter was not acted upon: and the government of the town, as a corporation, was dormant till 13 William III. when the preſent charter was obtained, under which the town is governed by twenty-four principal burgeſſes, who, with twenty-four aſſiſtants, act independent of the magiſtrates of the county. From theſe are annually elected two bailiffs and four juſtices, who, with the recorder, form the magiſtracy of the corporation. The privilege of ſending members to parliament was firſt obtained 7 James I. The right of election is in the freemen and freeholders within the borough: the latter of whom have a vote generally for the county. The number of voters amount to about 500, and the bailiffs are the returning officers. The principal manufacture for the employment of the inhabitants is ſtocking-frame work knitting, particularly cotton. This ſupplies work for the Houſe of Induſtry, which is a modern building, well adapted for the purpoſe of rendering the poor cleanly, moral, and induſtrious. The markets, which were eſtabliſhed as early as the Conqueſt, are held on Wedneſday and Saturday: and here are ſeven annual fairs. The town-hall, which is a handſome edifice, was erected by ſir William Codrington in 1788, at an expence of 1200*l*. The ground-floor is appropriated for holding

holding the quarter-feffions; the upper floor for a banquetting room, and for the meeting of the corporation. Among the charitable eftablifhments are a free grammar-fchool, a charity-fchool, and feveral alms-houfes. The Anabaptifts, Quakers, Independents, and Methodifts, have each a meeting-houfe in the town. The population, according to the returns of the year 1811, amounted to 4820; the number of houfes being 1003: the latter are chiefly of brick, and principally ranged in three fpacious ftreets. Since the year 1786, when an act was paffed for paving and lighting the town, many improvements have been made; and the buildings have affumed an air of refpectability.

The Abbey.—A monaftery was firft erected here, and endowed by two brothers, Oddo and Doddo, dukes of Mercia, A.D. 715, to the honour of the Bleffed Virgin, which having undergone many calamities during the civil and Danifh wars, about 980 became a priory, fubject to Cranbourn in Dorfetfhire: but Robert Fitzhamon, a noble Norman, who came to England with the Conqueror, enlarged the buildings and increafed the poffeffions of Tewkefbury fo much, that the monks of Cranbourn chofe, about 1102, to remove to this place, leaving only a prior and two monks behind, and made Cranbourn in future fubject to the abbey of Tewkefbury. From this time it became a great eftablifhment of Benedictine monks; and at the fuppreffion, the annual revenues amounted to 1598*l.* 1*s.* 3*d.*, exclufive of 136*l.* 8*s.* 1*d.* granted by the convent for fees and annuities: its plate alfo was very valuable, the facrifty alone containing 1421 ounces. After the diffolution, the deftruction of the monaftic buildings was rapid and complete, through the ineffectual oppofition of the monks to the vifitors appointed by the king, who, in revenge, deftroyed the Lady chapel, cloifters, chapter-houfe, and other appendages by fire. The remains of the buildings were afterwards purchafed by the inhabitants: and the Abbey Church was made parochial. This magnificent ftructure difplays an interefting example of early Norman architecture, combined with fpecimens of later ftyles, and is in other refpects well calculated to arreft the attention of the antiquary. It is built in the cathedral form, and confifts of a nave, choir, tranfept, and central tower, with the addition of feveral chapels, ranged round the aifle of the choir. The nave and choir are feparated from the aifles by eighteen maffive columns, fuftaining the roof, and four fubftantial piers which fupport the tower. At the weft end is a large window with a pointed arch, which appears to have been introduced within a femicircular arch in 1656. There were cloifters on the fouth fide of the nave, where fome fragments yet remain; and appear to have been highly ornamented in a fimilar ftyle to thofe at Gloucefter. The tower, according to the Abbey chronicles, was once terminated by a wooden fpire, which fell down on Eafter-day, 1559. The moft remarkable fpecimens of the architecture are three tiers of arcades in the upper part; the arches of the middle tier have interefting mouldings. The length of the church is 300 feet; of the tranfept 120; the breadth of the choir and fide-aifles is 70 feet; of the weft front 100; the height from the area to the roof is 120 feet; the height of the tower 152 feet. The monuments, which are numerous, have attracted the attention of various antiquaries, particularly Mr. Gough and Mr. Lyfons; the latter of whom has taken great pains in affigning the different tombs to the real perfons they were intended to commemorate: many miftakes, in this refpect, having been committed on traditional authority by former writers. Near the weft end of the church is the Abbey Gate-houfe, which appears of the age of the fifteenth century: it is embattled and ornamented with grotefque figures, projecting from a cornice; beneath which is a canopied niche between two fquare windows.—Dyde's Hiftory, &c. of Tewkefbury, 8vo. 1798. Rudge's Hiftory of Gloucefterfhire, vol. i. 1803. Beauties of England and Wales, vol. v. Gloucefterfhire; by J. Britton and E. W. Brayley.

TEWKESBURY, called *Wamefit*, or *Pawtucket*, by the Indians, a townfhip of Maffachufetts, in the county of Middlefex, containing 943 inhabitants; 24 miles N. of Bofton.

TEXALI, in *Ancient Geography*, the inhabitants of the fea-coafts of Aberdeenfhire; who had a town, called Devana, at the mouth of the river Deva (Dee), where old Aberdeen now ftands.

TEXAS, in *Geography*, a province of New Spain, which properly forms part of Louifiana. This province is claimed by Spain as part of the internal provinces, and included in the vaft intendancy of San Louis Potofi: It is bounded E. by the ftate of Louifiana, S. by the gulf of Mexico, W. by an imaginary limit, and N. by Red river, and contains an area exceeding 100,000 fquare miles. The capital of this province is the garrifon of San Antonio de Bejar, ridiculoufly called the New Philippines. It was founded in 1731, confifting of a captain, a lieutenant, and one company of foldiers. The ftation of Cenis in this province, is now a mere Indian village, with the ruins of a fort built by the French. That called Natchitoches, from an Indian tribe, friends of the French and enemies of the Spaniards, was a fmall fort, built on an ifland of the Red river by fome French veterans. But the ftation of Adayes, or Adaes, is regarded by the Spanifh writers as the extreme fortrefs in this quarter: it is feated in a fertile country, at the diftance of two leagues from a lake of the fame name, which abounds in fifh, and which in fome parts is five leagues in diameter, and probably ten in circumference, with a gulf which may be navigated by large veffels. In the middle of the lake is a hill, or rock, of a pyramidal form, more than 100 yards in circumference, the ftone of which refembles cryftal in its reflection of the folar rays, and it is the higheft in the diftrict. The vicinity abounds in wild cattle, bears and beavers; and the foil is fertile in maize and other grain. Pinkerton.

TEXEIRA, JOSEPH (PETER), in *Biography*, a Portuguefe hiftorian, was born in 1543, entered among the Dominicans, and became prior of the monaftery at Santarem in 1578. When Philip II. of Spain took poffeffion of Portugal, Texeira attached himfelf to Don Antonio, who had been proclaimed king by the Portuguefe, and accompanied him into France. In 1582 he was taken prifoner by the Spaniards, but made his efcape from Lifbon. He became confeffor to Don Antonio, and, in procefs of time, preacher and almoner to the French king Henry III. He afterwards attached himfelf to Henry IV., and in 1596 affifted at the abjuration of Calvinifm by the princefs of Condé. He was fent on one miffion to England, and favourably received by king James. He died at Paris in 1604, as fome fay; but according to another account, in 1620.

In 1582, Texeira printed his "Compendium de Portugalliæ ortu Regni initiis, &c." This work was anfwered by order of the king of Spain; and Texeira replied, in 1592, by a "Confutatio, &c." which profeffed to refute the hereditary right of Philip to the crown of Portugal, and to vindicate that of Don Antonio;—probably the fame work that is entitled "De Electionis Jure quod competit Viris Portugallenfibus inaugurandis fuis Regibus," Lyons, 1589.

As

As a genealogist, under which character he was distinguished, he published in 1590, "Exegesis Genealogica Arboris Gentilitiæ Henrici IV., Gallorum Regis," enlarged in 1598, with the addition of the princess of Condé's abjuration. In token of the indignation he felt at the seizure of his country by Philip, he affirmed, as it is said, in one of his sermons, that "we were bound to love all men, of whatever religion, sect or nation, even if they were Castilians." Bayle. Moreri.

TEXEL, or Tessel, in *Geography*, an island of Holland, about 11 miles in length, and six in its greatest breadth; situated at the mouth of the Zuyder See, with a capacious and good harbour, and a fort, which commands the entrance; besides a town of the same name, it contains six villages: the land is fertile in pasture, and the whole well secured with dikes of prodigious strength and height. Near this island was the celebrated sea-fight, between the fleet of Holland, under admiral Martin Harpertz Tromp, and that of England, under admiral Blake, in the year 1653, in which Tromp was killed. In the year 1673 a battle was fought between the fleet of Holland and the united fleets of England and France, in which the victory was doubtful. N. lat. 53° 5'. E. long. 4° 40'.

TEXEUIT, or Teyent, a town of Morocco; 100 miles W.N.W. of Morocco.

TEXT, a relative term, contradistinguished to *gloss* or *commentary*; and signifying an original discourse, exclusive of any note or interpretation.

Infinite pains have been taken by the critics, to restore, reconcile, settle, explain, &c. the text of the bible, and that of the classics. See Bible.

Mr. Whiston accounts for all those misunderstandings between the Old and New Testament, particularly as to the prophecies in the Old, cited as fulfilled in the New, from the corruption of the text of the Old Testament; and to obviate objections made against Christianity on that head, has published an "Essay towards restoring the true Text of the Old Testament." See Prophecy.

This restoration he attempts to effect from the Samaritan Pentateuch, the Roman Psalter, the Apostolical Constitutions, &c.

It sufficiently appears from the learned and acceptable labours of the late Dr. Kennicott, in collating the Hebrew manuscripts of the Old Testament, that the alterations introduced into the text, &c. are mostly of a trivial nature, and by no means affect the authority of the sacred writings.

Text is particularly used for a certain passage of scripture chosen by a preacher, to be the subject of his sermon.

A collection of texts appropriate to different subjects, and judiciously arranged, has been published by Dr. Enfield for the use of preachers in the composition of their discourses, and also of biblical readers and students.

Anciently, the lawyers began all their pleadings with like texts of scripture.

A text-book, in several universities, is a classic author written very wide, by the students, to give room for an interpretation dictated by the master or regent, to be inserted in the interlines.

In this sense, the French say, proverbially, *Glosse d'Orleans plus obscure que le texte.*

The Spaniards gave the name text to a kind of little poem, or set of verses placed at the head of a gloss, and making the subject of it: each verse being explained, one after another, in the course of the gloss.

Text, in *Ancient Law Authors*, is appropriated to the book of the Four Gospels, by way of eminence. These were written in gold letters, and carefully preserved in the churches.

"Codex aurato conseptus grammate scriptus.
Auctus evangelicum conservat corpore textum."

TEXTUARIES, Textuarii, a name given to the sect of the Caraites, among the Jews.

Hillel shone among the traditionaries, and Schammai among the textuaries.

The civil and canon lawyers sometimes also call a book containing the bare text, without any gloss or commentary, a textuary, *textuarium.*

TEXTURE, Textura, formed of *texo*, *I weave*, properly denotes the arrangement and cohesion of several slender bodies or threads interwoven or entangled among each other: as in the webs of spiders, or in cloths, stuffs, &c.

Texture is also used in speaking of any union or cohesion of the constituent particles of a concrete body; whether by weaving, hooking, knitting, tying, chaining, indenting, intruding, compressing, attracting, or any other way.

In this sense, we say a close, compact texture; a lax, porous texture; a regular or irregular texture, &c.

A great deal depends on the texture of the component parts of a body: hence most of its particular properties, its specific gravity, colour, &c.

TEXTUS Roffensis, is an ancient manuscript, containing the rights, customs, tenures, &c. of the church of Rochester, granted by the laws of Ethelbert, Hholthere, Eadred, and Withred, kings of Kent, collected by Ernulf, the venerable bishop of Rochester, about the year 1100.

TEYA, in *Geography*, a river of Austria, which rises about three miles N. from Germs, passes through a part of Moravia, and runs into the Marsch, 11 miles N.E. of Zistersdorf.

TEYN, a town of Bohemia, in the circle of Boleslau; 12 miles W.N.W. of Jung Buntzel.

TE-YUEN, a town of Asia, in the kingdom of Corea; 93 miles N.E. of King-ki-tao.

TEZA, a town of Africa, in the kingdom of Fez, with a castle. It was once a populous city, but is now much decayed, yet is still the residence of a governor and a garrison; 20 leagues N.N.E. of Fez.

TEZCUCO, or Tetzcuco, a lake of Spanish America, in the province of Mexico. The conjunct lakes of Tezcuco and Chalco are found to be about 30 British miles in length, and the former is about 15 miles in breadth; but as the latter is partly drained, so as to be at the distance of a league from the city, it is probably about twelve miles in breadth. This lake is celebrated in history, as originally containing the city of Mexico, and also as remarkable for the qualities of the water, partly fresh, and partly saline. The Chalco, or fresh-water lake in the south, appears to flow by a narrow channel into the salt lake of Tezcuco. See Mexico, substituting for Tezeuco, *Tezcuco.*

TEZELA, a town of Africa, in the kingdom of Algiers; 5 leagues S.W. of Oran.

TEZERGBE, a town of Africa, in the kingdom of Fez; 100 miles E.S.E. of Teza.

TEZOUT, or Tessot, a town of Africa, in the kingdom of Fez; 35 miles S. of Melilla.

TFENI, a town of Egypt, on the Nile; 10 miles S.E. of Rosetta.

TFUOI, in the *Chinese Manufactory of Porcelain*, a word used to express a particular sort of varnish for that ware, with

with violet-colour and gold. The ufual method of doing this at firft, was by mixing gold with the common varnifh, breaking the leaves very fmall, and then adding the common blue and the powder of calcined agate of a coarfe kind, found in great plenty on the fhores of their rivers. But they have fince found that the brown varnifh called *tfekin* fucceeds much better, for when the blue is mixed with this, its brown colour is loft, and the gold lies on much better than it would any other way.

They had once a method of a varied varnifh, which was very beautiful, but is much neglected now; this was the giving a veffel the brown varnifh on the outfide with a large portion of gold, and the common white varnifh within. They alfo varied the degree of colour on the outfide, by laying on more or lefs of the varnifh; and gave this way a variety, even in the fame colour. Obferv. fur les Coûtumes de l'Afie, p. 308.

TGIDT, in *Geography*, a town of Arabia, in the province of Oman; 48 miles N. of Fartach.

THABBA, in *Ancient Geography*, a town of Arabia Felix, fituated between Menambis and Seba, now *Ebba*. Ptol.—Alfo, an ancient town of Africa, in the vicinity of Tichafa.

THABET EBN KORRA, in *Biography*. See THEBIT BEN CORAH.

THABILIACA, in *Ancient Geography*, a town of Albania, between the rivers Gerrus and Soanes. Ptol.

THABIR, in *Geography*, a mountain of Arabia; 20 miles S. of Medina.

THABOR, in *Ancient Geography*. See TABOR.

THABORITES. See TABORITES.

THABRACA COLONIA, *Tabarka*, in *Ancient Geography*, a town and Roman colony of Africa, in Numidia, according to Ptolemy. It was fituated on the weftern bank, and near the mouth of the river Tufca. Some veftiges remain of walls and cifterns.

THABUCA, a town of Spain, in the interior of the Tarragonenfis, belonging to the Varduli. Ptol.

THACAS, θακας, in *Antiquity*, a general name given to the place or feat where the augurs made their obfervations.

THACCONA, in *Ancient Geography*, a town of Afia, in Babylonia, upon an arm of the Euphrates. Ptol.

THACES, a people of Scythia, on this fide of the Imaus, and near it. Ptol.

THACK TYLES. See TYLE.

THÆMA, in *Ancient Geography*, a town in the interior of Arabia Deferta. Ptol.

THÆNA, or THÆNÆ, a town placed by Strabo, Pliny, and Ptolemy, on the coaft of Africa, towards the commencement of the Leffer Syrtes.—Alfo, a town of Afia, in Syria, fituated, according to Ptolemy, in Cyrrheftica.

THAGIA, in *Geography*, a town of Africa; 100 miles S.S.W. of Fez.

THAGORA, TINGORAN, in *Ancient Geography*, a poft of India, at the bottom of a fmall gulf, in the eaftern part of the peninfula, beyond the Ganges.

THAGULIS, a town of Africa, fituated between the Two Syrtes. Ptol.

THAHAR KIAMEN, in *Geography*, a poft of Chinefe Tartary; 15 miles N.E. of Tcitcicar.

THAHATH, in *Ancient Geography*, the place of the 23d ftation of the Ifraelites, where they encamped, after having left Mauloth; fituated in the defert of Arabia, S. of Mauloth.

THAINEE, in *Geography*, a town of Africa, in the kingdom of Tunis, near the eaft coaft, but without a harbour, at a fmall diftance from the mouth of a river of the fame name; 120 miles S. of Tunis.

THAIS, a town of France, in the department of Paris; 2 leagues S.S.E. of Paris.

THAIS, a name given by Ægineta to a cofmetic cerate, intended to give a beautiful red to the face. Galen ufes the fame word to exprefs a fort of bandage.

THALA, *Ferre Anach*, in *Ancient Geography*, a town of Africa, in Numidia, according to Salluft and Tacitus.—Alfo, a mountain of Africa, in Interior Libya, and the people inhabiting its vicinity were called Thalæ.

THALACH, in *Geography*, a river of Bavaria, which runs into the Schwarzach; 5 miles W. of Greding.

THALAMEGUS, among the *Ancients*, a fhip of pleafure, or yatch ufed by princes. It was always provided with a good cabin, or bed-chamber. See SHIP.

THALAMI *Nervorum Opticorum*, in *Anatomy*, twio emnences in the brain. See BRAIN.

THALAMIA, in *Botany*, fee LICHENES, one of whofe kinds of *Apothecium*, or receptacle, is fo denominated by Acharius.

THALAMII, among the *Ancients*, thofe rowers who fat in the loweft part of the fhip. See the next article.

THALAMITÆ, in the *Naval Architecture of the Ancients*, a term ufed to exprefs thofe rowers in the polycrote galleys, or thofe who contained feveral feries of rowers, who fat on the thalamus of the veffel, and made the loweft row. Thefe moved their oars and hands under the feats of the row that fat next above them. See POLYCROTA.

THALAMIUM, among the *Ancients*, a port-hole, through which the oars of the rowers in the bottom of the fhip went.

THALAMUS, in *Botany*, a term ufed to exprefs that part of the flower in the capitated or flofculous-flowered plants, where the embryo fruits of every feparate flofcule are lodged, and where afterwards the feeds are contained. This is the bottom of the cup, in the central part of which it adheres to the ftalk.

THALASSAR, in *Ancient Geography*, a province of Afia, between Mefopotamia and Armenia.

THALASSOMELI, the name of a medicine ufed as a purge among the ancients. It was compofed of equal parts of honey, fea-water, and rain-water, expofed to the fun in the dog-days, in a veffel pitched on the infide. It purged in the fame manner that fea-water alone would do, but only in a milder way.

THALASSUS, in *Ancient Geography*, a town or port in the fouthern part of the ifle of Crete.

THALATHA, a town of Afia, in Babylonia, on the banks of the Tigris, and S. of Apamea.

THALATTA, a lake or marfh, at the foot of mount Caucafus, in the environs of the people called "Coraxi." It difcharged its waters into the Euxine fea, near a place called Beithea-Ponti.

THALBIS, a river of Albania, between the Gerrus and the Soanes. Ptol.

THALEA, a town of Paleftine, in the tribe of Simeon, according to the book of Jofhua.

THALER. in *Commerce*. See RIXDOLLAR.

THALES, in *Biography*, the founder of the Ionic fchool, and of the fcientific method of philofophifing among the Greeks, was born of Phœnician parents, at Miletus, in the firft year of the 35th Olympiad, or about the year 580 B.C. He acquired wealth and diftinction among his countrymen, and was employed at an early age in public affairs. He declined involving himfelf by marriage in the cares of a family, that he might devote his whole time and attention to the ftudy of philofophy; alleging, as it is faid, to his mother, who urged him to marry, at an early age "it "it is too soon," and at a more advanced period "it is too late." In order more entirely to disengage himself from every avocation that would divert his mind from his favourite pursuits, he committed the care of his estate to his sister's son, whom he adopted. In search of wisdom, he travelled to Crete, and afterwards to Egypt. From the priests at Memphis in the latter country, he is said by several writers to have gained his knowledge of philosophy and mathematics. But it is more probable that he was more indebted to his own talents and assiduity in the exercise of them, than to any communication from them; and accordingly it has been affirmed, that he taught them how to measure the height of their pyramids. Upon his return to Miletus, he was universally respected for his extraordinary wisdom and learning; and his acquaintance was eagerly courted by all who wished to improve in knowledge or to be ranked among philosophers. He was not prevented, however, by these engagements from prosecuting his mathematical, philosophical, and metaphysical studies. In this course of improvement and usefulness, and of imparting, as well as of acquiring knowledge, he protracted his life to the great age of ninety years, and died, through mere infirmity, whilst he was attending the Olympic games. Thales was ranked among the seven wise men of Greece, and might justly be reckoned one of this number, whether we consider his scientific attainments, or the moral maxims and aphorisms which are ascribed to him. Of these maxims, we shall select the following: "Neither the crimes, nor the thoughts, of bad men are concealed from the gods. Health of body, competent fortune, and a cultivated mind, are the chief sources of happiness. What is the most difficult thing? To know one's self. What the easiest? To give advice to others. How shall we best attain to virtue? By abstaining from all that we blame in others. Parents may expect from their children that obedience which they paid to their own parents. Take more pains to correct the blemishes of the mind, than those of the face. Stop the mouth of slander by prudence. Be careful not to do that yourself, which you blame in another. Friends should be remembered when absent, as well as when present." Laertius. Brucker by Enfield, vol. i. For an account of his philosophical doctrines and other particulars, we refer to the article IONIC *Sect*.

THALETAS *of Crete*, a famous lyric poet, celebrated by all antiquity as a *medical* musician, is said to have delivered the Lacedæmonians from the pestilence by the sweetness of his lyre; but credulity in the powers of music must be very strong indeed, in those who could believe it possible for music to drive away the pestilence. Thaletas, however, was universally believed to have possessed this power; but it is impossible to render the fact credible, without qualifying it by several circumstances omitted in the relation. In the first place, it is certain that this poet was received among the Lacedæmonians during the plague, by command of an oracle; that by virtue of this mission, all the poetry of the hymns which he sung, must have consisted of prayers and supplications, in order to avert the anger of the gods against the people, whom he exhorted to sacrifices, expiations, purifications, and many other acts of devotion; which, however superstitious, could not fail to agitate the minds of the multitude, and to produce nearly the same effects as public fasts, and, in Catholic countries, processions, at present, in times of danger, by exalting the courage, and by animating hope.

The disease having, probably, reached its highest pitch of malignity when the musician arrived, must afterwards have become less contagious by degrees; till, at length, ceasing of itself, by the air wafting away the seeds of infection, and recovering its former purity, the extirpation of the disease was attributed by the people to the music of Thaletas, who had been thought the sole mediator, to whom they owed their happy deliverance.

This is probably what Plutarch means, who tells the story; and what Homer meant, in attributing the cessation of the plague among the Greeks, at the siege of Troy, to music.

"With hymns divine the joyous banquet ends,
The Pæans lengthen'd till the sun descends:
The Greeks restor'd, the grateful notes prolong;
Apollo listens, and approves the song."
Pope's Homer's Iliad, book i.

For the poet, in this passage, seems only to say, that Apollo was rendered favourable, and had delivered the Greeks from the scourge with which they were attacked, in consequence of Chryseis having been restored to her father, and of sacrifices and offerings.

This poet-musician has been confounded by some writers with Thales the celebrated Milesian philosopher; but according to Plutarch (in Lycurg.) he was cotemporary with Lycurgus the Spartan legislator, and lived about three hundred years after the Trojan war. Plutarch also informs us, that though Thaletas was only styled a lyric poet and musician, he was likewise a great philosopher and politician; insomuch that Lycurgus brought him from Crete, when he returned from his travels, to Sparta, in order to have assistance from him, in establishing his new form of government. His odes, continues Plutarch, were so many exhortations to obedience and concord, which he enforced by the sweetness of his voice and melody. Plato, likewise, describes his captivating manner of singing; and Plutarch, in his Dialogue on Music, ascribes to Thaletas many musical compositions and inventions: such as Pæans, and new measures in verse, as well as rhythms in music, which he had acquired from the flute-playing of Olympus, whom he at first had imitated. Porphyry, in his Life of Pythagoras, says that this philosopher used to amuse himself with singing the old Pæans of Thaletas; and Athenæus likewise tells us, that the Spartans long continued to sing his airs; and, according to the scholiast on Pindar, this poet-musician was the first who composed the Hyporchemes for the armed, or military dance.

There was another poet and musician of the name of Thaletas, who was likewise a Cretan, but who flourished much later than the cotemporary and friend of Lycurgus.

THALFANG, in *Geography*, a town of France, in the department of the Sarre; 11 miles S.S.W. of Traarbach.

THALHEIM, a citadel of Bavaria, in the territory of Nuremberg; 6 miles S.E. of Hersbruck.

THALIA, in *Botany*, was so named by Linnæus, in memory of John Thalius, a physician at Nordhausen, in Germany, who wrote *Sylva Hercynia*, a catalogue of the plants of the Hercynian forest towards Saxony, which accompanies the *Hortus Medicus* of Joachim Camerarius, both having been printed together at Francfort on the Maine in 1588; and they are both illustrated by excellent wooden cuts. Thalius died in 1587, of a fractured thigh, in consequence of a fall from his carriage. His work abounds with original descriptions and remarks; but as Haller observes, it is not easy to ascertain all the numerous species or varieties of which he treats. The genus before us was originally called CORTUSA by Plumier; but that name remains with a very different plant, as the reader will find its proper place.—Linn. Gen. 4. Schreb. 6. Will[illegible] Pl. v. 1. 15. Ait. Hort. Kew. v. 1. 3. Roscoe T[illegible]

[illegible] Doc.

Soc. v. 8. 340. t. 20. f. 3. Brown Prodr. Nov. Holl. v. 1. 307. Purſh 584. Juſſ. 63. (Cortuſa; Plum. Gen. 26. t. 8. Peronia; Redout. Liliac. v. 6. 342.)—Claſs and order, *Monandria Monogynia.* Nat. Ord. *Scitamineæ*, Linn. *Cannæ*, Juſſ. *Canneæ*, Brown.

Gen. Ch. *Cal.* Perianth ſuperior, of three equal, ovato-lanceolate, permanent leaves. *Cor.* of one petal, irregular. Tube none. Limb double: the outer divided to the baſe into three equal, oblong, concave ſegments, much longer than the calyx: inner two-lipped; its upper lip convolute, abrupt, ſlightly three-lobed, hardly ſo long as the outer limb; lower twice as long, deeply three-lobed, with two awl-ſhaped appendages, the central lobe contracted in the middle. *Stam.* Filament one, declining, linear, depreſſed, the length of the upper lip, and attached to one of its edges; anther ſimple, ovate, of one cell, opening inwards. *Piſt.* Germen inferior, roundiſh; ſtyle cylindrical, longer than the ſtamen, revolute; ſtigma irregular, ringent, perforated, beardleſs. *Peric.* Berry oval, of one cell, with a thin pulp. *Seed* ſolitary, large, oval, with a large horny albumen, and a ſolitary, central, curved embryo, accompanied by an empty cell.

Eſſ. Ch. Calyx of three leaves. Corolla of one petal, in five deep unequal ſegments, without a tube. Anther ſimple, ovate. Style recurved. Stigma ringent, perforated. Berry with one ſeed.

Obſ. The characters and ſtructure of the flower have in few genera been involved in ſo much uncertainty as in *Thalia.* We have endeavoured to draw up as correct a deſcription as we could, from Mr. Sowerby's excellent plate of *Thalia dealbata*, publiſhed in 1794, by the late Mr. Fraſer, and delineated under our inſpection. Mr. Brown's learned remarks have aſſiſted us as to the ſeed. The above deſcription will be found to agree with Plumier's account of the original ſpecies, as far as any thing can be underſtood from thence; leaving little doubt that the two plants in queſtion form one genus. Linnæus has left many manuſcript corrections of his generic characters of *Thalia*, we know not from whence derived, which, though they accord as far as they go with our obſervations, do not ſuperſede them. The preſent genus, no doubt, is next akin to Maranta, but their differences will appear evident from a compariſon of their deſcriptions. They both belong to the new order of *Cannæ*, or *Canneæ*, recently ſeparated by Mr. Roſcoe and Mr. Brown from the Linnæan Scitamineæ. See that article.

1. T. *geniculata.* Diſtant-flowered Thalia. Linn. Sp. Pl. 3. Willd. n. 1. Swartz Obſ. 9. (Cortuſa arundinacea, amplis cannacori foliis; Plum. Gen. 26. Ic. 98. t. 108. f. 1.)—Leaves ovate. Flowers remote, alternate. Bracteas oblong.—Native of the Weſt Indies, but hitherto ſeen by Plumier only. His figures are our only certain authority for this ſpecies; for Dr. Swartz has well obſerved, that the ſynonyms which authors have accumulated, do not belong to it; and that what Rottboll has deſcribed and figured, ſeems more akin to *T. cannæformis*, hereafter mentioned. We have indeed ſpecimens, gathered by Mr. Fraſer in 1810, in Cuba, near the Havannah, which greatly reſemble Plumier's figure, and may be his plant, though from the impoſſibility of examining their fructification, we dare not aſſert them to be ſo. Nevertheleſs we ſhall deſcribe them, that botaniſts may form their own opinion. The *ſtem* is ſeveral feet in height, erect, round, ſmooth, leafy, alternately branched. *Leaves* alternate, ovate, pointed, ſmooth, above a foot long, with one rib, and many fine tranſverſe curved veins. *Footſtalk* ſheathing, compreſſed, half as long as the leaf, with an oblong cylindrical knot at the ſummit. *Panicle* ſubdivided, with long linear, obtuſe, flat, erect *ſcales*, or *general bracteas*, at each ſubdiviſion. *Flower-ſtalks* zigzag, knotty, round, two or three inches long. *Partial bracteas* two at each knot, the outermoſt much the largeſt, embracing and concealing the other, an inch in length, elliptic-oblong, green, finely ribbed, clothed with ſcattered ſhining hairs. Between theſe *bracteas* is ſituated a pair of *flowers*, whoſe dried *corolla* is partly purple, and whoſe pale, much convoluted and wrinkled lip bears ſome reſemblance to Plumier's figure.

2. T. *dealbata.* Mealy Thalia. Roſcoe Tr. of Linn. Soc. v. 8. 340. Dryand. in Ait. n. 1. Purſh n. 1. Fraſer's ſingle plate. Curt. Mag. t. 1690. (Peronia ſtricta; Redout. Liliac. t. 342.)—Leaves ovate. Flowers crowded. Bracteas ovate, mealy.—Native of impenetrable ſwamps in South Carolina, flowering in Auguſt and September. Mr. Purſh ſays it was firſt diſcovered there by T. Millington, eſq. Living plants were brought to England by the late Mr. Fraſer in 1791, by which this handſome and curious ſpecies firſt became known to botaniſts. Its *root* is of courſe perennial. *Stem* four or five feet high, erect, round, ſmooth; leafy at the bottom; panicled at the top, covered with a ſilvery mealineſs, which clothes alſo the general as well as partial *bracteas*, and is eaſily rubbed off by a touch. *Leaves* light green, ſmooth, above a foot long, on round ſheathing *ſtalks*, with a knot at the top. *General bracteas* lanceolate, concave, convolute, a ſpan long. *Flower-ſtalks* aggregate or compound. *Partial bracteas* crowded, in pairs, much more tumid, ovate, and ſhorter than in the foregoing, each pair containing two purple *flowers*, whoſe ſtructure is detailed in our generic character. *Fruit* purple, the ſize of a hazel-nut, ſlightly pulpy.

3. T. *cannæformis.* Elliptical Thalia. Forſt. Prodr. 1. Willd. n. 3. Buchanan in Symes's Embaſſy to Ava, ed. 2. v. 3. 305. t. 21.—Leaves elliptical. Partial bracteas linear-lanceolate, ſhorter than the divided partial flower-ſtalk.—Native of moiſt woods in the remote iſlands of the Eaſt Indies, and the New Hebrides, flowering in March and April. The *ſtem* is ſolid, branched, round, ſmooth, leafy, divaricated at the joints. *Leaves* alternate, broadly elliptical, pointed, ſmooth, on round ſheathing *ſtalks. Panicle* terminal, with long, ſlender, pendulous branches, upon which the *flowers* are arranged pretty cloſely. Every pair of long narrow *partial bracteas* contains a divided ſtalk, bearing two large white *flowers*, each with the rudiment of another at its baſe. The *corolla* is ſomewhat tubular, and the lower lip of its inner limb has two large equal lobes, but in other reſpects the parts of fructification ſeem to anſwer well enough to the generic character. The *fruit*, however, which muſt ſettle that point, is unknown.

Our learned and highly valued friend Mr. Roſcoe has ſuggeſted, that the *Maranta Cachibou*, Jacq. Fragm. Bot. 52. t. 69 and 70, of which we have a ſpecimen gathered by Mr. Maſſon at St. Kitt's, may probably be a *Thalia.* Its *ſeed* certainly confirms this opinion, but the parts of the *flower* are not yet ſufficiently deſcribed to authorize any concluſion, nor can we unravel their ſtructure from the dried plant. Whatever becomes of this ſpecies, the *Maranta Caſupo*, t. 63. f. 4, of the ſame work, and *M. Caſupito*, t. 64. f. 2, muſt aſſuredly be referred to the ſame genus.

Thalia, in *Mythology*, one of the nine Muſes, who preſided over comedy and paſtorals. She is diſtinguiſhed from the other Muſes by her maſk, and from the tragic Muſe by her ſhepherd's crook; her aſpect is likewiſe meaner than that of Melpomene, and her dreſs ſhorter and leſs noble than that of the other Muſes.

Thalia was alſo the name of one of the Graces.

THALICTRUM, in *Botany*, may poſſibly be, as generally ſuppoſed, the θαλικτρον of Dioſcorides, from whom the name is adopted. That point, however, was not determined by Dr. Sibthorp, though he noticed five ſpecies of this genus in Greece or its neighbourhood. The above name is, by Ambroſini and others, derived from θαλλω, *to be green and flouriſhing*. Some old authors occaſionally write it *Thalietrum*.—Linn. Gen. 280. Schreb. 277. Willd. Sp. Pl. v. 2. 1295. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 583. Prodr. Fl. Græc. Sibth. v. 1. 378. Ait. Hort. Kew. v. 3. 346. Purſh 388. Juſſ. 232. Tourn. t. 143. Lamarck Illuſtr. t. 497. Gærtn. t. 74.—Claſs and order, *Polyandria Polygynia*. Nat. Ord. *Multiſiliquæ*, Linn. *Ranunculaceæ*, Juſſ.

Gen. Ch. *Cal.* none, except the corolla be taken for ſuch. *Cor.* Petals four or five, roundiſh, obtuſe, concave, deciduous. *Stam.* Filaments numerous, dilated upwards, compreſſed, longer than the corolla; anthers terminal, oblong, erect. *Piſt.* Germens ſuperior, numerous, moſtly ſtalked, roundiſh; ſtyles none; ſtigmas thickiſh. There are alſo ſeveral very ſhort imperfect piſtils. *Peric.* none. *Seeds* ſeveral, ovate, furrowed, without any appendage.

Eſſ. Ch. Calyx none. Petals four or five. Seeds naked, without appendages.

Obſ. Linnæus remarks, that his *T. tuberoſum* and *cornutum* have five petals; *dioicum* has the ſtamens and piſtils on ſeparate plants; *aquilegifolium* and *contortum* have ſtalked pendulous ſeeds, furniſhed with three dilated or winged angles; moreover, that the number of ſtamens and piſtils differs in the different ſpecies, being ſometimes leſs than the characters of the claſs and order require.

This is a very diſtinct well-marked genus of perennial herbaceous plants, all natives of the cold or temperate climates of Europe and North America. The *leaves* are compound, with roundiſh, rarely oblong, lobed or notched *leaflets*; paler, or glaucous, underneath; uſually ſmooth. *Infloreſcence* panicled. *Flowers* white or yellowiſh, with ſome ſlight tinge of purple, generally of an elegant feathery appearance. Fourteen ſpecies are deſcribed in Linn. Sp. Pl.; twenty-one in Syſt. Veg. ed. 14. Willdenow has twenty-three. Four are Britiſh. Nineteen are enumerated in Mr. Aiton's *Hortus Kewenſis*. Their qualities in general are believed to be of an acrid nature, like thoſe of *Ranunculus* and *Clematis*; but milder.

We have ſome additions and corrections to make, which require a compendious review of the whole genus.

1. T. *alpinum*. Alpine Meadow-Rue. Linn. Sp. Pl. 767. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 262. Lightf. 286. t. 13. f. 1. Fl. Dan. t. 11. (T. minimum montanum atro-rubens, foliis ſplendentibus; Raii Syn. 204. Boerh. Ind. Alt. v. 1. 44. t. 1.)—Stem perfectly ſimple, and almoſt naked. Cluſter ſimple, terminal.—Native of moiſt black bogs, or the turfy margins of alpine rills, on the loftieſt mountains of Lapland, Scotland, and Wales, flowering in June. The *root* is perennial, creeping, with a few ſimple fibres. *Stem* erect, about ſix inches high, round, glaucous or purpliſh, with one leaf, more or leſs compound, about the middle. *Radical leaves* ſeveral, ſtalked, erect, half as tall as the ſtem; firſt ternate; then either again ternate, or pinnate; the leaflets roundiſh, or wedge-ſhaped, veiny; glaucous beneath. *Cluſter* at firſt drooping, then erect, of eight or ten alternate *flowers*, whoſe *petals*, and eight or ten *filaments*, are either white or purple; their *anthers* orange. *Germens* two or four only, roundiſh, green, each with a whitiſh, broadly-lanceolate, divaricated, downy *ſtigma*, about its own length. Linnæus deſcribes twelve *ſtamens*, and eight *piſtils*.

2. T. *fœtidum*. Fœtid Meadow-rue. Linn. Sp. Pl. 768. Willd. n. 2. Ait. n. 2. "Waldſt. et Kitaib. Hung. v. 2. 190. t. 174." (T. minimum fœtidiſſimum; Bauh. Prodr. 147. Pluk. Phyt. t. 65. f. 4. Moriſ. ſect. 9. t. 20. f. 13. T. n. 1140; Hall. Hiſt. v. 2. 58.)—Stem panicled, round, leafy. Leaves triply compound, minutely downy on both ſides. Flowers drooping. Petals ſlightly hairy. Stigmas auricled at the baſe.—Native of France, Switzerland, and Siberia, flowering in May. A ſpecies of a delicate aſpect, and glaucous hue, about a foot high, with innumerable, ſmall, rounded, lobed, tender *leaflets*. The *petals* are externally reddiſh, eſpecially in the young plant, and finely downy or hairy. *Stamens* long and capillary. *Seeds* ovate, ſtrongly furrowed, crowned with the permanent ſhrivelled *ſtigmas*, whoſe dilated or auricled baſe is diſtinguiſhable in our Swiſs ſpecimens. This laſt character is, in the *Supplementum*, p. 271, made the peculiar mark of *T. ſtyloideum*, there deſcribed from a Siberian ſpecimen, which Linnæus did not recognize as his own *T. fœtidum*. The *ſtyloideum*, Willd. n. 22, is therefore to be ſtruck out. Several Swiſs botaniſts have confounded the ſpecies before us with *T. minus*, hereafter deſcribed, which is Haller's n. 1139. That eminent writer had ſome doubts reſpecting the difference between the two, which we ſhall attempt to remove when we come to the other, Linnæus having placed them far aſunder. The *fœtidum* is ſaid to exhale a very bad and powerful odour, like *Geranium robertianum*, or, as Haller ſays, the urine of cats.

3. T. *tuberoſum*. Tuberous-rooted Meadow-rue. Linn. Sp. Pl. 768. Willd. n. 3. Ait. n. 3. Mill. Ic. v. 2. 177. t. 265. f. 2. (Oenanthe Myconi; Dalech. Hiſt. 785. Ranunculus thalictri folio minor, aſphodeli radice; Moriſ. ſect. 4. t. 28. f. 13.)—Leaflets rounded, glaucous, ſmooth. Petals five. Root tuberous.—Native of Spain and the Pyrenees. A hardy perennial in our gardens, flowering in June, but confined to the more curious collections. The *root* conſiſts of ovate knobs. *Herb* ſmooth, a foot or more in height, of a light glaucous green. *Flowers* panicled, not numerous, diſtinguiſhed by their five large, ovate, white *petals*, and ſmall *ſtigmas*. Moriſon's figure is badly copied from that of Dalechamp.

4. T. *Cornuti*. Canadian Meadow-rue. Linn. Sp. Pl. 768. Willd. n. 4. Ait. n. 4. Purſh n. 1. (T. canadenſe; Cornut. Canad. 186. t. 187. T. femine triquetro, foliis aquilegiæ; Moriſ. ſect. 9. t. 20. f. 15.)—Leaflets rounded, three-lobed, glaucous, ſmooth. Panicles terminal. Flowers dioecious. Petals five. Root fibrous.—On the banks of rivers, and in wet meadows, from Canada to New England, flowering in June and July. *Root* perennial. *Stem* from two to three feet high. *Flowers* ſmall, greeniſh-yellow. *Purſh*. Cornuti ſays the unexpanded *petals* are pale purple; the *ſtamens* white, numerous, with yellow *anthers*. *Seeds* triangular. The dioecious nature of the *flowers*, which we have had no opportunity of obſerving, was firſt noticed in *Hort. Kew.*

5. T. *dioicum*. Dioecious Early Meadow-rue. Linn. Sp. Pl. 768. Willd. n. 5. Ait. n. 5. Purſh n. 2. Muhlenb. Cat. 54.—Leaflets heart-ſhaped, many-lobed, very ſmooth. Panicles axillary. Flowers dioecious. Petals not longer than the filaments or germens. Stigmas almoſt capillary.—Native of ſhady woods and the banks of rivers, from Canada to Virginia, flowering from May to July, according to Purſh, who ſays the *flowers* are white. He conceives his plant to be the ſame with *T. lævigatum* of Michaux, Fl. Boreali-Amer. v. 1. 322, who confeſſes his inability to determine the North American *Thalictra*, they being almoſt all dioecious. Specimens from the late Dr. Muhlenberg, now before us, and agreeing exactly with thoſe ſent by Kalm to Linnæus,

Linnæus, as recorded in Sp. Pl., are certainly dioecious, about a foot high, very fmooth, with thrice-ternate *leaves*, whofe lobes are ufually from five to feven, blunt, and rather fhallow; both their furfaces reticulated with flightly prominent veins. *Panicles* folitary or in pairs from the bofoms of the leaves, fomewhat umbellate, on long ftalks, and often accompanied by a long-ftalked folitary flower. *Petals* of the *male flowers* white or reddifh, ovate, ribbed, the length of the very flender numerous *filaments*, whofe *anthers* are yellow, very narrow, pointed: thofe of the *female flowers* much fmaller and rounder, white or greenifh, hardly fo long as the little, oval, ribbed *germens*. The *ftigmas* are very flender, and remain in a prominent, almoft capillary, form, on the ovate-oblong, ftriated *feeds*.

6. T. *elatum*. Tall Meadow-rue. Jacq. Hort. Vind. v. 3. 49. t. 95. Willd. n. 6. Ait. n. 6.—Leaflets ovate, three-lobed, fmooth, fomewhat notched. Panicle much branched, terminal. Flowers erect. Filaments capillary. Stigmas ovate, fhort.—Native of Hungary. Introduced into England by Mr. Hunnemann in 1794. A hardy perennial, flowering from June to Auguft. *Aiton*. An unnamed fpecimen in the Linnæan herbarium manifeftly agrees with Jacquin's plant, which is four feet or more in height. The *ftem* is more furrowed in our fpecimen than he reprefents. The *leaves* are ternate from their very bafe, then twice or thrice pinnate, glaucous, incorrectly three-lobed, and fomewhat cut befides. *Flowers* white, erect, in an upright compound panicle. *Petals* ovate, rather fmall, fometimes purplifh. *Filaments* of equal thicknefs throughout, about thrice the length of their oblong, linear, pointed *anthers*, which Jacquin reprefents rather fhorter and rounder than we find them. *Germens* angular. *Seeds* elliptic-oblong, glaucous, furrowed, crowned with the fhort fhriveled *ftigmas*.

7. T. *majus*. Greater Meadow-rue. Jacq. Auftr. v. 5. 9. t. 420. Willd. n. 7. Fl. Brit. n. 3. Engl. Bot. t. 611. —Leaflets roundifh, fomewhat heart-fhaped, three-cleft; glaucous beneath. Panicle leafy, with aggregate branches. Flowers drooping.—Native of woods and bufhy places in Auftria, Hungary, Mount Athos, and the north of England, perennial, flowering in June and July. The late Mr. Robfon of Darlington found it at Baydales, near that town, as well as on the margin of Ulls-water, Cumberland. This is about the fize of the laft, but the *leaves* are of a darker green on the upper fide, very glaucous beneath. The branches of the *panicle* grow feveral together, from the bofoms of the upper leaves, and the *flowers*, at leaft their *ftamens*, are pendulous, with longer *anthers* than the preceding. The *petals* moreover are green. In the *germens* and *ftigmas* we perceive no particular diftinction.

8. T. *medium*. Intermediate Meadow-rue. Jacq. Hort. Vind. v. 3. 50. t. 96. Willd. n. 8. Ait. n. 8.—Leaflets oblong-wedge-fhaped, three-cleft, notched; the uppermoft lanceolate. Panicle much branched, flightly leafy. Stamens fpreading.—Native of hilly fituations in Hungary. A hardy perennial, flowering in June and July, introduced at Kew, by Mr. Hunneman, in 1789. Specimens in the herbarium of Linnæus, from the Upfal garden, which he fufpected might be *T. tuberofum*, n. 3, appear rather to belong to the prefent fpecies, which differs from the two laft in the narrownefs of its *leaflets*, agreeing with them in the *germens* and *ftigmas*. The *panicle* is more like *elatum* than *majus*. The *ftamens* are not pendulous, but divaricated. *Petals* elliptical, greenifh. *Leaves* light green, fomewhat glaucous.

9. T. *minus*. Leffer Meadow-rue. Linn. Sp. Pl. 769. Willd. n. 9. Fl. Brit. n. 2. Engl. Bot. t. 11. Fl. Dan. t. 732. Jacq. Auftr. v. 5. 9. t. 419. Segu. Veron. 476. Vill. Dauph. v. 3. 713. Ger. Em. 1251. (T. alpinum minus faxatile, rutæ folio, ftaminibus luteis; Segu. Veron. 476. t. 11.)—Leaflets roundifh, three-cleft, notched, fomewhat glaucous on both fides. Panicle flightly leafy. Flowers pendulous.—Native of various parts of Europe, from Sweden to Greece, generally on a limeftone or chalky foil, flowering in June and July. Our Britifh plant precifely agrees with what was found in Gothland by Linnæus, though he fubfequently confounded "things innumerable, both fmall and great," under *T. minus*. The true one is a bufhy fpreading herbaceous perennial, of humble growth, generally but a foot high, fmooth, of a glaucous hue, with tints of violet. *Leaflets* rather fmall, various in breadth. *Panicle* moderately branched. *Flowers* pendulous, though the ftalks become more erect when in feed. *Petals* elliptical, concave, light purple, fometimes jagged or fringed. *Stamens* capillary. *Anthers* long, linear, pointed, as in the laft. *Germens* and *feeds* fmall. Linnæus's fpecific definition, *foliis fexpartitis*, has puzzled every body, and is inapplicable to any thing ever taken for the prefent fpecies. He perhaps meant that each *leaf* confifted of fix primary divifions, which is moftly the cafe.

10. T. *rugofum*. Rugged Meadow-rue. Ait. ed. 1. v. 2. 262. ed. 2. n. 10. Willd. n. 10. Purfh n. 3. Muhlenb. Cat. 54.—Leaflets ovate or lanceolate, rugged, veiny, bluntly lobed. Stem round, ftriated. Panicle corymbofe. Flowers erect.—On the banks of rivers, and in fwamps, from Pennfylvania to Carolina, flowering from June to Auguft. Perennial, very tall, fometimes above five feet high. *Flowers* white. *Purfh*. The habit of this plant is more like fome of the large fpecies hereafter defcribed, with a large terminal denfe, almoft leaflefs, tufted *panicle*. *Stamens* capillary. *Anthers* linear.

11. T. *fibiricum*. Siberian Meadow-rue. Linn. Sp. Pl. 769. Willd. n. 11. Ait. n. 11. (T. orientale minimum, fumariæ folio; Tourn. Cor. 20. *Willd.*)—"Leaves in three divifions; leaflets fomewhat reflexed, fharply cut. Flowers drooping."—Found by Gmelin in Siberia; and by Tournefort, if we are right in his fynonym, in Armenia. Linnæus doubtingly cites a fynonym of Seguir, which, after Haller, we have referred to *T. minus*. His account of the prefent fpecies, of which we know nothing, is, that its habit accords with *T. minus*, or *purpurafcens*, but the *leaflets* are fmall, but one-fixth as large as thofe fpecies, glaucous like Rue or Fumitory. *Stem* green, copioufly panicled. *Panicle* brown at its divarications. It flowers later, at the fame time as *flavum* and *dioicum*.

12. T. *fquarrofum*. Squarrofe Meadow-rue. Willd. n. 12.—"Leaflets three-cleft or undivided. Footftalks membranous, winged, clafping the ftem. Flowers drooping."—Native of Siberia. Differs from all the foregoing fpecies which have drooping *flowers*, in the ftructure of its *footftalk*. The *leaves* are repeatedly compound, as in the reft; their lateral *leaflets* moftly ovate, acute, and entire, but the terminal, and even the uppermoft lateral ones, are divided or three-cleft. *Footftalk* greatly dilated at the bafe, with orbicular membranous wings, toothed at the margin. There are alfo leffer orbicular toothed *auricles*, upon the partial footftalks, by which mark the fpecies is eafily known. *Willdenow*. We have met with nothing anfwering to this defcription.

13. T. *purpurafcens*. Purplifh Meadow-rue. Linn. Sp. Pl. 769. Willd. n. 13. Ait. n. 12. Purfh n. 5.—(T. virginianum elatius glaucum, florum ftaminulis purpurafcentibus; Morif. v. 3. 324.)—"Stem twice as tall as the leaves. Leaflets roundifh, three-cleft, cut. Panicles

 nearly

nearly naked. Flowers drooping. Stamens coloured."— On dry funny hills, in Pennfylvania and Virginia. Perennial, flowering in May and June. A fmall plant. *Stem* and *filaments* purple. *Purſh.* Linnæus contrafts this with *T. minus*, a fpecies concerning which his ideas were too vague, for us to learn any thing from fuch a comparifon, nor does his herbarium lend us any certain aid. There is, however, an unmarked fpecimen, which he affociated with *T. dioicum*, but which may poffibly be the *purpurafcens*. It has broad ivy-like *leaflets*, but is more particularly diftinguifhed by fhort elliptical *anthers*, whofe *filaments* are gradually dilated upwards, approaching to thofe of *T. ſtamineum* hereafter defcribed.

14. T. *pubeſcens*. Downy Polygamous Meadow-rue. Purfh n. 4. Muhlenb. Cat. 54.—Leaflets ovate, fomewhat heart-fhaped, or wedge-fhaped; three-lobed at the end; flightly downy beneath. Panicles terminal. Flowers polygamous. Anthers linear. Styles awl-fhaped, twice as long as the germens.—On the banks of ditches and rivulets, in Pennfylvania and Virginia, flowering from June to Auguft. A tall fpecies, with white *flowers*. Purfh. We have this from our late venerable correfpondent, the Rev. Dr. Muhlenberg. The *leaflets* are rather large; dark green, and fomewhat rugged, above; paler, reticulated with prominent veins, and minutely downy, at the back. *Flowers* neareft to thofe of *T. dioicum*, and like them diftinguifhed by long tapering *ſtigmas*. The *anthers* are linear-oblong; their *filaments* almoft equally flender throughout.

15. T. *anguſtifolium*. Narrow-leaved Meadow-rue. Linn. Sp. Pl. 769. Willd. n. 14. Ait. n. 13. Jacq. Hort. Vind. v. 3. 25. t. 43.—Leaflets linear-lanceolate, or linear, moftly undivided, entire. Panicle much branched, denfe. Flowers erect. Stigmas heart-fhaped, half the length of the germens. Native of Switzerland and Germany, but not frequent any where. Dr. Sibthorp, however, gathered it on the Bithynian Olympus. Miller feems to have cultivated it, in his time, at Chelfea, but we have fcarcely ever feen a living fpecimen, and we are much inclined to concur in opinion with thofe who judge it a variety of the following, their habit, inflorefcence, and *flowers*, being exactly the fame, however different the breadth of their *leaflets*. Bauhin's fynonym, uniformly referred to this, certainly belongs to *T. ſimplex*, n. 17.

16. T. *flavum*. Common Meadow-rue. Linn. Sp. Pl. 770. Willd. n. 15. Fl. Brit. n. 4. Engl. Bot. t. 367. Fl. Dan. t. 939. (T. nigricans; Jacq. Auftr. v. 5. 10. t. 421. Willd. n. 16. T. nigrius, caule et femine ftriato; Bauh. Hift. v. 3. 486. T. majus, foliis rugofis trifidis; Morif. fect. 9. t. 20. f. 3.)—Leaflets rounded or oblong, three-cleft. Panicle much branched, denfe. Flowers erect. Stigmas heart-fhaped, half the length of the germens.—Found in moift meadows, and the reedy margins of rivers, throughout Europe, from Sweden to Greece, flowering in July. The *root* is yellow, perennial. *Stem* three feet high, erect, fmooth, leafy, furrowed or angular, fimple below. *Leaves* nearly feffile, twice ternate, with a fhort fheathing bafe, or *footſtalk*; *leaflets* flightly glaucous, moft fo beneath; either undivided or three-cleft, entire, veiny, varying extremely in breadth, length, and fharpnefs. *Panicle* terminal, erect, denfe, corymbofe, much branched, fomewhat leafy. *Flowers* and *ſtamens* erect, yellowifh-white, with oblong, flightly pointed, yellow *anthers*. *Stigmas* oblique, heart-fhaped, downy. *Seeds* deeply furrowed. The vague refemblance of this plant to the garden rue, and its place of growth, feem to have given the Englifh name of the whole genus. Jacquin's *nigricans*, found frequently in England, differs merely in the elongation and comparative narrownefs of its *leaflets*, which approach in thofe refpects to the *anguſtifolium*, laft defcribed.

17. T. *ſimplex*. Simple-ftalked Meadow-rue. Linn. Mant. 78, excluding the fynonym. Willd. n. 17. Ait. n. 15. Fl. Dan. t. 244. Ehrh. Phytoph. 15. (T. anguftifolium; Villars Dauph. v. 3. 712. T. anguftiffimo folio; Bauh. Prodr. 146. Morif. fect. 9. t. 20. f. 8.)—Leaflets linear. Stem angular, fimple. Panicle branched, compound, lax, fomewhat racemofe. Flowers pendulous. Stigmas roundifh-heartfhaped.—Native of Sweden, Denmark, Switzerland, and France. Introduced at Kew by the very eminent cultivator and botanift M. Thouin, in 1778. It is a hardy perennial, flowering in May and June. This is unqueftionably akin to the laft, but effentially diftinct. The whole plant is but half as large, with a much more angular *ſtem*. The *leaflets* are extremely narrow, and revolute, unaccompanied by any of the partial ftipulary fcales, feen on the leaves of *T. flavum*. The *panicle* is more oblong and lax, not corymbofe. *Flowers* fmaller, drooping, or rather quite pendulous, not erect. *Petals* green, not white or yellowifh. *Stigmas* remarkably round and convex. We have fpecimens from Villars, which prove the correctnefs of Willdenow refpecting his fynonym. We have alfo from profeffor Lachenal a fpecimen gathered at Michelfeld, which fhews this to be the plant of Bauhin, cited by Linnæus and others for *T. anguſtifolium*. Indeed Bauhin's wooden cut, copied by Morifon, fufficiently evinces this, though, being delineated perhaps from a dried fpecimen, it is not exact in the pofition of the *flowers*. *T. gallioides*, Willd. Enum. Hort. Berol. 585. we believe is a very narrow-leaved variety of *ſimplex*.

18. T. *lucidum*. Shining-leaved Meadow-rue. Linn. Sp. Pl. 770. Willd. n. 18. Ait. n. 16. (T. minus lucidum, libanotidis coronariæ foliis; Pluk. Phyt. t. 65. f. 5.)—"Stem leafy, furrowed. Leaflets linear, flefhy."—Said to be a native of France and Spain. Miller had fomething in his garden which paffed for this plant, and hence it is enumerated in Hort. Kew. We have never feen a fpecimen, nor did Linnæus know any more of the matter than what Dalibard, whofe fpecific character we more exactly copy, has given in his *Fl. Paris.* 162. The late Mr. Davall fent us a Swifs *Thalictrum* for *lucidum*, which anfwers to the character, but is indubitably the *ſimplex* in a luxuriant ftate. Linnæus thought the *lucidum* was probably a variety of *flavum*. We prefume various things have been taken for this plant, but in reality that it has no exiftence as a fpecies.

19. T. *aquilegifolium*. Columbine-leaved Meadow-rue, or Feathery Columbine. Linn. Sp. Pl. 770. Willd. n. 19. Ait. n. 17. Jacq. Auftr. v. 4. 10. t. 318. Curt. Mag. t. 1818. (T. atropurpureum; Jacq. Hort. Vind. v. 3. 34. t. 61. T. majus, florum ftaminibus purpurafcentibus; Bauh. Pin. 337. Morif. fect. 9. t. 20. f. 16.)—Leaflets rounded, lobed, and cut. Stem round. Panicle corymbofe. Flowers erect. Stamens dilated upwards. Germens ftalked. Fruit pendulous, with three dilated wings.—Native of Sweden, Germany, Switzerland, Thrace, and Greece, common and hardy in our gardens, flowering from May to July. The *ſtem* is three or four feet high, round, fomewhat ftriated, leafy, fmooth, either glaucous or purple. *Leaves* large and fpreading, much refembling thofe of *Aquilegia vulgaris*, though often more acute. *Flowers* large and elegant, white or pale violet; their *petals* reflexed; their very numerous *ſtamens* moderately dilated upwards, flattened, of the hue of the petals, with fhort yellow *anthers*. *Germens* triangular, on long ftalks, at length deflexed or pendulous, and becoming fomewhat obovate, obtufe, ftraightifh *ſeeds*, with three unequal, much dilated, fmooth wings.

wings. Retzius, in his *Obs. Bot. fasc.* 6. 30. sect. 52, justly indicates the identity of Jacquin's *T. atropurpureum* and the Linnæan *aquilegifolium*, confessing he could not decide concerning the *aquilegifolium* of Jacquin. We have a wild Swiss specimen of the latter, Haller's n. 1141, precisely answering to the plate in *Fl. Austrica*, and certainly not differing in any essential character from the true plant of Linnæus, so frequently cultivated for ornament, and preserved in his herbarium.

20. T. *contortum*. Twisted-seeded Meadow-rue. Linn. Sp. Pl. 770. Am. Acad. v. 4. 47. Willd. n. 20. Ait. n. 18.—"Fruit pendulous, triangular, contorted. Stem rather two-edged."—Native of Siberia. Linnæus thought it a hybrid offspring of *aquilegifolium* impregnated by the *minus*. His specimen is not to be distinguished from the former, and we cannot but agree with Willdenow's remark, that the contortion of the *seeds* is merely a sign of imperfection. Neither can any more solid dependance be had on the comparative number of the parts of fructification, on the white colour of the *flowers*, or the humbler stature of the herbage. We conclude this supposed species therefore to be scarcely even a variety of the last.

21. T. *petaloideum*. Daurian Meadow-rue. Linn. Sp. Pl. 771. Willd. n. 21. Ait. n. 19. (T. stamineum; Linn. Suppl. 271.)—Leaflets rounded, obtuse; partly three-lobed. Stem nearly leafless. Panicle somewhat umbellate. Stamens much dilated, linear-obovate. Germens sessile.—Native of Siberia. Mr. Loddiges is said to have introduced this curious and very distinct species to the knowledge of our cultivators, in 1799. It has a perennial *root*, with long, simple, rather fleshy fibres. *Stem* simple, about a foot high, striated, purple at the bottom, leafless, except an occasional leaf, accompanying a small lateral branch. *Radical leaves* two, spreading, thrice compound, on purplish stalks; *leaflets* very much like Common Rue, but smaller. *Flowers* white, large but not numerous, in a sort of *corymb*, or imperfect *umbel*, accompanied by a few small leaflets. *Petals* roundish, deciduous. *Stamens* very numerous, white, flat, and singularly dilated, with a mid-rib; their *anthers* yellow, narrow and short. *Germens* ovate, ribbed, with awl-shaped recurved *stigmas*. Willdenow makes *T. stamineum* a variety, little supposing that the very identical specimens, so minutely and accurately described in the *Species Plantarum*, could be again described, without a reference, in the *Supplementum*.

We have to exclude *T. japonicum*, Thunb. Tr. of Linn. Soc. v. 2. 337. Willd. n. 22, a specimen from Thunberg himself proving it to be no other than *Coptis asplenifolia* of Mr. Salisbury, Tr. of Linn. Soc. v. 8. 306, a circumstance as wonderful as that its discoverer should ever have thought this plant similar to a *Salvia*. See *Fl. Jap.* 364.

T. ranunculinum, Willd. Enum. Hort. Berol. 585. Pursh n. 6, having simple *leaves*, and being not noticed as a *Thalictrum* by Muhlenberg himself, who is quoted for it, is, we presume, best omitted here; as well as *T. concinnum*, Willd. Enum. 584, which is probably comprehended under some of the foregoing species.

Thalictrum, in *Gardening*, contains plants of the hardy, herbaceous, fibrous-rooted, perennial kinds, among the number of which the species mostly cultivated are; the tuberous-rooted meadow-rue (T. tuberosum); the Canadian meadow-rue (T. cornuti); the fetid meadow-rue (T. fœtidum); the narrow-leaved meadow-rue (T. angustifolium); the shining-leaved meadow-rue (T. lucidum); and the columbine-leaved meadow-rue, or feathered columbine (T. aquilegifolium).

In the second sort there is a variety, which is smaller, with pale purple filaments, than the common kind.

Also in the sixth sort there are varieties with a green stalk and white stamens, and with a purple stalk and stamens. Besides, there are other sorts that may be cultivated for variety.

Method of Culture.—All the sorts are readily increased by parting the roots, and planting them out in the autumn when the stems decay, or in the spring before the new ones are set forth, the strongest where they are to remain, and the weaker ones in nursery-rows for further growth: they may also be raised from seeds, which should be sown in a bed or border in the spring: when the plants rise, they should be kept clean, and be planted out where they are to remain, in the following autumn. They are all hardy durable plants that succeed and grow well in any common soil and exposure in the open ground, but which flourish most in moist shady situations. They afford variety in the borders, and other parts of ornamented grounds, when set out in a properly varied manner, requiring but little trouble or attention in such situations.

THALINA, in *Ancient Geography*, a town of Asia, in the Greater Armenia, upon the banks of the Euphrates. Ptol.

THALLABA, Talaban, a town of Asia, in Mesopotamia, upon the banks of the river Chaboras, situated E.S.E. of Resæina.

THALLAND, in *Geography*. See Dalia.

THALLITE, in *Mineralogy*; *Epidote*, Haüy; *Delphinite*, Saussure; *Shorl vert du Dauphiny*, Romé de Lisle; *Acanticene*, Dendrada; *Pistacit*, Werner. Few minerals have received so many names as this: it is at present better known by the name of epidote or thallite. It has frequently been confounded with actinolite or strahlstein, and with green hornblende and green asbestus. Some account of this mineral is given under Pistacite. We shall here add its distinctive characters and constituent parts. From actinolite it may be distinguished by the colour, the latter being generally a lighter green. The structure of the massive varieties of actinolite is generally radiated, that of epidote compact or foliated. Both the joints of actinolite are distinctly seen; but in epidote, frequently one joint only is seen. Epidote melts into a blackish scoria before the blowpipe, and is harder than actinolite or hornblende; the latter has generally a different shade of green: the fracture of hornblende is also less vitreous than that of epidote. Green asbestus is soft when pounded; the powder of epidote is harsh and rough. Thallite or epidote occurs both massive and crystallized. The joints are in two directions, one of which is more obvious than the other. The alternate angles are about $114\frac{1}{2}°$ and $65\frac{1}{2}°$; the cross fracture is splintery. The primitive form of the crystal is a prism with rhomboidal bases. The most common forms are six or eight-sided prisms, of which four are larger than the others. These prisms are terminated by several oblique planes, and are often flatly acuminated: the terminating planes of the crystals are smooth, and have a high natural polish; they are sometimes convex. The lateral planes, or sides of the crystals, are striated. This mineral is found in beds and veins, and sometimes as a constituent part of rocks. It is associated with augite, garnet, hornblende, quartz, calcareous spar, and magnetic iron-stone. The varieties that occur in veins are of a lighter colour, and the crystals are more acicular than those which are found in beds. The veins contain felspar, axinite, rock-crystal, chlorite, and other minerals; the epidote forming only a small part of the substance of the vein. It is found in several parts of the Scotch Hebrides, and in various alpine districts, in sienite, porphyry, and granitic rocks. The finest crystals have been procured at Arundel in Norway. The constituent

stituent parts of this mineral, from different situations, agree more nearly than is frequently the case with other minerals.

	From the Valais.	From Oisans.	From Arundel.

It differs in chemical composition from hornblende and actinolite, by the absence of magnesia, and by the large proportion of alumine which it contains.

THALLOPHORI, θαλλοφοροι, in *Antiquity*, the old men and women, who, in the procession of the festival *panathenæa*, carried olive-boughs in their hands.

THALLUS, in *Botany* and *Vegetable Physiology*, θαλλος, *an olive bud*, or *a green bough;* from θαλλω, *to be verdant*, *to shoot forth*, or *spread abroad;* a term aptly enough chosen by the distinguished professor Acharius, for the frond, or foliage, of a *Lichen*, whether that part be of a leafy, fibrous, scaly, or crustaceous nature. But this term, however apt, is superfluous, *frons*, used by Linnæus, being synonimous with it, and sufficient for every requisite purpose. See Lichen and Lichenes; also Frond.

THALMANSFELD, in *Geography*, a town of Germany, in the marggravate of Anspach; 4 miles W. of Thalmessing.

THALMESSING, or Thalmessingen, a town of Germany, in the principality of Anspach; 31 miles S.E. of Anspach. N. lat. 49° 1′. E. long. 11° 10′.

THALMIS, or Talmis, in *Ancient Geography*, a town of Egypt, between Taphis and Tutzis. Anton. Itin.

THALPUSA, a town of the Peloponnesus, in Arcadia; which belonged to the Orchomenians.

THALSEA, or Thelsea, a town of Phœnicia, marked on the route from Remmaris to Neapolis, between Geroda and Damascus.

THALUDA, a river of Africa, in Mauritania Tingitana, the mouth of which is placed by Ptolemy on the coast of the Iberian sea, between Jagath and the promontory Oleastrum.

THALYSIA, θαλυσια, in *Antiquity*, a sacrifice offered by the husbandmen after harvest. For the origin and ceremonies of which, see Potter, Archæol. Græc. tom. i. p. 400.

THAMALAPATHRA. See Folium *Indicum*.

THAMAR, a word used by the Arabian physicians to express a date. Hence a pectoral decoction, made with dates and other ingredients, was called *diathamyron;* and the word was afterwards corruptly written *dicameron*.

Thamar, in *Ancient Geography*, a town of Judea, near Malis or Malath, which, according to Eusebius, had a Roman garrison.

THAMARITA, a town of Africa, in Mauritania Cæsariensis.

THAMARO, a town of Palestine, on the western side of Jordan. Ptolemy.

THAMASCHALTIS, a town of Africa Propria, on the route from the Greater Leptis to Tacapæ, between Thramusdisis and Thentei. Anton. Itin.

THAMBES, in *Geography*, a mountain of Algiers; 30 miles S. of Bona.

THAME. See Team.

Thame, or *Tame*, in *Geography*, a market-town in a hundred of the same name, and county of Oxford, England, is situated on the banks of the river Thames (whence it derives its name), at the north-eastern extremity of the county adjoining to Buckinghamshire, 13 miles E. from Oxford, and 46 miles N.W. by W. from London. Dr. Stukeley calls this place Tamese, and it is unquestionable that a Roman military road went through the town, though it was by degrees neglected in the latter times of the empire. Thame was a place of some consequence in the tenth century; for we find that Wulferc, king of Mercia, granted a charter "in the vill called Thama;" and in the year 970, Osketyl, archbishop of York, is known to have died here. In 1010, when the Danes over-run these parts of the kingdom, this town, among others, suffered severely. The Domesday record describes the manor of Thame as a part of the bishop of Lincoln's extensive possessions in Oxfordshire. Leland says, "about Alexander, bishop of Lincoln's time, the town of Tame, being the king's, was given for rent, in fee-farm to the bishop of Lincoln and his successors." To the patronage of the bishops the town was indebted for numerous advantages. By them the church was erected, the vicarage and a prebend endowed, and a neighbouring abbey reared. Through their interest the fairs and market were granted; and Henry Lexington, bishop in Henry the Third's reign, rendered an important service, by turning the high road through the middle of the town. Thame continued dependant on the bishops till the reign of Edward VI., when the see was dismembered of many of its valuable possessions. Sir John Williams obtained a grant of the estate, which descending by marriages to the family of Bertie, it became vested in the earls of Abingdon, the present possessors. During the civil wars of the seventeenth century, Thame was surrounded by garrisons of the contending parties, and consequently experienced its full share of the miseries of that period. The town consists principally of one long and spacious street, gently rising from the river. The church is a large, well-built structure, of the cruciform description, and comprises a nave, two aisles, a north and south transept, and a chancel; with an embattled tower supported by four massy pillars. The interior exhibits numerous tombs and memorials of families once important in this neighbourhood. Near the church are the remains of the prebendal house, which evince considerable former grandeur, and consist of nearly three sides of a quadrangle. A school, once of great celebrity, was founded here by John, lord Williams: the house is a spacious building, and the school of noble dimensions. Through the whole of the seventeenth century, this establishment maintained a high character: but has now fallen into disuse; though the building is in excellent preservation. There is likewise a charity-school of an humble description for the education of twenty-five boys. Thame has a good weekly market on Tuesdays, and two annual fairs: the market is of ancient date, for we find that the prior of Rufford was restrained from holding a market at Haddenham, to the prejudice of that of Thame. In the year 1811, the number of houses was returned as 460; the population as 2328, of which more than half were paupers receiving alms from the parish. By the return of the expences attending the maintenance of the poor in 1811, those of this parish amounted to 3686*l.*, a sum exceeding the expenditure of any other parish in the county. The parish contains about 4600 acres of land, and is divided into six hamlets or liberties, Old Thame, New Thame, Priest End, Thame Park, Moreton, and North Weston: the town comprises the three first. In Thame park, about a mile from the town, stood an abbey of some importance, established by bishop Alexander in 1138. At the dissolution, the society consisted of an abbot and sixteen monks; and the annual revenue was 256*l.* 14*s.* 7*d.* The abbey, with all its possessions, was surrendered to the crown by Robert Kyng, the last abbot, who, for his ready compliance, was on the erection of the see of Oxford appointed its first bishop. On the scite of a part a part of the abbey the preſent manſion was built by Philip, the father of the late lord Wenman. Conſiderable fragments of the abbey ſtill remain, which are protected by the modern elevation. The park contains about 220 acres, and is ſkirted with woodland.

Sir John Holt, the celebrated chief juſtice of the court of king's bench, was born at Thame in 1642, and died in 1709. (See Holt, *Sir* John.)—Beauties of England and Wales, vol. xii. Oxfordſhire; by J. N. Brewer.

THAMES, the name of the moſt important river of Great Britain, is pre-eminently diſtinguiſhed for its commercial conſequence, the ſcenery, edifices, and towns on its banks; for the bridges which are raiſed acroſs its channel; for the vaſt docks, quays, and warehouſes which are annexed to it; and for the variety and intereſt of the hiſtoric occurrences which are connected or aſſociated with its name. Yet, though ſo eminent at the preſent time, it was neglected in former ages; and it is ſingular to remark, that its ſource and early progreſs have occaſioned much doubt and diſpute. Some topographers have aſſigned its origin to a ſpot in Oxfordſhire, near the town of Thame; while others, with more regard to probability and record, have traced its ſource to a ſpring near Cricklade, in Wiltſhire. In that diſtrict three or four ſtreams emerge from the earth, and each of theſe has been honoured with the appellation of Thames-head: but at preſent it is very generally admitted, that this name ſtrictly belongs to a fine ſpring, which riſes in the pariſh of Kemble, in Wiltſhire, about five miles N.W. of Cricklade, and two and a half miles S.W. of the town of Cirenceſter. Some writers ſtate that the ſpring-head is in the pariſh of Cotes, and county of Glouceſter. As a proof that this ſtream was deſignated as the Thames, or Tems, at an early period, we may refer to a Saxon charter of Malmſbury Abbey, wherein it is named "Temis," as the boundary of certain lands. Again, ſome of the old Monkiſh hiſtorians ſtate that the Danes croſſed the Thames at Cricklade in the early part of the tenth century.

It has been erroneouſly ſaid, that the name of this river is the *Iſis* till it arrives at Dorcheſter, and receives the waters of the Thame, where it attained the compound name of *Thameſis*. Some old Oxford poets have given currency and celebrity to this ſtory. Pope, in his "Windſor Foreſt," ſpeaking of the union of various ſtreams with this river, thus ſings:

"First the famed authors of its ancient name,
The winding Iſis, and the fruitful Thame;
The Kennet ſwift, for ſilver eels renowned;
The Loddon ſlow, for verdant alders crowned;
Cole, whoſe dark ſtreams his flowery iſlands lave,
And chalky Wey, that rolls a milky wave."

Denham, the poetical encomiaſt of "Cooper's Hill," thus characteriſes the Thames.

"My eye deſcending from the hill, ſurveys
Where Thames among the wanton vallies ſtrays.
Thames the moſt loved of all the Ocean's ſons
By his old ſire to his embraces runs;
Haſting to pay his tribute to the ſea,
Like mortal life to meet eternity."

The nature of the preſent work will not allow of a particular deſcription of the courſe of this river, with brief accounts of all the prominent objects on its banks. It muſt ſuffice to ſpecify the names of the towns, chief ſeats, and prominent features; and refer to the former, under their reſpective names in the Cyclopædia, for further information, and to ſuch books wherein the beſt accounts are to be obtained. One characteriſtic of this river is entitled to notice; and which ſhews, that at the original formation of ſhires, and ſubdiviſion of lands in England, the Thames was at that time a noted and conſiderable ſtream. From the town of Cricklade, to its junction with the ſea at Sheerneſs, this river is a boundary, or natural line of ſeparation, to counties. Soon after its ſource, it divides the counties of Wilts and Glouceſter; next, thoſe of Oxford and Berks, and Buckingham and Berks; afterwards Middleſex and Surrey; and, laſtly, Kent and Eſſex. The Thames is alſo a navigable river nearly the whole of its courſe, and thus affords an eaſy and cheap paſſage for heavy goods from the ocean, and the port of London, to the interior parts of the iſland. By means of a canal, extending from the town of Lechlade, in a north-weſterly direction, to the river Severn, the latter great weſtern river and the Briſtol Channel are joined by a navigable courſe to the Engliſh Channel. See Canal, Thame, and Severn.

As nearly the whole courſe of the Thames is through a plain or level country, we find its current is conſequently ſlow and irriguous: for fifteen or twenty miles it is only a narrow and ſmall ſtream, but after receiving the waters of ſeveral rivulets, it aſſumes a river-like appearance at Lechlade, and is capable of ſuſtaining barges of 100 tons burthen. From that town (about 138 miles by water from London) to Sheerneſs, it is ſtrictly a navigable river. In its courſe to the ſea, the following rivers, beſides ſeveral ſmaller ſtreams, pour their waters into the Thames: the Wainruſh, Evenlode, Cherwell at Oxford, Thame, Kennet, Loddon, Coln, Wey, Mole, Brent, Lea, Roding, Dart, and Medway.

The following cities, towns, and large villages are ſeated on the banks of this river: *viz.* the cities of Oxford, London, and Weſtminſter; the towns of Cricklade, Lechlade, Abingdon, Wallingford, Henley, Great Marlow, Maidenhead, Windſor, Staines, Kingſton, Richmond, Brentford, Greenwich, Woolwich, and Graveſend; the villages of Pangbourn, Wargrave, Eton, Datchet, Old Windſor, Shepperton, Walton, Sunbury, Moulſey, Hampton and Hampton-Court, Twickenham, Iſleworth, Barnes, Chiſwick, Fulham, Putney, Hammerſmith, Chelſea, Blackwall, &c. The banks of this river are alſo ornamented with the palaces of Windſor, Hampton-Court, Kew, Fulham, and Lambeth: likewiſe the following diſtinguiſhed ſeats of Engliſh nobility and gentry, beſides ſeveral ſmaller villas, &c.; Nuneham-Courtney, Baſildon Houſe, Combe Lodge, Purley, Park Place, Fawley Court, Culham Court, Temple Houſe, Harleyford Houſe, Biſham Abbey, Taplow, Cliefden, Cookham, The Willows, Beaumont Lodge, Oatlands, Garrick's Villa and Pope's Villa at Twickenham, Strawberry Hill, Thames-Ditton, Marble-Hill Cottage, the duke of Buccleugh's, lord viſcount Sidmouth's, and Mr. Keen's at Richmond, Keppel Houſe, Sion Houſe, Brandenburgh Houſe, and Ingreſs. Among the numerous bridges which croſs this national river, the following are juſtly noted either for their beauty or extent. The firſt ſtone bridge on its courſe is at Enſham, and the next at Lechlade; Oxford, Abingdon, Shillingford, Wallingford, Caverſham, Henley, Maidenhead, Eton, Staines, Walton, Kingſton, Richmond, Kew, Fulham, Batterſea, Vauxhall, (finiſhed 1816,) Weſtminſter, the Waterloo and Southwark (now erecting from deſigns by that ſcientific enigneer, John Rennie, eſq.), Blackfriars, and London. The laſt ſix may be ſaid to belong to the metropolis. The juriſdiction of the lord mayor of London over the river Thames, extends from Coln-Ditch, near Stains, to Yendal or Yenlech, near Sheerneſs, and alſo includes parts of the rivers Lea and Medway. A very intereſting account of the ſcenery and various objects on this river, with numerous beautiful etchings by

W. B.

W. B. Cooke, and George Cooke, is published in a work in 2 vols. entitled "The Thames, or Graphic Illustrations of Seats, Villas, &c. on the Banks of that noble River." See also an account of the "Police of the River Thames," by P. Colquhoun, esq. a magistrate of London; 8vo. 1800; and Skrine's "Account of Rivers of Note in Great Britain," 8vo. 1801. S. Ireland published "Picturesque Views on the River Thames," 2 vols. imp. 8vo. Boydell also published a work in 2 vols. folio, consisting of history and description by Dr. Combe, and views from drawings by Farringdon.

Under the word CANAL will be found an ample account of the commerce and navigation of this river, divided under the heads of THAMES RIVER (*lower part*); THAMES RIVER (*middle part*); THAMES and ISIS NAVIGATION; THAMES and MEDWAY CANAL; and THAMES and SEVERN CANAL.

THAMES, a river of New Zealand. Capt. Cook, Mr. (now sir Joseph) Banks, and Dr. Solander, sailed up this river in a pinnace; at about fourteen miles from the entrance, it is as wide as the Thames at Greenwich, and the tide at flood is as strong; it is not quite so deep, but has water enough for vessels of more than a middle size, and a bottom of mud so soft, that nothing could take damage by running ashore. The course is from south to north, and the entrance between Cape Colville and Point Rodney.—Also, a river of Upper Canada, which runs into lake St. Clair, N. lat. 42°45′. W. long. 82° 10′.—Also, a river of Connecticut, which runs into the sea, 4 miles below New London.

THAMESIS, called *Jamissa* by Ptolemy, in *Ancient Geography*, a river of the isle of Albion. See THAMES.

THAMETHIS, a town of Egypt. See DAMIETTA.

THAMMUZ, in *Mythology*, is a name under which the Phœnicians worshipped Adonis or Osiris.

THAMMUZ, in *Chronology*, a name given by the Jews to the tenth month of the civil year, containing twenty-nine days, and answering to our June.

THAMNA, in *Ancient Geography*, a celebrated town of Palestine, on the road from Diospolis to Jerusalem. It was the capital of the Thamnitic toparchy.

THAMNATH-SAAR, a town of Palestine, in Samaria, in the tribe and upon the mount of Ephraim, N. of mount Gaas. This town was built by Joshua, and his tomb was there in the time of Jerome.

THAMNERIA, a town of Asia, in Media, in the neighbourhood of the country belonging to the Cadusii. Xenophon.

THAMNIUM, in *Botany*, θαμνιον, *a little shrubbery*, from θαμνος, *a shrub*, a name chosen by Ventenat, in his *Tableau du Regne Vegetal*, v. 2. 35, for the shrubby kinds of Lichen, of which he makes a genus. Its character is

Stems branched in the form of a shrub. Tubercles fungous, coloured.

Lichen rangiferinus, and *L. Roccella*, are mentioned as species of this genus, which is now, like the rest of the author's labours in this department, disregarded, the whole tribe having been so much better studied and arranged by Acharius. See LICHENES.

THAMNOCHORTUS, so called by Bergius, from θαμνος, *a shrub*, and χορτος, *a grass*, alluding to the hard shrubby habit, and natural affinity, of the plant. Berg. Cap. 353. t. 5. f. 8. This genus is now sunk in RESTIO (see that article); and the particular species is *R. scariosus* of Thunb. Prodr. 15, and Willd. Sp. Pl. v. 4. 723, though those authors have used *Thamnochortus* as the specific name of another plant, immediately preceding this in Willdenow, who enumerates thirty species of *Restio*.

THAMSBRUCK, or THOMASBRUCK, in *Geography*, a town of Saxony, in Thuringia; 8 miles S.E. of Mulhausen. N. lat. 51° 5′. E. long. 16° 42′.

THAMUNDACANA, in *Ancient Geography*, a town of Asia, in Interior Libya, S. of the river Niger. Ptol.

THAMYRIS, a town of Mœsia, near the Danube. It was built, according to Jornandes, by Thamyris, queen of the Getæ.

THAMYRIS, in *Mythology*, called by Homer Κιθαριστης, one who plays on the cithara, was the son of Philammon. (See his article.) Plutarch, in his Dialogue on Music, tells us that Thamyris was born in Thrace, the country of Orpheus, and had the sweetest and most sonorous voice of any bard of his time. Homer, in his catalogue of ships, where he speaks of the cities under the dominion of Nestor, mentions Dorion as the place where Thamyris contended with the Muses, whom he had the arrogance to challenge to a trial of skill in poetry and music. The conditions and consequences of this contention are fully described by the poet.

"And Dorion, fam'd for Thamyris' disgrace,
Superior once of all the tuneful race,
Till, vain of mortals empty praise, he strove
To match the seed of cloud-compelling Jove!
Too daring bard! whose unsuccessful pride
Th' immortal Muses in their art defy'd:
Th' avenging Muses of the light of day
Depriv'd his eyes, and snatch'd his voice away;
No more his heav'nly voice was heard to sing,
His hand no more awak'd the silver string."

Iliad, book ii.

Homer availed himself of the popular story concerning the blindness of Thamyris, and embellished it by his versification. Probably the whole allegory of this blindness had its rise from his having injured the organ of sight by too intense an application to the study of music and poetry. And it is the opinion of Pausanias, that there was no other difference between his misfortune and that of Homer, than that Thamyris was wholly silenced by it, and Homer, without being discouraged, continued his poetical and musical occupation long after his blindness.

THAN, in *Geography*, a town of Hindoostan, in Guzerat; 55 miles N.N.E. of Junagur.

THANÆ, in *Ancient Geography*, a town of Palestine, in the half-tribe of Manasseh, on this side of Jordan.

THANE, or THAIN, *Thanus*, the name of an ancient dignity among the English, or Anglo-Saxons.

Skene makes thane to have been a dignity equal with that of the son of an earl: Camden will have it, that thanes were only dignified by the offices which they bore.

There were two kinds or orders of thanes; the *king's* thanes, and the *ordinary* thanes. The first were those who attended our English-Saxon kings in their courts, and who held lands immediately of the king: whence, in Domesday-book, they are promiscuously called *thani*, and *servientes regis*.

Soon after the Conquest this name was disused; and instead of it, they were called the *king's barons*, *barones regis*.

Their origin is referred to king Canutus, who, taking the chief of the Danish nobility, to the number of three thousand, for his guard, and arming them with battle-axes and sabres with gilt handles, called them *thing lith*, from the two Danish words *theing* or *thein*, *body of nobility*, and *lith*, *order of battle*.

The *ordinary* thanes, or *thani minores*, were the lords of manors, who had particular jurisdiction within their limits, and over their own tenants.

These changed their name for that of barons; and hence their courts are called *courts baron* to this day.

In old authors, charters, &c. we also meet with thane as signifying fignifying a nobleman; though fometimes only a freeman, and fometimes a magiftrate.

THANE *Lands*, were lands granted by charter of the Saxon kings to their thanes.

THANET, *Ifle of*, in *Geography*, is a tract of land on the fouthern coaft of the county of Kent, England, confifting of about 27,000 acres, and is feparated from the remaining part of the county by the narrow channel of the river Stour, and the fmaller ftream called the Nethergong. The marfhes which border thefe ftreams are extenfive, and afford rich pafturage for cattle, but the higher grounds are principally appropriated to the growth of corn. The ifle is in fhape a long oval, being about nine miles in length from eaft to weft, and nearly five miles broad from north to fouth. Solinus, who is quoted by Camden, calls it Athanatos, and in fome copies Thanatos, which probably gave origin to the Saxon appellation Tenet, or Tanetlond; though Lewis derives this from Tene, a fire or beacon; and he fuppofes the ifle to have been fo named on account of the beacons or fires which were kept here to give notice of Danifh or other pirates, to whofe ravages it was greatly expofed. Thanet is bounded on the north and eaft fides by the ocean; a circumftance which, connected with the falubrity of its air, and its convenient diftance from the metropolis, has led to the eftablifhment of feveral watering-places; and thefe, in the fummer and autumnal feafons, occafion a continual influx of vifitants, whofe expenditure adds greatly to the wealth of the fixed inhabitants. The chalk cliffs which furround the coaft abound in foffils; and among them, the cornua ammonis has been found, meafuring upwards of three feet in diameter. The whole of Thanet is divided into the two capital manors of Minfter and Monkton, by St. Mildred's Lynch, a narrow ftrip of land, left unploughed, and extending quite acrofs the ifle, from Weftgate by Woodchurch, to Sheriff's Hope near Monkton. The ifle anciently contained eleven parifhes; but thofe of Sarre and All Saints have been united to St. Nicholas, and that of Woodchurch to Birchington. The parifhes of Minfter, Monkton, and Stonar, with parts of thofe St. Nicholas and St. Lawrence, are under the jurifdiction of two conftables; the other parifhes, namely St. John's, including the town of Margate; Birchington, with Gore's End, St. Peter's, and Wood or Woodchurch, the ville of Ramfgate, and the ville of Sarre, with the remainder of St. Nicholas and St. Lawrence, are all members of, and fubject to the controul of the ports of Dover and Sandwich. The population return of the year 1811 ftated the inhabitants of the ifle to be 16,156; the number of houfes 3209. (See MARGATE, RAMSGATE, and RECULVER.)—Beauties of England and Wales, vol. xiii. Kent; by E. W. Brayley.

THANN, or DANN, a town of France, in the department of the Upper Rhine; 13 miles N.N.E. of Befort.

THANN. See TANNA.

THANNHAUSEN, or TANNHAUSEN, a town of Germany, in the circle of Swabia, and principal place of a lordfhip of the fame name, on the river Mindel; 14 miles N. of Mindelheim.

THANNURIS, in *Ancient Geography*, a town of Afia, in Ofrhoene; and another in Mefopotamia.

THANTIA, a town of Paleftine, in Batanæa, eaftward towards the mountains, S.E. of Adraa.

THANWALD, in *Geography*, a town of Silefia, in the principality of Breflau; 13 miles N.W. of Breflau.

THAOUAOUIS. See TAVAVIS.

THAPAUA, in *Ancient Geography*, a town fituated in the interior of Arabia Felix. Ptol.

THAPSA, a town of Paleftine, in the tribe of Ephraim.

THAPSACUS, or AMPHIPOLIS, a large and flourifhing town of Afia, in Syria, on the banks of the Euphrates. When Alexander, after leaving Egypt, came to Thapfacus, he found here two bridges over the Euphrates. Xenophon tells us that Cyrus fojourned here five days; and that it was here that he informed the Greeks of his intention to march to Babylon. The foldiers mutinied, but were afterwards appeafed by his promifes. Thapfacus is now a village, called "El-Der." The channel of the river is here about half a mile in breadth, and would appear to have been fordable from the earlieft times to the prefent day. It was paffed on foot by Cyrus and his whole army, and, as fome fay, by that of Alexander the Great.

THAPSIA, in *Botany*, a name adopted from the ancient Greeks, whofe θαψια, if not precifely a fpecies of our prefent genus, was certainly, like it, a large umbelliferous plant, yielding a gummy exudation, and bearing yellow flowers, fucceeded by broad feeds. Such is the defcription given by Diofcorides, who moreover adds, that his θαψια, fo named from the ifland of Thapfos, where it grew, was in every refpect like *Ferula*, but with a more flender ftem, and leaves nearly akin to fennel. The root was large; white within, black on the outfide, with a thick acrid bark. He attributes various virtues to its gum or juice, either taken as a purge, in oppreffions of the cheft; or applied externally, along with honey, wax, or frankincenfe, for cutaneous complaints, tumours, &c.—Linn. Gen. 144. Schreb. 193. Willd. Sp. Pl. v. 1. 1464. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 156. Sm. Prodr. Fl. Græc. Sibth. v. 1. 201. Juff. 220. Tourn. t. 171. Lamarck Illuftr. t. 206. Gærtn. t. 21.—Clafs and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*, Linn. *Umbelliferæ*, Juff.

Gen. Ch. *General Umbel* large, with about twenty rays, of nearly equal length; *partial* of as many, nearly equal, rays. *Involucrum* none, neither *general* nor *partial*. *Perianth* fcarcely difcernible. *Cor. Univerfal* uniform; all the flowers fertile; *partial* of five lanceolate incurved petals. *Stam.* Filaments five, capillary, the length of the corolla; anthers fimple. *Pift.* Germen inferior, oblong; ftyles two, fhort; ftigmas obtufe. *Peric.* Fruit oblong, encompaffed longitudinally with a membranous border, feparable into two parts. *Seeds* two, very large, oblong, convex, pointed at each end, encompaffed at each fide with a large, flat, entire-edged border, which is emarginate at each extremity.

Eff. Ch. Involucrum neither general nor partial. Fruit oblong, encompaffed with a membranous border. Petals uniform, lanceolate, inflexed. Flowers all fertile.

1. Th. *villofa*. Villous Deadly Carrot. Linn. Sp. Pl. 375. Willd. n. 1. Ait. n. 1. (Th. prima; Cluf. Hift. v. 2. 192. Th. latifolia Clufii; Ger. Em. 1030.)—Leaflets toothed, villous; confluent at the bafe.—Native of ftony ground, in Spain, Portugal, and the fouth of France. Dr. Sibthorp found it in the fields of Patmos and Cyprus, and Dr. Brouffonet at Algiers. The *root* is perennial, tap-fhaped, faid to be of an extremely fœtid, acrid, and naufeous quality, which has given rife to the Englifh name. Gerarde applies to this fpecies what Diofcorides fays of *T. garganica*, that exhalations from the root or plant exulcerate the fkin. The *ftem* is three or four feet high, erect, round, fmooth, leafy, branched at the top. *Leaves* large and fpreading, twice or thrice pinnate; their leaflets feffile, obtufe, pinnatifid, notched, confluent at the bafe, in the manner of a fern; hairy on both fides; whitifh and downy at the back. *Umbels* feveral, ftalked, terminal, large, fmooth, naked. *Flowers* yellow, rather fmall. *Fruit* about half an inch long, and a quarter broad, with four ribs at each

each ſide, and a thin, brown, membranous double wing at each margin.

2. Th. *fœtida.* Stinking Deadly Carrot. Linn. Sp. Pl. 375. Willd. n. 2. Ait. n. 2. (Th. vulgaris; Ger. Em. 1031. Th. vulgaris, carotæ effigie; Lob. Ic. 780. Moriſ. ſect. 9. t. 18. f. 7.)—Leaflets many-cleft, acute; contracted at the baſe.—Native of Spain, as well as of Zante and Cyprus. Gerarde had this plant in his garden, and it is ſtill, like the foregoing, to be ſeen in curious botanical collections, though not very commonly. It differs from the *villoſa* in having more finely, acutely, and deeply divided *leaflets*, which are wedge-ſhaped, not dilated at the baſe. The ſize of the whole plant is ſmaller, and the *ſtem* more branched.

3. Th. *Aſclepium.* Fine-leaved Deadly Carrot. Linn. Sp. Pl. 375. Willd. n. 3. Sm. Fl. Græc. Sibth. t. 286, unpubl. (Th. apula, foliis millefolii; Moriſ. ſect. 9. t. 18. f. 9. Panax Aſclepium Dioſcoridis et aliorum, gummiferum; Columm. Ecphr. p. 1. 87. t. 86.)—Leaves digitate; leaflets doubly pinnate, in many briſtle-ſhaped ſegments.—Native of the ſouth of Italy, and of the Levant; unknown in our gardens. Dr. Sibthorp met with this plant in Greece, Rhodes, and near Conſtantinople. The *root* is tapering, perennial, brown, gummy, crowned with briſtly fibres. *Stem* ſolitary, erect, a yard high, ſlightly branched, round, ſmooth, the thickneſs of a gooſe-quill, almoſt deſtitute of foliage, except about the bottom. *Leaves* on long ſtalks, of five principal unequal leaflets, radiating from the baſe, which are doubly, or almoſt triply, pinnate, their ſmall *leaflets* being divided very deeply into fine acute ſegments, one-eighth of an inch long, ſmooth, and of a bright green. *Flowers* yellow, in ſpreading long-ſtalked *umbels*. *Petals* dilated at the baſe, ſo as to be, from the inflexion of the point, almoſt heart-ſhaped. *Seeds* with broad, linear, obtuſe wings.

4. T. *garganica.* Garganian, or rather Greek, Deadly-Carrot. Linn. Mant. 57. Willd. n. 4. Ait. n. 3. Gouan. Illuſtr. 18. t. 10. Sm. Fl. Græc. Sibth. t. 287, unpubl. (Th. thalictri folio; Magn. Monſp. 287. t. 286. Th. ſive Turbith garganicum, ſemine latiſſimo; Bauh. Hiſt. v. 3. p. 2. 50.)—Leaves radiato-pinnate; leaflets deeply pinnatifid, with linear decurrent ſegments. Native of Barbary, the ſouth of Italy, and the Levant. Dr. Sibthorp finding it very common throughout Greece, and the neighbouring iſlands, juſtly concluded this ſpecies to be the true θαψια of Dioſcorides, with whoſe deſcription it agrees better than any of the reſt. It is a ſtately perennial plant, whoſe ſeeds were probably obtained from the garden of Montpellier, by our Britiſh cultivators, towards the year 1680. The firm round leafy *ſtem*, as well as the ſheathing baſes of the *footſtalks*, and the ripening *ſeeds*, are tinged with a fine glaucous purple. *Leaves* large, deep green; ſmooth above; glaucous, and ſometimes hairy, below; their ſegments near an inch long, linear, entire. *Common footſtalks* long, round, ſometimes very hairy. *Umbels* very large, yellow. *Petals* lanceolate, involute. *Fruit* an inch long, with broad, ſhining, brown wings; its ſides finely ribbed.

For *Th. trifoliata*, Linn. Sp. Pl. 376, ſee SMYRNIUM n. 6, *cordatum*.

Th. polygama, Desfont. Atlant. v. 1. 261. t. 75. Mart. Mill. Dict. n. 6, found on the ſea-coaſt of Barbary, cannot belong to this genus, having a general, as well as partial, *involucrum*, and abortive central *flowers*. It ſhould ſeem to be a LASERPITIUM. See that article.

THAPSIS, in *Ancient Geography*, a river of Scythia, in the environs of the Palus Mæotides, according to Diodorus Siculus.

THAPSOS, in the *Materia Medica of the Ancients*, a name given to a kind of wood of a pale yellow colour, uſed of old in dyeing of linen and woollen cloths. The Greek *Thapſos* ſignifies a pale dead yellow colour, and is applicable either to the ſubſtance, or the juice or tincture of all theſe.

The people of Crete at this time uſe the lycium-wood in dyeing a yellow colour, and it is probable that the *thapſos* was this very tree. Dioſcorides tells us, that the wood of this tree was alſo uſed in his time to tinge the hair yellow, which was a favourite colour with the Greeks. The lycium is of a colour ſomewhat deeper than our box-wood, and parts with its ſtain ſo eaſily, that it ſeems very proper for ſuch a purpoſe.

THAPSUM, among the old *Roman Writers*, a common name for the verbaſcum, or mullein; but as there were many other plants, very different in their nature, yet whoſe names reſembled this; ſuch as the *thapſia*, or deadly carrot, and the *thapſum* or *geniſtella tinctoria;* it was ſoon found neceſſary to add ſome other name, and it was then called *thapſum barbatum*, or *barbaſſum*.

The reaſon of the geniſtella being called *thapſum*, was, that its flowers were yellow, and were uſed to colour the ladies' hair; that being the favourite colour of thoſe days. The flowers of mullein are yellow, and ſeem more fit for the colouring of the hair than thoſe of the geniſtella; their colour being more eaſily ſeparated, and continuing on ſo well, that the glovers of many parts of England uſe them in the ſeaſon for colouring their yellow gloves.

It is probable, that the ladies of old uſed this, as well as the geniſtella, for this purpoſe: and it might hence obtain the common name *thapſum*. The other part of its diſtinction, *barbatum*, ſeems owing to the leaves being ſo coloured with a woolly down that they look bearded. And when this word is written *barbaſſum*, it may probably be given as the name of ſome of thoſe ſpecies of mullein which are not hairy, as our black or ſage-leaved mullein, and be a corruption of the word *verbaſcum*. This black mullein has no leſs title than the white or bearded kind to the name *thapſum;* its flowers being of a yet finer yellow than thoſe of that kind, and being as fit for the uſe of ſtaining. The glovers in ſome places uſe this ſpecies for their leather-gloves.

THAPSUS, DEMASS, in *Ancient Geography*, a maritime town of Africa, upon a tongue of low land, S. of the Leſſer Leptis. The place abounds with ruins.

THAPSUS, or *Tapſus*, in *Botany*, ſee VERBASCUM. This name ſeems to have originated with Gerarde, who gives no explanation, nor do we find any authority for the opinion of De Theis, that it alludes to the iſle of Thapſos, as the native country of the plant. Such indeed is the acknowledged derivation of THAPSIA, ſee that article; with which this *Verbaſcum*, a φλομος of the Greeks, has no relationſhip whatever.

THAR, in *Ancient Geography*, a town of Arabia Felix, belonging to the people called Themi.

THARAND, in *Geography*, a town of Germany, in the circle of Upper Saxony, and circle of Erzgeburg; 10 miles E.N.E. of Freyburg.

THARE, in *Ancient Geography*, a place of the encampment of the Iſraelites, whence they went to Methea. (Numb. xxxiii. 27.) Thare, ſituated in Arabia Deſerta, was the 24th ſtation of the Iſraelites.

THARELA, a town of Paleſtine, in the tribe of Benjamin.

THARGELIA, θαργελια, in *Antiquity*, an Athenian feſtival in honour of the ſun, and his attendants, the

 Hours:

Hours: or, as others think, of the Delian Apollo and Diana. For an account of the ceremonies of this solemnity, see Potter Archæol. Græc. lib. ii. cap. 20. tom. i. p. 400. seq.

THARGELION, Θαργηλιων, in *Chronology*, the eleventh month of the Athenian year. It contained thirty days, and answered to the latter part of our April, and the beginning of May.

It took its name from the festival Thargelia, kept in it.

THARNAU, in *Geography*, a town of Silesia, in the principality of Neisse; 1 mile N. of Grotkau.

THARO, in *Ancient Geography*, an island, situated, according to Ptolemy, in the Persian gulf.

THARPA, a town of India, beyond the Ganges, in the Golden Chersonesus. Ptolemy.

THARRANA, a town of India, beyond the Ganges, on the coast of the Great gulf. Ptol.

THARSIA, a town of Africa propria, or one of those which Ptolemy points out between Bagradas and the town of Thabraca.

THARSIS, Tharshish, or *Tarshish*. See Ophir.

THASO, in *Geography*, an island of the Grecian Archipelago, situated in the gulf of Contesa, anciently called *Æria*, or *Æthria*, being famous, even to a proverb, for its rich gold-mines. It has a town or village of the same name. N. lat. 40° 34′. E. long. 42° 30′.

THASSUS, Thassos, or *Thasus*, in *Ancient Geography*, an island situated on the coast of Thrace, opposite to the mouth of the river Nestus. Thasus, son of Agenor, king of the Phœnicians, is said to have remained many years in this island, to have peopled it, and to have given it his name. It was afterwards increased by a Greek colony. The Athenians made themselves masters of this island, and treated the inhabitants with great rigour; but they were expelled by the Macedonians, and these again by the Romans.

THATCH, in *Rural Economy*, prepared straw which is intended to be laid on the top of a building, rick, &c. to keep out the wet. There are many different sorts of materials that may be made use of as thatch, but those which are most commonly employed are the straw of different sorts of grain, as wheat, rye, &c. reed, stubble, heather, &c. The straw of wheat and rye, when well prepared and laid, probably forms the neatest and most secure covering for general purposes. It has indeed been stated, that the most suitable material for the purpose is that of good wheat-straw that has been much bruised in threshing out the grain. But when this cannot be had in sufficient quantity, rye-straw may be substituted in its place; however, from its rough and stubborn quality, it is neither so neat in its appearance, so durable, nor affords so secure a covering. And that barley and oat straw are sometimes made use of for the purpose, but they form very indifferent coverings, and such as are not by any means lasting. The former, when strong, is however preferable to the latter.

The reed is a highly valuable article for the purpose of thatch, where a lasting roof is required; but is much too expensive and stubborn for common purposes. It has been remarked by Mr. Marshall, in the Rural Economy of Norfolk, that there, the favourite material for roofs, and that which is the most eligible after good slate for farm purposes, is reed. And that a reed roof properly laid, will lie fifty years without touching; and thirty or forty more, with only adjusting (driving) it, and levelling the hollows with a little fresh reed. At an hundred years old it may be relaid; and will then, if laid upon the upper parts of the roof, last through a considerable part of another century. The reed is, he says, principally cut from the margins of the *broads*, (large pieces of water,) and is carried, perhaps, forty or fifty miles into the central and northern parts of the county. And it is added, that though a covering of reed is, in the first instance, costly; when its durability, and the high degree of preservation in which it keeps the roof, are taken into the account, it is of all other the cheapest covering; besides its being, whether in the extreme of heat or cold, the most comfortable.

And it is stated, that the price of reed, in the place of its growth, is from three pounds to three guineas a hundred, containing six score fathoms; each fathom (composed of five or six sheaves) measuring six feet in circumference. A hundred of reed will cover five squares of roof: the laying is a halfpenny a yard, or four shillings and twopence a square; and the tar rope and rods for fastening it on cost eighteen pence a square: so that a covering of new reed costs about eighteen shillings a square, containing 100 square feet; besides carriage, and what is called *roofing*; namely, a cap of wheat-straw placed upon the ridge, in a somewhat similar manner, and for the same purpose, as ridge-tiles are put on. This capping, which is done in a most effectual, but in a tedious and expensive manner, costs, in materials and workmanship, about sixteen pence each foot in length: which, upon a roof of sixteen feet and a half spar, is an additional expence of four shillings each square of reeding.

With regard to the carriage, it is in proportion to the distance. Taking twenty miles as a medium distance, and one shilling a mile as a medium price; the expence is, he says, twenty shillings a 'load' of sixty fathoms, or forty shillings a hundred; which laying five squares is a further addition of eight shillings a square: therefore, the whole expence of a covering of reed fetched twenty miles, may, he supposes, be laid at thirty shillings a square. The writer has been thus minute, he says, in his account of this material, as it has been much overlooked in other districts, where it may be found useful.

This material is a great deal more expensive in every respect which has any relation to this object, at the present time, than it was then.

And with respect to the stubble, it is said to be a material that may be made use of with propriety and advantage in some situations. This is the stubble of such wheat or other crops as have been cut at a great height; which, after being mown close to the ground and raked up, serves this purpose, especially for the more common purposes of the farm, such as covering hay and straw stacks, &c. the thatching potatoes when hogged in the ground, and many other such cases.

The last material, heather, is also found a highly valuable article for the purpose of thatch in districts where it grows in abundance, as it is extremely durable. See Heather.

The thatch which is removed from the stacks or buildings may be used as a litter for various purposes.

The modes of preparing and applying these different matters to the roofs of stacks and buildings will be pointed out in speaking of the operation of securing such roofs by means of such substances. See Thatching.

Where straw of the rye or wheat kind is very strong, it is often termed *reed* or *straw reed* by the thatcher, and used for covering large hay-stacks very commonly in many districts.

THATCHAM, in *Geography*, a village and parish in the hundred of Reading and county of Berks, England, is situated 3 miles E. from Newbury, and 53 miles W. from London. It appears to have been formerly a town of some consequence, from the Domesday Survey, and other records,

cords, in which it is defcribed as an ancient borough; but it does not appear ever to have fent reprefentatives to parliament. From a very early period it had a market on Sundays, which was confirmed to the abbot and convent of Reading by a charter of Henry II. The market-day was changed by Henry III. in 1218 to Thurfday; but the market has long been difcontinued. Two annual fairs are ftill held. The manor of Thatcham was given to the abbot and convent of Reading by Henry I. At the diffolution it was granted, in 1539, to John Winchcombe, fon of the celebrated Jack of Newbury: it is now the property of William Mount, efq. of Wafing. A charity-fchool was founded here, in 1707, by lady Frances Winchcombe, who endowed it with 53*l. per annum.* The fchool had been long difcontinued, and its revenue loft to the parifh; when Mr. Thompfon, a late vicar, inftituted a fuit for their recovery, and after a long conteft fucceeded in the re-eftablifhment of the fchool, with an income for the mafter increafed to 200*l. per annum;* forty boys are now clothed and educated, and fix of them annually apprenticed with premiums of 10*l.* each. The parifh of Thatcham is the moft extenfive of any in the county, excepting Lamborn, and includes fix townfhips. The population, according to the parliamentary report of the year 1811, was eftimated at 2104; the number of houfes at 424.—Lyfons's "Magna Britannia," vol. i. Berkfhire.

THATCHER, a rock in the Englifh Channel, on the north fide of Torbay.

Thatcher, in *Rural Economy*, a perfon who performs the bufinefs of thatching.

THATCHING, the operation of covering the roofs of buildings, ftacks, and other things, with fome fort of thatch. For this purpofe, articles of the ftraw kind are prepared in the following manner: After being well moiftened with water, they are drawn out in handfuls perfectly ftraight and even into regular lengths, and the fhort ftraw feparated from them, leaving them placed in convenient ranges for forming bundles to be carried to the thatcher by the perfon who has the ferving of him.

In regard to the application of the thatch to ftacks of hay or corn, there are different methods purfued, according to the nature of the materials employed. Where long ftraw is made ufe of, the operator or workman ufually begins at the eaves or bottom part of the roof, depofiting it in handfuls in regular breadths till he reaches the top, the different handfuls being fo placed endways as to overlap each other, the upper ends being conftantly pufhed a little into the bottom parts of the fheaves or other matters. In this manner he gradually proceeds, breadth after breadth, till the whole of the roof is covered, which is ufually done to the thicknefs of about four or five inches. And in order to retain the thatch in its place, fhort fharp-pointed fticks, termed *prods* in fome places, are occafionally thruft in, in a flanting direction upwards; and fometimes fmall fticks, often called *fpelks*, fharpened at the ends, are bent and thruft in along the top parts and fides. But as the water is apt to follow the courfe of the fticks, it is perhaps a better practice to make ufe of ropes of twifted ftraw for this purpofe. In fome cafes, thefe are applied only round the bottom parts of the roof and the fides; while in others, which is a much better and more fecure method, they are applied in fuch a manner over the whole ftacks, as to form a fort of coarfe net-work of nine or twelve inches in width in the niches, the ends being well faftened either to belt-ropes paffed in fuitable directions for the purpofe, or to different parts of the ftraw of the ftack.

In the application of ftubble as a thatch, it is moftly, after being prepared, put on by fticking one of its ends into the roof of the ftack in a regular and exact manner, fo as that it may ftand out very clofe and thick; when the other, with fuch loofe ftraws as may occur, is to be cut over or pared off, with a very fharp tool for the purpofe, fo as to form a neat and impenetrable thatch, having the appearance of a newly thatched houfe roof; the whole being well fecured in its place by fhort pegs made for the purpofe, fomewhat in the fame way as in the thatch of other ftacks.

In the thatching of the roofs of houfes or other buildings with any of the different forts of ftraw, the materials are to be laid on to a confiderable thicknefs, and firmly fecured. They are applied in regular narrow flips, or what in fome diftricts are termed *gangs*, from the eaves of the building to the ridges, the ladder being moved forward as the work proceeds. The thatch is fecured by fhort fharpened fticks, as above, thruft in where neceffary. And bended fticks, fharpened at each end, are likewife fometimes made ufe of near the ridges, being thruft in at each end. In finifhing the work, the thatcher moftly employs an iron-toothed rake, with which the whole is raked and trimmed over from top to bottom, fo as to render it completely fmooth and even, and take away all the fhort ftraws, and other irregular matters.

The method of thatching with reed, according to Mr. Marfhall, in his account of the Rural Economy of Norfolk, is this: no laths being made ufe of, in laying it, a little of the longeft and ftouteft of the reed is fcattered irregularly acrofs the naked fpars, as a foundation to lay the main coat upon: this partial gauze-like covering is called the "fleaking." On this fleaking the main covering is laid, and faftened down to the fpars by means of long rods, provincially "fways," laid acrofs the middle of the reed, and tied to the fpars with rope-yarn, or with "bramble bonds," formerly much ufed, but now pretty nearly laid afide. In laying on the reed, the workman begins at the lower corner of the roof, on his right hand, for inftance, and keeps an irregular diagonal line, or face, until he reaches the upper corner to his left, a narrow eaves-board being nailed acrofs the feet of the fpars, and fome fleaking fcattered on; the thatcher begins to "fet his eaves," by laying a coat of reed, eight or ten inches thick, with the heads refting upon the fleaking, and the butts upon the eaves-board. He then lays on his *fway* (a rod about the fize of a fmall edder) about fix or eight inches from the lower point of the reed; whilft his affiftant, on the infide, runs a needle, threaded with rope-yarn, clofe to the fpar; and, in this cafe, clofe to the upper edge of the eaves-board. The thatcher draws it through on one fide of the fway, and enters it again on the contrary fide, both of the fway and of the fpar: the affiftant draws it through, unthreads it, and with the two ends of the yarn makes a knot round the fpar; thereby drawing the fway, and confequently the reed, tight down to the roof: whilft the thatcher above, beating the fway and preffing it down, affifts in making the work the firmer. The affiftant having made good the knot below, he proceeds with another length of thread to the next fpar, and fo on, till the fway be bound down the whole length; namely, eight or ten feet. This being done, another ftratum of reed is laid on upon the firft, fo as to make the entire coat eighteen or twenty inches thick at the butts; and another fway laid along, and bound down, about twelve inches above the firft.

The eaves being thus completely fet, they are adjufted and formed, not fquare with the fpars, but nearly horizontal: nor are they formed by cutting, but by "driving" them with a "legget," a tool made of a board eight or nine inches fquare, with a handle two feet long, fixed upon the back of it, it, obliquely, in the manner of the tool ufed by gardeners in beating turf. The face of the legget is fet with large-headed nails, to render it rough, and make it lay hold of the butts of the reeds. Then another layer of reed is laid on, and bound down by another fway, fomewhat fhorter than the laft, and placed eighteen or twenty inches above it; and above this another, and another, continuing to fhorten the fways, until they be brought off to nothing, and a triangular corner of thatching formed. After this the fways are ufed their whole length, whatever it happens to be, until the workman arrives at the finifhing corner.

In order to give a finifh to the ridge, a *cap* (provincially a "roof") of ftraw is fet on in a mafterly, but in an expenfive manner. In this operation, the workman begins, it is obferved, by bringing the roof to an angle, with ftraw laid the long way upon the ridge, in the manner in which a rick is topt up; and to render it firm, to keep it in its place, and to prevent the wind from blowing it off, or ruffling it, he pegs it down flightly with "double broaches;" namely, cleft twigs, two feet long, and as thick as the finger, fharpened at both ends, bent double, and perhaps with the twifting of the crown, and perhaps barbed, by partial chops on the fides, to make them hold in the better. This done, the workman lays a coat of ftraight ftraw, fix or eight inches thick, acrofs the ridge; beginning, on either fide, at the uppermoft butts of the reed, and finifhing with ftraight handfuls evenly acrofs the top of the ridge. Having laid a length of about four feet in this manner, he proceeds to faften it firmly down, fo as to render it proof againft wind and rain. This is done by laying a "broachen ligger" (a quarter-cleft rod as thick as the finger, and four feet in length) along the middle of the ridge, pegging it down at every four inches with a double broach, which is firft thruft down with the hands, and afterwards driven with the legget, or with a mallet ufed for this purpofe. The middle ligger being firmly laid, the thatcher fmooths down the ftraw with a rake and his hands, about eight or nine inches on one fide, and at fix inches from the firft lays another ligger, and pegs it down with a fimilar number of double broaches, thus proceeding to fmooth the ftraw, and to faften on liggers at every fix inches, until he reach the bottom of the cap. One fide finifhed, the other is treated in the fame manner; and the firft length being completed, another and another length is laid, and finifhed as the firft, until the other end of the ridge be reached. He then cuts off the tails of the ftraw fquare and neatly with a pair of fhears, level with the uppermoft butts of the reed; above which the cap (or moft properly the *rooflet*) fhews an eaves of about fix inches thick. And laftly, he fweeps the fides of the main roof with a bow of holly, when the work is completed. This, when well performed, muft be a durable and ufeful mode of thatching, and at the fame time one which has a neat appearance.

In thatching with heather, that material moftly undergoes fome fort of preparation, fo as to render it as equal as poffible in fize and ftrength, being laid and faftened upon the roofs then in fomewhat the fame manner as that of ftraw. It is afterwards fwept, cleaned, and finifhed off in a neat and exact manner, fo as to look extremely well.

In fome of the more expofed fituations in the northern parts of the ifland, they have other modes and practices of thatching buildings with ftraw in ufe, fuch as performing it with clay, or thin turf and that material.

If the roof be covered with thin turf or divots, the workman is to twift the upper part of the ftraw into a fort of knot; then, with a ftick prepared for the purpofe, to force the knot thus formed either under or through the turves or divots, fo that it may have a firm hold of the roof; after which, to fpread the lower part of the bundle of ftraw nicely on the roof, continuing to do the fame to the very top of the roof; and then to clay it all over, and begin another tier, gang, or row of the thatch. In this way, the thatch fhould not be laid thinner than fix inches, and when it is laid eight inches thick, it is the more durable. Thin turf, or divots, were originally thought the beft foundation; but it has been fince found by experience, that they rot the ftraw, and that ftraw alone, when ftitched on with rope-yarn, lafts much longer. If ftraw alone be ufed in this manner, it will laft twenty years; but the ftraw muft be laid on two inches thicker than when clay is added. A roof that is thatched with divots, ftraw, and clay, in the common way, will laft from feventeen to twenty years; and is alfo capable of being mended without raifing any part of the roof that is entire. The above kind of roof is much lefs liable to catch fire than ftraw roofs without clay. The clay that anfwers the purpofe beft is that which has a due proportion of fand in it. If ftiff clay fhould be ufed, it will be neceffary to add one cart-load of fand to every two of the clay.

This fort of claying may, of courfe, be ufeful and advantageous in thatching the roofs of buildings in many fituations and places.

THAU, in *Geography*, a lake of France, in the department of the Herault, near the Mediterranean, between Frontignan and Agde.

THAUANA, in *Ancient Geography*, a town fituated in the interior of Arabia Felix.

THAUBA, a town in the interior of Arabia Felix. Ptol.

THAUGHTS, or THOUGHTS, in a *Boat*, are the benches on which the rowers fit to row.

THAUMASIUS MONS, in *Ancient Geography*, a mountain of Arcadia, N.W. of Mantinea, above the river Moloffus.

THAUMATURGUS, formed from θαυμα, *wonderful thing*, and εργον, *work*, *worker of miracles*; an appellation which the Romanifts gave to feveral of their faints, eminent for the number and greatnefs of their miracles.

St. Gregory, called *Thaumaturgus*, or Gregory of Neocæfarea, was a difciple of Origen about the year 223, and afterwards bifhop of Cæfarea, in Pontus; and in that capacity he affifted at the firft council of Antioch, and at that of Ephefus, againft Paulus Samofatenus. St. Leo of Catanea is alfo called *Leo Thaumaturgus*. He lived in the eighth century; and his body is ftill honoured at Rome, in the church of St. Martin de Tours. St. Francis Paul, and St. Francis Xavier, are the great Thaumaturgi of thefe laft ages.

THAWING, the refolution of ice into its former fluid ftate, by the warmth of the air.

THAXTED, in *Geography*, an ancient market-town in the hundred of Dunmow, and county of Effex, England, is fituated 19 miles N.N.W. from Chelmsford, and 43 miles N.N.E. from London. The town was known in the Saxon times, as the church is recorded to have belonged, in the reign of Edward the Confeffor, to the college of St. John Baptift, at Clare, in Suffolk. Thaxted was incorporated by charter of Philip and Mary, which was confirmed by queen Elizabeth; under this the civil government is vefted in a mayor, recorder, two bailiffs, and twenty principal burgeffes. In the reign of James II. the corporation experienced a temporary fufpenfion; for being ferved with a writ of quo warranto, the corporate officers, either through fear or poverty, thought fit to retire from their offices. The market was granted by Edward II., but was difcontinued for a long period: it has been recently revived, and is now held on Fridays. Here are alfo two annual fairs. In the population return of the year 1811, Thaxted was ftated to contain 390 houfes, occupied by 1733 perfons. The church is a very large and beautiful ftructure, and appears, from the various arms and cognizances on feveral parts, to have been built at different times in the fourteenth and fifteenth centuries. The whole fabric is embattled, and fupported by ftrong buttreffes, terminated by canopied niches, and curioufly purfled pinnacles. At the weft end is an embattled tower, fuftained by buttreffes, and furmounted by a neat octagonal fpire, rifing to the height of 181 feet. The interior confifts of a nave, tranfept, chancel, and fide aifles: the arches of the nave are pointed, and fupported by eight cluftered columns on each fide. The expence of the erection of this church was principally defrayed by the noble families of Clare and Mortimer, who then poffeffed the manor, with fome affiftance from king Edward IV. A chantry, befides various chapels and altars, were ufed here before the reformation. The charitable benefactions for the ufe of the poor inhabitants of Thaxted are confiderable. An eftate, called Yendleys, deriving its name from Thomas Yendale (who refided on it temp. Henry VI.) was, on his death, vefted in truft for his four fons and their iffue; and in default of fuch iffue, to be fold for the benefit of the church and poor. The fons all dying childlefs, the eftate was fold 5 Henry VII. and the produce is applied to the fupport of a fchool, repairing the church, improving the highways, &c. In 1698, William, lord Maynard, bequeathed 4000*l.* in truft, the produce to be applied for increafing the minifter's falary, repairing the church, marrying poor young women, binding out apprentices, and relieving poor people overburthened with children. Among other benefactions are endowments for alms-houfes in feveral parts of the town: one of the buildings appropriated for that purpofe is the old chantry-houfe. The ancient guildhall is now the parifh workhoufe: the mote-hall is ufed for a public fchool.—Beauties of England and Wales, vol. v. Effex; by J. Britton and E. W. Brayley. Morant's Hiftory, &c. of Effex, 2 vols. folio.

THEA, in *Ancient Geography*, a town of the Peloponnefus, in Laconia.

Thea, in *Botany*, the Tea-tree, a name of barbarous derivation, originating in the Chinefe *Tcha*, or Japanefe *Tsja*, of which the various nations of Europe have made, according to their fancy, Chaa, Tea, Thé, &c. and which Kæmpfer has formed in Latin into *Thea*. This laft has been admitted by Linnæus, for the fake of its Greek orthography, exactly that of θεα, *a goddefs*, a coincidence highly welcome to thofe who honour the cordial beverage of tea as it deferves.—Linn. Gen. 269. Schreb. 361. Willd. Sp. Pl. v. 2. 1180. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 303. Juff. 262. Lamarck Illuftr. t. 474. Gærtn. t. 95.—Clafs and order, *Polyandria Monogynia*, Linn. Rather *Monadelphia Polyandria;* fee Sm. Introd. to Bot. ed. 3. 335. Nat. Ord. *Columniferæ*, Linn. *Aurantiis et Meliis affine*, Juff.

Gen. Ch. *Cal.* Perianth inferior, fmall, of one leaf, in five deep, rounded, obtufe, permanent fegments. *Cor.* of one petal; tube none; limb in fix, or more, deep, unequal, rounded, concave, imbricated fegments, much longer than the calyx; the outer ones fmalleft. *Stam.* Filaments numerous, about two hundred, thread-fhaped, fhorter than the corolla, united at the bafe into a fhallow cup-like tube, inferted into the receptacle, and connected with the bottom of the petal; anthers peltate, fimple, nearly globofe. *Pift.* Germen fuperior, globofe, with three obtufe angles; ftyle triangular, with three furrows, the length of the ftamens, fplitting into three parts; ftigmas three, linear-oblong, deflexed. *Peric.* Capfule three-lobed, three-celled, burfting along the upper fide of each lobe. *Seeds* folitary, globofe, fomewhat angular.

Eff. Ch. Calyx in five deep rounded fegments. Corolla in fix, or more, deep imbricated fegments. Capfule fuperior, three-lobed. Seeds folitary.

Obf. Gærtner remarks that there are rudiments of four or fix feeds in each cell of the germen. The genus is, doubtlefs, nearly related to Camellia, (fee that article,) and fhould ftand next to it in the artificial, as well as natural fyftem. Whether the connection of the ftamens varies, or whether we have fometimes in our gardens Thunberg's *C. Safanqua* for the true Tea-plant, is extremely difficult to determine. The flowers in England are certainly never fo large as in his plate of *Safanqua*, which latter may poffibly be a fpecies of *Thea*, though very diftinct from the Linnæan fpecimens marked *T. Bohea*, and from all we have ever examined in gardens. Plukenet's Fruticis Theæ fpecies altera Sinarum, Amalth. t. 405. f. 3, may belong to this *Safanqua*. The fpecies of *Thea* are involved in much obfcurity. Linnæus was led to defcribe two, under the popular names of *Bohea* and *viridis*, which he diftinguifhed by the former having fix *petals*, or rather fegments of the *corolla*, and the latter nine. But for thefe characters he is indebted to Hill, whofe authority is little to be relied on. We have never feen perfect fpecimens of more than one fpecies, which anfwers to the definition of the *Bohea*, with fcarcely any variation; nor do the leaves of common green or black tea, when expanded by hot water, betray any difference in their ferratures, veins, or other refpects, from that or from each other. The *Pekoe*, whofe filky young branches are confpicuous in the tea-cheft for their whitenefs, agrees in that particular with our garden fpecimens of *Thea*, and not with *Camellia Safanqua* fent by Thunberg, for this laft is hairy in a very different manner. Such being the ftate of the cafe, we can undertake to defcribe only one fpecies of *Thea*.

1. T. *viridis*. Green Tea. Gærtn. v. 2. 83. t. 95. f. 1. Linn. Sp. Pl. 735. Willd. n. 2. (T. bohea; Linn. Sp. Pl. 734. Amœn. Acad. v. 7. 253. t. 4. Willd. n. 1. Ait. n. 1. Thea; Kæmpf Am. Exot. 605. t. 606. Woodv. Med. Bot. fuppl. 116. t. 256. T. chinenfis; Curt. Mag. t. 998. T. cantonienfis; Lour. Cochinch. 339. Thée; Barth. Act. v. 4. 1. t. 1. Tea-tree; Letfom Monogr. t. 1.)—Native of China and Japan. The late Mr. John Ellis is faid to have firft raifed it from feed in England, about the year 1768. The fhrub is propagated by cuttings, and will bear our winters with a flight degree of fhelter, though it rarely flowers, except in a greenhoufe or ftove. The *ftem* is from three to fix feet high, bufhy, with numerous, alternate, round, leafy branches, fmooth, except at the very extremity, where the youngeft fhoots are finely filky, with clofe-preffed hairs. *Leaves* alternate, on fhort, thick, channelled, fmooth *footftalks*, evergreen, elliptic-oblong, with a blunt emarginate point, copioufly ferrated, except at the bafe, with inflexed pointed ferratures, fmooth on both fides, with one rib and many tranfverfe veins, interbranching towards the margin; paler beneath; their length two or three inches; their breadth about one inch: the young ones finely filky before expanfion, with a deciduous point. *Stipulas* none. *Flowers* axillary, or, on the lateral fhoots, nearly terminal, white, not unlike thofe of a Myrtle, but rather larger, and on fhort, thick, recurved, round, fmooth *ftalks*, ufually two together, accompanied by a few alternate, fhort, ovate, deciduous *bracteas*. The two outer fegments of the *corolla*, fmaller than the reft, are green, or purplifh, at the back. *Anthers* and *ftigmas* yellow.

For the economical hiftory of this plant, fee Tea. We have

have been greatly at a lofs for a fpecific name, and have adopted *viridis* to avoid any needlefs change, thinking it rather preferable to *Bohea*, which is a partial name, and of corrupt orthography. Dr. Sims, in *Curt. Mag.*, has ufed *chinenfis*, but this is liable to objection, as the name of a country to which the plant is not quite peculiar; and Loureiro's *cantonienfis* is therefore ftill more exceptionable. This laft author concurs in the opinion that all the common Chinefe teas belong to one fpecies. He defcribes indeed two others, *T. cochinchinenfis*, which feems a trifling variety of the above; and *T. oleofa*, growing wild near Canton, faid to bear a yellow *berry*, whofe feeds fupply the Chinefe with lamp-oil.

Thea, in *Gardening*, furnifhes plants of the exotic fhrubby kind, the fpecies of which chiefly in ufe is the tea-tree (thea).

This tree, as it is commonly defcribed, differs in height, in its native climate, from five or fix feet to thirty, and even one hundred and fifty, or more, when let grow to its full fize and dimenfions.

And in refpect to the varieties of it, Martyn has confidered them all as forming one fpecies, in which he is, he afferts, fupported by the beft authorities. Kæmpfer, he contends, attributes their difference to foil, culture, age of the leaves, and method of curing them. Mr. Ellis alfo directly afferts, that the green and bohea tea are one and the fame fpecies; and that it is the nature of the foil, the culture, and manner of gathering and drying the leaves, that make the difference. So alfo fir George Staunton maintains, that every information received concerning the tea plant concurred in affirming, that its qualities depended upon the foil in which it grew, and the age at which the leaves were plucked off the tree, as well as upon the management of them afterwards. See Tea and Thea.

The bohea tea-trees now introduced into many botanic gardens near London, exhibit very obvious varieties: the leaves are of a deeper green colour, and not fo deeply ferrated; and the ftalk is ufually of a darker colour: but the botanical characters are the fame. Thunberg alfo diftinguifhes two varieties from the leaves, which in one are fmaller, flat, darker green, with ftraight ferratures, and in the other larger, waved, brighter green, with finuate ferratures: but they can fcarcely be confidered as diftinct fpecies. Loureiro obferved little difference in the fou-chong which he examined: both thefe have a brown colour, but are more odoriferous and precious than the common bohea of the province Fo-kien, which he had not an opportunity of feeing in a living ftate, though it is the moft common and cheapeft of all. He examined the dry flowers of the green-tea from the province of Kiang-fi, and obferved the fame inconftancy as to the number of parts in the calyx and corolla, as in the bohea. Upon the whole, he concludes that all the differences of Chinefe tea form only one botanical fpecies, owing their variation to foil, culture, and method of preparation; all retaining the fame inconftancy in the parts of the flower, which gave occafion to Linnæus to confider them as two fpecies. Befides, it is evident that many varieties of tea are known in China, which arife from mixture and management.

The diftinctions chiefly regarded in Europe are the following.

Green Teas.—1. Bing, imperial or bloom tea, with a large loofe leaf, of a light green colour, and a faint delicate fmell.

2. Hy-tiann, hikiong, hayffuen or heechun, known to us by the name of hyfon tea: the leaves are clofely curled and fmall, of a green colour verging towards blue. Another hyfon tea, with narrow fhort leaves, is called hyfon-utchin. There is alfo a green tea named globe, with long narrow leaves.

3. Song-lo or finglo, which name it receives, like feveral others, from the place where it is cultivated.

Bohea Teas.—1. Soo-chuen, fut-chong, fou-chong, or fu-chong, called by the Chinefe faa-tyang, and fact-chaon or fy-tyann, is a fuperior kind of cong-fou tea. It imparts a yellowifh-green colour by infufion, and has its name from a place or province in China. Padre futchong has a finer tafte and fmell: the leaves are large and yellowifh, not rolled up, and packed in papers of half a pound each. It is generally conveyed by caravans into Ruffia: without much care it will be injured at fea. It is rarely to be met with in England.

2. Cam-ho or foum-lo, called after the name of the place where it is gathered: a fragrant tea with a violet fmell; its infufion is pale.

3. Cong-fou, congo, or bong-fo: this has a larger leaf than the following, and the infufion is a little deeper coloured. It refembles the common bohea in the colour of the leaf.

There is alfo a fort called lin-kifam, with narrow rough leaves. It is feldom ufed alone, but mixed with other kinds. By adding it to congo, the Chinefe fometimes make a kind of pekoe tea.

4. Pekao, pecko, or pekoe, by the Chinefe called back-ho or pack-ho: it is known by having the appearance of fmall white flowers intermixed with it.

5. Common bohea or black tea, called moji or mo-ee by the Chinefe, confifts of leaves of one colour. The beft is named Tao-kyonn. An inferior kind is called An-kai, from a place of that name. In the diftrict of Honam, near Canton, the tea is very coarfe, the leaves yellow or brownifh, and the tafte the leaft agreeable of any. By the Chinefe it is named honam-te, or kuli-te.

But befides thefe, tea, both bohea and green, is fometimes imported in balls, from two ounces to the fize of a nutmeg and of peas. The Chinefe call it poncul-tcha. The fmalleft in this form is well known under the name of gunpowder tea.

And fometimes the fucculent leaves are twifted like pack-thread, an inch and a half, or two inches long; three of thefe are ufually tied together at the ends by different coloured filk threads. Both green and bohea teas are prepared in this manner.

The manner of gathering and preparing the leaves, as practifed in Japan, according to Kæmpfer, as far as our information reaches, is in a great meafure conformable to the method ufed by the Chinefe. See Tea.

Whether the Chinefe collect the tea precifely at the fame feafons as in Japan, we are not well informed; but moft probably the tea harveft is nearly at the fame periods, the natives having frequent intercourfe, and their commercial concerns with each other being very extenfive.

For an account of the preparation of the tea-leaves, &c. fee Tea.

The country people cure their tea-leaves in earthen kettles, which anfwer every neceffary purpofe, at lefs trouble and expence than by the procefs defcribed under the article Tea, and they are thus enabled to fell them cheaper. After the tea has been kept for fome months, it is taken out of the veffels in which it was ftored, and dried again over a very gentle fire, that it may be deprived of any humidity which remained, or it might have fince contracted.

The

The common tea is kept in earthen pots with narrow mouths; but the beſt ſorts, uſed by the emperor and nobility, is put into porcelain or china veſſels. The coarſeſt tea is kept by the country people in ſtraw baſkets, made in the ſhape of barrels, which they place under the roofs of their houſes, near the hole that lets out the ſmoke.

Method of Culture.—Theſe plants may be raiſed in this country by ſeeds, layers, and cuttings of the young branches. The editor of Miller's Dictionary adviſes that the ſeeds ſhould be procured from China, and that care ſhould be taken that they be freſh, ſound, ripe, white, plump, and moiſt internally. After being well dried in the ſun, they may be incloſed in bees-wax, or, left in their capſules, they may be put into very cloſe caniſters of tin or tutenague. Thouin, in his directions to Perouſe, it is ſaid, recommends theſe and other ſeeds to be placed in alternate layers of earth or ſand, in tin boxes, cloſed up exactly, and placed in ſolid caſes, covered with waxed cloth; the boxes to be placed in a part of the ſhip the leaſt acceſſible to moiſture, and the moſt ſheltered from extreme heat or cold. And Mr. Sneyd, it is added, was very ſucceſsful in having ſeeds packed up in abſorbent paper, and ſurrounded by raiſins or moiſt ſugar, which kept them in a ſtate fit for vegetation. American ſeeds are frequently brought over, by putting them into a box, not made too cloſe, upon alternate layers of moſs, in ſuch a manner as to admit the ſeeds to vegetate. This might be tried with the ſeeds of the tea-tree; and to ſucceed more certainly, ſome of the ſeeds might be ſown in pots or boxes, when the veſſel arrives at St. Helena, and after paſſing the tropic of Cancer, near the latitude of thirty degrees north. But the beſt method ſeems to be, to ſow ripe ſeeds in good light earth in boxes, at leaving Canton, covering them with wire, to prevent rats and other vermin from getting to them; and taking care that the boxes be not expoſed to too much air, nor to the ſpray of the ſea. A little freſh or rain-water ſhould be ſprinkled over them now and then; and when the ſeedling plants appear, they ſhould be kept moiſt and out of the burning ſun. If young plants can be procured in China, they may be ſent over in a growing ſtate in boxes, forty inches long by twenty broad, and as much in depth, having a few holes bored through the bottom. When the trees arrive here, they muſt be kept in a greenhouſe during the winter, and in the open air during the ſummer; and if they come in bad condition, it may not be amiſs to plunge the pots into which they are tranſplanted in a gentle hot-bed, or to ſet them in a tan-pit, to make them ſtrike and ſhoot more freely. It is further remarked, that though the tea-tree will not at preſent bear the rigour of our winters in the open air, yet it is not impoſſible but it may gradually become naturalized to our climate, like the magnolia, among ſeveral other trees and ſhrubs; eſpecially if it were to be brought from the coldeſt provinces of China, where it grows, or from the parts of Europe a little to the ſouthward of us, when it has been naturalized there. It is increaſed freely from cuttings, when managed in the ſame manner as gardenias: and it alſo ſometimes grows from layers laid down in the autumn or ſpring.

Some of theſe plants ſhould be always kept in pots, to be removed under the ſhelter either of a greenhouſe, glaſs caſe, or deep garden frame, in winter; and others be planted in a dry, well-ſheltered, warm, conſpicuous part of the ſhrubbery, to be afforded occaſional covering from rigorous froſts.

They afford variety in greenhouſe collections, as well as in the ſhrubberies.

Although in this country, plants of this kind are only cultivated for the purpoſe of curioſity, variety, and diverſity among greenhouſe and other collections, in ſmall quantities; in China, where they are natives, they are raiſed in vaſt abundance in plantations of very great extent for their leaves, which form a great and valuable article of merchandize to that country for the ſupply of England and moſt other parts of Europe, they being employed, in their different prepared ſtates, for the making of an infuſion with boiling water, which is called tea, and which is very generally in uſe, eſpecially in this and ſome other countries. For other particulars, ſee TEA.

THEAK, in *Rural Economy*, a word provincially uſed to ſignify thatch.

THEAKIKI, in *Geography*, a river of North America, which runs into lake Illinois, N. lat. 40° 52′. W. long. 89° 15′.

THEAME, in *Ancient Geography*, a town of Aſia, in Babylonia, on the confines of Arabia Deſerta. Ptol.

THEANDRIC, θεανδρικος, *dei-virile;* a term ſignifying divine and human, formed from Θεος, *God*, and ανηρ, *man*.

St. Dionyſius, biſhop of Athens, firſt uſed the word *theandric*, to expreſs a double operation, or two operations united in Jeſus Chriſt; the one divine, the other human. The Monophyſites afterwards abuſed it, to ſignify the one only operation which they admitted in Jeſus Chriſt; in whom they believed there was a mixture of the divine and human nature, whence reſulted a third nature, which was a compound of the one and the other, whoſe operations followed the eſſence and qualities of the mixture, and were neither divine nor human, both at once, or, in one word, *theandric*.

Θεανδρικη ενεργεια, *theandric*, or *dei-virile* operation, in the ſenſe of Dionyſius and Damaſcenus, is thus exemplified by Athanaſius. When Chriſt healed the perſon who was born blind, the ſpittle he voided was human, but the opening of the eyes was done by his divine power. And thus, in raiſing Lazarus, he called as man, but awaked him from the dead as God.

The term theandric, and the dogma of theandric operations, were examined with great care and attention, at the council of Lateran, held in 649, where pope Martin ſolidly refuted the notion of theandric operations, and ſhewed, that the ſenſe in which St. Dionyſius firſt uſed the word was Catholic, and quite remote from that of the Monophyſites and Monothelites.

THEANGELA, in *Ancient Geography*, a town of Aſia Minor, in Caria.

THEANO, or TEANO, in *Geography*, a town of Italy, in the kingdom of Naples, and province of Lavora; the ſee of a biſhop, ſuffragan of Capua; 15 miles N. of Capua.

THEANTHROPOS, Θεανθρωπος, formed from Θεος, *God*, and ανθρωπος, *man*, denominated *God-man*; a term ſometimes uſed in the ſchools to ſignify Jeſus Chriſt, who was regarded as God-man; or repreſented by ſome ſcholaſtic theological writers, as comprehending two natures in one perſon.

THEANUM, in *Ancient Geography*, a town of Italy, in Campania, upon the Latin way, S.E. of Caſinum. See THEANO.—Alſo, a river of Italy.

THEATER, or THEATRE, *Theatrum*, formed from θεατρον, *ſpectacle*, of θεαομαι, *I ſee*, among the *Ancients*, a public edifice, for the exhibition of ſcenic ſpectacles or ſhows to the people.

Under the word *theater* was comprehended, not only the eminence on which the actors appeared, and the action paſſed,

paſſed, but alſo the whole area or extent of the place, common to the actors and ſpectators.

In this ſenſe, the theater was a building encompaſſed with porticoes, and furniſhed with ſeats of ſtone, diſpoſed in ſemicircles, aſcending gradually over one another; which encompaſſed a ſpace called the *orcheſtra*, in the front of which was the proſcenium, or pulpitum, on which the actors performed, and which is what we diſtinctly call the theater, or ſtage. The proſcenium was divided into two parts; the one higher, on which the actors declaimed, and the other lower, on which the chorus was commonly placed. This latter was raiſed ten or twelve feet above the pit, from which there was an aſcent to it; and thus ſituated, the chorus might eaſily turn either towards the actors or towards the ſpectators.

On the proſcenium ſtood the ſcena, a large front, adorned with orders of architecture, behind which was the poſtſcenium, or places where the actors made themſelves ready, retired, &c. So that the ſcena, in its full extent, comprehended all the part belonging to the actors. In the firſt ages of the Roman commonwealth, theaters were only temporary, and formed of wood: the moſt celebrated of theſe was that of M. Scaurus, mentioned by Pliny. The firſt fixed theater was erected by Pompey the Great, who built it very magnificently with ſquare ſtone.

In the Greek theaters, the orcheſtra made a part of the ſcena, but in the Roman theaters, none of the actors ever deſcended into the orcheſtra; which was taken up by the ſeats of the ſenators.

The moſt celebrated theaters remaining of antiquity, are the theater of Marcellus, and that of Pompey; which are alſo called *amphitheaters*.

At Athens are ſtill ſeen the remains of the temple of Bacchus, which was the firſt theater in the world, and was a maſter-piece in architecture. All theaters were conſecrated to Venus and Bacchus.

Theater, among the *Moderns*, more peculiarly denotes the ſtage, or place on which the drama, or play, is exhibited; anſwering to the proſcenium of the ancients.

In its full latitude, however, the theater includes the whole play-houſe: in which ſenſe it is a ſpacious room, or hall, part of which is taken up by the ſcena, which comprehends the ſtage, the decorations, and the machines; and the reſt is diſtributed into a ſpace, called the *pit*, or *parterre*, which is covered with ſeats, boxes, &c. and terminated with an elevation of one or two galleries, diſpoſed into benches aſcending over one another. See Dramatic *Scenery*, Play-*Houſe*, and Scenography.

Theater is alſo uſed in *Architecture*, chiefly among the Italians, for an aſſemblage of ſeveral buildings, which, by a happy diſpoſition and elevation, repreſents an agreeable ſcene to the eye.

Such are moſt of the vineyards at Rome; but particularly that of Monte Dragone, at Freſcati; and in France, the new caſtle of St. Germain en Laye.

Theater, *Anatomical*, in a ſchool of *Medicine* and *Surgery*, is a hall, with ſeveral rows of ſeats, diſpoſed in the circumference of an amphitheater, having a table, bearing on a pivot, in the middle, for the diſſection of bodies.

Such is the anatomical theater of the royal garden at Paris.

The Theater at Oxford is a beautiful building, erected by archbiſhop Sheldon, for the uſe of ſcholaſtic exerciſes. See Oxford.

THEATINES, an order of nuns, under the direction of the Theatins.

There are two kinds of Theatines, under the title of "Siſters of the Immaculate Conception," who form two different congregations, the one engaged by ſolemn vows, and the other only by ſimple vows. Their common foundreſs was Urſula Benincaſa. Thoſe who make the ſimple vows are the moſt ancient, and are called abſolutely "Theatines of the Congregation:" they had their riſe at Naples in 1583.

The others are called "Theatines of the Hermitage:" the whole buſineſs of theſe is praying in retirement, and an auſtere ſolitude, to which they engage themſelves by ſolemn vows.

The Theatines of the firſt congregation take care of the temporal concerns of theſe laſt. Their houſes ſtand together, and communicate by a large hall. Their foundreſs drew up their conſtitutions, and laid the foundation of their houſe at Naples; but died before it was finiſhed.

Gregory XV. who confirmed the new inſtitute under the rule of St. Auguſtine, appointed that they ſhould be under the direction of the Theatins. Urban VIII. revoked this article by a brief in 1624, and ſubjected them to the nuncio of Naples: but Clement IX. annulled this brief, and ſubmitted them anew to the Theatins by a brief in 1668.

THEATINS, a religious order of regular prieſts: thus called from their firſt ſuperior Don John Pietro Caraffa, archbiſhop of Chieti, in the kingdom of Naples, which was anciently called *Theate*.

The ſame archbiſhop became afterwards pope, by the name of Paul IV. after having been a companion of Gaetan, or Cajetan, a Venetian gentleman, the firſt founder of this order, at Rome, in 1524.

The Theatins were the firſt who aſſumed the title of *regular clerks*. They have not only no lands, or fixed revenues, either in common, or in propriety; but they do not even aſk or beg any thing; but wait for what Providence ſhall ſend them for their ſubſiſtence.

They employ themſelves much in foreign miſſions; and in 1627, they entered upon Mingrelia, where they have an eſtabliſhment: they have had the like in Tartary, Circaſſia, and Georgia; but this they have ſince abandoned.

Their firſt congregation appeared at Rome in 1524, and was confirmed in the ſame year by Clement VII Their conſtitutions were drawn up at a general chapter in 1604, and approved by Clement VIII. They wear the prieſt's habit.

THEATRE. See Theater and Amphitheater.

THEATRIC Bandages, a term uſed by Hippocrates, to expreſs the parade of ſurgery in applying bandages for ſhow, when there was no real uſe in them. All ſuch bandages he called *theatric*, only proper to be looked at.

THEAUA, in *Ancient Geography*, a town of Spain, in the interior of the Tarragonenſis.

THEAVE, a term applied in ſome diſtricts to an ewe of the firſt year. It is ſometimes written *thave*, and alſo *thief* in different diſtricts.

THEBÆ, or Thebes, in *Ancient Geography*, a conſiderable, and in ſome reſpects the principal, town of Bœotia, ſituated towards the middle of the country, near the river Iſmené, S.E. of the lake Copais. This town owed its origin to Cadmus; but being conſiderably augmented, the part of the town which was ſeated upon an eminence, and which was called Cadmæa from the name of its founder, was regarded as a citadel in reference to the lower town. Here was a ſpring, which conveyed water to the city by ſubterraneous channels. Amphion and Zethus, having taken poſſeſſion of the country, joined the upper and lower towns, and called the place Thebes. According to Homer it had ſeven gates, the intervals being occupied by walls. It is

ſaid

faid to have been 43 ftadia (1 league 1563 toifes) in circumference. Its environs are embellifhed by two rivers, by meadows and gardens. Myron of Byzantium fays, that Amphion was the firft perfon who erected an altar to Mercury, and that the god recompenfed his zeal by giving him a lyre. The Thebans carried on various wars with the Platæans for afcertaining their refpective limits; and againft the Athenians at Platæa for having fought the friendfhip of the king of Perfia againft the common intereft of the Greeks. In procefs of time, the Thebans avenged themfelves by defeating the Athenians at Delium, near the Tanagra. The Macedonians, after the battle of Cheronæa, placed a garrifon at Thebes, where it remained till after the death of Philip. Alexander having taken the city, and expelled its inhabitants, who retired to Athens, Caffander, the fon of Antipater, re-eftablifhed them there, with the affiftance of the Athenians, the Meffenians, and the Megalopolitans. Sylla at length reduced them to extreme mifery, for having declared in favour of Mithridates.

In the time of Paufanias, the whole lower part of the town was in ruins, except the temples, and the citadel only was inhabited and denominated Thebes. The temple of Apollo was feated on an eminence near one of the gates, and the river Ifmené, which paffed by it, gave to the god and the hill on which his temple ftood the name of Ifmenius. Mercury and Minerva had each a ftatue of marble at the entrance of the veftibule of this temple: that of Mercury was the work of Phidias, and that of Minerva was executed by Scopas. The ftatue of Apollo in the temple was wrought of cedar-wood. In this temple were alfo brazen tripods of excellent workmanfhip. Hercules Promachus had a temple near another of the gates of the city, in which was his ftatue of marble; a coloffal figure by Alcamenes, and his labours by Praxiteles. The temple of Ammon had a ftatue executed by Calamis and dedicated by Pindar. Here was alfo the temple of Fortune, and the goddefs held Plutus in her arms under the form of an infant. The temple of Ceres Thefmophorus, or the legiflator, had been anciently the houfe of Cadmus, in which was exhibited a buft of the ftatue of the goddefs. The theatre was near another gate, and near it a temple of Bacchus Lyfius. The temple of Diana Euclea was in the fame quarter; the ftatue of the goddefs was the work of Scopas. Jupiter, furnamed the *Higheft*, had a temple near the gate of this appellation. Here were a place of exercife and a ftadium; and in the midft of the ftadium was the tomb of Pindar. The river Irce paffed near Thebes, and beyond it were the ruins of the houfe of Pindar, and a kind of chapel which this poet had built in honour of Cybele. Her ftatue was formed of Pentelic marble. Entrance into the chapel was allowed only one day in the year. The temple of Themis was near one of the gates of Thebes, and her ftatue was of white marble. Jupiter Agoreus and the Parcæ had alfo their temples. The ftatue of Hercules Rhinocolustes was in full view in this part of the city. The facred wood of Ceres Cabiria and of Proferpine lay at about 25 ftadia from Thebes. The temple of the Cabiri was at the diftance of feven ftadia. According to Paufanias, there was feen at Thebes a ftatue of Venus Urania, which was faid to have been formed of parts of the fhips that brought Cadmus into Greece. It was the moft ancient ftatue in Greece. The population of this city was very confiderable. When it was taken by Alexander, more than 6000 perfons perifhed, and more than 30,000 were fold for flaves. Some priefts were fpared and many citizens fled. Hence we may prefume, that the number of inhabitants in Thebes and its diftrict might amount to 50,000 of all ages and fexes, without including flaves. The inhabitants, like thofe of Athens, were divided into three claffes; the firft compofed of citizens, the fecond of naturalized foreigners, and the third of flaves. The Thebans were deemed to be courageous, infolent, and vain; and murders were frequently the confequence of the moft frivolous quarrels. The women were both well made and generally of a fair complexion, of a noble carriage, and not inelegant drefs; their voice was remarkably fweet and tender; and that of the men harfh and difagreeable, and in fome meafure fuited to their character. The "facred battalion" of Thebes is famous in hiftory. It confifted of a body of young warriors, brought up together, and maintained at the public expence, in the citadel. Their exercifes, and even their amufements, were regulated by the melodious founds of the flute; and in order to prevent their courage from degenerating into blind fury, care was taken to infpire them with the nobleft and moft animated fentiments. Each warrior chofe from the band a friend, to whom he remained infeparably united. Thefe 300 warriors were anciently diftributed in troops at the head of the different divifions of the army. Pelopidas, who had frequently the honour of commanding them, having made them fight in a body, the Thebans were indebted to them for almoft all the advantages they gained over the Lacedæmonians. Philip deftroyed this hitherto invincible cohort at Cheronæa; and the prince, feeing thofe young Thebans ftretched on the field of battle, covered with honourable wounds, and lying fide by fide on the ground on which they had been ftationed, could not reftrain his tears, but bore a noble teftimony to their virtue as well as their valour. Travels of Anacharfis, vol. iii. See THIVA.

THEBÆ, a town of Upper Egypt, on the right bank of the Nile. According to the ideas given us of this town by Homer, it was the moft celebrated of antiquity. Ancient authors have given very different accounts of its extent. In the time of Strabo, this city had been deftroyed. It had been ravaged by Cambyfes; it was afterwards defpoiled of its riches by Ptolemy Philometer; and under the reign of Auguftus, it was feverely treated by Gallus on account of its rebellion. From this time it fell into a ftate of decline, from which it has not recovered. Tacitus mentions it as a town in ruins; and Juvenal fpeaks thus of it: This city extended on both fides of the Nile, although it was more particularly fituated on the right bank of this river: a confiderable portion of it lay to the left, which, according to Strabo, bore the name of "Memmonium." For a further account of this city, fee THEBES.

THEBÆ was a name given to many ancient towns. *Thebæ* was a town of Afia, in Cilicia hypoplaciana, fituated on a plain, at the foot of mount Placion.—Alfo, a town of Judea, in the half-tribe of Manaffeh, on this fide of Jordan.—Alfo, a town of Macedonia, in the Phthiotide, 100 ftadia from the town of Alos, according to Strabo.—Alfo, a town of Afia Minor, in Ionia, in the vicinity of Miletus.—Alfo, a town of Greece, in Attica.—Alfo, a town of Afia, in Cataonia.—Alfo, a town of Afia, in Syria.—Alfo, a town of Paleftine, in the tribe of Ephraim.—Alfo, a town of Arabia Felix, upon the coaft of the Red fea, in the country of the Cinædocolpites. Ptolemy.

THEBAID, THEBAIS, a famous heroic poem of Statius, the fubject of which is the civil war of Thebes between the two brothers Eteocles and Polynices; or Thebes taken by Thefeus.

Statius was twelve years in compofing his Thebaid, which confifts of twelve books: he wrote under Domitian. He is cenfured by the beft critics, as Boffu, &c. for a vicious multiplicity of fables and actions, for too much heat and extra-

extravagance, and for going beyond the bounds of probability.

Several Greek poets had compofed Thebaids, or poems of this name, before him; the principal were Antagoras, Antiphanes of Colophon, Menelaus the Ægean; and an anonymous author mentioned by Paufanias, lib. ix.

Ariftotle, praifing Homer for the fimplicity of his fable, oppofes to him the ignorance of certain poets, who imagined that the unity of fable or action was abundantly provided for by the unity of the hero, and who compofed Theifeids, Herculeids, &c. in each of which, they collected every thing that had ever happened to their principal perfon.

THEBAIS, or Thebaid, called alfo *Said*, in *Ancient Geography*, a name given to Upper Egypt, from its principal city Thebes. It is in fcripture called Pathros. This is the moft fouthern part of Egypt next to Æthiopia, and is almoft as extenfive as all the other parts of Egypt, including the country on both fides of the Nile down to the Heptanomis or Middle Egypt; its beft city, according to the ancients, being Lycopolis, (fee Siut,) on the weftern, and Antæopolis on the eaftern fide of the river. Thefe dimenfions agree pretty exactly with the prefent extent of Al Said, the moft northern city of which is Manfelût. In this part of Egypt there were formerly feveral cities of great note; fuch as Lycopolis, on the fcite of which is fuppofed to be the prefent Manfelût; Hypfele, or Aboutig, about a mile W. of the Nile; Aphroditopolis; Ptolemais; Abydus, once the fecond city of the Thebaid, famous for the magnificent palace of Memnon, but in the time of Strabo only a village; Little Diofpolis, probably the prefent *Hou* (which fee); Tentyra, the inhabitants of which were famous for their enmity to the crocodile, the ruins of which are ftill to be feen at *Dendera* (which fee); Latopolis, or *Efneh* (which fee); Great Apollinopolis, on the fcite of which Etfu is now fuppofed to ftand (fee Apollinis Urbs, and Etfu); and Elephantine, on an ifland of that name, where are the ruins of a fmall temple. On the eaft fide of the Nile are Antæopolis, on the fcite of which Siout is fuppofed to have been built; Paffalus, conjectured to be the prefent Gava-Kiebre, where is feen a very beautiful portico of a temple, with eighteen pillars, in three rows; Panopolis and Cheramis, fuppofed to be the fame city, but diftinguifhed by Herodotus; the fcite of Panopolis is faid to be that of the prefent Akraim, about a mile from the river; Chenobofcia; Cæne or Neapolis, perhaps the prefent Kene, a fmall town on an eminence, about a mile from the river Coptos or Kept, and called by Pliny the emporium of commodities brought from India and Arabia; Coptos, where Chriftians were formerly very numerous (fee Coptos); Apollinopolis (fee Apollinis Urbs, or *Apollinopolis Parva* or *Kous*); and *Thebes*; which fee. To the fouth of Thebes, and on the fame fide of the river, were the following cities: *viz.* Chnumis or Cnuphis; Elethya or city of Lucina; Onebos, now Comombo, or the hill of Ombo, on which are feen the ruins of an ancient temple (fee Comombo); Syene; Philæ, (fee Philoe,) an ifland deemed facred from an opinion that Ofiris was buried there. The Thebaid in the firft ages of the church was rendered famous by the number of hermits who reforted thither.

Thebais, a river of Afia Minor, in Caria. Pliny fays that it traverfed the town of Trallis.

THEBAN Harp. See Harp.

THEBANUS Ophites, in *Natural Hiftory*, a name given by fome of the ancients to that fpecies of the ophites, or ferpentine marble, more commonly called *ophites niger*, the black ferpentine.

THEBARMAI, in *Ancient Geography*, *Ormed*, a town of Afia, S.W. of lake Spauta, and at fome diftance from it, lies between a mountain and a fmall river that falls into this lake. The worfhip of fire prevailed in this province, under a perfuafion that the firft pyræum was kindled by Zoroafter himfelf.

THEBES, the capital city of the Thebais, or Upper Egypt, which was defervedly reckoned one of the fineft cities in the world. It was alfo called Diofpolis, or the city of Jupiter, and was built, as fome fay, by Ofiris, but according to others, by Bufiris. Its length, in the time of Strabo, was eighty furlongs, or ten miles; but this was very inconfiderable, compared with its ancient extent, before it was ruined by Cambyfes, which, we are told, was no lefs than 420 ftadia, or $52\frac{1}{2}$ miles. Its wealth was fo great, that, after it had been plundered by the Perfians, what was found, on burning the remains of the pillage, amounted to above 300 talents of gold, and 2300 of filver. The 100 gates of Thebes are mentioned by Homer, and, after him, by many others; but fome think that this was not the number of the gates, but of the temples; and that from them the city had the epithet Hecatompylos, expreffing a definite for an indefinite number. Pomponius Mela, and others, by the 100 gates, underftand fo many palaces of princes, each of whom could, on any occafion, arm and fend out 20,000 fighting men, and 200 chariots. A modern traveller could obferve no figns or remains of walls round Thebes: and if it had none, we muft conclude, that by 100 gates, were meant the gates of the temples, or rather the palaces of great men. In Strabo's time the city ftood chiefly on the eaft fide of the river. At Thebes there were anciently four remarkable temples; one of them is faid, by Diodorus Siculus, to have been $1\frac{1}{2}$ mile in circumference, and 45 cubits in height, with walls 24 feet thick.

The venerable ruins of this city, probably the moft ancient in the world, fays Mr. Browne (Travels, &c.), extend for about three leagues in length along the Nile. Eaft and weft they reach to the mountains, a breadth of about $2\frac{1}{2}$ leagues. The river here is about 300 yards broad; the circumference of the ancient city muft therefore have been about 27 miles. In failing up the Nile, the firft village that occurs within the precincts is Kourna, on the W., with few houfes, as the people chiefly live in the caverns. Next is Abuhedjodj, a village, and Karnac, a fmall diftrict, both on the E. The largeft portion of the city ftood on the eaftern fide of the river. On the S.W. Medinet-Abu marks the extremity of the ruins; for Arment, which is about two leagues to the S., cannot be confidered as a part. Modern authors have ftyled the fcite of Thebes, "*Luxor*" (which fee); and others have denominated it "Akfor;" both which terms are, in Mr. Browne's opinion, corruptions of "El Kaffur," the appellation ftill applied to the ruins by the Arabs. The moft confiderable ruins are thofe on the E. of the Nile. The chief of thefe is the "great temple," an oblong fquare building of vaft extent, with a double colonnade, one at each extremity. The maffy columns and walls are covered with hieroglyphics. The "great temple" ftands in the diftrict called Karnac. Next to this in importance is the temple at Abu-Hedjadj, and here are numerous ruins, avenues marked with fphinxes, &c. On the W. fide of the Nile appear two coloffal figures, apparently of a man and woman, formed of a calcareous ftone like the reft of the ruins:—remains of a large temple, with caverns excavated in the rock:—the magnificent edifice ftyled the "palace of Memnon," fome of the columns being about 40 feet high, and about $9\frac{1}{2}$ in diameter: the columns and walls are covered with hieroglyphics: this ftands at Kourna. Behind the palace is the paffage denominated "Bibân-

"Bibân-el-Molûk," leading up the mountain; at the extremity of which paſſage, in the ſides of the rock, are the celebrated caverns known as the ſepulchres of the ancient kings. Theſe ſepulchres, which have lately been diſcovered, are particularly deſcribed by Mr. Browne. In the cells or receſſes of the paſſage of the largeſt of theſe, appear the chief paintings, repreſenting the myſteries, which, as well as the hieroglyphics covering all the walls, are very freſh. Our traveller particularly obſerved the two harpers deſcribed by Bruce, but his engraved figures, he ſuggeſts, ſeem to be from memory. Although Pococke and many others are of opinion that Thebes was never ſurrounded by a wall, Mr. Browne inclines to a contrary opinion, from ſome faint remains which are ſtill viſible.

We are principally indebted to Denon (Travels in Upper and Lower Egypt, in 3 vols. 8vo. tranſlated by Aikin), for an intereſting account of the magnificent ruins of Thebes, as well as of other places in Egypt, illuſtrated by beautiful engravings. Four large hamlets (ſays Denon) divide amongſt them the remains of the ancient monuments of Thebes, whilſt the river, by the ſinuoſity of its courſe, ſeems ſtill proud of flowing among its ruins. In croſſing the ground occupied by the ancient Thebes, Denon found nothing but temples; not a veſtige of the 100 gates ſo celebrated in hiſtory; no walls, quays, bridges, baths, or theatres; not a ſingle edifice of public utility or convenience. Temples indeed were numerous, and walls covered with obſcure emblems and hieroglyphics, which atteſted the aſcendancy of the prieſthood, who ſtill ſeemed to reign over theſe mighty ruins. The ſpace occupied by this incomprehenſible town now enfolds four villages and as many hamlets, thinly ſcattered over immenſe fields. Paſſing through the territory of Thebes on another occaſion, Denon ſaw at the diſtance of three-fourths of a league from the Nile, the ruins of a large temple not before noticed by any traveller, which may give an idea of the immenſity of that city, ſince, if we ſuppoſe that it was the laſt edifice on the eaſtern ſide, it is more than $2\frac{1}{2}$ leagues diſtant from Medinet-Abu, where the moſt weſtern temple is ſituated. The temple, on the ſcite of which the village of Karnac has been built, is of ſuch a circumference, that it would require half an hour to walk round it. Herodotus has given us a more correct idea of its grandeur and magnificence. Diodorus and Strabo, who examined it in its ruinous ſtate, appear to have furniſhed a deſcription of its preſent condition, but none of the travellers who have copied the accounts of theſe writers have preſumed (ſays Denon) to prefer to this temple that of Apollinopolis at Etfu, that of Tentyra, and the ſimple portico at Eſneh. It is probable (ſays this writer) that the temples of Karnac and Luxor were built in the time of Seſoſtris, when the flouriſhing condition of the Egyptians gave birth to the arts among them, and when theſe arts were diſplayed to the world for the firſt time. Of the 100 columns of the portico of the temple of Karnac or *Carnac* (which ſee), the ſmalleſt are $7\frac{1}{2}$ feet in diameter, and the largeſt 12. The ſpace occupied by its circumvallation contains lakes and mountains. This edifice is now in a degraded ſtate. The ſphinxes have been wantonly mutilated; and the avenue that leads from Karnac to Luxor, nearly half a league in extent, contains a ſucceſſion of chimerical figures to the right and left, with fragments of ſtone walls, of ſmall columns, and of ſtatues.

Luxor (which ſee), the fineſt village in theſe environs, is alſo built on the ſcite of the ruins of a temple, not ſo large as that of Karnac, but in a better ſtate of preſervation, the maſſes not having as yet fallen through time, and by the preſſure of their own weight. The moſt coloſſal parts conſiſt of fourteen columns of nearly eleven feet in diameter, and of two ſtatues in granite, at the outer gate, buried up to the middle of the arms, and having in front of them the two largeſt and beſt preſerved obeliſks known.

A peculiarity belonging to the temple of Luxor, is, that a quay, provided with an epaulement, ſecured the eaſtern part, which was near the river, from the damages the inundations might otherwiſe have occaſioned. The epaulement, which ſince its original ſtructure has been repaired and augmented in brick-work, proves that the river has not changed its bed; and its preſervation is an evidence that the Nile has never been banked by other quays, ſince no traces of ſimilar conſtructions are elſewhere to be met with.

Nothing can be more grand, and at the ſame time more ſimple, than the ſmall number of objects of which this entrance is compoſed. No city whatever makes ſo proud a diſplay at its approach as this wretched village, the population of which conſiſts of two or three thouſand ſouls, who have taken up their abodes on the roofs and beneath the galleries of this temple, which has, nevertheleſs, the air of being in a manner uninhabited.

Denon has particularly deſcribed the tombs above-mentioned, in the village of Kurnu, the ancient Necropolis of Thebes; and he concludes with remarking, that the myſtery and magnificence obſervable within theſe excavations, and the number of ſlaves by which they are protected, indicate, that the religious worſhip which had ſcooped out and decorated theſe grottoes, was the ſame as that which had raiſed the pyramids; but our limits forbid a farther detail.

THEBET, in *Chronology*. See TEBET.

THEBIT BEN CORAH, or THABET EBN KORRA, in *Biography*, an Arabian teacher of philoſophy and mathematics, was a native of Harran, and belonged to the ſect of the Sabæans, and on this account was ſurnamed "Al-Sabi-Al-Harrani." The time in which he flouriſhed is uncertain. Some ſay that he was born in the 221ſt year of the Hegira, or A.D. 835; others refer him to the 10th century; and others again have placed him in the 12th or 13th century. He was ſecretary to the caliph Mothaded; and was diſtinguiſhed by his ſkill in the mathematics, and by his knowledge of aſtronomy. He is ſaid to have obſerved the declination of the ecliptic, which he fixed at $23°\cdot 33' 30''$: and from this circumſtance it has been concluded, that he lived in the 12th or 13th century, or that he was contemporary with Almeon and Profalius, who about that period aſſigned to the ecliptic the ſame declination. To Thebit has been aſcribed the origin of the aſtronomical ſect, which maintained the trepidation of the fixed ſtars. It was his opinion, founded on ſome erroneous obſervations, that the fixed ſtars moved for ſome time according to the order of the ſigns; that they afterwards proceeded in a retrograde direction and returned to their former places, after which they aſſumed a direct motion; and that then they had an irregular motion, which was rapid for a certain period, then became ſlower, and at laſt inſenſible. According to Thebit, the obliquity of the ecliptic was variable, and ſubject to ſimilar periods of increaſe and decreaſe. His opinions prevailed for a conſiderable time, not only among the aſtronomers of his own nation, but among ſome Chriſtians. Montucla Hiſt. de Math. Pococke, p. 377. Fabr. Bib. Græc. v. ii. p. 354.

THECA, SHEATH, in *Anatomy*, hollow organs, ſerving to contain others. The thecæ of the fingers are ſtrong ſheaths binding down the flexor tendons. The theca vertebralis is the ſheath of dura mater lining the vertebral canal, and containing the medulla ſpinalis.

Theca, in *Botany*, the Latin word for a *cell*, *ſheath*, or *caſe*, is uſed occaſionally by ſome botaniſts in their deſcriptions of ſeed-veſſels; and eſpecially by Acharius, for thoſe minute vertical parallel cells, in the diſk of the ſhields or tubercles of a *Lichen*, in which its ſeeds are lodged. See Lichenes and Peziza.

THECHES, in *Ancient Geography*, a mountain of Aſia, in Armenia, according to Xenophon, who ſays that the Greeks, after leaving Gymnias, arrived on the fifth day at the ſacred mountain called Theches, and from thence they for the firſt time perceived the Euxine ſea, which occaſioned loud exclamations of joy.

THECUA, a town of Paleſtine, in the tribe of Juda; ſituated 12 miles S. of Jeruſalem, according to Euſebius and Jerome. Joſephus ſays that it was in the vicinity of Herodium. See Tekoa.

THEDINGHAUSEN, in *Geography*, a town of Germany, in the county of Hoya; 12 miles N.N.W. of Hoya.

THEDO, in *Ichthyology*, a name given by Figulus and others to the trout.

THEFT, Furtum, in *Law*, an unlawful, felonious taking away another man's moveable and perſonal goods, againſt the owner's will, with an intent to ſteal them. See Larceny.

Open theft from the perſon, or in the preſence of the owner, is properly called *robbery;* which ſee.

THEFTBOTE, the receiving of a man's goods again from a thief, or other amends, by way of compoſition, and to prevent proſecution, that the felon may eſcape unpuniſhed; the puniſhment of which is now fine and impriſonment.

This is frequently called compounding of felony. By 25 Geo. II. c. 36. even to advertiſe a reward for the return of things ſtolen, with no queſtions aſked, or words to the ſame import, ſubjects the advertiſer and the printer to a forfeiture of 50*l.* each.

THEIFENEGE, in *Geography*, a town of Carinthia; 3 miles N.E. of Wolfsberg.

THEIMSDORF, a town of Luſatia; 6 miles E. of Rothenburg.

THEINRED, in *Biography*, precentor of the monaſtery of Dover, and author of a treatiſe on muſic, in Latin, preſerved among the MSS. of the Bodleian Library, in three books, written about the year 1371.

The firſt book treats of muſical proportion; "De Proportionibus Muſicorum Sonorum." This is a very early treatiſe upon harmonics, in which, when he ſpeaks of the major and minor ſemitone, and of the different portions into which they are diviſible, his doctrine is illuſtrated by many numerical tables, and nice ſplittings of tones into commas; "De Comatis; alia Proportio ejuſdem Comatis, &c." which prove a *temperament* of the ſcale to have been then in uſe.

The ſecond book treats of muſical concords; "De Conſonantiis Muſicorum Sonorum." Here, after ſpecifying the different kinds of concords, he informs his reader, that in *organiſing*, major and minor thirds, as well as ſixths, are admiſſible in ſucceſſion.

The third book contains diagrams and ſcales innumerable of different ſpecies of octave, in a literal notation. No muſical characters, or examples of practical muſic in common notes, appear throughout the treatiſe.

The praiſes beſtowed by Pits, Bale, Tanner, and others on Theinred, whoſe name is ſometimes written Thaured, and Thinred, make it neceſſary to acquaint ſuch of our readers as may be inclined to take the trouble of examining this tract themſelves, that, like many other muſical writings of the middle and lower ages, it but ill rewards the drudgery of an entire and careful peruſal; for after perſeverance has vanquiſhed the abbreviations, and the barbariſm and obſcurity of the Latin, the vain ſpeculations and uſeleſs diviſions of the ſcale, with which this work ſo much abounds, and which could have been but of ſmall utility to practical muſic, at the time when it was written, are ſuch, that now, ſince the theory of ſound is ſo much better underſtood and explained by the writings of Galileo, Merſennus, Holder, Smith, and many others; our old countryman, Theinred, may henceforth remain peaceably on his ſhelf, without much loſs to the art or ſcience of muſic. Bodl. 842. 1. De legitimis ordinibus Pentachordorum et Tetrachordorum, Pr. Quoniam Muſicorum de his Cantibus frequens eſt diſtinctio, &c. 46 folios, ſmall ſize. Walther in his Lexicon calls this work a Phœnix.

THEIOCRUS, in the *Materia Medica of the Ancients*, a name given by ſome to the melanteria.

The name *theiocrus* ſignifies only ſulphur-coloured, and was at firſt uſed with the name of vitriol, as expreſſive of the difference of this kind from others; but in time it became common to uſe it alone.

THEISM. See Deism.

THEISOA, or Thisoa, in *Ancient Geography*, a town of the Peloponneſus, in Arcadia.

THEIUM, a town of Greece, in Athamenia.

THEIUS, a river of the Peloponneſus, in Arcadia, which diſcharged itſelf into the Alphæus.

THEKA, in *Botany*, the Malabar name of the Teak tree, retained as generic by Juſſieu. See Tectona.

THEKUPHÆ. See Tekuphæ.

THELA, in *Botany*, ſo named by Loureiro, Cochinch. 119, from θηλη, *a nipple*, in alluſion to the little glandular prominences which cover the calyx, appears, by his deſcription, to be the ſame genus with the Linnæan Plumbago. See that article.

THELARY, in *Geography*, a town of Hindooſtan, in Bahar; 18 miles S.W. of Bahar.

THELBALANA, in *Ancient Geography*, a town of Aſia, in the Greater Armenia. Ptol.

THELBENCANA, a town of Aſia, in Babylonia, on an arm of the Euphrates.

THELDA, a town of Aſia, in Meſopotamia, on the banks of the Euphrates. Ptol.

THELE, a word uſed by ſome to expreſs the nipple, and by others for the whole breaſt.

THELEBOÆ, in *Ancient Geography*, a people of Epirus, in Acarnania, who paſſed into Italy, and eſtabliſhed themſelves in the iſland of Caprea.

THELEBOLUS, in *Botany*, from θηλη, *a nipple*, and βολος, *a caſt*, or *throw*, becauſe the little veſicle, lodging the ſeeds, reſembles a nipple, and is thrown off with a degree of elaſticity. The name was originally written *Theleobolus*, but the above is juſtly preferred.—Tode Mecklenb. v. 1. 41. Perſ. Syn. 116.—Claſs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi angiocarpi*.

Eſſ. Ch. Receptacle cup-like, ſomewhat globoſe, entire at the edge, diſcharging a papillary, nearly naked, ſeed-veſſel.

1. Th. *ſtercoreus*. Small Nipple-fungus. Perſ. n. 1. Tode n. 1. t. 7. f. 56.—Found by Tode on the dung of ſwine, after rainy weather in June and July. He compares it to the roe of fiſh in appearance, and to poppy-ſeed nearly in ſize. The colour is a tawny yellow. Each individual is globular, attached at the bottom by capillary roots, and crowned with a ſmall papillary tubercle, of a more

more orange or golden hue than the reft. This is at length thrown off, with a fudden and ftrong elaftic force, leaving a minute, bordered, vifcid pit, or cup, which gradually dilates into a level furface.

The minute fungus above defcribed is clofely related to SPHÆROBOLUS, and ftill more nearly perhaps to PILOBOLUS. (See thofe articles.) Whether it might be allowable to comprehend them under one genus, may admit of much difpute. Even the many-cleft *receptacle*, or *involucrum* of *Sphærobolus* can hardly be deemed a fufficient important difference to fuperfede this meafure, and ftill lefs the elongated figure, or pellucid fubftance, of *Pilobolus*. Botanifts who beftow their concentrated attention exclufively on particular tribes of plants, are prone to multiply diftinctions; but they are not rafhly to be corrected by thofe who have not looked fo clofely, nor, perhaps, fo well.

THELEDA, in *Ancient Geography*, a town of Afia, in Syria, fituated on a plain W. of Seriana, and E. of Capparæ.

THELEPHORA, in *Botany*, from θηλη, *a nipple*, and φερω, *to bear*, becaufe of the generally papillary covering of the under furface.—Willd. Berol. 396. Perf. Syn. 565. Schrad. Spicil. 182. (Craterella; Perf. Obf. Mycol. v. 1. 39. Corticium; ib. 37.)—Clafs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi gymnocarpi*.

Eff. Ch. Head coriaceous, dilated; minutely papillary, briftly, or fmooth, beneath. An ample, and, in our opinion, rather vague genus of the fungus tribe, of which Perfoon reckons up forty-feven fpecies, ranged under three fections, once confidered by him as diftinct genera. We fhall, after our ufual manner, felect a few examples of each.

Sect. 1. CRATERELLA. *Head undivided, hollow or funnel-fhaped above, with a fhaggy difk.* Two fpecies.

Th. *pallida*. Pale Thelephora. Perf. n. 1. "Ic. et Defcr. Fung. 3. t. 1. f. 3, fub *Craterella*."—"Aggregate, corky, pale. Head concave, fhaggy with fcales."—Rarely found on the ground in moift woods. The *ftalk* is very fhort; villous at the bafe. *Head* rough beneath, with little briftles, vifible under a magnifying glafs. *Perfoon.*

Th. *caryophyllea*. Carnation Thelephora. Perf. n. 2. Albert. and Schwein. Nifk. 272. (Craterella ambigua; Perf. Obf. Mycol. v. 1. 39. t. 6. f. 8—10. Helvella caryophyllea; Schæff. Fung. v. 4. 115. t. 325. Dickf. Crypt. fafc. 1. 20. Auricularia caryophyllea; Bulliard. t. 278. 483. Sowerb. Fung. t. 213.)—Head funnel-fhaped, thin, purplifh-brown, fringed, varioufly jagged or crifped.—Found on the ground in fir woods. Mr. Woodward firft met with this fpecies in Britain, near Bungay, Suffolk. Continental botanifts ufually fpeak of it as rare, but Mr. Sowerby fays it is "a very common parafite on the expofed fantaftic roots of old firs, in autumn." The fubftance is tough and fomewhat woody; the colour a chocolate-brown. The plants often grow in maffes, attached by their upper fide to fticks, old bark, &c., and are from one to three inches in diameter. Sometimes the fhaggy edge is white. Perfoon in his Obf. Mycol. above quoted feems difpofed to think the prefent fungus may vary fo much as to become *Ramaria palmata* of Holmfkiold, Fung. Dan. v. 1. 106. t. 33; but furely the multiplied divifions and ramifications of the latter, as well as its fmoothnefs and colour, preclude fuch an idea.

Sect. 2. STEREUM. *Head halved, finally horizontal.* Thirteen fpecies.

Th. *terreftris*. Ground Thelephora. Perf. n. 3. Ehrh. Crypt. n. 179. (Th. mefenteriformis; Willd. Berol. 397. t. 7. f. 15.)—Somewhat imbricated, dull brown. Head flattened, fhaggy with fibres. On fandy ground. This feems to us a mere variety of the laft, or rather its moft ufual form, as reprefented in Mr. Sowerby's t. 213. Yet Perfoon cites this plate, with doubt, under his fourth fpecies, *Th. laciniata*. He feems to lay too much ftrefs on the abfence or prefence of a ftalk, and perhaps makes too many diftinctions.

Th. *rubiginofa*. Rufty Thelephora. Perf. n. 6. (Th. fragilis; Ehrh. Crypt. n. 238. Helvella rubiginofa; Dickf. Crypt. fafc. 1. 20. Auricularia ferruginea; Bulliard. t. 378. Sowerb. Fung. t. 26.)—Imbricated, rigid, rufty-brown, fmooth on both fides, with fcattered, rather large, knobs.—Not uncommon on gate-pofts or pales, generally placed fo low as to be partly hid by the earth and neighbouring plants, as Mr. Sowerby remarks. It is very diftinct from the foregoing, foft like velvet to the touch; the under fide bearing fcattered, roundifh prominences, which, however, do not appear concerned in the fructification. The edge is ufually pale. No part is hairy or fhaggy. The diameter of each plant is about an inch.

Th. *ferruginea*. Snuff-coloured Thelephora. Perf. n. 9. Albert. and Schwein. Nifk. 273. (Auricularia tabacina; Sowerb. Fung. t. 25.)—Wavy, fomewhat reflexed, bright brown. Head thin, nearly even, flightly downy; hairy underneath.—Frequent on ftumps and rotten branches, in various fituations. The plants are feffile, attached by the back, projecting over each other, of an elegant undulated figure; the colour of both fides a bright reddifh-brown, efpecially the upper, elegantly contrafted with the light-yellow border.

Th. *hirfuta*. Common Hairy Thelephora. Perf. n. 11. Willd. Berol. 397. Albert. and Schwein. Nifk. 274. (Th. pallida; Ehrh. Crypt. n. 169. Auricularia reflexa; Bulliard. t. 274. Sowerb Fung. t. 27.)—Aggregate, rounded, coriaceous, convex, fomewhat zoned, yellowifh; fhaggy above; fmooth and tawny beneath.—Frequent on rotten ftumps, pofts, pales, tubs, &c.; either growing folitary, and roundifh, about an inch in diameter; or in continued, confluent, fomewhat imbricated maffes. The under fide is yellow or tawny; the upper of a pale yellowifh-brown, marked with different concentric fhades, and rough with imbricated foft fhaggy hairs. The whole is often tinged with black, as if fmoked. It varies in fize as well as colour, and often confifts of an expanded orange-coloured furface, clofely preffed by its back to the wood, previous to its acquiring any projection by which the upper fide is expofed. In this ftate it might be referred to the next fection. *Auricularia papyrina*, Bulliard t. 402, feems nearly akin to this.

Sect. 3. CORTICIUM. *Plant laid entirely on its back, indeterminate in form, papillary, various in fubftance.*—Thirty-two fpecies, divided into fubordinate fections, according to the colour, whether pale or dark red, yellowifh, brown, grey, or white.—It is very neceffary to trace the progrefs of the fpecies of this divifion, in order to be certain they do not, at any period, acquire a diftinct upper furface, fo as to range under the preceding.

Th. *quercina*. Oak Thelephora. Perf. n. 16. Albert. and Schwein. Nifk. 276. (Th. carnea; Ehrh. Crypt. n. 269. (Auricularia corticalis; Bulliard t. 436. f. 1.)—Oblong, coriaceous, rugofe, pale flefh-coloured; the margin fomewhat involute, of a blackifh-brown at the back.—Found running longitudinally along decayed branches of oak. Each plant is two or three inches in length, fomewhat oval, of a light flefh-coloured hue, with a powdery or downy furface, which water will not moiften, and which is befprinkled with round depreffed protuberances, obfcurely repre-

repreſenting the ſhields of a *Lichen*. The margin ſoon becomes elevated and inflexed, eſpecially by drought or cold, and diſplays the blackiſh under ſide, which ought to be the upper.

Th. *cruenta*. Blood-red Thelephora. Perſ. n. 24.—"Smooth, coriaceous, tuberculated, blood-red."—An elegant ſpecies, found on the branches of trees, and communicated by Ludwig from Miſnia. *Perſoon*.

Th. *ſanguinea*. Gory Thelephora. Perſ. n. 25. (Tremella cruenta; Engl. Bot. t. 1800.)—"Widely ſpreading on the ground, ſomewhat gelatinous, blood-coloured, ſmooth."—"This ſingular ſpecies," ſays Perſoon, "grows in the ſtreets of towns, about the walls of houſes, looking at a diſtance like blood poured on the ground. By drying it becomes paler. Is it not rather to be referred to the order of *Algæ*?" In this laſt ſuggeſtion we readily concur. The whole is truly an expanded maſs of minute, uniform, gelatinous, pellucid granulations, with nothing of a coriaceous or fungous texture, nor any other character of the preſent genus.

Th. *hydnoidea*. Awl-bearing Thelephora. Perſ. n. 28. Albert. and Schwein. Niſk. 279. (Corticium hydnoideum; Perſ. Obſ. Mycol. v. 1. 15.)—Spreading, concealed, orange-yellow, bearing awl-ſhaped elongated prominences.—This ſpreads under the ſeparated cuticle of decayed dry branches of beech, which it ſometimes totally encircles, extending to the length of four or ſix inches. Its great peculiarity conſiſts in the awl-ſhaped projections, thrown out from its ſurface, to the height of two or three lines, which either penetrate, or force off, the ſuperjacent cuticle of the tree, and, except in their great irregularity of ſize and figure, reſemble the prickles of a *Hydnum*.

Th. *umbrina*. Umber-brown Thelephora. Perſ. n. 36. Albert. and Schwein. Niſk. 281.—Spreading on the ground, ſoft, of an umber brown; the margin whitiſh and rather downy.—Found on the ground, in a ſandy ſoil, ſpreading to the extent of two or three inches, and not of a very thin ſubſtance. Perſoon ſpeaks of it as very rare, hut the obſerving authors of the *Fungi Niſkienſes* find it not unfrequently, in Auguſt and the following months, in ſhady ſandy places.

Th. *cæſia*. Grey Ground Thelephora. Perſ. n. 40. (Corticium cæſium; Obſ. Mycol. v. 1. 15. t. 3 f. 6.)—Orbicular, on the ground, nearly ſmooth, of a greyiſh aſh-colour.—Not unfrequent in autumn, on the bare ground, from one and a half to three inches broad, with a white, fibrous, rounded, ſcolloped edge. The grey ſurface is beſprinkled with minute powdery *ſeeds*, regularly diſpoſed in ſpots, four together. *Perſoon*.

Th. *lactea*. Milk-white Fir Thelephora. Perſ. n. 45.—"Nearly orbicular, of a livid white; ſomewhat fleſhy in the middle; fibrous at the margin."—Rarely found on the bark of the Spruce Fir. The ſurface is ſmooth. The colour becomes paler by drying. *Perſoon*.

Albertini and Schweiniz deſcribe ſeveral more ſpecies of this genus, to which every thing of a membranous texture, and fungous aſpect, ſeems to be referred by authors. Some ſuch may poſſibly be imperfect vegetable productions, whoſe growth, when completed, might prove them of a different nature. When their ſmooth ſurface diſcharges powdery *ſeeds*, they are to be conſidered as perfect ſpecies of *Thelephora*.

THELIGONUM. See Thelygonum.

THELMENISSUS, in *Ancient Geography*, a town of Aſia, in Syria, on an immenſe plain on the E. of the Orontes, N. of Apamea, and S.W. of Chalcis.

THELONIUM, Telonium, ſignifies toll.

Among the Romans, *telonium* denoted a cuſtom-houſe, or place where the toll was collected.

Thelonio, *Breve eſſendi quieti de*, a writ lying for the citizens of a city, or burgeſſes of a town, that have a charter or preſcription to free them from toll, againſt the officers of any town or market, who would conſtrain them to pay it, contrary to the ſaid grant or preſcription.

Thelonio *rationabili habendo pro dominis habentibus dominica regis ad firmam*, a writ lying for him that hath of the king's demeſne in fee-farm to recover reaſonable toll of the king's tenants there, if his demeſne hath been accuſtomed to be tolled.

THELOTREMA, in *Botany*, from θηλη, *a nipple*, and τρημα, *an orifice*, in alluſion to the pierced protuberances of the cruſt; a genus of the order of *Lichen s*, inſtituted by Acharius, in his *Methodus*, 130. The original type of this genus is *Lichen pertuſus* of Linnæus, which is reduced, by the writer of the preſent article, to Endocarpon, (ſee that article,) in *Prodr Fl. Græc.* v. 2. 304. The reſt of the ſuppoſed ſpecies may perhaps be in like manner diſpoſed of, or referred to *Urceolaria*.

THELPUSA, in *Ancient Geography*. See Thalpusa.

THELSEA. See Thalsea.

THELYGONUM, in *Botany*, a name of very whimſical derivation, concerning which Linnæus has fallen into an error, like profeſſor Martyn and M. De Theis, who have both of them been leſs penetrating than uſual in their enquiries. They all deduce it from θηλυ, *female*, and γονυ, *a joint*, or *knee*; and the laſt of them ſuppoſes the original plant, which was our Mercurialis, (ſee that article,) to have been called θηλυγονον, becauſe its ſwelled joints reſembled the knees of a woman. This we modeſtly preſume to be a very unanthorized compariſon; and Pliny, from whom the name is borrowed, leads us to a leſs injurious, if not a wiſer, ſolution His ſapient pages aſſure us that Arſenogonon (αρσενογονον, or αρρενογονον) was taken to procure male children, its fruit reſembling a part of the male organs; while *Thelygonon*, which, though otherwiſe the ſame, bore no ſuch fruit, was ſuppoſed to cauſe the production of females. The word therefore is compoſed of θηλυ, and γονος, *generation*, or *offspring*, φυλλον, *a leaf*, being underſtood, a confirmation of which may be found under the 6th ſpecies of our article Mercurialis, above-mentioned. If we may be allowed to play further upon this word, we ſhould remark that its own generation is truly *anile*. Yet hence aroſe Bauhin's *Mercurialis teſticulata, ſive mas*, and *ſpicata, ſive fœmina*; appellations perverſely beſtowed on the two ſexes of our *Mercurialis annua*, as well as of *perennis*. How Linnæus came to transfer *Thelygonum* to the genus which now bears it, can no otherwiſe be accounted for, than from the ſuppoſed affinity of the plants to each other, and both having borne the name of *Cynocrambe*, or Dog's Cabbage; a name retained by Gærtner, after Tournefort, and liable to no objection, except being compoſed of one already eſtabliſhed, which doubtleſs cauſed Linnæus to reject it. The imaginary affinity juſt alluded to has apparently ſtamped a poiſonous character on the herb before us, which, conſidering its natural order, is probably undeſerved.—Linn. Gen. 494. Schreb. 644. Willd. Sp. Pl. v. 4. 420. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 285. Sm. Prodr. Fl. Græc. Sibth. v. 2. 237. Juſſ. 405. Lamarck Illuſtr. t. 777. (Cynocrambe; Tourn. t. 485. Gærtn. t. 75.)—Claſs and order, *Monoecia Polyandria*. Nat. Ord. *Scabridæ*, Linn. *Urticæ*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth of one leaf, turbinate, coloured, cloven half way down into two revolute ſegments. *Cor.* none. *Stam.* Filaments numerous, from ſix to twelve or or more, capillary, prominent, as long as the calyx, anthers verfatile, linear, ftraight.

Female, on the fame plant, *Cal.* Perianth minute, of two erect, lanceolate, acute, lateral leaves, permanent. *Cor.* none. *Pift.* Germen fuperior, globofe; ftyle lateral, between the calyx-leaves, thread-fhaped, much longer than the germen; ftigma fimple, curved. *Peric.* none. *Seed* folitary, globofe, feated on a callous annular *receptacle*, which falls off with it.

Eff. Ch. Male, Calyx in two revolute fegments. Corolla none. Stamens about twelve.

Female, Calyx lateral, of two leaves. Corolla none. Style one. Seed naked, on a deciduous annular receptacle.

1. Th. *Cynocrambe.* Dog's Mercury. Linn. Sp. Pl. 1411. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 941, unpublifhed. (Cynocrambe Diofcoridis; Bauh. Prodr. 59. C. alfinefolia; Barrel. Ic. t. 335. Alfines facie planta nova; Column. Phyt. 28. t. 30. ed. alt. 120. t. 36.)—The only known fpecies, found in wafte ground and the fiffures of rocks, efpecially in fhady or moift places, in the fouth of Europe, as well as in Afia, flowering at almoft all feafons. About Rome and Naples it is very frequent. Its feeds may have been brought, from time to time, into our curious botanic gardens, but the plant has no charms, nor any known quality, to render it a popular favourite. The *root* is annual, fimple, cylindrical, with many fibres below. *Stems* feveral, fpreading or proftrate, a fpan long, leafy, fcarcely branched, round, very fmooth and fhining, moftly purplifh. *Leaves* alternate, ftalked, each with an axillary tuft of fmaller ones, ovate, rather fucculent, an inch, or thereabouts, in length, of a bright fhining green, very fmooth on both fides; roughifh at the edges. *Footftalks* almoft as long as the leaves, dilated at the bafe into an annular toothed *ftipula*. *Flowers* fmall, whitifh, from the bofoms of the upper leaves. The *calyx* of the males is not unlike the *corolla* of a honey-fuckle in miniature. *Seed* purplifh-brown, furrowed, not much bigger than muftard-feed. The general afpect of the plant evinces its affinity to *Parietaria*, though the *flowers* in detail are extremely different.—Dr. Sibthorp's figure has but fix *ftamens*. We have ufually found more, and authors defcribe from twelve to nineteen.

That this herb is the κυνια, or κυνοκραμβη, of Diofcorides, there can fcarcely be a doubt. He defcribes it fufficiently well, and informs us that it was fometimes called Wild Male Mercury; which renders the name of *Thelygonum* ftill more unfuitable; but Linnæus did not always fearch deeply into fuch matters, though he will commonly be found quite as learned as moft of his critics or correctors. Diofcorides fpeaks of the plant in queftion as a gentle purge. This probably caufed the *Mercurialis* to be taken with the fame intention, though at the peril of the patient's life, as we have already mentioned in its proper place; where alfo it may be feen that fome of the earlier European botanifts took that very plant for the κυνοκραμβη.

THELYMITRA, from θηλυ, *female*, and μιτρα, *a diadem*, or *ornament for the head.* This name of Forfter's, not one of the moft happy, alludes to the cap or hood, ornamented with a pair of plumy tufts, and covering the immediate organs of fructification.—Forft. Gen. t. 49. Swartz Act. Holm. 1800. 228. t. 3. f. L. Ejufd. in Schrad. Neues Journ. v. 1. 56. t. 1. f. L. Sm. Exot. Bot. v. 1. 55. Brown Prodr. Nov. Holl. v. 1. 314. Willd. Sp. Pl. v. 4. 79. Ait. Hort. Kew. v. 5. 200.—Clafs and order, *Gynandria Monandria.* Nat. Ord. *Orchideæ.*

Gen. Ch. *Cal.* Perianth of three equal, ovato-lanceolate, coloured leaves, exactly refembling the petals. *Cor.* Petals two, ovato-lanceolate, the fize of the calyx, and exactly like it. Nectary a feffile lip, of the fhape, fize, and appearance, of the petals and calyx, without a fpur. *Stam.* Anther parallel to the ftigma, permanent, of two cells clofe together, attached to the central lobe of a three-cleft hooded appendage to the column; "maffes of pollen powdery, pendulous by a thread from the gland of the ftigma." *Brown. Pift.* Germen inferior, obovate; ftyle fhort, united with the hood; ftigma in front, obtufe. *Peric.* Capfule obovate, furrowed, with one cell and three valves. *Seeds* numerous, chaffy.

Eff. Ch. Calyx-leaves coloured, the fize and figure of the petals and lip. Column encompaffed by a three-lobed hood. Anther parallel to the ftyle, permanent.

1. Th. *Forfteri.* Forfter's Thelymitra. Swartz Act. Holm. 1800. 228. t. 3. f. L, c. Willd. n. 1. (Th. longifolia; Forft. Gen. t. 49. Serapias regularis; Forft. Prodr. 59.)—Lateral fegments of the hood plumous: intermediate one vaulted. Clufter many-flowered.—Gathered by Forfter in New Zeeland. The *ftem* is above a foot high, round, ftriated, fomewhat fpiral, clothed with a few fheathing lanceolate *leaves*. *Clufter* terminal, erect, three inches long, of about a dozen upright *flowers*, fcarcely half the fize of the next fpecies, each accompanied by an elliptic-lanceolate acute *bractea*, longer than the partial ftalk. Of the colour of the *flowers* we have no information. Their *hood* appears, by the dried fpecimen, as well as Forfter's figure, to have its middle fegment vaulted, convex, and undivided.

2 Th. *ixioides.* Large-flowered Thelymitra. Swartz Act. Holm. 1800. 228. t. 3. f. L, a, b, d—g. Willd. n. 2. Br. n. 1. Ait. n. 1. Sm. Exot. Bot. v. 1. 55. t. 29.—Lateral fegments of the hood plumous: intermediate one three-cleft; its lateral lobes jagged; central one fhorteft, cloven, crefted at the back. Clufter many-flowered.—Found in the neighbourhood of Port Jackfon, New South Wales, from whence we received fpecimens and drawings about the year 1790. Mr. G. Caley fent out plants to Kew in 1810, but they do not appear to have fucceeded there. This is a larger taller fpecies than the foregoing; its *flowers* above an inch in diameter, very handfome, of a fine blue, fpotted, according to Mr. Brown, with a deeper colour. The *hood* is fringed with hairs, juft below the fummit, and overtopped by its two lateral, ftalked, plumous tufts. The *calyx*, *petals*, and *lip*, fpread almoft equally in both thefe, and, we believe, all the following fpecies, except our n. 9, Mr. Brown's *venofa*.

3. Th. *media.* Intermediate Thelymitra. Br. n. 2.—"Outer fegments of the hood plumous; intermediate one naked at the back, three-cleft; its central lobe emarginate, half the length of the others. Spike (or clufter?) many-flowered."—Gathered by Mr. Brown, near Port Jackfon.

4. Th. *canaliculata.* Channelled Thelymitra. Br. n. 3.—"Outer fegments of the hood plumous: intermediate one naked at the back, many-cleft; lobes corrugated; the outer one longeft and moft remote. Spike many-flowered."—Found by Mr. Brown, in the tropical part of New Holland.

5. Th. *pauciflora.* Few-flowered Thelymitra. Br. n. 4.—"Hood half the length of the petals: its outer fegments plumous: intermediate one naked at the back, emarginate, with rounded entire lobes. Spike of few flowers."—Gathered by Mr. Brown, near Port Jackfon.

6. Th. *nuda.* Naked Thelymitra. Br. n. 5.—"Hood half the length of the petals; its outer fegments plumous; intermediate one naked at the back, emarginate, with rounded entire lobes. Spike many-flowered."—Gathered in the ifland of Van Diemen, by Mr. Brown. By the above definition,

nition, this species differs from the last only in having more numerous *flowers*.

7. Th. *angustifolia*. Narrow-leaved Thelymitra. Br. n. 6. —" Outer segments of the hood plumous; intermediate one naked at the back, emarginate, with toothed lobes. Spike of few flowers. Leaf as tall as the flower-stalk."—Found by Mr. Brown, in the neighbourhood of Port Jackson.

8. Th. *carnea*. Flesh-coloured Thelymitra. Br. n. 7. —" Calyx and petals spreading. Outer segments of the hood finely toothed, beardless. Stalk with one or two flowers."—Found by Mr. Brown, near Port Jackson. A drawing in our possession, which seems to belong to this species, represents the *stalk* about four inches high, with a light-red terminal *flower*, above an inch wide, and a few short, radical, lanceolate *leaves*.

9. Th. *venosa*. Veiny Thelymitra. Br. n. 8.—" Calyx and petals converging. Outer segments of the hood beardless, spirally involute."—Gathered also near Port Jackson, by Mr. Brown.

10. Th. *tigrina*. Tiger-spotted Thelymitra. Br. n. 9. —" Lateral segments of the hood distinct, with tufted beards; intermediate one shorter, crested. Leaves linear, channelled." —Discovered by Mr. Brown, on the south coast of New Holland. The *flowers* are yellow, with darker spots.

11. Th. *fusco-lutea*. Brownish-yellow Thelymitra. Br. n. 10. —" Lateral segments of the hood converging, connected, fringed; intermediate one erect, naked. Leaves lanceolate." —Gathered by Mr. Brown, in the same country with the *tigrina*. He describes the yellow colour of the *flowers* as peculiar to these two last species; all the rest, as far as hitherto discovered, having them generally blue, sometimes white, or flesh-coloured. We have necessarily, for want of authentic specimens, except of the first two species, adopted the specific characters of the excellent author whose name we have cited.—He establishes a genus under the name of EPIBLEMA, which appears to differ from *Thelymitra*, in having a stalked lip with tufts of fibres at its base; an appendage to the base of the column, connected with the claw of the lip underneath; and the anther accompanied at each side by a petal-like lobe. Of this there is only one species, *E. grandiflorum*, found on the south coast of New Holland. Its *flowers* are large, blue, and handsome.

THELYPHONON, from θηλυς, *female*, and φονος, *murder*, or *destruction*, the name of an herb mentioned by Pliny, book 25, chap. 10, which he says is by some called Scorpion, from the resemblance of its root to a scorpion, and the touch of which is fatal to that animal, as a remedy for whose sting it is given internally. He adds, that the same root kills any sort of quadruped, if applied to the parts of generation; and that its leaf, which resembles that of *Cyclamen*, produces the same effect within the course of a day. His description answers to the *Doronicum scorpioides*, Willd. Sp. Pl. v. 3. 2114; *D. latifolium*, Clus. Hist. v. 2. 16; Great Leopard's-bane, Ger. Em. 759; but there is apparently much superstition, mistake, or exaggeration, intermixed in his relation.

THELYPTERIS, from θηλυς, *female*, and πτερις, *a fern*, a name by which Pliny designates a species of the Fern tribe, whose habit appears to be more delicate than that of his *Filix mas*, or Male Fern. The latter should seem, by his description, to be our *Pteris aquilina*. (See PTERIS.) The name of *Filix mas*, however, has remained with a large species of *Aspidium*, Sm. Fl. Brit. 1121. Engl. Bot. t. 1458; and that of *Filix fœmina* with a more slender and finely-divided one of the same genus, Engl. Bot. t. 1459: while a third, whose texture is more thin and tender than either, has received the appellation of *Aspidium Thelypteris*. They were all referred by Linnæus, under the same specific names, to POLYPODIUM. (See that article.) Our present *Thelypteris*, therefore, must not be taken for that of Pliny, being rather a north-country plant, not hitherto noticed in Greece by any botanical traveller.

THEMA, in *Ancient Geography*, a town of Syria, in the Chalibonitide territory; and also of Arabia Deserta.

THEMAN, a town of Arabia Petræa, 5 miles from Petra, which had a Roman garrison.—Also, a town of Judea, in the half-tribe of Manasseh, on the other side of Jordan; famed for the wisdom of its inhabitants. Eliphaz, one of Job's three friends, came from this place.

THEMAR, in *Geography*, a town of Germany, in the county of Henneberg, on the Werra; 12 miles S.E. of Meinungen.

THEME, THEMA, a subject or topic, upon which to write or compose.

THEME, among *Astrologers*, denotes the figure they construct when they draw the horoscope; representing the state of the heavens for a certain point, or moment, required; *i. e.* the places of the stars and planets for that moment.

The celestial theme consists of twelve triangles, inclosed within two squares, and called the *twelve houses*.

THEME, in *Grammar*, denotes a verb, considered in its primary and absolute sense, and not limited to any particular mode or tense: or it is the verb in its primitive radical state, whence its different formations are derived.

THEME, in *Music*; *Thema*, Lat.; *Tema*, Ital.; *Mottivo*, *Soggetto*, is a series of notes selected as the text or subject of a new composition, or an old favourite and well-known air to grace and embellish with variations. About the middle of the last century, the musical world was overwhelmed with dull, unmeaning, and monotonous variations to old and new tunes, which consisted of nothing more than a regular multiplication of notes, without fancy, taste, or harmonical resources; till Haydn, in the slow and graceful middle movements of his quartets and symphonies, by a richness of imagination, by double counterpoint, and inexhaustible resources of melody and harmony, rendered variations the most ingenious, pleasing, and heart-felt of his admirable productions *à grand orchestra*; and Mozart, in a totally different style, and for a totally different purpose, has rendered little favourite French, Italian, German, and English airs the most beautiful, amusing, and useful compositions for the piano forte that have ever been produced since the invention of that instrument. More than twenty of these have been printed in England that were brought from Vienna by Mrs. Peploe, who played them, as she did all other music, with a firmness, accuracy, and spirit, which neither dilettante nor professor has ever exceeded.

These themes seem to have been a series of lessons, composed expressly to form the hand and taste of some disciple of the author, who promised to be a great performer. In every one of these themes, there are some peculiar difficulties of execution, refinement, and expression to vanquish, at which it is in vain for mediocrity to aspire.

THEMEDA, in *Botany*, a genus of grasses, so called from its Arabic name *Thæmed*.—Forsk. Ægypt-Arab. 178. Juss. 447.—It is found in Yemen, near Hadîe. Forskall names the only species *T. triandra*, and describes it as follows.

" A polygamous grass. *Spikelets* proceeding from a sheath, capitate; the outer ones whorled, male. *Calyx* of one valve, single-flowered. *Corolla* of two valves. *Styles* and *awns* wanting. In the middle of the head of flowers arises a short stalk, bearing two stalked male *spikelets*, and a sessile hermaphrodite one; the *calyx* is of one valve, *corolla* of two; *awn* proceeding from the receptacle, much longer than the flower.

Stems racemose. *Sheaths* compressed, broad, sword-shaped, concealing the branches, and the heads of *flowers*, before expansion. All the *heads* are originally concealed in the sheath of a leaf."

This can only be the Linnæan *Anthistiria*, a genus which Mr. Brown, in his Prodr. Nov. Holl. v. 1. 200, asserts to have been first described by Forskall, but he gives no reference to the *Themeda*, which omission has caused us much trouble, and after all, leaves the matter in some uncertainty. Desfontaines, in his Fl. Atlant. v. 2. 380, has reformed the character of *Anthistiria*, and has given a figure, t. 254, of *A. glauca*, called by some authors *Stipa paleacea*, which agrees, as nearly as possible, with Forskall's description. It does not appear that Vahl, Willdenow, or any other author, has adverted to *Themeda*, except Jussieu, who has merely admitted it, on Forskall's authority, into his appendix, without examination or elucidation.

We presume here to observe, that every correct writer ought invariably to cite the page of his author; especially in referring to a confused posthumous work, without an index, like that of Forskall.

THEMIS, in *Ancient Geography*, a town of Africa Propria, situated between Tabraca and the river Bagradas.

Themis, in *Geography*, a river of Transylvania, which runs into the Alaut, near Marienburg.

Themis, in *Astronomy*, a name given by some to the third satellite of Jupiter.

Themis, in *Mythology*, the daughter of Cœlum and Terra, or of Uranus and Titaia, the eldest sister of Saturn, and aunt of Jupiter.

Themis, according to Diodorus, established divination, sacrifices, the laws of religion, and every regulation that contributed to maintain order and peace among men. She also applied herself to astrology, issued predictions, and after her death temples were erected to her, in which oracles were delivered. She had a temple on mount Parnassus, and another in the citadel of Athens.

THEMISCYRA, in *Ancient Geography*, a town of Asia Minor, in the kingdom of Pontus, situated in the open country to which it gave name, upon the banks of the river Thermodon, towards its mouth in the Euxine sea. Diodorus Siculus says that it was a royal city of the Amazons, and that they founded it.

THEMISONIUM, a town and country of Asia, in Phrygia.

THEMISSUS, a town of Asia Minor, in Caria.

THEMISTEAS, a promontory of Asia, in Carmania.

THEMISTIUS, surnamed *Euphrades*, or the fine speaker, in *Biography*, an Eclectic philosopher, was born in an obscure village of Paphlagonia, about the year 317, and having fixed his residence at Constantinople, taught eloquence and philosophy with great reputation and success. His disciples, both Pagan and Christian, were numerous; to the former class belonged Libanius, and to the latter, Gregory Nazianzen. By the emperors he was highly esteemed, and they conferred upon him distinguished honours. In the year 355, Constantius admitted him into the senate; and in return for an eloquent eulogium, presented him with a brazen statue. Julian corresponded with him as a friend; and in 362, appointed him præfect of Constantinople. His character and eloquence induced other emperors to bestow upon him peculiar favours. When Jovian issued his edict of toleration, Themistius was deputed by the senate to express its loyalty; and on this occasion he expatiated with elegance and liberality on the rights of conscience, and the independence of the human mind. Of his candour and liberality, the following memorable instance is recorded by Socrates, Sozomen, and other ecclesiastical historians. The emperor Valens, who favoured the Arian party, treated the Trinitarians with great severity. Themistius, disapproving the measures which the emperor pursued, addressed him in an eloquent speech, stating that the diversity of opinions among Christians was inconsiderable, compared with that of the Pagan philosophers; and urging upon his attention, that this diversity could not be displeasing to God, since it did not prevent men from worshipping him with true piety. By such arguments, Themistius, it is said, prevailed upon the emperor to treat the Trinitarians with greater lenity. What an example does this Pagan philosopher exhibit even to Christian divines! In the year 376 Themistius visited Rome, but though solicited to take up his abode there, he preferred returning to Constantinople. It redounds very much to the honour of this philosopher, and also to the liberal sentiments of Theodosius the Great, that during his visit to the Western empire, the emperor entrusted Themistius, notwithstanding difference of religion, with the care and education of his son Arcadins. Themistius was no less distinguished by gentleness of temper and urbanity of manners, than by his eloquence and wisdom, and ability in the conduct of public affairs. After a long course of civil honours, he withdrew about the year 387, at an advanced age, from public business; and soon after died. Themistius, the subject of this article, who does not appear to have ever deserted the Pagan schools, should be distinguished from a Christian deacon of the same name, who lived after the council of Chalcedon, held in the year 551, and who was the head of the sect called *Agnoetæ*; which see. As a philosopher, Themistius illustrated several of the works of Aristotle, particularly the Analytics, the Physics, and the book on the Soul, in commentaries, written with great perspicuity and elegance. His "Orations," which were thirty-six, and of which thirty-three are still remaining, are strongly marked with the same characters. The best editions of his Orations are those of Petau, Gr. and Lat. Paris, 4to. 1618; and of Hardouin, Gr. and Lat. Paris, fol. 1684. Fabr. Bib. Græc. Brucker by Enfield. Gibbon. Lardner's Works, vol. viii.

THEMISTOCLES, an Athenian statesman and commander, the son of Neocles, a person of middle rank at Athens. At a very early age he manifested, both in his amusements and in his literary pursuits, those views and inclinations, which marked the character and destiny of his maturer years. To those who ridiculed him on account of his apparent contempt of ornamental accomplishments, he replied, "It is true, I never learned how to tune a harp, or play upon a lute; but I know how to raise a small state to a great one." Ambition seems to have been his ruling passion, and he lost no opportunity of acquiring military and political distinctions. He sought popularity with a view to his personal advancement; and less pure and disinterested in his principles than Aristides, his solicitude for the glory of his country was subservient to his own reputation and eminence. After the defeat of the Persian invasion by the battle of Marathon, an event which interested his feelings and roused into exercise his predominant love of glory, he foresaw that the attempt might be renewed by sea as well as by land; and he therefore exerted his influence in rendering the Athenian state a naval power. With this view, he induced his countrymen to appropriate the revenue accruing from the silver mines to the equipment of a number of galleys; and as he possessed the chief authority at Athens, in consequence of the banishment of Aristides, he found no obstacle to the execution of his design. In the course of three years after this event, the hostile preparations of Xerxes for an expedi-

tion

tion into Greece to enforce the demand of fubjection, furnifhed him with a plea for urging the Grecian ftates to compromife their mutual diffentions, and to unite in defending themfelves againft the invader. In the choice of a general, with whom the command fhould be intrufted in this emergency, the Athenians favoured the claims of a democratical orator, named Epicydes, who had fafcinated them by his eloquence; but Themiftocles induced him to furrender his pretenfions to an office for which he was totally unqualified by a bribe, and thus fecured the appointment for himfelf without a competitor. When news arrived that the Perfian army, conveyed by a fleet, was approaching the ftraits of Thermopylæ, Themiftocles propofed that the Athenians fhould fit out their galleys and fail to meet them; but this counfel being rejected, he took the command of their troops, and having joined the Lacedæmonians, marched towards Tempé. In the mean while, intelligence was received that the paffage of the ftraits had been forced, and that Bœotia had fubmitted to the invaders; and upon this alarm the army returned without feeing the enemy. In thefe circumftances of apprehended danger, the Athenians, according to their cuftomary practice, had recourfe for counfel to the Delphic oracle. The anfwer, probably fuggefted by Themiftocles himfelf, was, that they fhould rely folely on their fleet. It was now propofed, that the city fhould be wholly abandoned to the Perfians, without any attempt for its defence; that the women, children, and aged fhould be removed to fome place of fecurity; and that all who were able to bear arms, fhould embark on board the galleys, and watch the event. A decree was obtained, after much fruitlefs oppofition, to this purpofe; and this was followed by another, which permitted all exiled citizens to return. Ariftides was one of this number, who nobly facrificing, in the moment of his country's danger, all private animofities, concurred in all the fpirited meafures of his former rival.

Eurybiades, a Spartan, to whom the command of the confederate fleet was affigned, and who was very unequal to the office, differed with Themiftocles as to the meafures proper to be purfued; and behaved with an infolence, which, probably for the fake of the public fervice, the latter did not think proper to refent. Eurybiades was pacified by the gentlenefs and felf-command of Themiftocles, and convinced by his reafoning. Finding it prudent, however, to change the meafures which he originally contemplated, he employed a ftratagem to induce the Perfians to advance and make an attack. This was followed by the famous battle of Salamis, which took place in the year B.C. 480, and which terminated in the fignal defeat of the Perfian navy. The victory has been chiefly afcribed to the fkill and valour of Themiftocles; and having thus fucceeded, he advifed the confederates to fail immediately to the Hellefpont, in order to deftroy the bridge of boats by which the army of Xerxes had paffed over, and thus to intercept his communication with Afia; but being overruled in this propofal, he difpatched a fecret meffenger to the Perfian king, with information that the Greeks intended to break his bridge, and advifing him to retreat immediately before the defign was executed. The policy of Themiftocles, as we may judge from this inftance, was not always uniform and confiftent; and in another cafe, which remains to be mentioned, on the authority of Plutarch, it was inexcufably flagitious. When the combined Grecian fleet was wintering at Pegafa in Magnefia, he informed the Athenians, that he had conceived a project which would be of infinite fervice to the republic, and at their defire, he would communicate it to Ariftides. This virtuous man told them, that the fcheme of Themiftocles would be highly advantageous, but that nothing could be more unjuft; upon which, very much to their honour, they determined not to adopt it. The plan was to burn all the fhips of the fleet, except thofe of Athens, by which fhe would remain complete miftrefs of the feas.

The victory at Salamais advanced the name and character of Themiftocles to the higheft pitch of glory throughout Greece. On his vifit to Sparta, he was received with every token of refpect; and whilft the firft prize of valour was decreed by the people to their countryman Eurybiades, the olive wreath of fuperior wifdom was placed on the head of the Athenian; and they alfo prefented him with a magnificent chariot, and ordered three hundred of their youth to attend him back to the borders. At the next Olympic games, the eyes of the whole affembly were fixed upon Themiftocles, and he was pointed out to ftrangers as the moft interefting object at the fpectacle. Themiftocles himfelf acknowledged, that this was the nobleft day of his life. When the conftitution of Athens was about to be re-eftablifhed, after the rebuilding of the city, Themiftocles, in conformity to the political principles which he had adopted, propofed that every citizen fhould have an equal right to participate in the government, and that the members fhould be chofen from the body of the people, without diftinction; and in his propofals the people unanimoufly acquiefced. He alfo propofed to fortify the city; but as the Lacedæmonians objected to the propofal, he was deputed upon an embaffy to Sparta with a view of conciliating them. He contrived, however, by various artifices, to prolong the negociation, fo that the Athenians had conftructed their walls before the Spartans were duly apprized of the fact. Themiftocles vindicated this artifice by alleging, "that all things are lawful in ferving our country;" and the Spartans, admiring his patriotifm, filently acquiefced. In the following year, his fcheme for rendering the Pyræum the principal port of Athens, and connecting it with the city by long walls, was adopted and accomplifhed.

Independently of the deceits which Themiftocles had practifed with regard to the Lacedæmonians, another circumftance had occurred which increafed their enmity againft him. He had fuccefsfully oppofed their fending deputies to the Amphictyonic council, and thus degraded their authority in Greece. Incenfed againft him, they joined his rivals at Athens, and ufed all their influence to deftroy his reputation. His own conduct alfo had excited jealoufy and refentment; for he had caufed to be erected near his own houfe a temple to "Diana Ariftobule," or "of the beft counfel," thus intimating, that his counfels had been the beft for the Grecian community. His enemies prevailed, and procured his banifhment from Athens by the fentence of Oftracifm. During his exile at Argos, his enemies gained an additional advantage over him. Apprized of the treafonable defigns of Paufanias, the Spartan, againft the liberty of Greece, he declined the difclofure of them; and after the detection and death of Paufanias, letters of Themiftocles were found, which proved that they had conferred on this bufinefs. The Lacedæmonians preferred an accufation againft him to the Athenians; and they called him to account in the prefence of the ftates of Greece. Dreading a trial, he fled to Corcyra, and thinking himfelf infecure there, he withdrew to Epirus: and at length was reduced to the neceffity of feeking the protection of Admetus, king of the Moloffi, whom he had formerly offended. The vengeance of the Spartans purfued him, and Admetus was threatened with a war, if he protected the criminal. The king difmiffed him with money acrofs the continent to a port in the Ægean fea, whence he reached Afia in fafety. In the year B.C. 462, he arrived at the Perfian court; but here his

his name was so obnoxious, that a reward of 200 talents had been offered for apprehending him. Here he appeared in disguise, and pretending that he had important information which he wished to communicate to the king in person, he was admitted to the royal presence, and favourably received: the 200 talents, which were the price of his head, were paid to himself, and a more ample recompence was offered to him, if he would give useful information concerning Greece. He was granted time for acquiring the Persian language, and after a year he appeared at court like a native. The king and royal family treated him with distinction; and it is said that the revenues of three cities, *viz.* Magnesia, Lampsacus, and Myus, were assigned him, under the name of bread, wine and meat; and as some say, two more, for lodging and wardrobes. In this state of luxury and magnificence he was joined by the members of his family, who had been conveyed to him by his friends, and to them he expressed a kind of satisfaction with his condition, which proves that moral meanness may accompany exalted talents.

The close of his life is involved in obscurity. Plutarch relates, that upon the revolt of Egypt, supported by the Athenians, against the Persian dominion, the Greek king, resolving to send an expedition into Greece, dispatched an order to Themistocles at Magnesia, reminding him of his promises, and claiming the fulfilment of them: upon which it is said, that, in order to avoid the disgrace of bearing arms against his country, after sacrificing to the gods and taking solemn leave of his friends, he drank poison, and died in that city at the age of sixty-five years. Thucydides, his contemporary, says that he died of a distemper; and others again report, that he poisoned himself, because it was not in his power to accomplish what he had promised. The Magnesians honoured his memory with a sumptuous tomb; but his remains, according to his own orders, were privately conveyed to Attica, where they were interred. It is further said, that the Athenians, repenting of their treatment of him, raised a tomb for him in the Pyræum, which was an interesting object to all who visited that port. His singular talents, and the services which he rendered to his country, must be acknowledged; and those who think favourably of him, ascribe his desertion of them to unjust persecution. But in Themistocles we look in vain for the virtues of an Aristides; and he can only be allowed the honour of a distinguished general and statesman. Thucydides. Plut. in Them. Ancient Un. Hist.

THEMNA, Timna, or *Thamnata*, in *Ancient Geography*, a town of Palestine, in the tribe of Dan. Josh. xix. 43.—Also, a town of Arabia Deserta, on the confines of Mesopotamia.

THEN, in *Geography*, a river of France, which runs into the Weze, near Francremont.

THENA, in *Ancient Geography*, an ancient town of Africa, situated N.E. of the Tanais and near it, and two miles in circuit.—Also, a town of Samaria, in the vicinity of Sichem.

THENAC, or Thanac, a royal town of Judæa, in the half-tribe of Manasseh, on this side of Jordan. It was given to the Levites of this tribe, and its king was one of those who were vanquished and slain by Joshua.

THENÆ, a town of the isle of Crete, near Cnossus.

THENAR, in *Anatomy*. The eminence in the palm of the hand, formed by the muscles of the thumb, has been called thenar: and some of the muscles have been described under the same name.

The thenar of Riolan and Winslow includes the abductor pollicis brevis, and the opponens pollicis.

THENEATE *el Gannim*, the *Sheep Cliffs*, in *Geography*, mountains of Africa, in Sahara; 90 miles S. of Algiers.

THENEZAY, a town of France, in the department of the Two Sevres; 10 miles N.E. of Partenay.

THENGEN, a town of Germany, which gives name to a principality, situated in the Hegau, bordering on Schaffhausen; 8 miles N. of Schaffhausen.

THENON, a town of France, in the department of the Dordogne; 6 miles miles N.W. of Montignac.

THENONGOUN, a town of the Birman empire; 4 miles S.W. of Ava.

THENOPSYCHITES. See Thnetopsychites.

THENSA, among the Romans, a veil or canopy, used in the chariots of games; and likewise to cover a seat of state.

Thensæ could not be granted to any but by the express allowance of the senate. Hist. Acad. Inscript. vol. i. p. 359.

THEOBALD, Lewis, in *Biography*, a professed writer, was the son of an eminent attorney at Sittingbourn, in the county of Kent, and is here noticed as one of the numerous editors of Shakspeare. Of his various works, critical, poetical, and dramatic, it is needless to give any account, as they have sunk into oblivion. He had the misfortune of becoming, to an undue degree, the object of Mr. Pope's contempt and satire, and of having the first place assigned him in the Dunciad, though he was afterwards superseded by Cibber. His edition of Shakspeare was preceded by a work entitled "Shakspeare restored," and published in 1726; and also by that of Mr. Pope. It is thus characterized by Dr. Johnson: "Pope was succeeded by Theobald, a man of narrow comprehension and small acquisitions, with no native and intrinsic splendour of genius, with little of the artificial light of learning, but zealous for minute accuracy, and not negligent in pursuing it. He collated the ancient copies, and rectified many errors. A man so anxiously scrupulous might have been expected to do more; for what little he did was commonly right." Of the tragedy which he brought on the stage, and which is entitled "The Double Falsehood," the greater part is ascribed by him to Shakspeare; but Dr. Farmer has proved that this is a mistake.

THEOBROMA, in *Botany*, the Chocolate-tree, received that name from Linnæus, who probably, like the president Bachot, cited by De Theis, was fond of the delicious produce of this tree; for the word is formed of θεος, *a god*, and βρωμα, *food*. A French writer, M. Tussac, in his magnificent Flore des Antilles, has objected to the above generic name, for a reason which we confess to have been one of the last we should have thought of; that "it carries with it the signification of a quality, and seems therefore more fit for the name of a species." Surely nothing can be more desirable than a generic appellation which conveys information; on which account *Amaranthus*, *Artocarpus*, *Biserrula*, are excellent; we need not run through the botanical alphabet in search of numerous others. Such probably was the origin of most names, in every language, and who can tell that the American word *Cacao*, substituted, or rather restored, by Tussac, may not express some quality of the plant? Neither is it an objection to any significative generic names, that they express merely some general property or peculiarity, not found in every one of the species, witness *Urtica*. The idea of stinging is associated with the name of a Nettle; like redness with that of a Rose; though there are Dead Nettles, and White Roses.—Linn. Gen. 391, with an erroneous description, corrected in Linn. Suppl. 341. Schreb. 513. Willd. Sp. Pl. v. 3. 1422. Mart.

Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 408. Juss. 276. Lamarck Illustr. t. 635. (Cacao; Tourn. t. 444. Gærtn. t. 122.)—Class and order, *Polyadelphia Decandria*. Nat. Ord. *Columniferæ*, Linn. *Malvaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of five ovato-lanceolate, acute, spreading, coloured, deciduous leaves. *Cor.* Petals five, rather longer than the calyx; their claws dilated, concave, hooded, marked internally with two ribs from the base, and one from the summit: their borders roundish-ovate, pointed, spreading, each contracted at the base into a narrow, erect and recurved stalk, connected with the claw. Nectary short, cup-shaped, crowned with five long, erect, awl-shaped, pointed, equal, converging segments. *Stam.* Filaments five, thread-shaped, erect, recurved at the upper part, concealed in the hollow claws of the petals, inserted into the outside of the nectary between its segments, but not above half so long; anthers two to each filament, (one on each side, at the summit,) vertical, two-lobed, one lobe over the other. *Pist.* Germen superior, nearly sessile, ovate, with five furrows; style cylindrical; stigma in five awl-shaped segments. *Peric.* Berry elliptic-oblong, beaked, coated, of one cell. *Seeds* large, ovate, smooth, numerous, in five rows: their cotyledons in many deep lobes.

Eff. Ch. Calyx of five leaves. Petals five, vaulted at the base. Nectary cup-shaped, with five taper points. Anthers two to each filament. Stigma five-cleft. Berry coated. Seeds ovate.

Obs. Gærtner observes that he could find no traces of the five cells attributed by authors to this fruit. It is probable, however, from analogy, that they may exist in the germen, and Aublet's account is sufficiently explicit of their presence in the fruit. The drawing in the Linnæan herbarium, which appears to have been sent by Allamand from the West Indies, has led us to suppose each filament bore four anthers; but it seems there are only two, each of two round, distinct, vertical lobes, as represented by Aublet, t. 275, and copied by Lamarck. The order of *Decandria* must therefore be restored in the class *Polyadelphia*. See Sm. Intr. to Bot. ed. 3. 340. Linnæus's characters of *Theobroma* in Gen. Pl. were taken chiefly from Plumier's *Guazuma*, the Bubroma of Schreb. Gen. 513; see that article. He has left a more correct description in manuscript, from which perhaps his son composed what is given in the *Supplementum*. From these sources, with the help of Allamand's drawing, and what is to be found in Aublet and Schreber, we have drawn up our account, having no opportunity of examining a flower.

1. Th. *Cacao*. Smooth-leaved Chocolate-tree. Linn. Sp. Pl. 1100. Suppl. 341. Willd. n. 1. Ait. n. 1. (Th. n. 2 and 3; Browne Jam. 306. Cacao; Merian. Surin. t. 26 and 63. C. Theobroma; Tussac Flore des Antilles, t. 13. Arbor cacavifera americana; Pluk. Almag. 40. Phyt. t. 268. f. 3.)—Leaves entire, smooth on both sides.—Native of South America. Miller appears to have had this plant alive at Chelsea, but it has never long succeeded in our stoves; being extremely tender, even in some parts of the West Indies. Browne says the Chocolate-trees, though naturalized in the woods of Jamaica, are very delicate, and rarely survive when once they are loosened in the ground by hurricanes. (See Chocolate.) These trees are the size of a middling apple-tree, but seldom exceed six or seven inches in diameter. They are very beautiful, especially when laden with *fruit*, which is dispersed, on short stalks, over the *stem*, and round principal *branches*; its yellow hue and warty surface somewhat resembling a citron. The *leaves* are alternate, stalked, drooping, a foot long, and three inches broad, elliptic-oblong, pointed, entire, slightly wavy, very smooth on both sides, with one mid-rib, and many transverse ones, connected by innumerable, minute, reticulated veins. *Footstalks* round, hairy, an inch long. *Stipulas* minute, deciduous. *Flowers* small, several together in tufts, at the sides of the branches, on simple stalks, only one in each tuft, commonly producing fruit. *Calyx* light rose-coloured. *Petals* yellow.

2. Th. *guianensis*. Downy-leaved Chocolate-tree. Willd. n. 1. Ait. n. 1. (Cacao guianensis; Aubl. Guian. v. 2. 683. t. 275.)—Leaves wavy, and somewhat toothed; downy beneath.—Native of marshy woods in Guiana, bearing flowers and fruit in September. Of rather more humble growth than the foregoing. The *leaves* are, at most, but eight inches in length, and three in breadth; their margin wavy, or rather bordered with shallow teeth, towards the extremity; their upper surface smooth and green; the under clothed with short, ash-coloured, or rusty pubescence, and reticulated with fine veins. *Footstalks* short, channelled, downy. *Flowers* situated like the former. *Calyx* green without, yellow within. *Petals* yellowish. *Fruit* elliptical, with five angles, and clothed with short rusty down. Aublet says it has five cells, separated by membranous partitions; the *seeds* enveloped in a gelatinous, white, melting substance; their kernel white, very good eating when fresh. He speaks of this species as the Chocolate of Guiana, though he mentions a *Cacao sativa*, with entire leaves, as a cultivated kind, under which he cites *Theobroma Cacao* of Linnæus, and its acknowledged synonyms.

Aublet has also a *Cacao sylvestris*, v. 2. 687. t. 276, with entire *leaves*, downy beneath, and a downy *fruit*, without ribs. Willdenow asserts, we know not on what authority, that this last is *Duroia Eriopila*, Linn. Suppl. 209, of which we, unfortunately, have met with no specimen. A branch of Aublet's plant, communicated from his own herbarium by sir Joseph Banks, appears a variety of the last, its *leaves* being obscurely toothed in a similar manner; but for want of *flowers* we cannot say how far it answers to *Duroia*, between which and *Theobroma* there is no affinity in that respect. Aublet clearly describes his as a *Theobroma*, and we cannot help suspecting some error in Willdenow, as well as, possibly, a disagreement between Aublet's figure and our above-mentioned specimen, which latter may be, as above hinted, his *Cacao guianensis*. At any rate, the two species of *Theobroma* which we have described, are certainly and permanently distinct.

Theobroma, in *Gardening*, contains a plant of the exotic tree kind, of which the species usually cultivated is the chocolate nut-tree (T. cacao).

In its natural state, this tree produces a nut or fruit which is smooth, of a yellow, red, or of both colours, about three inches in diameter: it has a fleshy rind, near half an inch in thickness, which is flesh-coloured within: the pulp being whitish, of the consistence of butter, separating from the rind in a state of ripeness, and adhering to it only by filaments, which penetrate it, and reach to the seeds. Hence it is known when the seeds are ripe by the rattling of the capsule when it is shaken: the pulp has a sweet and not unpleasant taste, with a slight acidity; it is sucked and eaten raw by the natives; it may be easily separated into as many parts as there are seeds, to which it adheres strongly, and they are wrapped up in it, so that each seed seems to have its own proper pulp: the seeds are about twenty-five in number: when fresh, they are of a flesh-colour: gathered before they are ripe, they preserve them in sugar, and thus they are very grateful to the palate: they quickly lose their power of vegetation, if taken out of the capsule, but kept in it, they preserve that power for a long time: the tree

 bears

bears leaves, flowers, and fruit all the year through; but the usual seasons for gathering the fruit are June and December: in two years from the seed, the tree is above three feet high, and spreads its branches, not more than five of which are suffered to remain. Before its third year is complete, it shews for fruit; a tree yields from two to three pounds of seed annually. Such trees are of course very productive.

Method of Culture.—It is increased by seed obtained from abroad, sowing it as soon after its arrival as possible, in pots filled with light earth, and plunging them in a bark-bed, where they will soon come up; and when the plants are about three inches high, potting them off separately, and replunging them in the bark-bed in the stove, managing them as other woody exotics of the stove kind afterwards. They afford an agreeable variety in stove collections.

This tree is cultivated to considerable extent, and with very great attention in its native situations in the hot parts of America, for the sake of its fruit, the kernels of which are much used in the making of chocolate there, as well as in this country. In this intention, they are first brought to a pulverizable state by drying or roasting in a proper apparatus; they are then reduced into a fine powder by mills or other contrivances: after which, this fine powder is wrought up into a paste with orange-water, milk, and other liquids, and has sugar, different sorts of aromatic spices, and some aromatic perfumes, mixed and incorporated with it, when it is formed into cakes, or made into pretty large rolls, for exportation and sale in the European and other markets, if prepared in the places of its native growth.

It is employed somewhat in the manner of coffee as a fine rich breakfast article of diet, and used pretty extensively for that purpose in this and some other countries.

THEOCATAGNOSTÆ, formed from Θεος, *God*, and καταγινωσκω, *I judge*, or *condemn*, a sect of heretics, or rather of blasphemers, who presumed to find fault with certain words and actions of God, and to blame many things in the Scriptures.

Marshal, in his Tables, places these heretics in the seventh century; for what reason we know not. Damascenus is the only author that mentions them, but without taking any notice of the time of their appearance.

THEOCRACY, formed from Θεος, *God*, and κρατος, *power*, *empire*, a state governed by the immediate direction of God alone.

According to Josephus, the ancient government of the Jews was theocratic; God himself ordering and directing every thing belonging to the sovereign authority.

By the oracle of Jehovah himself, all laws were enacted, war was proclaimed, and magistrates were appointed; in which three particulars the *summa potestas*, or sovereign authority, of any state, consists. And as Jehovah was the king, as well as the God of Israel, the priests and Levites, who were the stated attendants on his presence, and to whom the execution of the law in many cases was committed, were properly ministers of state and of civil government, as well as of religion. The sacrifices also, beside their religious use, were intended for the support of the state, and civil government.

This theocracy lasted till the time of Saul; when the Israelites, weary of it, desired they might have a king like other nations; and thence forward the state became monarchic.

There was also a kind of imaginary theocracy at Athens: while the sons of Codrus were disputing the succession, the Athenians, wearied out with the miseries of an intestine war, abolished the royalty, and declared Jupiter the only king of the people at Athens.

THEOCRITUS, in *Biography*, a Greek poet, esteemed as the model of pastoral poetry, was a native of Syracuse, and the son of Praxagoras and Philina. The time in which he flourished is ascertained by two of his poems, one addressed to Hiero, king of Syracuse, who began his reign about the year B.C. 265, and the other to Ptolemy Philadelphus, whose reign comprehended the interval between 281 and 246 B.C. Although Hiero is reported to have been a patron of literature, persons of rank, as we may infer from Theocritus's poem, did not follow his example, at least in granting encouragement to poets; and therefore Theocritus left Sicily, and visited the court of Ptolemy Philadelphus at Alexandria, on whom he pronounces a splendid eulogy. The compositions of this poet are denominated "Idylls;" they are written in the Doric or rustic dialect, and few of them are pastorals, though most of them relate to rural life and manners. The purely pastoral are distinguished by the truth and simplicity of the manners, descending sometimes even to coarseness, and the pleasing description of natural objects, drawn from the life. To those who have a taste for genuine simplicity, and the beauties of nature, says one of his biographers, the poetry of Theocritus is highly agreeable. The most esteemed editions of his works, are D. Heinsius's, 4to. Commel. 1604; R. West's, Oxon. 8vo. 1699; Th. Warton's, Oxon. 2 vols. 4to. 1770; Valkenaer's, cum Bione et Moscho, Lugd. Bat. 8vo. 1779. Suidas. Vossius. Gen. Biog.

THEODOLITE, or THEODOLET, is an instrument used for measuring horizontal and vertical angles in land-surveying. This instrument was at first made on a small portable scale, supported by a tripod that will shut up into the form of a walking-stick, when the mechanism of brass-work is dismounted: and the state of dividing circles is now brought to that perfection in England, that small portable theodolites are still in use among land-surveyors, who confine themselves to the planning of single estates, for which these instruments are competent; but for surveys on a large scale, such as county surveys, or trigonometrical measurement of distant stations, theodolites of an enlarged construction have been used with corresponding advantage. Out of the numerous modifications of this instrument, that different artists have contrived, we propose to select two for particular description, which are generally considered as the best for accurate surveys; one by Ramsden, and the other by Troughton. We will begin with that large instrument already referred to in a former article, which was made by Ramsden, in the year 1777, for the use of general Roy, when he undertook his grand trigonometrical operations, and which is described in the 80th vol. of the Philosophical Transactions of London (1790), with all the constituent parts given separate in four large plates. A similar instrument, by the same maker, has since been used for the grand general survey of the different counties, by Messrs. Mudge and Dalby. *Plate* VIII. *fig.* 1. *of Surveying*, shews the perspective view of this masterpiece of workmanship, nearly as represented in general Roy's third plate; but his account, having reference to the several plates, will not answer our purpose. The stand on which the instrument is placed for use, is a four-legged mahogany stool A B C, braced as seen in the figure, with an octagonal top perforated at the centre by a hole of nine inches diameter. This stool or stand, when used, has its feet screwed fast to the tops of four piles driven into the ground, and nicely levelled, before the instrument is placed

placed on it, and one of the four faftening fcrews may be feen at B, at the junction of the bracing bars. Upon this ftool another, but larger, octagonal board of mahogany, D E, refts, which has a ring or circular curb on its plane, about half an inch from the fides of the octagon: this upper octagonal board may be fixed to, or releafed from, the top of the ftand by four vertical fcrews, which penetrate both boards, but which allow one to flide over the other, fo as to be either concentric or excentric, as the adjuftment of a plumb-line to the mark or hole under the inftrument may require, for the exact place of the ftation, over which the centre of the inftrument muft be exactly fixed. The four horizontal fcrews of adjuftment, of which three are feen at F, F, and F, carried by the board D E, are fo contrived as to effect this adjuftment by preffure againft the edge of the ftand, after which the two octagonal boards are made faft together by the faid four vertical fcrews not fhewn. The upper octagonal D E has an open conical focket of brafs, three inches in diameter, in its centre. Next above the board D E, thus adjufted and fecured, comes the third board, which is circular, and which forms the bafis of the inftrument. In the centre of this bafe another brafs conical focket, three inches and a quarter in diameter, is made faft, and flips over the fmaller conical focket of the board D E of adjuftment for central pofition, fo that the centre of the inftrument being concentric with this board partakes of the adjuftment, while the plumb-line defcends through both fockets down towards the ground. The large mahogany circle G H, of more than three feet in diameter, is fupported by feveral pillars connected with the circular board, which we have called the bafe of the inftrument, and forms with them a baluftrade, that protects the inftrument, as feen in the figure. A brafs circle of three feet diameter, within the baluftrade, is attached by ten ftrong conical radii to the large vertical hollow axis, formed into the fruftum of a cone, of twenty-four inches in height above the metallic wheel, which we fhall in future denominate the graduated circle, when confidered with its radii and hollow axis attached to it. This axis, by way of diftinction, may be called the *exterior* axis; it has a collar of caft-fteel driven faft into the cavity of its inferior or thicker end, and a plate of bell-metal, with a floping edge, furmounts the fuperior end, which plate may be raifed or lowered by means of five fcrews acting vertically. The inftrument ftands on three fhort feet near D and E, and at an equidiftant point not feen behind, which feet are firmly united together, at the place where they branch off, by a circular ftrong plate of bell-metal, upon which is carried an attached vertical cone of metal fmaller than the former one, and as it fills the cavity of the other, we will call it the *interior* conical axis; the exterior one being moveable round the interior one without the leaft perceptible liberty, beyond what is neceffary for rotatory motion. On the vertex of this interior axis is inferted a caft-fteel pivot with floping cheeks, which, entering the central hole of the bell-metal plate, exactly fits its cheeks there, while the bell-metal bafe of the interior axis fits the caft-fteel collar inferted into the lower extremity of the exterior conical axis. This mode of centering allows the wheel to be taken off and put on without injury, and is alfo free from the objection that applies to thofe large inftruments that have the fuperior end of the vertical axis fupported in a frame that is liable to alter in its dimenfions by expofure to the fun; of which imperfection, as we have noticed in our article Circle, Piazzi had great reafon to complain. Befides, this kind of centre-work allows of carriage from one place to another, without any danger of injury being done to the inftrument when properly packed. There are two achromatic telefcopes with double object-glaffes of each thirty-fix inches focus, with eye-pieces of different powers both for erect and inverted pofitions. One of thefe telefcopes lies acrofs the body of the inftrument, with the ends feen between the oppofite pillars of the baluftrade, the ufe of which is to watch the pofition of the inftrument during the time of an obfervation being made; and, therefore, it requires but little elevation in altitude: the other is mounted, exactly like a tranfit-inftrument, over the top of the exterior vertical axis, and has a femi-circle attached to the extreme end of its horizontal axis of motion, of fix inches radius, and graduated for fhewing angles of altitude or of depreffion. The Y's in which the pivots of the upper telefcope move, are fupported by the horizontal bar I K, which is braced by the ladder-pieces attached to the thick part of the exterior conical axis, and made faft to the top of this axis by its focket, as feen in the fection in *fig.* 4; which fection exhibits moreover the internal fittings of both the internal and external axes at their fuperior ends. This upper telefcope has a fpirit-level with the ufual adjuftments at the Y's, and at the bar of fufpenfion for the horizontal pofition; and, as it will reverfe in the Y's, and has moveable wires in the focus of the eye-piece, it may alfo be adjufted by a horizontal mark for collimation, and for taking exact altitudes, (as well as for taking minute angles of elevation without the femi-circle by the motion of the micrometrical wires,) when the level is applied to a rod on the *fide* of the tube, as is the cafe in our drawing. When thefe adjuftments are made, by dividing the errors between the proper fcrews, as ufual, the level is hung to the crofs-bar I K to watch its pofition while this telefcope is ufed, and when both telefcopes continue to bifect the fame diftant mark during an obfervation, with the bubble of the level in the middle, it is a proof that the inftrument keeps its pofition. When a ftar or other object is viewed by night, the illuminating lamp K throws light into the axis of the telefcope, which has a diagonal perforated reflector, as is ufual in tranfit telefcopes. A fyftem of darkening prifms is alfo applied to the fame end of the axis to regulate the quantity of light that fhall come to the eye. All thefe adjuftments and appendages have been minutely explained under our articles Circle and Transit-*Inftrument*, and therefore need not be detailed in this article; but it may be proper to obferve, that the femi-circle has a moveable clamping-piece, bearing the fteel arbor of a vertical fcrew, the lower end of which falls on a polifhed piece of fteel on the plane of the horizontal bar I K, the ufe of which clamp and fcrew is not only to give a flow motion in altitude, but to allow the preponderating eye-end of the telefcope to reft fteady thereon, while the obfervation has been read and repeated. The obfervation in altitude is read by the compound microfcope at I, which is nine inches long, and which, by means of its micrometrical fcrew, reads the divifions of the femi-circle to the accuracy of 5″, when an allowance of 12″ is made for excentricity.

When this theodolite was firft brought into ufe, it was found that the fcrew L, with an ivory thumb-piece, moved the circle in azimuth by jerks, on which account the apparatus for flow motion, feen in *fig.* 2, was fubftituted, in which two crown-wheels and a Hooke's joint are introduced to give motion to the tangent-fcrew; which addition not only remedied the jerks, but allowed the obferver to reach the handle while his eye remained at the upper telefcope. The large brafs horizontal circle is divided into quarters of a degree, and the fubdivifions are made by the vertical micrometrical microfcopes, the divided heads of which read exact feconds, when properly adjufted for zero, for

for diſtinct viſion, and for power. The ſcrew of the vertical micrometers has ſeventy-two threads in the inch, and the notches that indicate the fifteen minutes on the micrometrical ſcale of ſteel, are formed by this ſcrew, which we mention particularly, becauſe this mode of reading was probably an original mode, though now become common. Theſe vertical microſcopes, G and H, have each a ſtage, repreſented by *Plate* IX. *fig.* 4; and a *dot* made on a thin ſlip of gold, called a *gold tongue*, lies under the object-lens in ſuch a ſituation, that the capſtan ſcrews can adjuſt it to a given place in the field of view of each microſcope, ſo as to become a *mark* for making the adjuſtments by, and for biſecting the circle at reverſed oppoſite readings. The poſition of the three glaſſes of each microſcope is ſeen in *fig.* 3. of the ſame plate, together with the magnified appearance of the notched ſcale and diviſions of the circle. In *fig.* 5. the general plan of the micrometer is exhibited, and in *fig.* 6. is the plan of the ſtage where the pillars enter, that ſupport the microſcope. *Fig.* 7. ſhews the lower or ſteel ſlide, and *fig.* 8. the upper or braſs ſlide, that ſeparate the wires of the micrometer; while *fig.* 9. is a repreſentation of the long horizontal microſcope that reads the diviſions of the ſemi-circle above noticed, at the letter I in the large figure of *Plate* VIII. As it was not eaſy to deſcribe the conſtruction of the three feet, two of which, we have ſaid, only are viſible, oppoſite to D and E, we have added *figs.* 3. and 5. in *Plate* VIII. to illuſtrate their poſition. In *fig.* 3. the piece F F, as before, is a portion of the ſtand, and D E a portion of the octagonal board, to which the ſcrew F is attached, that preſſes againſt the angular corner of the ſtand, into which a piece of braſs is let for the ſcrew to preſs againſt, an end ſection of which is ſhewn in *fig.* 5, with the ſame letters of reference to the ſame parts: M N is a ſection of the baſe of the inſtrument, and O one of the three braſs branches that bears the foot-ſcrew P, and its two ſide ſcrews or tightening ſcrews Q, R, as ſeen in *fig.* 5. At S is a curved piece of box, faſt to M N, which bears the principal part of the weight laid on this ſcrew, and does not gall the parts on which it ſlides, when a circular motion is given; but, to take off a part of the weight, a cylindrical roller near S is put to a horizontal ſpring bearing the central pin of the roller, which ſpring preſſes the roller even with the face of the curved block of box, and may be made to take more or leſs of the weight by a ſcrew preſſing upon it from above, and giving it more or leſs tenſion. Hence all the parts of this large inſtrument are ſtrong, and yet the moving parts are made to go freely and ſmoothly; and the only alteration that can apparently be made for the better, is the addition of a third vertical microſcope, for which the conſtruction is peculiarly adapted; for each branch of the triple bar that carries the three feet, being braced firmly, is made as though each was intended to have a microſcope over it, which is the caſe with only one; and an additional foundation for the ſecond ſtage is made to receive the ſecond microſcope, as we think, unneceſſarily; for if three equidiſtant microſcopes had been uſed inſtead of two oppoſite ones, not only would the errors of diviſion and of eccentricity have been leſſened thereby, but in the reverſed poſition new parts of the circle would have been pointed to, equidiſtant from the former three, ſo that ſix portions of the circle would thus have been employed in meaſuring a reverſed obſervation, which the preſent aſtronomer royal firſt pointed out to be an advantage peculiar to three readings on a horizontal circle. We have been informed, that it is yet intended to have three microſcopes attached to the horizontal circle of this large inſtrument, to be uſed as we have here ſuggeſted. For the advantage of a triple reading, ſee our table for three verniers in the article Circle.

After having given a deſcription of Ramſden's great theodolite, we proceed, in the next place, to explain how its different adjuſtments are made, for putting it into a ſtate proper for uſe, which we cannot do better, than by adopting the directions laid down by general Roy himſelf.

The Adjuſtment of the Axis Level.—The axis of the upper or tranſit teleſcope, being brought over any one of the feet, and the circle being clamped, hang the axis level on the pivots, or anſæ of the teleſcope, and bring the bubble to the two indices; then reverſe the level, that is, turn it end for end, and note the difference. Biſect this difference, one half by the level's adjuſting ſcrew, and the other half by that foot-ſcrew only which is in a line with the axis. This operation being repeated until the difference wholly vaniſhes, the level will be truly adjuſted, that is to ſay, the bubble will reſt between the ſame points in both poſitions.

Adjuſtment of the Elevation Level.— This level being ſuſpended on the rod attached to the outſide of the tranſit teleſcope, ſcrew the erect eye-tube on, to make that end preponderate. Adjuſt the bubble to the indices by the ſteel finger-ſcrew at the tail of the ſemi-circle's clamp, reverſe the level, and note the difference. Then biſect that difference, and correct one half by the finger-ſcrew, and the other half by the proper adjuſting ſcrew under the level, and ſo on, repeatedly, until the difference wholly vaniſhes. The level may then be hung on the two pins that project from the horizontal bar which carries the teleſcope, where, being parallel to the axis level, it will ſhew, when that is removed (as is commonly the caſe when terreſtrial objects only are obſerved) whether the plane of the inſtrument ſuffers any alteration. If this ſhould have happened, the level on the horizontal bar is at all times ſufficient to correct it.

To ſet the vertical Axis perpendicular.—This may be done by either level, but beſt with the axis level, which, being ſuſpended on its pivots, muſt be brought parallel with two of the feet of the inſtrument; and by the ſcrews of theſe two feet, the bubble is to be brought between its indices. The circle being then turned round 180°, if the bubble changes its place, half the difference is to be corrected by one of the feet-ſcrews, and the other half by two capſtan-headed ſcrews, that act againſt each other, under and belonging to one of the Y's, or ſupports, in which the pivots reſt. When the bubble is found to be juſt in theſe two poſitions, turn the circle 90°, which will neceſſarily bring the axis over the third foot of this inſtrument: then correct any error there may be by that foot-ſcrew. In this manner the circle will be made to revolve again and again, without any alteration whatever of the bubble, which ſhews that the vertical axis is then truly perpendicular to the horizon.

To make the Line of Collimation in the Teleſcope at right angles with the tranſverſe Axis.—The pivots reſting in their Y's, direct the teleſcope to ſome diſtant well-defined object, and let the circle be clamped. Then reverſe the axis, that is, turn the teleſcope upſide down. If the interſection of the wires does not coincide with the object in both poſitions, half the difference muſt be corrected by the motion of the circle with the Hooke's joint, and the other half by the motion of the braſs ſlide in the eye-end of the teleſcope, by applying the milled-head key in the ſmall ſocket ſeen in the figure; and ſo repeatedly until the difference wholly diſappears.

To ſet the Rod on which the Elevation Level hangs parallel to the Line of Collimation.—The vertical axis being ſuppoſed to

be

be nearly vertical, hang the level on its rod, and rectify the bubble by the finger-fcrew of the clamp. Set the horizontal wire on the fteel flide, to interfect the centre of the oblique wires, and place the dart or index at zero on the micrometer head. Then obferve fome diftant diftinct object covered by the horizontal wire. Invert the femicircle, that is, turn the azimuth circle 180°, and the telefcope upfide down, fo as to bring the wire upon, or nearly upon, the fame object. Now, if the level be not right, rectify it by the finger-fcrew at the tail of the clamp. If the telefcope does not now accurately cover the fame object, as in the former pofition, bifect the difference by the finger-fcrew of the clamp, and then rectify the bubble by the captan-nuts under one end of the rod. Repeat this operation until the level is right, when the telefcope fees the fame object in both pofitions, and thereby the rod will be brought parallel in altitude to the line of collimation, or axis of vifion.

We have defcribed other and more recent conftructions of large circular inftruments, under the word Circle, that have all the properties of the theodolite which we have here defcribed, and fome of which have the advantage of a large vertical circle, that renders their ufe in aftronomy co-extenfive with their application to geodetical operations, and which therefore we recommend in preference to the bulky inftrument with which the Englifh trigonometrical furveys were performed.

A theodolite of a portable fize, and of Troughton's beft conftruction, is exhibited in *Plate* IX. *fig.* 1. *of Surveying*, fuch as is adapted for land-furveying, or for the furveying of harbours. A, B, C, are the three mahogany legs of a tripod, furmounted with brafs joints which allow the legs to form one entire cylinder, about four feet long. The brafs-work above the three joints has a male fcrew, upon which a focket, under the brafs circular plate D E, fcrews, and bears the inftrument, which is almoft entirely of brafs. This plate D E has four fockets made faft into it, projecting both above and below, as feen in the figure, in which are exhibited three out of the four, with as many fcrews with milled heads, that afcend and defcend as they are turned round, forwards or backwards, by means of their connection with their refpective fockets, that have each a female fcrew: the heads of thofe fcrews prefs againft the inferior face of the upper circular brafs plate F G, to which a ball, ending with a vertical axis, is attached, and is embraced by the upper portion of the focket of plate D E, within the four fcrews. The intention of the ball and focket, and of the two plates with the four intervening fcrews, is to place the axis of the ball in a vertical pofition, and to keep it in that pofition while the parts above are employed in making an obfervation; which office this mechanifm will perform on floping as well on level ground. The axis of the ball, however, is made hollow, to admit of a fmaller folid axis within it, and has alfo two fockets or tubes furrounding it; all which have feparate motions, when the ball is made faft by the preffure of the four fcrews. The inner tube is attached to the graduated circle L M, of eight inches diameter, the chamfered edge of which circle is folid filver, that receives the dividing ftrokes read by the microfcope K: and the clamping piece, feen feparately in *fig.* 2, will fix the faid tube and graduated plate in any given fituation by means of the fcrew F, after which the fcrew G with the milled head, attached to the plate F G, will produce the flow motion when neceffary. The lower telefcope H I turns on two pivots not feen, one of which pivots has its hole in a cock, borne by a fmaller circular plate under the graduated plate, into which the two fcrews H and I enter, and the other pivot enters the outermoft tube; fo that an elevation or depreffion of about 20° can be effected by this telefcope, before its motion is limited by the fuperior and inferior plates. This telefcope has a proper motion in azimuth, independently of the graduated plate, which motion is produced by the thumb-fcrew H, the axis of which has a pinion acting with a concealed wheel made faft to the graduated plate; but when the clamping-fcrew I is made faft, then the telefcope and graduated plate have but one common motion, which is commanded by the tangent-fcrew G of the clamping-piece F G. The ufe of the feparate motion of this telefcope will be explained prefently. Above the graduated plate L M, and in clofe contact with it, the vernier-plate revolves with the folid or innermoft axis, that is faft to it, and its clamp and fcrew of flow motion are hid from the fight by the fuperincumbent frame. This plate, which has four oppofite verniers, each reading to the accuracy of 15″, will move feparately, or may be clamped to the graduated plate, as occafion may require. Upon the plane of this vernier-plate, two fpirit-levels are placed with their proper adjufting-fcrews, one of which is feen at N; but the other, which ftands at right angles to this, is concealed in the drawing by the frame-work. A compafs and magnetic needle are alfo concealed within the frame, but may be conceived to be concentric with the vernier-plate within the faid frame. The tail-piece of the revolving microfcope K fits into a circular groove under the graduated plate L M, and, without having a centre of motion, will flide along the groove into any of the four pofitions, where the verniers require to be read, without interfering with any of the other motions. The inftrument now before us has been fome years in ufe, and is drawn on an enlarged fcale, that all the parts may be the better defcribed; but the moft recent theodolites of this conftruction have only three verniers, in preference to four, by reafon of the property, which this number has, of meafuring at *fix* different and equidiftant points on the graduated limb, when the meafurement of an angle is repeated in a reverfed pofition of the fuperior telefcope; fo that whatever errors of excentricity or of graduation may exift in the horizontal circle, they will be made to vanifh, in a great meafure, by their counteraction in the reverfed pofition of the verniers. Upon the plane of the vernier-plate is fcrewed, by three fcrews, forming an ifofceles triangle, the frame which fupports the pivots of the horizontal axis of the femi-circle P Q, on which the upper telefcope T U is placed. The arm, which bears the microfcope O for reading the altitude or depreffion meafured by the femicircle, has a tube that flides upon the projecting horizontal axis, that allows of fome degrees of motion between the end-bars of the frame; and another arm, that clamps the oppofite end of the faid axis, has a tangent-fcrew of flow motion at R, which finifhes the final contact of the interfecting point of the fpider's lines, within the eye-end of the telefcope, with the object viewed. The vernier for the femi-circle is fcrewed to the frame, after fpanning over the compafs-box; and its exact place may be adjufted by the fcrew of the frame above M, which ftands at the apex of the ifofceles triangle formed by the three fcrews. The level, that is feen under and parallel to the upper telefcope, is attached to it by two pairs of fcrews, one pair of which adjufts for the elevation or depreffion of one end of the tube that holds the bubble, and the other pair adjufts laterally for true parallelifm in this refpect: when the pins T and U are removed, the upper femi-circle of each ring, V and W, will turn back each on a hinge, and allow the telefcope to be taken out of its Y's, for the purpofe of being reverfed in pofition;

pofition; and in both fituations the telefcope is capable of having a circular motion, that carries the attached level round with it an entire revolution. During this revolution, an eye obferving the interfected point of the field of view, as projected on a diftant point, will fee whether or not any adjuftment of the fpider's lines is neceffary, and in what refpect. The aperture of each telefcope is an inch and a half, and the ordinary magnifying powers are from ten to eleven, with nearly fourteen inches of tube; but the upper or meafuring telefcope has a fecond eye-piece of the pofitive kind, which produces a magnifying power of twenty times. There are three fpider's lines in each eye-piece, one horizontal, and two croffing it fo as to include a fmall angle between them; which method of fixing the lines, allows the obferver an opportunity of bifecting the faid fmall angle by a vertical ftaff erected at a diftance, which is better than covering the ftaff with a vertical line, that would difappear upon the plane of fuch ftaff. Before we proceed to explain how this theodolite is ufed in the field, it will be requifite to fhew how the previous adjuftments are to be performed.

When the inftrument is fcrewed to the head of the tripod, the legs muft be opened wide enough to enfure a firm pofition, and the points muft be preffed into the ground equally, exactly over the hole into which a ftation ftaff has been, or is intended to be, inferted; fo that the plumb, fufpended from a pin at the junction of the legs, will fall exactly upon the faid hole; in which fituation the *ftation*, marked ⊙, is faid to be taken.

When the theodolite has been properly fixed in its ftation, the firft adjuftment that will require to be made, is that which regards the *line of collimation*. When all the parts of the inftrument are properly in their places, let the upper telefcope be pointed in a horizontal line, that paffes over two of the four fcrews of plate D E, and note what point in a diftant object is covered by the horizontal fpider's line, near the middle of the field of view; then turn the telefcope half round in the Y's, till the level lies above it, and obferve if the fame point is again cut by the faid line; if not, elevate or lower the horizontal line by the proper fcrews in the eye-piece, releafing one and fcrewing up the other, till the diftance between the two points, correfponding to the two pofitions, is bifected by the horizontal fpider's line: and if, when the telefcope is turned back to its original pofition, with the level under it, the fpider's line covers the point adjufted to, the line of collimation in altitude or depreffion will be correct; but if not, the operation muft be repeated delicately, till the horizontal line covers the fame diftant point in both pofitions. The fame operation will alfo put the vertical line correct, or rather the point of interfection, when there are two oblique lines inftead of a vertical line, as in Troughton's theodolite; and the adjuftments will be known to be complete, when the point of interfection continues on the fame diftant point, while the telefcope is made to revolve round the line of collimation as an axis.

The fecond adjuftment is that which puts the long *level* parallel to the rectified line of collimation. While the telefcope remains parallel to the line that joins two oppofite fcrews of plate D E, adjuft thofe two fcrews by turning them in oppofite directions, until the bubble is obferved to be in the middle of its tube under the telefcope: then, the femi-rings V and W being previoufly turned back, reverfe the ends of the telefcope, and alfo of the level attached to it; and if the bubble will refume its former fituation in the middle of the tube, both the line of collimation and the level will be truly horizontal, and confequently parallel to each other; but if the bubble recedes to one end, bring it back one half by the fcrews that elevate or deprefs one end of the level, and the other half by the fcrews of plate D E. Let this operation be repeated till the bubble will remain in the middle of the tube, after the telefcope has been reverfed into both pofitions. The adjuftment of the level, however, is not yet complete; for though the axes of the two tubes may be equidiftant at both ends of the level, yet may they be inclined fo as to form an horizontal angle with each other at fome diftance, and in this cafe the bubble will run to the higher end of its tube, when the telefcope rotates; there are therefore two lateral fcrews, which adjuft the parallelifm of the two tubes, fo that the bubble will remain in the middle, in every part of a rotation of the telefcope round its line of collimation, which adjuftment muft now be made; and if this lateral adjuftment fhould be found to derange the vertical one before made, it muft be re-adjufted, and the level will then be in a proper ftate for ufe, provided the Y's are alike, and alfo the cylinders that reft in them; but if not, the bubble will not reft in the middle in both of the reverfed pofitions, till they are made fo.

The third adjuftment that we propofe to explain, is that which puts the line of collimation exactly at right angles to the axis of the femi-circle's vertical motion, which has not yet been defcribed, but which is effentially neceffary to be attended to, more particularly by the maker. Let the upper telefcope be directed to fome horizontal well-defined mark, that is included within the angular fpace formed by the two oblique lines, juft where the vertical line would have been, if fuch line had been ufed, while zero of the vernier coincides with zero ($360°$) of the horizontal limb of plate L M; then all the fcrews being faft, except the one which allows the vernier-plate to revolve, turn $180°$ in azimuth, and reverfe the telefcope by taking it out of its Y's, into its original pofition with refpect to the mark; and if this is feen in precifely the fame fituation in the angular fpace, (though not perhaps with refpect to altitude, if the axis of the vernier-plate was not previoufly adjufted,) the line of collimation will be at right angles to the axis of the vertical motion; but fhould this not prove to be the cafe, one of the Y's will require to be altered laterally, but the adjuftment of the level will not be deranged thereby. This alteration of one of the Y's had, however, better be effected by a regular workman, and fhould never be neglected by the maker.

The fourth adjuftment, which might have preceded the third without inconvenience, is that which makes the common *axis* of motion of the vernier-plate and horizontal graduated circle truly *vertical*. This is done partly by the fcrews that fix the ball and focket, inferted into plate D E, and partly by the adjufting-fcrew R of the vertical femicircle. Hitherto the upper telefcope has lain over two of the four fcrews only, and in a horizontal line, with the bubble in the middle. Let it now be turned along with the vernier-plate juft $90°$, till it lies over the other pair of oppofite fcrews, and fee if the bubble be now alfo in the middle, if not, make it fo by thofe fcrews; and if, after this operation, the bubble will remain in the middle during a whole revolution of the vernier-plate, in both the reverfed pofitions of the telefcope, the vertical axis of motion will be truly adjufted.

The fifth adjuftment relates to the levels fixed to the plane of the horizontal graduated circle, which are ufeful in watching the horizontal pofition of the inftrument, while an obfervation is making; thefe, which are at right angles to each other horizontally, muft alfo be feparately at right angles to the vertical axis that carries them round. When this axis has been adjufted, as we have juft explained, by the level of the upper telefcope, the bubbles of both the

the fixed levels muft be brought to the middle of their refpective tubes by their proper fcrews, fo that the bubbles of all the three levels may remain ftationary in every part of the revolution of the vernier-plate, which they will do if its axis is truly vertical.

The fixth adjuftment is that which puts the axis of the femi-circle's motion truly horizontal, or at right angles to the vertical axis of the horizontal circles: this is known to be fo, when the point of interfection of the fpider's lines will cover a long plumb-line, fufpended at a diftance, as the angle of elevation increafes, from the inferior to the fuperior end of the fufpended line; and ftill better by trying if the pole ftar, and its reflected image, feen in a bafon of quick-filver, will be fucceffively covered by the faid point of interfection of the fpider's lines. In fome theodolites, the horizontal axis lies in adjuftable Y's, like thofe of a tranfit-inftrument; but in the inftrument before us, the adjuftment was made permanent by the maker.

Laftly, the adjuftment of the vernier to zero of the femi-circle is made by the fcrew near M, which elevates or depreffes the whole frame in which the telefcope and femi-circle move, and confequently alters the fituation of the level, which has its bubble brought back again by the fcrew R, that gives flow motion to the femi-circle, when the clamp at the fuperior end of the arm is made faft to the axis of motion; but it is not effential that zero of the vernier fhould be at zero of the femi-circle when the level is right, becaufe when an altitude or depreffion is repeated in the reverfed pofitions of the telefcope, the two readings will have equal and oppofite errors; and one half of the difference of thofe readings will be the conftant index error, which may be afcertained with great precifion from an average of a number of reverfed obfervations.

The lower telefcope, being placed as a guard to watch any azimuthal alteration in the pofition of the inftrument, requires no adjuftments, except that for diftinct vifion, after it is brought to its object by its proper vertical and horizontal motions, in which fituation its horizontal motion is clamped by the fcrew I under the horizontal plate.

After the adjuftments are all made, or examined, the theodolite may be ufed for meafuring either horizontal or vertical angles in the following manner. Let us fuppofe two ftaves erected vertically on level ground, one towards the eaft and the other towards the fouth of the ftation where the inftrument ftands in a ftate of adjuftment; and let it be required to afcertain the angle fubtended at the centre of the inftrument by a line joining thefe ftaves: in the firft place, the lozenge of the vernier No. 1. muft be clamped to 360° on the horizontal circle, and the clamping fcrew F muft be releafed, fo that the upper telefcope, vernier-plate, and graduated horizontal circle, may all move in azimuth together, till the ftaff to the eaft is feen in the field of view; this clamp F may then alfo be made faft, and the fcrew of flow motion, G, will bring the ftaff to bifect the angle formed by the fpider's lines, in which fituation zero of the meafuring circle is truly placed: in the next place, bring the lower telefcope, by its proper fcrew H, into precifely the fame fituation, and fix it there by the fixing fcrew I: then, having examined that the upper telefcope has not moved from the ftaff by any accident, releafe the clamping fcrew that held the vernier-plate, and turn the upper telefcope, till the fecond ftaff in the fouth bifects the angle of the fpider's hairs; which may firft be done roughly before clamping, and afterwards more exactly, by the tangent-fcrew of the clamp; then, having examined the pofition of the lower telefcope again, let all the four (or three) readings of the vernier-plate be put down, and take the fourth (or third) part of their amount as the true angle, and fee that both telefcopes have their ftaves bifecting their refpective angular fpaces as at firft, after the meafures are read, and then the average thus afcertained will be nearly the true angle: but to prove the exactnefs of the meafure thus taken, and alfo the accurate conftruction of the inftrument, the telefcope refting in the Y's may now have its pofition reverfed, and then No. 3. of the four verniers muft be clamped to the point 360° of the graduated circle, and the fame operation muft be repeated, when another average of four meafures will be had, and an average of thefe two refults with oppofite index errors, may be confidered as very near the truth; and more particularly if there are only three verniers; for then, as we have ftated above, the readings will be at fix equidiftant points of the circle, and will correct for excentricity as well as inequality of divifions, if any exift. In ordinary meafurements of angles, in fmall furveys of land, this attention to extreme accuracy may be fuperfluous, where the inftrument is well centered and graduated: but where the lines to be meafured are long, the angles cannot be taken with too much care; particularly when any fide of a triangle is to be determined, or checked, by the oppofite angle.

In taking an angle of altitude or of depreffion with the femi-circle of the theodolite in queftion, very great accuracy is not to be expected, feeing there is but one vernier; but by proper attention to the previous adjuftment of the level of the upper telefcope, and by ufing the telefcope in the reverfed pofitions, two meafures will be obtained with oppofite errors, that counteract each other's effects, fo as to render the meafure true to 15″. It is hardly neceffary to add, that the meafure of a vertical angle is taken by the horizontal fpider's line, and that the lower telefcope is of no ufe in taking fuch meafure.

We proceed, laftly, to exemplify the ufe of a common theodolite by an actual furvey of a fmall eftate, fuch as will come within the limits of one of our plates, and by an explanation of the manner in which a *field-book* is kept in practice, and its contents transferred to the formation of a map, agreeably to the moft approved methods of meafuring and plotting an eftate of any affigned dimenfions. For this part of our article we are indebted to Mr. James Wadmore, whofe experience and acknowledged fkill, in his profeffion of land-furveyor, eminently qualify him for communicating the requifite information which we have referved for this place, to render the fubject of *furveying* complete.

" Preparatory to making a furvey with the affiftance of a theodolite, I confider it indifpenfably neceffary, (fays Mr. Wadmore,) that the furveyor fhould feel well affured that his inftrument is in a perfect ftate of adjuftment, and alfo that his chain is correct, otherwife no dependance can be placed upon the moft particular and minute field-book he could make; for if thefe primary things are not attended to, the refult of his labours, on plotting his dimenfions, will turn out to be only fo much time loft, as well as that which he may have beftowed upon his furvey.

" In order to obviate thefe difficulties in fome meafure, I moft earneftly recommend to the young practitioner, that, in choofing his theodolite, as well as his protractor, cafe of inftruments, plotting fcales, &c. on which every thing depends to enable him to complete his furveys with correctnefs, that he be not fparing of a little money in purchafing thofe that are good, and can be relied upon for accuracy; as the being furnifhed with fuch, in the firft inftance, will be the means of enfuring to him that ultimate difpatch in the progrefs of his profeffion, which will lead him to the moft fatisfactory refults.

" As nearly the whole of the profeffion of furveyors have fome material or nice diftinctions in keeping their field-books, arising either from the peculiar methods they have been taught, the instruments they use, the methods the more experienced have been led to adopt; from the more enlarged and enlightened views they may have taken to ascertain the best possible mann r of facilitating the desired object, that of making a correct survey; or from the more improved state of mathematical science; I trust I may be permitted to offer the following method of taking dimensions, the form of keeping a field-book, and the method to be adopted in plotting the same. Having made use of the theodolite, and endeavoured, by practical experience, to avail myself of its most beneficial services, I have no doubt but the specimen I now submit will be most readily comprehended, and the most intricate and difficult surveys accomplished by the same means; *viz.* with the assistance of the theodolite, where other methods, by possibility, may be found partially (if not wholly) to fail.

"On commencing a survey, I have always found it necessary to look out for an intelligent labourer, well acquainted with the locality of the neighbourhood, with whose assistance, and another to carry the theodolite, I usually commence; invariably taking the chain myself after the leader: and here it may not be amiss to remind the young practitioner, that, in following, he must be most particular in directing his chain-leader in a straight line, otherwise the relative bearings of the stations forward, taken by the theodolite, will be rendered incorrect, and the protractor in plotting will not fail to convince him of his error, to his great chagrin and disappointment. I must also remind him of the necessity of keeping his chain-hand, and also directing that of his chain-leader to be kept as near the surface as conveniently can be done, and the chain properly stretched, by which means he will obtain more correct lengths in measuring from station to station, insuring thereby the greater accuracy in his survey (particularly if it be large); as he will very early find, in the course of his practice, that errors, when once begun, will rapidly increase; to prevent which, it will be found very convenient to plot every day's work on his return home, before he commences another, when, if any error is found, it can be rectified on the following day.

"Many other necessary cautions might be given to the young surveyor, which by some may be thought superfluous, but the following I cannot help recommending to his attention; *viz.* that of being exceedingly particular in marking and describing his exterior boundaries, having myself, more than once, seen litigation prevented by the production of correct surveys, where the boundaries of estates in dispute were clearly defined. And let him not be fearful of taking too many offsets, or dimensions; for by trusting observations necessary to his survey to memory, he cannot but fail to omit some; whereas by a copious field-book, not even the slightest bend in a fence, or object of any sort, can possibly be omitted. Above all, let him feel well satisfied of the correctness of his chain; to enable him to do which, he should always have a spare one, on a large survey, to correct by; as it is well known that accidents will happen by the breaking of the same, by loss of rings, &c.; and the offset staff, from being too short, cannot be depended upon for this purpose.

"Having said thus much, I now proceed to shew the method I have practised in surveying with the theodolite; in doing which, I shall first premise that I have always considered it advantageous to take a view of the estate to be surveyed, by doing which, I have been enabled to avail myself of studying the best stations, and to judge how the business may be accomplished with the greatest facility.

"The theodolite which I have been accustomed to use is a very good one, made by Cary, about five inches diameter on the limb, which is finely graduated, with a vernier reading minutes, and with degrees numbered from 1 to 360; it has an achromatic telescope and vertical arc, for the purpose of ascertaining the angles of elevation and depression in hilly surveys, on one side, and the corresponding deductions to be made in the chain lines on the other, and moves by rack-work.

"The method adopted by me, after some years' practice, in keeping a field-book, perhaps may be thought singular, namely, that of commencing at the bottom of the last page of the same, and working upwards therefrom; but it will readily be seen, on reference to the accompanying field-book in *Plate* X. to be the best way, as in proceeding, you meet the objects you have to describe in succession as you advance, and it affords a much greater facility in laying off the offsets from the chain-lines, than in the other way.

"It is well known that the needle is frequently affected, in the first place, by the atmosphere, and liable to get out of order; in the second, the chain being made of iron as well as the arrows, and their not being moved a sufficient distance in general, when the theodolite is planted for taking an angle, it may thereby be very materially affected; in the third, articles of iron or steel may be about the persons attending the survey, which may have the same effect; in the fourth, it may not be found improbable, from the very nature of the ground on which a survey may be carried on, that veins of iron, or metallic ore, may exist under the surface, which will not fail to influence the polarity, to the utter detriment of ascertaining the true bearings; and, lastly, without a vernier, the angle cannot be read with sufficient accuracy.

"Trusting that the foregoing remarks will suffice to convince those, who may be carrying on surveys by the needle alone, of the danger of trusting to this method, as well as to prevent the student in the profession from so doing, I now proceed to shew, that by taking the included angles of the survey upon the limb of the theodolite, and by carefully noting them in the field sketch, (as seen in the plate,) no such danger can possibly exist. The following problem will give sufficient proof of the accuracy of this method of measuring the internal angles of any geometrical figure, whatever may be the number of its sides; *viz.* double the number of sides, and multiply them by 90°; and then, if 360° be subtracted from the product, the remainder will be the sum of all the internal angles; for if we suppose lines drawn from every angle to one common point in or near the middle of the figure, there will be as many triangles as there are sides, and the sum of all the angles at the apex, or point assumed, will be 360°, as will appear when circumscribed by a small circle: therefore, as every triangle contains 180°, the amount of all the triangles will be as many times 180° (or $90^\circ \times 2$) as there are bases, when diminished by 360°. In our example, the survey is bounded by five chain lines, with as many included angles, and therefore the amount of the angles will be $\overline{5 \times 90^\circ \times 2} - 360^\circ$; or $900^\circ - 360^\circ = 540^\circ$, agreeably to the subjoined measurements taken in the field; *viz.*

Having

"Having ſaid ſo much relative to the means of applying the theodolite moſt beneficially, I ſhall now explain an example of each of the methods I have alluded to; in doing which, I beg it may be underſtood, that although the difficulties I have enumerated may in ſome caſes exiſt, yet it is poſſible a ſurvey of moderate extent may be carried on by the needle with caution ſufficient to obviate them; though I am fully ſatisfied, from experience, that the latter method is the moſt to be relied upon: I ſhall, however, proceed to exemplify both in the order before-mentioned.

"*The Method of uſing the Theodolite in aſcertaining the Bearings by the Needle.*—It will be ſeen by the field-book, that I commence at (ſtation) 1, at the back of the manſion: here, having the theodolite firmly fixed in the ground, by means of the four adjuſting-ſcrews, I ſet it perfectly level, firſt in the direction of the magnetic north, and afterwards at right angles: being thus ſatisfied, I ſet the vernier on the upper limb correctly to 360° on the graduated circle, and looſen the ſcrew that fixes the inſtrument. I then move the graduated circle round until I aſcertain that the needle points to N. in the compaſs-box, and then tighten the ſame ſcrew, which prevents it from moving. Being now ready to take the bearing from ⊙ 1 to ⊙ 2, I direct the teleſcope to ſome object in that direction, keeping as near to the boundary-fence as can well be admitted, in order to reduce the length of the offsets; and having brought the croſs-wires in the teleſcope to bear upon the object, I then look to ſee what part of the limb is cut by the vernier, which I find to be 330° 2′, and in a north-weſt direction. This I note down as in the field-book, and afterwards examine whether it is correct. I then direct the chain-man to move forward towards that object, leaving a mark behind, to return to, and proceed by firſt taking the following offset at 00; that is, at the place of commencement, I find an offset to the right of 86 links to lady Buckinghamſhire's fence, and 40 from thence back to the building, which I note down. I then proceed, and at 212, I meaſure 5 links to the right, to a tree; and going forwards at 274, I meaſure 2 links to the left, to another tree, (which objects I am always induced to mark in the ſurvey, for the purpoſe of embelliſhing the fair map): proceeding onwards at 310, the offset to the corner of lady Buckinghamſhire's ſummer-houſe is 10; at 360, the chain touches the fence, conſequently I mark the offset 0 (nothing); at 738, there is an offset to the left of 23 links, to a tree; and at 917, one to the fence of 13: continuing the line, I ſet up a mark at 950, and write the ſame down in the field-book, thus "950 3 mark left," meaning it for a ſtation, to join to hereafter: I call it ſtation 3, being the next number following the ſtation I am meaſuring towards; and I incloſe it in a circle, to make it more prominent to refer to; and mark the 950, the number of links on the chain-line, alſo in a circle, that I may not err in plotting off the ſituation of the ſame. I then go on, and at 960 come to the outer edge of a ſmall clump of trees; at 975, an offset to the left aſcertains the width of the clump that way to be 50 links, and one to the right of 13 links to the fence; 986 paſſes the outer edge of the clump; at 1031, an offset of 31 links on the left to the canal; at 1100, paſſing cloſe to the edge of the canal, there being no offset on the left, I mark it 0 (nothing); at 1155, I croſs the gravel-walk, the width of which was previouſly noted in the field-book to be 8 links; and at 1180, I halt, and mark the offset to the fence on the right 5 links. Here I again plant my theodolite, as before, exactly over the ſtation-hole; and after ſetting it perfectly level, and having brought the vernier 360° on the circle, and aſcertained that the needle was correctly pointing to N. in the compaſs-box, I tighten the fixing ſcrew, then move the teleſcope round gently to the left, until the croſs-wires cut a conſpicuous object in the direction in which I mean to proceed, and aſcertain that the vernier cuts 235° 7′ in a ſouth-weſt direction in the box. This I note down immediately in the field-book, as there repreſented; and after examining that I had done ſo correctly, I proceeed on to meaſure the line from ⊙ 2 to ⊙ 4, taking the offsets right and left, and making the neceſſary remarks, to enable me to give a correct map and deſcription of the eſtate, and ſo on throughout the ſurvey. I have been particular in the field-book, which I truſt, by the above deſcription, will be conſidered to be a plain and facile way.

"*The Method of uſing the Theodolite in aſcertaining the Angles upon the graduated Circle, without Reference to the Needle.*—On commencing, I plant the theodolite firmly in the ground, and after adjuſting the level perfectly, and ſetting the vernier to 360° on the limb, I move the circle round, until I aſcertain that the needle in the compaſs-box points correctly to N.; then tightening the ſcrew that fixes the inſtrument, as before, I move the teleſcope gently round in the direction of the line to ⊙ 2, in doing which, I find that the vernier cuts upon 330° 2′ N.W. This is noted down, in order to ſhew the bearing of the eſtate upon the map, and which, on being deducted from 360°, leaves an angle to the left of the meridian of 29° 58′, as ſhewn in the example: then leaving a mark at ſtation ⊙ 1, and having proceeded along the line to ſtation ⊙ 2, and taken the offsets, and made the neceſſary remarks in the field-book, as in the former method, on arriving at ⊙ 2, I again plant the theodolite firmly in the ground, and adjuſting it as before, move the teleſcope round until the croſs-wires cut the lower part of the mark left at ⊙ 1: then noting in my field ſketch the number of degrees cut by the vernier upon the limb, without regarding zero, I afterwards move the teleſcope carefully round to the right, and direct it towards 4; and bringing the croſs-wires in the teleſcope to cut the object propoſed to be meaſured to, I look and ſee the number of degrees cut by the vernier on the limb, as before: deducting one from the other, I get the ∠ at ⊙ 2, *viz.* 85° 14′; and after having meaſured the line, on my arriving at ⊙ 4, I proceed exactly in a ſimilar way, by firſt looking back to the laſt ſtation, and then forward to the next, deducting the number of degrees and minutes in one direction from thoſe read in the other, which gives the angle 88° 18′. Following this courſe, I proceed on the ſurvey until all the angles and ſides are completed.

"It is neceſſary, however, before quitting each ſtation, to take particular care in reading off the angles by the vernier, and alſo in writing them down correctly: and in this way of proceeding, the trouble of adjuſting for zero of the vernier to 360° at every ſtation is avoided.

"By plotting, is underſtood the making of a draught of the eſtate from the field-book; and as the inſtruments neceſſary to be uſed by the ſurveyor, in taking the dimenſions in the field, are ſuch, that he may be enabled to aſcertain diſtances and angles correctly; it naturally occurs that correſponding requiſites are neceſſary to make a ground-plot, or draught thereof, for laying down the quantities of the ſeveral angles, and of the diſtances meaſured by the chain upon paper, which are uſually accompliſhed by means of the protractor for the former, and ſcales of equal parts for the latter.

"With reſpect to the protractor, I have hitherto uſed, and recommended the young ſurveyor to uſe, one of eight inches

inches diameter, graduated to half a degree, and numbered from 1 to 360°, to correfpond with my theodolite, with a vernier to mark off the angles to one minute of a degree, and a projecting pointer of two inches and a half beyond the outer radius of it, which in general furveying will be found, with care, to be fufficiently correct. This I had alfo from Mr. Cary of the Strand, together with the fet of ivory plotting-fcales, of about twelve inches long, decimally divided the whole length clofe by the edges, which are chamfered, to lay clofe to the paper, and give additional facility in pricking off the chain-lines, numbered 1, 2, 3, 4, &c. which are chains: thefe again are fubdivided into tenths, every one of which divifions are reckoned 10 links. The numbers are fo placed as to reckon backwards and forwards for convenience; but the method of ufing them is now fo univerfally known, and fo eafily underftood, as to preclude the neceffity of any further defcription. I fhall, therefore, proceed directly to ftate the method ufed by me of transferring the dimenfions of the eftate from the field-book, which is as follows; *viz.*

"Having provided myfelf with a fheet of drawing-paper of fufficient fize, I proceed to draw a line acrofs the fame in pencil, which line is nominally reprefentative of the magnetic meridian, or that which the needle in the compafs box points to. On a convenient fituation on this line, with a fine pointer, I make a mark thus ⊙, and calling that (ftation) ⊙ 1, I lay the protractor with its centre upon the ftation-point, and take care that 360° of the protractor cuts the line on the northern fide, and 180° the fouthern fide of the meridional line: I then turn the moveable pointer to the left, until the centre of the vernier thereof cuts 330° 2′ on the limb of the protractor, when I prefs down the pointer fufficiently hard to make a vifible mark; then taking off the protractor, I draw a fine line with a pencil from ⊙ 1 to the point fo pricked off; and afterwards, with a fcale of chains, mark off the length of the firft chain-line, *viz.* 1180 links: I alfo mark off 950 links for ⊙ 3, where a mark was left to join to. This done, I draw a line parallel to the firft magnetic meridional line through ⊙ 2; when I put the protractor upon the fame, taking care that the centre is exactly upon ⊙ 2, and that 360° and 180° exactly cut the meridional line north and fouth refpectively; which being done, I move the pointer to the left; and when I find the vernier cuts 235° 7′ on the limb, I again prefs down the pointer, and make a fufficient impreffion on the paper, to which I draw a line from ⊙ 2: then taking the fcale, I prick off the length of the chain-line from ⊙ 2 to ⊙ 4, being 1274 links, and alfo 994 links on the fame line from ⊙ 2 to a mark left there, and called in the field-book ⊙ 5. I proceed in this manner until the whole of the bearings and chain-lines are laid down, the laft of which, or the connecting-line, *viz.* from ⊙ 10 to ⊙ 1, on being laid down, and the protractor having pricked off the angle 62° 41′ N.E., I draw the pencil-line, and finding that it clofes upon ⊙ 1, both as to bearing and diftance, I am fatisfied the whole is correct.

"In laying down the angles and chain-lines of the furvey taken by the latter method, without the ufe of the needle, little need be faid; for, having firft drawn the magnetic meridian line, marked N. S., a mark is made on fome convenient part thereof for ⊙ 1; then laying the centre of the protractor thereon, and 360° and 180° thereof cutting the meridian line north and fouth refpectively, I prick off 29° 58′ on the left-hand, or north-weft fide, as being the relative bearing of ⊙ 2 from ⊙ 1; then drawing a fine line, I mark off the length of the chain-line, and lay the centre of the protractor upon ⊙ 2, and mark off the ∠ between ⊙ 1, which I firft look back to, and ⊙ 4, the angle of which, on deducting the quantity of one from that of the other, I find to be 85° 14′: this I prick off, and drawing a line thereto, I mark off the length of the chain-line 1274 links, and fo continue to proceed until the boundary is finifhed. I then proceed to mark off the offsets at their proper points in each chain-line, and connecting the points of fuch offsets, I have the boundary defined of its true fhape and dimenfions, as feen in the map. Laftly, I caft up the dimenfions of the feveral triangles and offsets, confidered as fmall trapezia, the method of doing which has been explained under the word CHAIN, and find the contents as expreffed in the fubjoined table.

THEODORE I. pope, in *Biography*, was the fon of a bifhop of the fame name, and born at Jerufalem. He fucceeded John IV. in the papal chair in the year 642. Of this pope no material circumftance occurs, except his controverfy with the church at Conftantinople, concerning the doctrine of the Monothelites; and this controverfy is fo little interefting to our readers, that we fhall pafs it over without any farther notice. Theodore died in the year 649. Befides fome letters relating to the above-mentioned controverfy, a memorial againft Pyrrhus, the depofed patriarch of Conftantinople, and his errors, addreffed to the Eaftern bifhops, is preferved. Bower.

THEODORE II. pope, a native of Rome, fucceeded Romanus about the clofe of the year 898. During his poffeffion of the fee, which he held only for twenty days, he caufed the body of his predeceffor Stephen to be taken out of the Tyber, and interred in the Vatican, and declared all his acts to be legal and valid. Bower.

THEODORE LASCARIS I. a Greek emperor, was fon-in-law of Alexius Angelus, who imprifoned his brother Ifaac and ufurped the throne. Having valiantly but unfuccefsfully defended Conftantinople againft the French and Venetians in the year 1204, he withdrew from the fcene of conteft acrofs the Bofphorus, and put himfelf at the head of a body of troops; but when he found that the confederates were purfuing him, he fought refuge with the Turkifh fultan of Iconium. Being joined by the inhabitants of Bithynia, he took poffeffion of the country from the river Meander to the Euxine fea, and fixed his refidence at Nice, where he was crowned by the patriarch of Conftantinople. When his father-in-law heard of his fuccefs, he went over from Greece,

Greece, where he had remained concealed, to Aſia, and implored the aſſiſtance of the ſultan of Iconium in recovering that part of his dominions of which Theodore had taken poſſeſſion; and having induced him to march with 20,000 men, he laid ſiege to Antioch on the Meander. Theodore, at the head of 2000 men, marched to its relief, and routed the beſiegers. The ſultan renewed the conteſt, and ſingling out Theodore, beat him off his horſe; but the emperor recovering himſelf, unhorſed the ſultan, cut off his head, and placing it on a pole, terrified his enemies, ſo that they all fled. Alexius was carried, as a priſoner, to Nice, where he was confined. Theodore, having made peace with the Turks, formed a treaty with the Latin emperor of Conſtantinople, and ſpent the remaining eighteen years of his reign, in ſecuring his newly-founded empire, which he tranſmitted to his deſcendants; bequeathing it, at his death, to his ſon-in-law, John Ducas Vataces. The Nicæan empire terminated about fifty-ſeven years after its eſtabliſhment by the elevation of its poſſeſſor, Michael Palæologus, to the throne of Conſtantinople. Anc. Un. Hiſt. Gibbon. Gen. Biog.

Theodore, biſhop of Mopſueſtia in Cilicia, was prieſt, and probably native, of Antioch, a diſciple of Diodorus, and an intimate friend of John Chryſoſtom. He was ordained biſhop in 392 or 394, and died in 428 or 429. Sozomen ſays, that he was well ſkilled in the ſacred ſcriptures, and in the liberal ſciences of the rhetoricians and philoſophers: and Theodoret calls him the doctor of the whole church, ſaying that he was biſhop thirty-ſix years, and that he wrote againſt all hereſies, particularly thoſe of Arius, Eunomius, and Apollinarius. He wrote commentaries probably upon all the books of the Old and New Teſtament, though two or three of them are not particularly mentioned: and in theſe commentaries, as Photius ſays, he avoided all allegorical interpretations, and confined himſelf to the hiſtorical and literal ſenſe. He defended this mode in a work concerning allegory and hiſtory againſt Origen. Some have charged him with treating the book of Job, the Canticles, and the Pſalms, with diſreſpect; but theſe are the accuſations of his enemies, and perhaps founded in error, as he actually wrote comments on ſome of theſe books. The book of Job he is ſaid to have repreſented as written in a fabulous manner, though founded on truth; the Canticles he is ſaid to have conſidered as a nuptial poem, and the Pſalms as chiefly referring to the hiſtory of the times. His other works were numerous, and related to the controverſies of his times, and to various theological doctrines. Moſt of Theodore's works are now loſt, but ſome fragments of them may be found, chiefly in Latin, and perhaps not fairly repreſented, in the Acts of the ſecond general council of Conſtantinople, or the fifth general council, held in 553, and alſo in Facundus, and in the Greek Chains. Fabricius aſſures us, that his commentary upon the Twelve Prophets is ſtill extant in manuſcript in the emperor's library at Vienna; and Montfaucon ſpeaks of its being in the library of St. Mark at Venice, as well as in the library at Vienna, and in the Vatican.

Theodore was no leſs celebrated as a preacher, than as a commentator and general writer: under the former character he was admired at Antioch, at Conſtantinople, and all over the Eaſt. Diſtinguiſhed by his learning and liberality, conſidering the time in which he lived, he has been charged with adopting the ſentiments of Neſtorius and Pelagius; and ſome moderns have called him the parent both of Pelagianiſm and Neſtorianiſm; whilſt others allow, that he held the Pelagian principle, but are of opinion that the charge of Neſtorianiſm is not ſo clear. The above-mentioned council devoted a conference to the examination of Theodore's writings; and began with reading a creed attributed to him: upon which the biſhops clamoured for an anathema againſt his books and his perſon, and againſt all who did not join in that anathema. Several biſhops, however, roſe in his defence, and refuſed to concur in the anathema. Some learned moderns have charged him with adopting ſentiments concerning the perſon of Chriſt ſimilar to thoſe of the preſent Unitarians; but of this fact there is no ſatisfactory evidence. Moſheim. Lardner.

Theodore *of Tarſus*, a monk of that city, was ordained biſhop by pope Vitalian, and being ſent into England in the year 668, at the deſire of king Egbert, was appointed to govern the church of Canterbury. In this high ſtation he aſſiduouſly employed himſelf in ſettling the faith and eccleſiaſtical diſcipline of England; and after having ſpent twenty years in the performance of various important and uſeful ſervices, he died in 690, at the age of eighty-eight years. With a view to the reſtoration of the neglected diſcipline of penance, he publiſhed a book of canons, under the title of "Penitential." In this book, ſins were diſtributed into various claſſes, according to their reſpective nature and aggravation; and various kinds of penance were aſſigned to them; forms of conſolation, exhortation, and abſolution were preſcribed, and other ſuch matters reſpecting diſcipline were regulated. This Penitential paſſed from Britain to other countries, and became the model of ſimilar works. It is ſtill extant, in an imperfect ſtate; and an edition of it was publiſhed at Paris by Petit, in 1679, 4to. with notes and diſſertations. Dupin. Moſheim.

Theodore Studita, an eminent eccleſiaſtic of the ninth century, was educated under Plato, head of the monaſtery upon mount Olympus, the government of which was committed to him in the year 795. By avowing his oppoſition to the marriage of Conſtantine Copronymus to one of the maids of honour of his wife, whom he had compelled for this purpoſe to take the religious vows, and by his ſeparation from the communion of the patriarch of Conſtantinople, Theodore incurred baniſhment; but at the death of the emperor he returned, and was appointed abbot of the monaſtery of Studa, in the ſuburbs of Conſtantinople. On account of his diſapprobation of the deciſion of a ſynod which declared the ſecond marriage of Conſtantine lawful, he was baniſhed a ſecond time. After the death of the emperor Nicephorus, in 811, he returned from baniſhment, and was reconciled to the patriarch. For his zealous defence of image-worſhip in the reign of Leo, he was baniſhed a third time, and treated by the emperor with great ſeverity. In 821 the emperor Michael allowed him to return to Conſtantinople, where he indulged a freedom of ſpeech that obliged him to withdraw. He died in the year 826, in his ſixty-ſeventh year. He was a man of learning, and author of many works, which were publiſhed by Sirmond, in Greek and Latin, at the end of his own works. Dupin. Moſheim. Gen. Biog.

THEODORET, a learned prelate of the Greek church, was born at Antioch about the year 386, and placed at the age of ſeven in the monaſtery of St. Euprepius. He was educated under Theodore of Mopſueſtia and John Chryſoſtom, and from his youth addicted himſelf to all the auſterities and exerciſes of a monaſtic life. Upon the death of his parents, he diſtributed his whole property among the poor. In the year 420, or 423, he was conſecrated, againſt his own inclination, biſhop of Cyrus in Syria, in the Euphratenſian province, the inhabitants of which were ignorant and barbarous, and notorious for their ſuperſtitious practices and heretical errors. Theodoret laboured induſtriouſly and ſucceſsfully in enlightening and reforming them. In his own conduct he was an exemplary paſtor; and in every thing

thing that related to his own gratification, he was ſelf-denying and frugal, that he might poſſeſs more ample means of relieving the poor and promoting works of public utility. No biſhop of his time was more active in performing the duties that pertained to his profeſſion and ſtation, or had greater influence in every kind of public buſineſs, particularly of an eccleſiaſtical nature. He was prudent in counſel, pacific in his temper, and always diſpoſed to compromiſe differences that occurred, and to recommend mutual forbearance and union among contending parties. But like other pacificators, he could not eſcape obloquy and harſh treatment. Between him and Cyril, however, an irreconcileable antipathy ſubſiſted, as was generally the caſe between the Eaſtern and Egyptian biſhops; and this antipathy was manifeſted, even after Cyril's death, by his ſucceſſor Dioſcorus, who cauſed Theodoret to be anathematized, and to be depoſed in a general ſynod at Epheſus. In the reign of the emperor Marcian, a general council was aſſembled at Chalcedon; and this council decreed, that Theodoret was worthy to hold his ſee, and he was accordingly reſtored to the church of Cyrus. He died, without any further moleſtation, in the beginning of the reign of the emperor Leo, A.D. 457 or 458.

Theodoret bears a high rank among the ancients as a commentator on the ſcriptures for the purity of his Attic ſtyle, and the clearneſs and good ſenſe of his explanations. He wrote commentaries upon moſt parts of the ſacred ſcriptures. His canon of the Old Teſtament was very little, if at all, different from that of the Jews. With regard to the New Teſtament, it appears that he received only four goſpels, the book of Acts, which he aſcribed to St. Luke, and fourteen epiſtles of the apoſtle Paul, upon which he wrote commentaries; digeſting them according to the order of time in which they were written, and noticing the places from which they were ſent. He has ſeldom quoted the Catholic epiſtles, though they are not wholly overlooked. He ſeems to have received the epiſtle of James, the firſt of Peter, and the firſt of John; but there is no certain proof that he received the book of the Revelation, or the other four Catholic epiſtles: ſo that we may conclude, that his canon of the New Teſtament was the ſame with that of the Syrian Chriſtians. His "Eccleſiaſtical Hiſtory," compriſed in five books, may be conſidered as a ſupplement to thoſe of Socrates and Sozomen; beginning where that of Euſebius ends, at the riſe of Arianiſm in 322 or 323, and terminating in 428. Its ſtyle, according to Photius, is clear and ſublime, but too much abounding in metaphors. It is deficient in chronological preciſion, but contains many valuable documents, and ſome remarkable circumſtances, which other eccleſiaſtical hiſtorians have omitted. His "Philotheus," or treatiſe on the monaſtic life, the genuineneſs of which ſome have queſtioned without ſufficient reaſon, relates the actions and extols the piety of the Eaſtern monks, and abounds with inſtances of the credulity and ſuperſtition of the times. In his work entitled "Of Heretical Fables," in five books, he diſtributes the different hereſies into claſſes, and concludes with a ſtatement of the faith of the Catholic church. "The Cure of the falſe Opinions of the Heathens," in twelve diſcourſes, is a learned and valuable apology for Chriſtianity. Lardner has given copious extracts from this performance, which merit high commendation. His other works conſiſt of letters and tracts on different theological ſubjects. They are all compriſed in the beſt edition of his writings, which is that of Father Sirmond, in four vols. fol. Gr. and Lat. printed at Paris in 1642. To theſe the Jeſuit Garnier added a fifth in 1684. Beauſobre gives the following candid account of Theodoret. "Theodoret is, in my opinion, one of the moſt valuable of the Fathers. He is learned; he reaſons well, eſpecially in his dialogues againſt the Greek hereſies of his times: he is a good literal interpreter of the ſcriptures. I cannot but admire his prudence and moderation, when I conſider that he ended his eccleſiaſtical hiſtory at the time when the Neſtorian diſputes, in which he was ſo deeply intereſted, begun. But, I fear, his zeal againſt heretics impoſed upon him almoſt as much, as his admiration of the heroes of the Aſcetic life, with whom he was charmed. Monaſteries have undoubtedly ſent forth great men into the world; but the diſciples of the monks contracted in their youth a ſuperſtitious diſpoſition which is ſcarcely ever ſhaken off; and the weak ſide of this able man ſeems to have been an exceſſive credulity." Dupin. Moſheim. Lardner. Beauſobre.

THEODORIC I., king of the Viſigoths, was the ſon of Alaric, and in 419 ſucceeded Wallia in the kingdom eſtabliſhed in the ſouth of France. After raiſing the ſiege of Arles, he made peace with the Romans, and was ſubſidized by them in the Spaniſh war; but being deſirous of renewing his attempts in Gaul, he took an opportunity, in 435, of reſuming his hoſtilities againſt them, and laid ſiege to Narbonne; but being compelled to raiſe the ſiege, he was under a neceſſity of directing his attention to the ſafety of Toulouſe, his own capital, which was inveſted by a body of Huns, under the command of count Litorius. In a very ſanguinary engagement with the aſſailants, he totally routed them, and took Litorius priſoner; who was firſt expoſed to the inſults of the populace at Toulouſe, and then thrown into a dungeon, where he died. After this event, Theodoric made peace with the Romans. His rank among the ſovereigns of that period was reſpectable; and both his ſons and daughters were well educated. The latter formed matrimonial connections with the eldeſt ſons of the kings of the Suevi and Vandals, who reigned in Spain and in Africa. But theſe connections proved unfortunate. The huſband of the Suevian princeſs was maſſacred by his brother; and the Vandal princeſs, being ſuſpected of a deſign to poiſon her father-in-law, Genſeric, was doomed to loſe her noſe and ears, and in this mutilated condition was ſent home to her father. Theodoric eagerly ſought an opportunity for revenging this cruel inſult. With this view, the Viſigoths and Romans formed an alliance to reſiſt Attila the Hun, who, inſtigated by Genſeric, invaded Gaul in 441; and Theodoric, at the head of his army, marched to the relief of Orleans, which was beſieged by the Huns. In their way the hoſtile armies met on the plains of Chalons, and a dreadful battle enſued. Theodoric was wounded by a Goth in the ſervice of Attila, and being diſmounted, was trampled to death under the feet of his own cavalry. When his body was found, his funeral rites were performed in the face of the retiring enemy.

THEODORIC, king of the Oſtrogoths, ſurnamed the *Great*, was a deſcendant of the Gothic race of the Amali, and born near Vienna, A.D. 455. At the age of eight years, he was ſent to Conſtantinople as a hoſtage for the fulfilment of the ſubſidiary treaty formed by the emperor Leo with the Goths. Here he had an opportunity of acquiring that character which he ſuſtained among the princes of that age: but his means of inſtruction muſt have been very limited, when it is conſidered that, though he excelled in all military exerciſes, he was ſo badly taught, as not to be able to write his own name. After ten years' reſidence at the court of Leo, he returned to his father, Theodomir, who was then the ſole ruler of the Oſtrogoths, in whoſe ſervice he diſtinguiſhed himſelf by his martial ſpirit. Upon the death of his father, in 475, the crown devolved on Theodoric. The emperor

peror Zeno, wiſhing to ſecure the attachment of the young prince, invited him to his court, and conferred upon him the rank of patrician. After having rendered ſubſtantial ſervice to the emperor, he was reduced to the neceſſity of deſerting the Roman cauſe, and forming an alliance with Theodoric, the ſon of Triarius. Having been altogether neglected by Zeno, he marched in an hoſtile manner into the fertile provinces of Thrace, which he laid waſte with wanton cruelty. In the war that enſued between the empire and the Goths, a variety of events occurred; but, upon the whole, Theodoric became more and more formidable, and by the death of the ſon of Triarius, he was placed at the head of his nation. Such was the power he acquired, that the emperor found it neceſſary to cede to him part of Lower Mœſia and Lower Dacia, and to honour him with the conſulate, which office he diſcharged at Conſtantinople. But conceiving that he was an object of jealouſy, and that his life was in danger, he withdrew into Thrace, and afterwards avowed himſelf an undiſguiſed enemy to the empire. Declining to lay ſiege to Conſtantinople, he determined, as it is ſaid, at the ſuggeſtion of Zeno, to turn his forces againſt Odoacer, who having depoſed Auguſtulus, the laſt Weſtern emperor, had aſſumed the title of king of Italy.

In the year 488, Theodoric, having collected together all the ſwarms of Goths that had ſucceſſively arrived on the frontiers of the empire, ſet out on his Italian expedition; and after encountering many difficulties in his progreſs, deſcended from the Italian alps, and reached the banks of the Sontius near Aquileia. Here, in Auguſt 489, he attacked Odoacer's numerous hoſt, and forced him to retreat as far as the plains of Verona. The reſult of a ſecond engagement was a complete victory on the part of the Goths, which compelled Odoacer and his fugitives to take refuge within the walls of Ravenna, while the conqueror obtained poſſeſſion of the cities of Pavia and Milan. But, as the fortune of war is uncertain, one of Odoacer's commanders, having deſerted to Theodoric, proved treacherous, and induced ſeveral of the officers of the Gothic king to join his former maſter. Odoacer, having alſo gained an acceſſion of other fugitives from the Gothic ſervice, recovered Milan, and obliged Theodoric to immure himſelf in Pavia. Theodoric, however, in this criſis of danger, obtained a powerful reinforcement from Alaric II. king of the Viſigoths, ſettled in Gaul, and attacking Odoacer on the Addna, totally defeated him. Upon this diſaſter, Odoacer fled to Ravenna; where, in the autumn of 492, he was beſieged by Theodoric, who had made himſelf maſter of all Italy, except this city. In the following ſpring, Odoacer was reduced to the neceſſity of propoſing terms of accommodation, with which Theodoric complied; and the conſequence was the ſurrender of Ravenna to the Gothic army. It was ſtipulated between theſe two ſovereigns, that they ſhould govern Italy with equal authority. Such a ſtipulation was not likely to produce any permanent effect; and it was very ſoon violated on the part of Theodoric, by an act which entails on his memory eternal diſhonour. Having invited Odoacer to a banquet, he ſtabbed him, as it is ſaid, with his own hand, under a pretext that his dead rival had formed a ſimilar deſign with regard to himſelf. After this event, Theodoric aſſumed the enſigns of royalty, and cauſed himſelf to be proclaimed by his army "king of Italy." This aſſumption was reluctantly confirmed by Anaſtaſius, the ſucceſſor of Zeno. The manner in which he exerciſed the royal authority, however unwarrantable the means by which he acquired it, placed him far above all the ſovereigns of that age. Sicily having been united to Italy by a voluntary ceſſion, Theodoric ſheathed the ſword of war, and cultivated alliances with neighbouring powers for the ſecurity of his kingdom. He eſtabliſhed peace with the imperial court at Conſtantinople, married a daughter of the king of the Franks, and beſtowed his own two daughters by a concubine, one on the king of the Viſigoths, and the other on the ſon of the king of the Burgondians, and his ſiſter on the king of the Vandals. He ſecured the attachment of his ſoldiers by aſſigning to them a third part of the lands of Italy; and he reſtricted the military profeſſion to his countrymen the Goths, whilſt he encouraged induſtry and the arts of peace among his Italian ſubjects. The Goths held their lands and benefices as a military ſtipend, in conſideration of which they were engaged to march on a ſummons under their provincial officers: and the whole extent of Italy was diſtributed into the quarters of a well-regulated camp. The civil offices were committed to the native Italians; and the form of government, and diſtribution of magiſtracies and of provinces, which had prevailed under the emperors, were continued; ſo that the transfer of power from the Romans to the Goths was ſcarcely perceived. The taxes remained the ſame, and on occaſion of any public calamity, were remitted. He fixed his ordinary reſidence at Ravenna; and when he removed his court, it was to Verona. In the year 500 he viſited Rome, and was treated with reſpect. He iſſued edicts for preventing the demolition of ancient monuments, and appropriated revenues to the repair of public edifices. He decorated other cities of Italy; and it has been ſaid, that, after the flouriſhing times of Rome, this country was never ſo proſperous and happy. He provided a fleet for guarding the country againſt maritime attacks: and thoſe wars by land in which he engaged, were terminated without diſturbing the peace and hazarding the ſecurity of Italy. By his prudent conduct, and military achievements, he maintained the balance of power in the Weſt, till it was overthrown by the ambition of Clovis, who defeated and put to death Alaric, the Viſigoth king: neverthleſs he ſaved the remainder of his family and people, and checked the career of the Franks.

Theodoric, with regard to his religious ſentiments and profeſſion, was an Arian; but he manifeſted no ardent zeal for making proſelytes to his own opinions, nor did he moleſt others in their profeſſion. Such was the government of Theodoric, that it reflected a ſhort-lived luſtre on the Gothic name, and eſtabliſhed an era of public happineſs which it is pleaſing to contemplate. His ſecretary Caſſiodorus, who was himſelf a man of erudition, and who cauſed his untaught maſter to patronize literature, has recorded in his twelve books of Epiſtles, the events at which we have here glanced. It muſt not be diſguiſed, however, that the reign of Theodoric was not exempt from the evils inſeparable from a deſpotiſm upheld by military power. The yoke of a foreigner was galling; and more eſpecially that of a foreigner who was conſidered as a barbarian and a heretic. The tolerant principles of Theodoric did not accord with the orthodox zeal of his ſubjects; and his puniſhment of ſome outrages committed againſt the Jews, who were ſettled in the cities of Italy, was repreſented as a perſecution of the church. An intolerant edict againſt the Arians, iſſued by the Byzantine court, provoked the king to retaliate on the Catholics under his juriſdiction; and ſhortly before his death an order was prepared to forbid the exerciſe of the Catholic worſhip in Italy after a certain day. In the mean time, jealouſies of the ſenatorial party in Rome, and of their connection with the imperial court, took poſſeſſion of the mind of Theodoric, who was made ſuſpicious by age; and an inſtance of tyranny inflicted upon two exemplary characters, ſays one of his biographers, is unhappily the laſt act recorded of a ſovereign diſtinguiſhed for the mildneſs and equity of his adminiſtration. For an account

count of the circumftances to which we here refer, fee the article BOETHIUS. Theodoric, at the clofe of life, reflected without doubt with remorfe and felf-reproach on his conduct towards Boethius and Symmachus. It is faid that, whilft he was fitting at table, he perceived the gaping head of a large fifh, which was ferved up before him, and at the fight exclaimed, that he beheld the angry and menacing countenance of Symmachus. Then probably did that fever commence, which being attended with a dyfentery, terminated his life within three days, Auguft, A.D. 526, in the 72d year of his age, and the 34th of his reign, dating its commencement with the death of Odoacer. His dominions were divided by his teftament between his two grandfons, Amalaric and Athamaric, affigning the Rhone as their boundary; and the guardianfhip of the latter, who was king of Italy, was entrufted with his daughter Amalafuntha. He erected to his memory a fplendid monument in a confpicuous fituation above the city of Ravenna. Anc. Un. Hift. Gibbon's Rom. Hift. Gen. Biog.

THEODORIC, or THIERRY *of Niem*, an ecclefiaftiral writer, was born at Paderborn, and ferved Gregory XI. Urban VII. and feveral fucceeding popes, as under-fecretary. The time in which he lived may be inferred from his "Hiftory of the Schifm of the Popes," written between the years 1400 and 1410; in which work he fays that he had lived near thirty years at the court of Rome, and that being then worn down with age, it was his intention to withdraw from public bufinefs. This work, compofed in Latin, comprifed, in three books, the interval from the death of Gregory XI. to the election of Alexander V. Another work relating to the fame fubject was entitled "Nemus Unionis." In 1412 he publifhed a "Treatife on the Rights and Privileges of the Emperors in the Inveftiture of Bifhops and Abbots." He alfo wrote a journal of the proceedings of the council of Conftance, ending in June 1416, in which year he died. From bis own obfervation, he exhibits a fhocking picture of the court of Rome, and the clergy of that period. Dupin. Moreri.

THEODOROPOLIS, in *Ancient Geography*, a town of Mœfia, founded by the emperor Juftinian, who called it after the name of his wife.

THEODORUS, in *Biography*, a Cyrenaic philofopher, was a difciple of Anicerris, and for fpeaking freely concerning the gods, he was ftigmatifed with the appellation of Atheift, and banifhed from Cyrene. At Athens, where he fought refuge, he was protected by Demetrius Phalereus, and gained accefs to the court of Ptolemy Lagis. Afterwards, upon his return to Athens, he is faid to have fuffered death by hemlock; but it has been difputed whether atheifm, or contempt of the Grecian fuperftitions, was the caufe of his death. He is joined by Sextus Empiricus with Eumerus, and others, who maintained, that thofe who were efteemed gods, were men who had poffeffed great power on earth; and Clemens Alexandrinus expreffes his furprife, that Eumerus, Nicanor, Diagoras, Theodorus, and others, who had lived virtuoufly, fhould be pronounced atheifts from their oppofition to gentile polytheifm. Brucker by Enfield, vol. i.

THEODORUS, an Athenian flute-maker, the father of Ifocrates the orator. How great the demand was at this time for flutes at Athens, may be conceived from a circumftance mentioned by Plutarch in his life of the orator. His father, fays he, acquired wealth fufficient by his bufinefs, not only to educate his children in a liberal manner, but alfo to bear one of the heavieft public burdens to which an Athenian citizen was liable; that of furnifhing a choir or chorus for his tribe, or ward, at feftivals and religious ceremonies. See ISMENIAS.

THEODOSIA, in *Ancient Geography*, a town fituated on the S.E. coaft of the Tauric Cherfonefus. See CAFFA.—Alfo, a town of Afia, in the Greater Armenia.

THEODOSIOPOLIS, a town of Afia, in the Greater Armenia, on the frontiers of Perfarmenia.—Alfo, a town of Afia, in Mefopotamia, upon the river Chaborras.

THEODOSIUS I. furnamed the *Great*, in *Biography*, a Roman emperor, was the fon of an eminent general of the fame name, who was executed for treafon at Carthage in the year 376. He was born about the year 346, as fome fay, at Caucha, in Gallicia, or according to others, at Italica, near Seville. His education was liberal, and he learned the art of war by ferving under his father, both in Britain and in Africa. The death of his father put a temporary ftop to his military career, and he retired to Spain for the improvement of his mind and the culture of his paternal eftate. He was in this fituation when the emperor Valens was killed in battle, and the empire was left in great danger. Thus circumftanced, the other emperor, Gratian, fent for Theodofius, and in January, A.D. 379, declared him his partner in the empire. To him was committed the care of Thrace and the eaftern provinces, threatened at this time by numerous bands of barbarians. The refult of his campaign was, that fome of the Goths fubmitted to his authority, and the reft evacuated Thrace. Having been baptized in the fecond year of his reign, in confequence of a dangerous difeafe, he became a zealous advocate for the orthodoxy of the church, and was much applauded by the Catholics. He iffued an edict, enjoining the fubjects of his government to adhere ftedfaftly to the religion taught by St. Peter, which afferts the fole deity of the Father, the Son, and the Holy Ghoft, under an equal majefty and a pious Trinity; and to affume the title of Catholic Chriftians, all other perfons who did not embrace this doctrine being branded as infamous heretics, and their churches being declared conventicles. It alfo announces, that befides the condemnation of divine juftice, thefe perfons muft expect the fevere penalties which his authority, guided by heavenly wifdom, fhall think proper to inflict upon them. This declaration, fo incompatible with the genuine fpirit of the religion and the profeffion in which he had been initiated, was followed by correfpondent deeds. When he entered Conftantinople, after the campaign of 380, his firft act was to remove the patriarch Demophilus, and to offer him the alternative of fubfcribing the Nicene creed, or refigning all his dignities to the orthodox party. The patriarch nobly chofe the latter alternative, and withdrew into exile. Soon after he iffued a decree for expelling from their churches all the clergy who refufed to accept the Nicene creed, and he appointed a military force for the execution of it. By thefe meafures the emperor fucceeded, without tumult or bloodfhed, in eftablifhing, through the provinces of the Eaft, the Catholic faith upon the ruins of Arianifm. So affiduous was the emperor in this exercife of his zeal, that he is faid to have promulgated, in fifteen years, at leaft fifteen penal edicts againft heretics, fome of which denounced capital punifhment: and it is moreover afferted, that the office of inquifitors of the faith was firft inftituted in his reign. It has been affirmed, however, that he chiefly meant intimidation, and that the threatened penalties were feldom carried into effect.

The military ardour of this emperor feems to have been exercifed with greater prudence than his religious zeal. In order to liberate the provinces from the barbarians, he contrived to weaken their ftrength by fomenting divifions among their chiefs, and he conciliated others by his generofity: fo that about four years after the death of Valens, he figned a capitulation with the whole nation of the Goths;

 and

and as their own country was occupied by the Huns, he permitted them to fettle in Thrace and Mœfia, with exemptions from tribute and taxes. With Maximus, who had revolted againft the emperor Gratian, Theodofius entered into a treaty, by which it was ftipulated that the ufurper fhould retain the countries beyond the Alps, and that Valentinian, the brother of Gratian, fhould be fecured in the poffeffion of the remaining part of the Weftern empire. Maximus was acknowledged by Theodofius as his colleague in the Roman empire, and Arcadius, the fon of Theodofius, though only eight years of age, was admitted to a fhare in the purple. At this time Theodofius iffued fome fevere edicts againft heathen idolatry: and he paffed a law againft the marriage of coufins-german, which condemned both parties to be burnt alive, and which declared their children illegitimate. In 386, the Gruthungi, or Oftrogoths, in their attempt to pafs the Danube, were defeated with great flaughter. In 387, Maximus invaded Italy; and Valentinian, deferted by his fubjects, took refuge in the dominions of Theodofius, who married Galla, the fifter of that emperor. In this year the people of Antioch, having without effect remonftrated againft the proceedings of Theodofius, both as to religious matters and the impofition of an extraordinary tax, broke out into an infurrection; threatened the life of the governor; and, difappointed in this effort of their rage, demolifhed the ftatues of the emperor and his family. Theodofius, in the firft tranfports of refentment, upon receiving intelligence of their conduct, ordered the city to be laid in afhes, and all the inhabitants, without difcrimination of age or fex, to be put to the fword. Upon cooler reflection he revoked this fanguinary order, and contented himfelf with degrading Antioch from the rank of a city, and depriving the inhabitants of their cuftomary largefs of bread. Thofe who upon inquiry were found guilty, were condemned to death. But by the interceffion of the bifhop of Antioch, and other holy men, the culprits were pardoned, and the city reftored to all its privileges.

Theodofius, on a vifit to Valentinian at Theffalonica, prevailed on him to renounce Arianifm, and to adopt the Nicene faith; and determined to take up arms in his caufe againft Maximus. After feveral fuccefsful encounters with the ufurper, he was defpoiled of all his imperial ornaments, and dragged like a malefactor into the prefence of Theodofius, who caufed him to be beheaded. His fon Victor was alfo put to death; and the civil war terminated A.D. 388. In confequence of thefe events, Theodofius became the fole head of the Roman world; and he invefted the fon of Valentinian, now a minor, with the fovereignty of the provinces wrefted from him by Maximus, and alfo with the poffeffion of Gaul, Spain, and Britain, of which Gratian had been deprived by this ufurper. Theodofius remained three years in Italy, giving vigour to the law, correcting abufes, and adopting a variety of meafures for totally eradicating paganifm.

In 390, a fedition took place at Theffalonica, which was followed by many difaftrous confequences, and by the exercife of a degree of cruelty, which the emperor was obliged to expiate by a public penance. About this time he took advantage of a religious tumult at Alexandria for demolifhing the famous temple of Serapis, and of all the heathen temples throughout Egypt. He alfo iffued a final edict againft the ancient worfhip.

In 392, the emperor Valentinian was murdered by his general Arbogaftes, and Eugenius was placed on the throne. When this meafure was announced to Theodofius, he prepared for war; and having obtained a favourable anfwer from a holy hermit in Thebais, whom he confulted, iffued new edicts againft herefy, and abrogated the ancient penalties of treafon againft thofe who uttered feditious words againft the prince; he openly took up arms, A.D. 394, and forcing the paffage of the Alps, defcended into Italy. He met Eugenius and Arbogaftes with a great force, and after feveral conflicts, Eugenius was totally defeated, and put to death by the foldiers. His children, however, and thofe of Arbogaftes, who put an end to his own life after the battle, were treated humanely, and removed to their paternal poffeffions.

After this fuccefs, Theodofius fent for his fon Honorius to Milan, and declared him emperor of the Weft; Arcadius having been already put in poffeffion of the Eaftern empire. In January 395, Theodofius terminated his life by a dropfical diforder at Milan, at the age of fifty years, and at the clofe of the fixteenth year of his reign.

The name of Theodofius has been celebrated, but his character has been very differently appreciated. Politically confidered, whilft it exhibits many virtues and excellencies, it is chargeable with many errors and obliquities. Connected with the ecclefiaftical interefts of the period in which he lived, his conduct on various occafions was altogether indefenfible; and we may add, that how much foever he has been extolled by partial hiftorians, his bigotry and intolerance were very reprehenfible. Anc. Un. Hift. Gibbon's Rom. Hift. Gen. Biog.

Theodosius II., fon of the emperor Arcadius, and grandfon of the preceding Theodofius, was born in the year 401; and being of feeble faculties, was educated merely to fuftain the pageantry of a throne; or, as Mr. Gibbon expreffes it, "to reprefent with grace and dignity the external figure of a Roman emperor." His only active purfuit was hunting; and his more private exercifes were painting and carving, making elegant tranfcripts of religious books, and finging pfalms. He alfo fafted, gave credit to miracles and doctrines prefented to his faith, and paid due homage to all the dead and living faints of the Catholic church. His difpofition was gentle and kind; in his conduct he was free from vices, and yet, as his biographer fays, "he did not rife to virtues." Upon his father's death, A.D. 408, he fucceeded him in the Eaftern empire. To the influence of his fifter Pulcheria, fuperior in talents to himfelf, he implicitly fubmitted; and in 414 he raifed her to the rank of Augufta, and entrufted with her the reins of government. By her felection and recommendation he married, A.D. 421, the celebrated Athanais, aftewards named Eudocia. The war which broke out in 422, in confequence of a perfecution excited by the Magi againft the Chriftians, terminated in a truce of a hundred years, and a divifion of the kingdom of Armenia between the contending powers. On the death of the emperor Honorius, in 423, the throne of the Weft was ufurped by John; but Theodofius reftored it to its proper heir, Valentinian III., who afterwards married his daughter. When Attila made an irruption into the Roman empire, he was oppofed by Theodofius, whofe armies were repeatedly defeated: and Theodofius himfelf was compelled in 446 to make a humiliating treaty with the king of the Huns. By one of his favourites, the eunuch Chryfaphius, he was induced to free himfelf from Attila by affaffination, but the treachery was defeated, and he received a juft and fevere reprimand from the barbarian. Soon after this mortification, he died in confequence of a fall from his horfe, A.D. 450, in the fiftieth year of his age. What his grandfather had done towards the fubverfion of the Pagan religion in the Eaft, Theodofius completed. He always approved himfelf a dutiful fon of the church, but he is faid to have favoured the Eutychian herefy. His principal merit was the publication, A.D. 438, of the "Theodofian

"Theodosian Code." Anc. Un. Hist. Gibbon. Gen. Biog.

Theodosius, an eminent mathematician, was born at Tripoli, and flourished about the second or third century. On the doctrine of the Sphere he wrote three books, containing a considerable number of propositions, demonstrated in the pure geometrical manner of the ancients, and establishing the geometrical principles of astronomy. Ptolemy and succeeding writers availed themselves of these books, which were translated by the Arabians from the original Greek into their own language. They were afterwards translated from the Arabic into Latin, and printed at Venice; but the defects of the Arabic version were supplied in a more complete edition, published in Greek and Latin at Paris in 1556, 4to. by John Pena, regius professor of astronomy. On this work there have been many comments; but the edition of Theodosius's Spherics now generally used is that of Dr. Barrow, published in 1675, illustrated and demonstrated in a new and concise method. Theodosius was also the author of two other treatises, one "De Habitationibus," and the other "De Diebus et Noctibus." Greek copies of these were preserved in the king's library at Paris, and a Latin edition was published by Peter Dasypodius in 1572. Montucla Hist. des Mathem.

THEODULF, a learned prelate of a Gothic family, was a native of Cisalpine Gaul; and being invited to France by Charlemagne, he was promoted to the bishopric of Orleans, A.D. 794, and the abbacy of the monastery of Fleury. He continued in favour at court till the death of Charlemagne, and for some time under the emperor Lewis. But being implicated in the conspiracy of Bernard, king of Italy, against Lewis, he was committed to prison at Angers, where he remained in confinement for three years. After his liberation, and before his return to his diocese, he died at Angers, about the year 821. Theodulf was the friend of Alcuin, and deserves honourable mention as one of the votaries and promoters of literature in a dark age. He was the author of several works, published by Father Sirmond, in 1646, 8vo. One of his hymns, beginning

"Gloria, laus et honor tibi sit, Rex Christe Redemptor,"

has been adopted by the Catholic church for the service on Palm-Sunday. Dupin. Gen. Biog.

THEOGAMIA, Θεογαμια, in *Antiquity*, a Sicilian festival, in honour of Proserpine, which seems to have been instituted in memory of her marriage with Pluto.

THEOGNIS, in *Biography*, a Greek poet, was a native of Megara, in Attica, and flourished about the year B.C. 546. He has been denominated "Gnomologus," or the writer of sentences: and we have extant a work written by him, without order, consisting of moral maxims or precepts, simply expressed and destitute of poetical ornaments, versified probably for assisting the memory. Athenæus reckons him among the advocates for licentious pleasures; and Suidas refers to a work of his composition, entitled "Exhortations" or "Admontions," which contained various impurities. In the verses that now remain, nothing of this kind appears; so that if the charge be true, they must have undergone castigation. "The Sentences of Theognis" have been often printed by themselves, and with the works of other minor Greek poets. Among the best editions are those of Camerarius and Sylburgius. Vossii Poet. Græc. Gen. Biog.

THEOGONY, formed from Θεος, *God*, and γονη, *geniture*, *seed*, *offspring*, that branch of the heathen theology which taught the genealogy of their gods.

Hesiod gives us the ancient theogony, in a poem under that title. This poem treats of the origin and descent of the gods; or rather, under the allegorical dress of theogony, represents the formation of the world, and the history of eminent men. The plan of this work is intricate and confused. (See Hesiod.) The writer seems to have made use of several different theogonies, and to have blended them together with little regard to consistency. He also frequently adds, for the sake of poetical ornament, fictions of his own, which have no relation to the history and origin of the world. Aristophanes, in his comedy of "The Birds," has introduced a description of the formation of the world, which was borrowed, without doubt, from the ancient theogonies; but it deserves little attention. All the theogonies make an eternal chaos the origin of all things. Thus Ovid. Met. l. 1. v. 5.

"Ante mare, et terras, et quod tegit omnia cœlum,
Unus erat toto naturæ vultus in orbe,
Quem dixere Chaos, rudis indigestaque moles,
Nec quicquam nisi pondus iners, congestaque eodem
Non bene juncturam discordia semina rerum."

"Ere sea and earth, and heav'ns high canopy
Were form'd, great Nature's face was one;
A lifeless, rude, and undigested mass
Of jarring seeds in one wild chaos lay." See Chaos.

Whether, besides this chaotic mass, the ancient theogonies suppose an infinite, active, intelligent principle, who from the first matter formed the universe, is a question that has occasioned much debate. It is evident, upon the most cursory review of the ancient theogonies, that God, the great Creator of all things, is not expressly introduced; but it is doubted, whether the writers meant to exclude him from their system, or indirectly to suppose his existence, and the exertion of his power in giving motion to matter. In the solution of this question, it ought to be considered, whether the theogonists supposed God to have existed before chaos, and to have created it from nothing; or thought him to have sprung from a pre-existing chaos; or conceived God and matter to have been two co-existing and independent principles: whether they imagined God to have been the soul of nature, informing the eternal mass of matter; or were of opinion, that God sent forth matter as an emanation from himself; if the latter, whether this emanation was the effect of necessity, or of a free act of volition; whether it was from all eternity, or began at some limited period of duration. It must also be inquired, whether, according to the doctrine of the theogonies, a divine mind interposed in the formation of the world, or the effect was produced by the necessary laws of motion acting upon homogeneous and heterogeneous portions of matter. If the latter of these was their doctrine, it is to be farther considered, whether it necessarily follows, that they denied the existence of God, or whether it may not be supposed, that, neglecting all consideration of deity, they only endeavoured to explain the physical formation of the world, by laws originally impressed upon matter by the author of nature.

The theogonies certainly do not suppose God to have been prior in the order of time to matter: they speak of chaos as eternal, and seem to have been wholly unacquainted with the doctrine of creation from nothing. But, on the other hand, they never suppose the Deity to be derived from chaos: for Jupiter is not to be confounded with the Supreme Being, but merely to be considered as the chief of those inferior divinities, who, according to the Grecian theology, were either portions of the divinity, inhabiting and animating parts of nature, or departed spirits of heroes and illus-

illustrious men, exalted to divine honours. There is no sufficient proof, that Orpheus, Hesiod, or any other Grecian cosmogonist, supposed two independent principles in nature: for, though they ascribe the origin of evil to Chaos, they might, nevertheless, be of opinion, as we shall find to have been the case with many later philosophers, that matter is derived from God.

There were, perhaps, different opinions among the ancient cosmogonists, concerning the first cause of nature. Some might, possibly, ascribe the origin of all things to a generating force, destitute of thought, which they conceived to be inherent in matter, without looking to any higher principle. But it is probable, that the general opinion among them was that which had prevailed among the Egyptians and in the East, and was communicated by tradition to the Greeks, that matter, or chaos, existed eternally with God, and that by the divine energy of emanation, material forms were sent forth from him, and the visible world arose into existence. This principle being admitted, the whole system of the ancient theogonies appears consistent, and a satisfactory explanation may be given of most of the Grecian fables. Upon this supposition, the sum of the doctrine of the theogonies, divested of allegory and poetry, will be as follows:

The first matter, containing the seeds of all future being, existed from eternity with God. At length, the divine energy upon matter produced a motion among its parts, by which those of the same kind were brought together, and those of a different kind were separated, and by which, according to certain wise laws, the various forms of the material world were produced. The same energy of emanation gave existence to animals and men, and to gods who inhabit the heavenly bodies, and various other parts of nature. Among men, those who possess a larger portion of the divine nature than others, are hereby impelled to great and beneficent actions, and afford illustrious proofs of their divine original, on account of which, they are after death raised to a place among the gods, and become objects of religious worship.

Upon the basis of these notions, it is easy to conceive, that the whole mythological system, and all the religious rites and mysteries of the Greeks, might be founded. Brucker's Hist. Phil. by Enf. vol. i.

Among the most ancient writers, Dr. Burnet observes, that theogony and cosmogony signified the same thing. (See Cosmogony.) In effect, the generation of the gods of the ancient Persians, fire, water, and earth, is apparently no other than that of the primary elements.

THEOLOGICAL Criticism. See Criticism.

Theological *Prebend*. See Prebend.

THEOLOGIUM, formed from Θεος, and λογος *speech*, or *discourse*, in the ancient theatre, was a place, or little stage, above that on which the ordinary actors appeared. See Theater.

The theologium was the place where their gods appeared. It also included the machines on which they descended, and from which they spoke.

There was a theologium required for the representation of the Ajax of Sophocles, the Hippolitus of Euripides, &c. Scal. Poet. lib. i. cap. 1.

THEOLOGY, compounded of Θεος, *God*, and λογος, *discourse*, *divinity*; a science, which instructs us in the knowledge of God, and divine things; or which has God, and the things he has revealed, for its object.

Theology is a science which shews us what we are to believe of God, and the manner in which he would be served. It is divided into two branches, the *natural*, and the *revealed* or *supernatural*.

Theology, *Natural*, is the knowledge we have of God from his works, by the light of nature, and reason.

Theology, *Supernatural*, is that which we learn from revelation. See Religion.

Theology, *Positive*, is the knowledge of the holy Scriptures, and of the signification of them, conformably to the opinions of the fathers and councils; without the assistance of any argumentation. But some will have it, that this ought to be called *expositive*, rather than *positive*.

Theology, *Moral*, is that which teaches us the divine laws relating to our manners and actions; in contradistinction to

Theology, *Speculative*, which explains and establishes the doctrines of religion, as objects of faith.

Theology, *Scholastic*, or *School*, is that which proceeds by reasoning; or that derives the knowledge of several divine things from certain established principles of faith. See Scholastic *Divinity*.

The ancients, according to Varro, Scævola, and Plutarch, had a three-fold theology; the first μυθικη, *mythic*, *fabulous*, which flourished among the poets; and was chiefly employed in the theogony, or genealogy, and history of the gods: to whom all things were attributed, which men, and even the vilest of men, could be guilty of. Nevertheless, the popular religion and worship were in a great measure founded upon that mythology, which run through the whole of their religion, and was of great authority with the people. Many unexceptionable proofs of this are produced by Dr. Leland, in his "Advantage and Necessity of the Christian Revelation," vol. i. part i. chap. 6.

The second, πολιτικη, *political*, or *civil*, was that established by the Roman laws, and chiefly embraced by the politicians, priests, and people, as most suitable and expedient to the safety, quiet, and prosperity of the state. This, though not the true, was the vulgar theology, and constituted the public and authorized religion. It was that which the philosophers themselves, whatever private opinions or speculations they might entertain, or dispute of in their schools, universally conformed to in their own practice, and also exhorted others to do so. Varro informs us, that this theology particularly determined what gods they were publicly to worship, what sacred rites they were to observe, and what sacrifices to offer.

Although even the vulgar among the Pagans seem, in general, to have had some notion of one supreme God, yet their theology was properly polytheism; and the providence they acknowledged, was the providence, not of one God, but of many gods. The learned Dr. Cudworth, who seems inclined to put the most favourable construction upon the Pagan theology, acknowledges, that the civil theology, as well as the poetical, had not only many fantastic gods in it, but an appearance of a plurality of independent deities; several being made supreme in their respective territories or functions. Aristotle (Oper. tom. i. p. 1246. edit. Paris, 1629) intimates, that according to the laws of cities and countries, that is, in the civil or political theology, there seems to be no one absolutely powerful or all-perfect being, but a plurality of gods, one of whom is supposed to be more powerful in one respect, and another in another respect. Besides, the public religion was made up partly of the physical, and partly of the poetical theology. Those poetical fables, which Varro censures as unworthy of the gods, and as ascribing to them actions which none but the vilest of men

men would be guilty of, were not only permitted to be acted on the public theatres, and heard with pleafure by the people, but they were regarded as things pleafing to the gods themfelves, by which they were propitiated and rendered favourable; and accordingly they were taken into the public religion. Games were celebrated, and plays were founded upon them; and the public games and plays were on certain occafions confidered as acts of religion, encouraged by their deities, and celebrated in honour of them. It is alfo juftly obferved, that the images, forms, habits, and ornaments of their gods, their different fexes and ages, and the facred feftivals inftituted to their honour, had all of them a reference to the fables of the poets and mythologifts, and were founded upon them; fo that the civil and the fabulous theology might each of them be called civil, and each fabulous. Hence proceeded many abfurd and ridiculous, and many immoral and inhuman rites, which were made ufe of in the worfhip of their gods, and which were either prefcribed by the laws, or were eftablifhed cuftoms, countenanced by the magiftrates, and which had obtained the force of laws, and may, therefore, be regarded as belonging to the public religion of the Pagans. See Leland's Chriftian Revelation, ubi fupra, cap. 7.

The third, φυσικη, *natural*, was chiefly cultivated by the philofophers, as moft agreeable to nature and reafon. The phyfical or natural theology acknowledged one only fupreme God; to which it added dæmons or fpirits, as mediators between him and man.

Dr. Leland has urged a variety of confiderations to prove that, notwithftanding the high encomiums which have been beftowed upon the philofophical theology of the Pagans, it was of little ufe in leading the people into a right knowledge of God and religion, and for reclaiming them from their idolatry and polytheifm. To this purpofe he obferves, that, if the philofophers had been right in their own notions of religion, they could have but little influence on the people, for want of a proper authority to enforce their inftructions. The affected obfcurity of the Pagan philofophers was another caufe which rendered them unfit to inftruct the people in religion: to which it may be added, that fome of them ufed their utmoft efforts to deftroy all certainty and evidence, and to unfettle men's minds as to the belief of the fundamental principles of all religion; and even the beft and greateft of them acknowledged the darknefs and uncertainty they were under, efpecially in divine matters. The philofophers themfelves were alfo, for the moft part, very wrong in their own notions of the Divinity; they very much corrupted the ancient tradition relating to the one true God and the creation of the world, and endeavoured to account for the formation of all things without the interpofition of a Deity. And the opinions of thofe philofophers who were of a nobler kind, were chargeable with great defects: they generally expreffed themfelves in the polytheiftic ftrain, and inftead of leading the people to the one true God, they fpoke of a plurality of gods, even in their moft ferious difcourfes; afcribing thofe works to the gods, and directing thofe duties to be rendered to them, which properly belong to the fupreme. The philofophers likewife referred the people for inftruction in divine matters to the oracles, which were managed by the priefts: this was particularly the cafe with Socrates, Plato, and the Stoics.

It was an univerfal maxim among them, that it was the duty of every wife and good man to conform to the religion of his country; and they not only worfhipped the gods of their refpective countries according to the eftablifhed rites, and exhorted others to do fo; but when they took upon themfelves the character of legiflators, and drew up plans of laws, and of the beft forms of government, polytheifm, and not the worfhip of the one true God, was the religion they propofed to eftablifh. Moreover, they employed their learning and abilities to defend and juftify the popular idolatry and polytheifm. The worfhip of inferior deities was recommended by them, under pretence that it tended to the honour of the fupreme. Some of the moft eminent of them endeavoured to colour over the moft abfurd part of the Pagan poetical theology, by allegorizing the moft indecent fables. They apologized for the Egyptian animal worfhip, which the generality of the vulgar Pagans in other nations ridiculed. They vindicated idolatry and image-worfhip, as neceffary to keep the people from falling into irreligion and atheifm; and befides, fome of the more refined philofophers were againft any external worfhip of the fupreme God.

Many of the philofophers, and of the learned and polite Pagans, denied a providence. Of thofe who profeffed to acknowledge it, fome confined it to heaven and heavenly things; others fuppofed it to extend to the earth and to mankind, yet fo as only to exercife a general care and fuperintendency, but not to extend to individuals; others, again, fuppofed all things, the leaft as well as the greateft, to be under the care of providence; but they afcribed this not to the fupreme God, who, they thought, was above concerning himfelf with fuch things as thefe, and committed the care of them wholly to inferior deities. See the illuftration and proof of thefe feveral allegations by Dr. Leland, ubi fupra, cap. 10—17.

THEOLOGY, *Myftic*. See MYSTIC.

THEOLOGY, *Polemical*. See POLEMICAL.

THEOMANTIA, Θεομαντεια, in *Antiquity*, divination by the fuppofed infpiration of fome deity. For a particular account of which, fee Potter, Archæol. Græc. lib. ii. cap. 12. tom. i. p. 298.

THEON, in *Biography*, a mathematician of the Platonic fchool, was a native of Smyrna, and flourifhed under the emperors Trajan and Adrian. His mathematical treatifes are faid to have been written for the purpofe of elucidating the philofophy of Plato; and his difcourfes, treating of geometry, arithmetic, mufic, aftronomy, and the harmony of the univerfe, may ferve to throw fome light upon the Pythagorean fyftem. Part only of his work, "De iis quæ in Mathematicis ad Platonis lectionem utilia funt," or that which relates to arithmetic and mufic, has been publifhed. The remainder, which pertained to aftronomy and geometry, is faid to have been preferved in the Ambrofian library at Milan. Ptolemy refers to his aftronomical obfervations. Brucker by Enfield. Montucla Hift. des Math.

Another mathematician of the fame name belonged to the Alexandrian fchool, and flourifhed about A.D. 365. He was the father of the learned but unfortunate Hypatia. His works are various: among thefe we may mention his "Recenfio Elementorum Euclidis," publifhed by Commandeni; his "Fafti Græci priores, et Fragmenti Commentarii in Ptolomæi Canonem expeditum, five Recenfio fuccincta Chronologica regem a Nabonaffaro ad Antoninum Pium:" "Scholia in Aratum," faid to be interpolated; and "Commentarius in Magnum Ptolomæi Syntaxin," which is incomplete. Montucla.

THEOPASCHITES, THEOPASCHITÆ, in *Ecclefiaftical Hiftory*, a fect of heretics in the fifth century, the followers of Petrus Fullenfis, or Peter the Fuller, who ufurped the fee of Antioch; and after having been feveral times

times depofed, and condemned, on account of his oppofition to the council of Chalcedon, was at laft fixed in it, A.D. 482, by the authority of the emperor Zeno, and the favour of Acacius, bifhop of Conftantinople; whence they are alfo fometimes denominated *Fulloniani.*

Their diftinguifhing doctrine was, that the whole Trinity fuffered in the paffion of Jefus Chrift.

This herefy was embraced by the Eutychian monks of Scythia, or, according to La Croze, of Egypt; who ufing their utmoft efforts to make it obtain, raifed great diforders towards the beginning of the following century.

It was condemned, at its firft rife, in the councils of Rome and Conftantinople, held in 483. It was again revived in the ninth century, and again condemned in a council at Rome, held in 862, under pope Nicolas I.

F. le Quien, in his notes on Damafcenus, fays, that the fame error had been taught before Fullenfis, by Apollinarius, whofe difciples were the firft that were called *Theopatitæ*, or *Theopafchitæ*.

THEOPHANES, in *Biography*, a Greek hiftorian and poet, was of noble extraction, and born at Mitylene, in the ifland of Lefbos. About the commencement of the Mithridatic war, he is fuppofed to have come to Rome in his youth; and when Pompey was appointed to the chief command againft Mithridates, he took Theophanes with him to record his exploits, procuring for him the citizenfhip of Rome, and adding to his name thofe of "Cornelius Balbus." It is alfo fuppofed that it was principally on his account, that on his return he vifited Lefbos, and reftored to the Mitylenians the privileges of which they had been deprived by the Roman fenate. At Rome he connected himfelf with the moft diftinguifhed citizens, and he was deputed to Alexandria for the confirmation of treaties of alliance with Ptolemy Auletes. After the defeat of Pompey at Pharfalia, he accompanied him in his flight; and by his advice this commander declined to take refuge with Juba, king of Mauritania, and failed to Egypt, where he met his fate. Theophanes afterwards joined the party of Cæfar. The moft important of his writings was a "Hiftory of the Wars of the Romans, in different Countries under the Command of Pompey." Of this work there remain only five fragments, quoted by Strabo, Plutarch, and Stobæus; but Plutarch is fuppofed to have made great ufe of his authority in his life of Pompey, though he does not fpeak favourably of his character. He fays, "Theophanes afferts, that in the private papers of Mithridates taken at Cænon, there was found a memorial, compofed by Rutilius (Rufus), exhorting Mithridates to maffacre all the Romans in Afia. But it is generally believed, that this was a malicious fiction of Theophanes to blacken Rutilius, whom probably he hated, becaufe he was a perfect contraft to himfelf; or it might be invented by Pompey, whofe father was reprefented by Rutilius in his hiftory, as one of the worft of men." Rutilius was a man of fuch excellent character, as to be incapable of the crime with which he is charged; and without doubt fuch a falfification of hiftory, for bafe and private purpofes, is fufficient to deftroy all efteem for the writer.

Of the poetry of Theophanes, which was celebrated in his time, there remain only two epigrams, inferted in the Anthologia. Voffius. Moreri. Gen. Biog.

Theophanes, George, a Conftantinopolitan Greek, of a rich and noble family, married young, but from fuperftitious motives lived in a ftate of celibacy. He afterwards became a monk. At the general council held in 787, he was prefent, and was treated with refpect. When Nicephorus, patriarch of Conftantinople, was exiled by the emperor Leo the Armenian, Theophanes paid him extraordinary honours, and was himfelf banifhed to the ifle of Samothrace, where he died in 818. His chronicle, commencing where that of Syncellus terminated, was extended to the commencement of the reign of Michael Curopalata. This was printed at Paris, with the Latin verfion and notes of F. Goar, under the care of Combefis, in 1665, fol. It is valuable for its facts, but difplays the credulity and weak judgment of a fuperftitious mind. Voffius. Gen. Biog.

Theophanes Prokopovitch (the fon of Procopius), archbifhop of Novogorod, a learned Ruffian hiftorian, and mifcellaneous writer, was born at Kiof in the year 1681, and having ftudied under his uncle Theophanes at the Bratfkoi convent in Kiof, travelled into Italy in his eighteenth year. In three years he completed his courfe of preparatory ftudy, and then returned to his native town, where he read lectures on the Latin and Slavonian art of poetry, at the feminary where he had received his education. Having affumed the monaftic habit, with the name of Theophanes, he was appointed, at the age of twenty-five, prefect of the feminary, and profeffor of philofophy. By a Latin oration and a fermon, delivered before czar Peter the Great, he attracted his notice, and was chofen his companion in his war againft the Turks. In 1711 he was made abbot of the monaftery of Bratfkoi, rector of its feminary, and profeffor of divinity. By cenfuring the ignorance of the clergy, and endeavouring to excite a tafte for literature, he recommended himfelf to the czar as a proper coadjutor in his plans for reforming the church. He was accordingly placed at the head of the fynod, in the new ecclefiaftical eftablifhment, the plan of which he had prepared, and in 1718 he was promoted to the bifhopric of Plefkof. In 1720 he was created archbifhop of the fame diocefe, and foon after the acceffion of Catharine I. he was advanced to the rank of archbifhop of Novogorod, and metropolitan of all Ruffia; and in this ftation he died in 1730. This prelate was in a high degree the patron of literature, and engaged in a variety of ways, by his perfonal munificence and labour, in promoting it. His works were fermons and theological tracts, a treatife on rhetoric, and rules for compofing Latin and Slavonian poetry, Latin verfes, and more efpecially the Life of Peter the Great, terminating with his battle of Pultawa. Le Clerc afferts that he endeavoured to perfuade Peter to introduce the Proteftant religion into Ruffia, and that this event would have taken place, if it had not been prevented by Peter's death. The prelate's education at Rome, and the high rank he fuftained in his own church, render this anecdote improbable. Coxe's Travels in Ruffia.

THEOPHANIA, Θεοφανια, formed of Θεος, *God*, and φαινω, *I appear*, in *Antiquity*, a feftival obferved by the Delphians upon the day on which Apollo firft manifefted himfelf to them.

THEOPHANY, in *Church Hiftory*, is fometimes ufed in the fame fenfe with *Epiphany*.

THEOPHILA, in *Ancient Geography*, a town of India, on this fide of the Ganges.

THEOPHILE, named *Viaud*, in *Biography*, a French poet, was born at Clerac, in the Agenois, about the year 1590. By education he was a Calvinift, but in his conduct and writings he was licentious. In 1619 he withdrew to England, and unfuccefsfully attempted to introduce himfelf to king James. After his return he abjured Calvinifm, but his manners remained the fame. On account of a work entitled "Le Parnaffe Satirique," publifhed in 1622, and attributed to him, in which were feveral pieces offenfive to decency

decency and religion, he was profecuted. Being arrefted in Picardy, he was brought to Paris, and thrown into the dungeon that had been occupied by Ravaillac, where he remained for two years. He was at length releafed by the parliament, and fentenced to banifhment. The duke of Montmorency took him under his protection, and at his hotel he died in 1626. His writings are partly profe and partly verfe. His verfes are negligent and irregular, but they difplay genius and imagination. His works confift of odes, elegies, fonnets, &c.; tragedies; a dramatic dialogue on the immortality of the foul, entitled "Socrate Mourant;" apologies for himfelf, and letters. A collection of his poems and apologies was printed at Rouen in 1627, 8vo.; and his friend Mairet printed his French and Latin letters at Paris, in 1642, with his portrait prefixed. Nouv. Dict. Hift. Gen. Biog.

THEOPHILUS, emperor of Conftantinople, was the fon of Michael the Stammerer, and fucceeded his father in 829. He began his reign with the exercife of juftice in its utmoft rigour, heedlefs not only of the claims of gratitude, but of the feelings of humanity. His father had been indebted for his life and crown to the murderers of his predeceffor Leo IV. Theophilus, under a pretence of paying the debts of his father to thofe who had contributed to his elevation, fummoned them, among other confiderable perfons in the empire, to his prefence; and defiring the former to withdraw into an adjoining apartment, that their claims might be examined, he ordered them, on their own confeffion, to be capitally punifhed. In another cafe, a poor woman threw herfelf at his feet, complaining of the injury which fhe had fuftained from a powerful neighbour (the emprefs's brother), who had raifed the wall of his palace fo high, that her humble dwelling was deprived of light and air. Theophilus gave her the palace, with the ground upon which it ftood, and caufed the offender to be ftripped and fcourged in the public fquare of the city. The effect of his fingular rigour, though altogether indefenfible, was, that a fcrutiny of feventeen days coud not difcover a fingle crime or abufe in the court or city.

During this emperor's whole reign he was engaged in wars with the Saracens, the detail of which we fhall omit. Theophilus died in 842, after a reign of more than twelve years. His zeal againft the worfhip of images has caufed his character to be treated with great feverity, and his faults to be exaggerated. Although he was inexcufably rigorous in his adminiftration, he was a reformer of manners. Of his fuperiority to avarice, and high ideas of the dignity of the regal character, the following anecdote furnifhes an inftance. Seeing one day a merchant-fhip, which was deeply laden, entering the harbour of Conftantinople, he afked the mariners to whom it belonged: they replied, "to the emprefs." "God has made me (he exclaimed) a prince, and is my wife a merchant? If princes trade, their fubjects muft ftarve:" he then ordered the veffel to be fet on fire with all her cargo. Anc. Un. Hift. Gibbon's Rom. Hift.

THEOPHILUS, bifhop of Antioch, was ordained to this fee in 168 or 170, and governed it for twelve or thirteen years. In his zeal againft herefy, he wrote againft Marcion and againft Hermogenes, and he compofed other tracts, fome of which are preferved. We have alfo extant three books againft Autolycus, a learned heathen, in which he difplays great learning, and from which it appears that he had once been a heathen. Thefe works afford, as it is faid, the earlieft example of the ufe of the term "Trinity," applied by the author to the three perfons of the Godhead. Some have fuppofed that he approaches to Arianifm, when he afferts that the Word may exift in *place*, and that he was begotten in *time*. Theophilus's books to Autolycus were publifhed in Latin by Conrad Gefner at Zurich, in 1546, and were inferted in the "Orthodoxographia," Bafil, 1555. They were annexed in Gr. and Lat. to the Supplement of the "Bibliotheca Patrum," 1624; and were printed at the end of St. Juftin's Works by Morellus. Lardner.

THEOPHILUS, bifhop or patriarch of Alexandria, of violent and turbulent difpofition, was ordained to that fee in 385. He gained reputation and influence by his zeal in deftroying the temple of Serapis, and other pagan temples of Egypt in 389. (See THEODOSIUS.) He was, under the guife of a friend, a fecret enemy to John Chryfoftom, after he had been ordained to the fee of Conftantinople in 397. Without much real regard for religion, he was the zealous champion of orthodoxy; and having called a council at Alexandria in 399, he prevailed with the affembly to condemn all the followers of Origen, and with the affiftance of a band of foldiers, compelled them to abandon their refidence on mount Nitria. The poor monks, failing to find a fecure refuge, repaired to Conftantinople, to lay their complaints before the emperor. The humanity of John Chryfoftom irritated Theophilus, who was employed by the emprefs Eudoxia, for profecuting her revenge againft Chryfoftom. Accordingly, he arrived at Conftantinople at the head of a body of Egyptian failors and dependent bifhops, avowing that he was going to depofe John. His purpofe was executed at the fynod of Chalcedon in 403. (See CHRYSOSTOM.) His malignity purfued this venerable prelate in his exile, by a libel filled with abufive expreffions, which was tranflated at his requeft by Jerom, from Greek into Latin. Theophilus died at Alexandria in 412. The moft confiderable of his works was a large treatife againft Origen. Some of his epiftles are found among thofe of Jerom, and fome of his canonical epiftles are contained in the collections of Zonaras and Balfamon. Of this prelate Dupin has given the following character: "There is nothing in the writings of Theophilus that can turn to his commendation; they are obfcure, unintelligible, and full of falfe and impertinent reafonings and reflections. He was a good politician, but a bad author. He knew better how to manage a court intrigue, than to refolve a queftion in divinity The only rule for his opinions was his intereft or his ambition. He was ready to embrace any opinion or party that fuited his purpofe, without examining whether it was juft or reafonable." Dupin. Lardner. Gibbon.

THEOPHRASTA, in *Botany*, fo called in memory of the father of all natural hiftorians, Theophraftus, native of Erefos in the ifle of Lefbos; whence Plumier named this genus ERESIA. (See that article.) Linnæus on fuch occafions always preferred the appellation by which the perfon intended to be celebrated was beft known.—Linn. Gen. 84. Schreb. 110. Willd. Sp. Pl. v. 1. 824. Mart. Mill. Dict. v. 4. Swartz Obf. 58. Juff. 150. Lamarck Illuftr. t. 119. (Erefia; Plum. Gen. 8. t. 25.)—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Apocineis affine*, Juff.

Gen. Ch. *Cal.* Perianth inferior, fmall, of one leaf, in five deep, obtufe, permanent fegments. *Cor.* of one petal, bell-fhaped, fpreading, cut more than half way down into five rounded equal fegments. "Nectary five fmall, ovate, obtufe glands, thickeft at the point, lying upon the fegments of the corolla." *Jacq.*—*Stam.* Filaments five, thread-fhaped, united below to an internal membrane, fo as to form a fhort, thick, furrowed column, crowned with a five-rayed horizontal difk; anthers five, of two feparate oblong lobes,

lobes, attached to the fides of each fegment of the difk, underneath. *Pift.* Germen fuperior, ovate; ftyle cylindrical, the length of the ftamens, erect; ftigma in five obtufe lobes. *Peric.* Berry globofe, coated, of one cell. *Seeds* feveral, roundifh, fomewhat compreffed.

Eff. Ch. Corolla bell-fhaped, in five obtufe fpreading fegments, with a nectary of five incumbent glands. Berry coated, of one cell, with feveral feeds.

1. Th. *americana.* Large-fruited Theophrafta. Linn. Sp. Pl. 212. Willd. n. 1. Swartz Obf. 59. (Erefia foliis aquifolii longiffimis; Plum. Ic. 119. t. 126.)—Leaves obtufe. Clufters terminal, erect.—Native of barren dry bufhy fhady places in Hifpaniola. *Swartz.* *Stem* fhrubby, one or two feet high, erect, fimple, leafy in its upper half, round, thorny, clothed with rufty down. *Leaves* oppofite or whorled, on very fhort ftalks, erect, oblong-lanceolate, obtufe, tapering at the bafe, very rigid, ferrated; their ferratures alternately inflexed and reflexed, each tipped with a fmall, prominent, rigid, black-pointed fpine. *Footftalks* thick, rufous, clofely preffed to the ftem. *Clufters* fhort, terminal, from the midft of the terminal leaves, many-flowered, partial *flower-ftalks* numerous, fhort, curved, fingle-flowered. *Fruit* two inches in diameter, yellow, brittle, often for the moft part hollow or empty, its *receptacle* juicy at the bottom. *Seeds* black, hard, attached by their bafe. *Swartz.* We prefume the *clufters*, from Plumier's figure, to be erect, and the *feeds* numerous.

2. Th. *longifolia.* Small-fruited Theophrafta. Jacq. Coll. v. 4. 136. Hort. Schoenbr. v. 1. 62. t. 116. Willd. n. 2.—Leaves acute. Clufters lateral, drooping.—Native of the Caraccas. It flowered in the ftove at Schoenbrun from Auguft till November. The *ftem* is faid to be twenty feet high, but always unbranched. *Leaves* imperfectly whorled, near two feet long, reclining, with fpinous ferratures, fmooth, of a dark fhining green, with numerous tranfverfe veins from the mid-rib. *Clufters* numerous, fcattered between the whorls of leaves, ftalked, drooping, a fpan long, of numerous little orange-coloured or fcarlet *flowers.* *Fruit* in its native country about an inch in diameter, with about four *feeds;* but in the garden it did not attain more than half that fize, and perfected only one. If there be no miftake in Dr. Swartz's defcription of the firft fpecies, there is a prodigious difference between the ftature of the two. Yet we have a fufpicion, that they may poffibly not be more than varieties of each other. As to the generic character, Plumier's reprefentation of the parts of the *flower* is too imperfect for us to fuppofe him more right than the faithful Jacquin. Swartz's defcription may eafily be reconciled with the *Hortus Schoenbrunenfis.*

THEOPHRASTICS, a name given to the followers of Paracelfus, from his name Theophraftus.

THEOPHRASTUS, in *Biography*, a diftinguifhed Greek philofopher, the favourite pupil of Ariftotle, and nominated by him as his fucceffor in the fchool of the Lyceum, was born at Erefium, a maritime town of Lefbos, in the fecond year of the 102d Olympiad, B.C. 371. His firft rudiments of education were received under Alcippus in his own country, and being fent by his father to Athens, he became firft a difciple of Plato and afterwards of Ariftotle. Such were his natural talents, that, under fuch tuition, he made great progrefs both in philofophy and eloquence: fo that his original name, Tyrtamus, was changed, either by his mafter or his followers, into Theophraftus. After he undertook the Peripatetic fchool in the year B.C. 323, his reputation was fo diftinguifhed, that the number of his fcholars was about 2000. His erudition and engaging manners recommended him to the notice of Caffander and Ptolemy: by the former he was invited to Macedon, and by the latter to Egypt; and among the Athenians he was fo great a favourite, that, when he was accufed by one of his enemies of teaching impious doctrines, the accufer could not without difficulty efcape the punifhment which he endeavoured to bring upon Theophraftus. Theophraftus is no lefs highly celebrated for his generofity and public fpirit, than for his induftry, learning, and eloquence. He is faid to have twice faved his country from the oppreffion of tyrants; and he contributed liberally towards defraying the expence of public meetings held by philofophers for learned and ingenious converfation. In the public fchools he appeared, after the manner of Ariftotle, in an elegant drefs, and was very attentive to the graces of elocution: and hence it is faid he obtained the appellation of Theophraftus, the divine fpeaker. Towards the clofe of life, which was prolonged to the age of 85 years, he became very infirm, and was conveyed to the fchool in a carriage. In contemplating the fhortnefs of life, he expreffed great regret; complaining that long life was granted to ftags and crows, to whom it was of little value, but was denied to man, who, if it were of longer duration, might attain the fummit of fcience: whereas now, as foon as he arrives within fight of it, he is taken away. His laft advice to his difciples was, that fince it is the lot of man to die as foon as he begins to live, they fhould take greater pains to enjoy life as it paffes, than to acquire pofthumous fame. A large body of Athenians attended his funeral.

The works of Theophraftus comprehended a variety of fubjects, and were numerous. His doctrine differed in fome refpects from that of his mafter Ariftotle. He taught that the predicaments, or categories, were as numerous as the motions and changes to which beings are liable; and that among motions, or changes, are to be reckoned defires, appetites, judgments and thoughts. He maintained, that all things are not produced from contraries; but fome from contraries, fome from fimilar caufes, and fome from fimple energy; that motion is not to be diftinguifhed from action; and that there is one divine principle of all things, by which all things fubfift. By this divine principle, it is thought that Theophraftus meant the Firft Mover, without whom other things could not be moved, and therefore could not fubfift. Of his moral maxims, the following are the moft worthy of notice. "Refpect yourfelf, and you will never have reafon to be afhamed before others. Love is the paffion of an indolent mind. Blufhing is the complexion of virtue. Time is the moft precious expenditure."

Few of his works, of which Diogenes Laertius enumerates more than 200, have reached our time: of thefe, the moft famous is entitled "Characters," defcribing different moral claffes of men, fuch as the flatterer, the impudent, the difcontented, the garrulous, the fuperftitious, &c.; fo diftinguifhed and defcribed, as to fhew great knowledge of mankind. Of his other works on natural hiftory, the principal are his "Hiftory of Plants," in nine books, which Haller has particularly recommended to the notice of botanical ftudents; "On the Caufes of Plants," relating chiefly to the natural and artificial means of bringing them to maturity; to agriculture and horticulture; to the taftes and odours of vegetables; "On Stones;" "On Winds;" "On Fire;" "On Honey;" "On the Signs of Fair Weather, and of Tempefts and Rain;" "On Animals which change their Colour;" "On Animals which are born fuddenly;" "On Fifh which live out of Water." Theophraftus ranks amongft the moft diftinguifhed of the ancients for comprehenfive genius and diligent enquiry into nature. The laft edition of the whole extant works of Theophraftus is that of of Dan. Heinſius, Greek and Latin, fol. Lugd. Bat. 1613. Of his hiſtory of plants, the moſt complete is that of Budæus, Greek and Latin, fol. Amſt. 1644. Among the moſt eſteemed editions of his "Characters," which are numerous, we may reckon thoſe of Iſ. Caſaubon, of Needham, with the notes of Duport, Cantab. 1712, and of I. Fr. Fiſcher, Coburg. 1763. Diog. Laert. Brucker by Enfield. Haller Bib. Bot.

THEOPHYLACT, named *Simocatta*, a Greek hiſtorian, a native of Greece, but of Egyptian origin, flouriſhed about A.D. 612. His hiſtory of the reign of the emperor Maurice is comprehended in eight books, and terminates with the maſſacre of this prince and his children by Phocas. Caſaubon reckons Simocatta one of the beſt of the later Greek hiſtorians. The work juſt mentioned was printed at the Louvre, in 1647, fol. and forms a part of the Byzantine hiſtorians. An edition of his "Epiſtles, Moral, Rural, and Amatory," was given by Aldus. His "Phyſical Problems" were publiſhed firſt by Vulcanius at Leyden, and afterwards by Andrew Schottus. His "Hiſtory of the Habitable World" is cited by Euſtathius, in his Commentary on the Periegeſis of Dionyſius. Gen. Biog.

THEOPHYLACT, archbiſhop of Acris, the capital of Bulgaria, was a native of Conſtantinople, and flouriſhed under the emperors Michael Ducas, Nicephorus Botoniates, and Alexis Comnenus. After his elevation to the archbiſhopric of Acris, by the perſuaſion of the wife of Ducas, he diligently laboured in propagating the Chriſtian faith, and compoſed ſeveral works, which give him rank among the principal eccleſiaſtical writers of his age. The time of his death is not known; but he was living in 1071. His "Commentaries on the Four Goſpels, the Acts of the Apoſtles, and the Epiſtles of St. Paul," which are his chief work, are for the moſt part abridged from Chryſoſtom and others. He alſo wrote "Commentaries on the Minor Prophets." Several editions of his Commentaries have been publiſhed in Greek and Latin, and alſo in Latin only. "Seventy-five Epiſtles" of this author were publiſhed by Meurſius, in Greek, in 1617, and a Latin tranſlation in 1622. Some other tracts have been attributed to this author. Dupin ſays, that the Commentaries of Theophylact are very uſeful for the literal explanation of the Scriptures: and Lardner obſerves, that he quotes no forged writings or apocryphal books of the New Teſtament, many of which he excludes by his obſervation on John, i. 31—34. that Chriſt wrought no miracle in his infancy, or before the time of his public miniſtry. Dupin. Lardner.

THEOPNEUSTÆ, Θεοπνευσται, formed of Θεος, *God*, and πνεω, *I breathe*, an epithet given to enthuſiaſtical diviners.

THEOPOLIS, in *Ancient Geography*, a town of Gallia Narbonnenſis, belonging to the Aventici, N.E. of Forum Novum.

THEOPROPRIA, Θεοπροπια, formed of Θεος, *God*, and πρεπω, *I excel*, a deſignation given to oracles. See ORACLE.

THEOPSIA, Θεοπτια, formed of Θεος, *God*, and οπτομαι, *I ſee*, in *Mythology*, denoted the appearance of gods. Cicero, Plutarch, Arnobius, and Chryſoſtom, mention appearances of this kind.

THEORBO, THIORBA, or TIORBA, a muſical inſtrument, made in form of a large lute; except that it has two necks, or juga, the ſecond and longer of which ſuſtains the four laſt rows of chords, which are to give the deepeſt ſounds. See LUTE.

The word is formed from the French *teorbe*, or *theorbe*, and that from the Italian *tiorbe*, which ſignifies the ſame, and which ſome will have to be the name of the inventor.

The theorbo is an inſtrument which for many years ſucceeded to the lute, in the playing of thorough baſſes; it is ſaid by ſome to have been invented in France, by the ſieur Hotteman, and thence introduced into Italy, &c.

The only difference between the theorbo and the lute is, that the former has eight baſs or thick ſtrings twice as long as thoſe of the lute; which exceſs of length renders their ſound ſo exceedingly ſoft, and keeps it up ſo long a time, that it is no wonder many prefer it to the harpſichord itſelf. At leaſt it has this advantage over it, that it is eaſily removed from place to place, &c.

All its ſtrings are uſually ſingle; though there are ſome who double the baſs-ſtrings with a little octave, or the ſmall ſtrings with an uniſon; in which caſe, bearing more reſemblance to the lute than the common theorbo, the Italians call it the *arcileuto*, or arch-lute.

THEOREM, in the *Mathematical Method*, a propoſition which terminates in theory, and which conſiders the properties of things already made or done.

Or, a theorem is a ſpeculative propoſition, deduced from ſeveral definitions compared together. Thus, if a triangle be compared with a parallelogram ſtanding on the ſame baſe, and of the ſame altitude, and partly from their immediate definitions, and partly from other of their properties already determined, it is inferred, that the parallelogram is double the triangle: that propoſition is the theorem.

Theorem ſtands contradiſtinguiſhed from *problem*.

There are two things to be chiefly regarded in every theorem, *viz.* the propoſition and the demonſtration: in the firſt is expreſſed what agrees to ſome certain thing under certain conditions, and what does not.

In the latter, the reaſons are laid down, by which the underſtanding comes to conceive, that it does or does not agree to them.

Theorems are of various kinds: as,

THEOREM, *Univerſal*, is that which extends to any quantity without reſtriction, univerſally. As this, that the rectangle of the ſum and difference of any two quantities is equal to the difference of their ſquares.

THEOREM, *Particular*, is that which extends only to a particular quantity. As this: in an equilateral right-lined triangle, each of the angles is ſixty degrees.

THEOREM, *Negative*, is that which expreſſes the impoſſibility of any aſſertion. As, that the ſum of two biquadrate numbers cannot make a ſquare number.

THEOREM, *Local*, is that which relates to a ſurface. As, that triangles of the ſame baſe and altitude are equal.

THEOREM, *Plane*, is that which either relates to a rectilinear ſurface, or to one terminated by the circumference of a circle. As, that all angles in the ſame ſegment of a circle are equal.

THEOREM, *Solid*, is that which conſiders a ſpace terminated by a ſolid; that is, by any of the three conic ſections. *E. gr.* this: that if a right line cut two aſymptotic parabolas, its two parts terminated by them ſhall be equal. See SOLID.

THEOREM, *Reciprocal*, is one whoſe converſe is true. As, that if a triangle have two equal ſides, it muſt have two equal angles: the converſe of which is likewiſe true, that if it have two equal angles, it muſt have two equal ſides.

THEOREM, in *Algebra* and *Analyſis*, is ſometimes uſed to denote a rule, particularly when that rule is expreſſed in ſymbols or formulæ, of which there is of courſe a great number; but of theſe, ſome few, either from their importance,

portance, curiosity, or other considerations, have retained particular denominations, under which they are frequently referred to by modern authors: it is therefore necessary to have them so classed, that a reader may be able to ascertain the principles on which they are founded, the purposes they are intended to answer, and the cases to which they will best apply. The theorems to which we here allude, are Bernoulli's theorem, the Binomial theorem, Cotes's, Taylor's, Maclaurin's, &c.

Bernoulli's Theorem, is a general formula for the developement of any fluent or integral, of any proposed fluxion or differential; which may be stated as follows: *viz.* X being any function of x,

$$\int X\, d\, x = X\,\frac{x}{1} - \frac{d\,X}{d\,x}\cdot\frac{x^2}{1\,.\,2} + \frac{d^2\,X}{d\,x^2}\cdot\frac{x^3}{1\,.\,2\,.\,3} - \frac{d^3\,X}{d\,x^3}\cdot\frac{x^4}{1\,.\,2\,.\,3\,.\,4}, \ \&c.$$

Let us denote by Y, the value of this integral when $x = 0$, X, $\frac{d\,X}{d\,x}$, $\frac{d^2\,X}{d\,x^2}$, &c. being also denoted by Y′, Y″, Y‴, &c. and we shall have generally,

$$\int X\, d\, x = Y + Y'\,\frac{x}{1} + Y''\,\frac{x^2}{1\,.\,2} + Y'''\,\frac{x^3}{1\,.\,2\,.\,3} + \&c.$$

Now, in order to pass from the general value of $\int X\, d\, x$, which we shall represent by y, to that which answers to the case of $x = 0$, it is evident that we must in Taylor's formula make $h = -x$, which gives

$$Y = y - \frac{d\,y}{d\,x}\cdot\frac{x}{1} + \frac{d^2\,y}{d\,x^2}\cdot\frac{x^2}{1\,.\,2} - \frac{d^3\,y}{d\,x^3}\cdot\frac{x^3}{1\,.\,2\,.\,3} + \&c.$$

substituting in this equation, in the place of y, $\frac{d\,y}{d\,x}$, $\frac{d^2\,y}{d\,x^2}$, &c. their respective values, and taking that of $\int X\, d\, x$, we shall have

$$\int X\,d\,x = Y + X\,.\,\frac{x}{1} - \frac{d\,X}{d\,x}\,.\,\frac{x^2}{1\,.\,2} + \frac{d^2\,X}{d\,x^2}\,.\,\frac{x^3}{1\,.\,2\,.\,3} - \&c.$$

the quantity Y being still a constant arbitrary. By integrating, we arrive also at this developement: thus, if we decompose the differential X d x into its two factors X and d x, and integrate the second, we shall have

$$\int X\, d\, x = X\, x - \int x\, d\, X.$$

But

$$\int x\, d\, X = \int \frac{d\,X}{d\,x}\,.\,x\, d\, x = \tfrac{1}{2}\, x^2\, \frac{d\,X}{d\,x} - \tfrac{1}{2}\int x^2\,\frac{d^2\,X}{d\,x}$$

$$\int x^2\,\frac{d^2\,X}{d\,x} = \int \frac{d^2\,X}{d\,x^2}\,.\,x^2\, d\, x = \tfrac{1}{3}\, x^3\, \frac{d^2\,X}{d\,x^2} - \tfrac{1}{3}\int x^3\,\frac{d^3\,X}{d\,x^2}$$

$$\int x^3\,\frac{d^3\,X}{d\,x^2} = \int \frac{d^3\,X}{d\,x^3}\,.\,x^3\, d\, x = \tfrac{1}{4}\, x^4\, \frac{d^3\,X}{d\,x^3} - \tfrac{1}{4}\int x^4\,\frac{d^4\,X}{d\,x^3}$$

&c. &c. &c.

And putting successively for $\int x\, d\, X$, $\int x^2\,\frac{d^2\,X}{d\,x}$, &c. their respective values, there results,

$$\int X\, d\, x = X\,\frac{x}{1} - \frac{d\,X}{d\,x}\,.\,\frac{x^2}{1\,.\,2} + \frac{d^2\,X}{d\,x^2}\,.\,\frac{x^3}{1\,.\,2\,.\,3} - \&c.$$

which is the theorem of John Bernoulli, and is the same with regard to the integral calculus, as that of Taylor to the differential.

Binomial Theorem, or Newtonian theorem, is a general formula for the developement of any binomial of the form $(a + x)^{\frac{m}{n}}$; *viz.*

$$(a + x)^{\frac{m}{n}} =$$

$$a^{\frac{m}{n}} \times \left\{1 + \frac{m}{n}\left(\frac{x}{a}\right) + \frac{m}{n}\,.\,\frac{m-n}{2\,n}\left(\frac{x}{a}\right)^2 + \frac{m}{n}\,.\,\frac{m-n}{2\,n}\,.\,\frac{m-2\,n}{3\,n}\left(\frac{x}{a}\right)^3 + \&c.\right\}$$

See Binomial *Theorem*.

Briggs's Theorem.—There are more than one formula that have received this designation, but we believe that the following is generally understood to be implied; *viz.*

"The nth differences of any consecutive nth powers, or of any nth powers whose roots are in arithmetical progression, are expressed by the formula

$$n\,(n-1)\,(n-2)\,(n-3)\,(n-4)\,\ldots\,1\,.\,d^n$$

d being the common difference of the roots."

The demonstration of this theorem is commonly made to depend upon principles drawn from the fluxional analysis; but we prefer giving a sketch of that which appeared in vol. xi. of the Irish Transactions by Mr. Burk, being deduced from the most elementary considerations.

We know that the expansion of $(p + x)^n$, is of the form

$$p^n + n\,x\,p^{n-1} + C\,x^2 p^{n-2} + D\,x^3 p^{n-3} + \&c.$$

Let o, p, q, r, s, &c. be the terms of any decreasing arithmetical progression, of which the difference is d; then since $o = p + d$, $p = q + d$, &c. we have

$$o^n = (p + d)^n = p^n + n\,d\,p^{n-1} + C\,d^2 p^{n-2} + \&c.$$
$$p^n = (q + d)^n = q^n + n\,d\,q^{n-1} + C\,d^2 q^{n-2} + \&c.$$
$$q^n = (r + d)^n = r^n + n\,d\,r^{n-1} + C\,d^2 r^{n-2} + \&c.$$

Taking the first, second, third, &c. differences, we have

First Differences

$$n\,d\,p^{n-1} + C\,d^2 p^{n-2} + \&c.$$
$$n\,d\,q^{n-1} + C\,d^2 q^{n-2} + \&c.$$
$$n\,d\,r^{n-1} + C\,d^2 r^{n-2} + \&c.$$

And since $p^{n-1} = (q + d)^{n-1} = q^{n-1} + (n-1)\,d\,q^{n-2}$ &c. we have for the

Second Differences

$$n\,d\,(n-1)\,d\,q^{n-2} + \&c.$$
$$n\,d\,(n-1)\,d\,r^{n-2} + \&c.$$
$$n\,d\,(n-1)\,d\,s^{n-2} + \&c.$$

Third Differences

$$n\,d\,(n-1)\,d\,(n-2)\,d\,r^{n-3} + \&c.$$
$$n\,d\,(n-1)\,d\,(n-2)\,d\,s^{n-3} + \&c.$$

Fourth Differences

$$n\,d\,(n-1)\,d\,(n-2)\,d\,s^{n-3}\,(n-3)\,d\,r^{n-4} + \&c.$$

Whence, by an infallible and obvious deduction,

nth *Differences*

$$n\,d\,(n-1)\,d\,(n-2)\,\ldots\ldots\,(n - \overline{n-1})\,d\,w^{n-n}$$

$(n+1)$*th Differences*

$$n\,d\,(n-1)\,d\,(n-2)\,\ldots\ldots\,(n-n)\,d\,v^{-1}.$$

But

But since $n - n = 0$, the $(n + 1)$th differences $= 0$; and since $w^{n-n} = w^0 = 1$, the nth differences become

$$n(n-1)(n-2)(n-3) \ldots\ldots 3 \cdot 2 \cdot 1 \, d.^n$$

It may not be amiss to observe, that we have only employed the first term of the several orders of differences, which however is sufficient for our purpose, since it is obvious that the nth difference can have but one term; for the developement of $(p + d)^n$ gives $n + 1$ terms; and since one term vanishes with every difference, the first difference will have n terms, the second $n - 1$, the third $n - 2$, &c.; and consequently the nth difference will have $n - (n - 1) = 1$ term only. See Irish Transactions, vol. xi. or Monthly Review, vol. lxxiv.

Cotes's Theorem, or *Cotesian Theorem*.—The geometrical properties of this very interesting theorem are explained under the article COTESIAN *Theorem;* it will only be necessary therefore in this place to state the same analytically. In this case, the general enunciation is:

"All the imaginary roots of the binomial equation $x^n - 1 = 0$, are contained in the general formula $x^2 - 2 \operatorname{cos.} \frac{2k\pi}{n} x + 1 = 0$; and those of $x^n + 1 = 0$, in the formula $x^2 - 2 \operatorname{cos.} \frac{(2k+1)\pi}{n} x + 1 = 0$, k being any integer not divisible by n, and π representing the semi-circumference." See RECIPROCAL *Equations*.

Euler's Theorem is used to denote the theorem or formula first given by this author, for ascertaining the direct integrability of differential equations, which is as follows. The equation being reduced to the form

$$M\,dx + N\,dy = 0,$$

where M and N are functions of x and y; if $\frac{M}{dy} = \frac{N}{dx}$, then the integration may be obtained by a direct process; but if this equality have not place, the integration can then only be effected by indirect means, which frequently involve considerable difficulty.

Fermat's Theorem.—There are several theorems in the theory of numbers which are due to this ingenious analyst; but that which is more particularly designed by Fermat's theorem is this; *viz.* "Neither the sum nor difference of any two integral powers, above the square, can be equal to a rational power of the same dimension:" or, which is the same, the equation

$$x^n \pm y^n = z^n$$

is always impossible in rational numbers, if n be greater than 2.

The cases of $n = 3$ and $n = 4$ have been demonstrated; but notwithstanding the numerous attempts of the most celebrated analysts of the last and of the present age, the case of $n = 5$, and all the succeeding values of n, remain without demonstration; and as this is now the only theorem of this author which has not submitted to the power of the modern analysis, the National Institute of France has made it the subject of the prize of 3000 francs, to be decided by 1818.

Under the article NUMBERS, amongst the miscellaneous propositions, we have mentioned another theorem of Fermat's, which had not then been demonstrated, but which has since been effected by M. Cauchy, corresponding member of the Institute. The reader will also find some farther remarks relative to the equation $x^n \pm y^n = z^n$, under our article POWER.

Gauss's Theorem is used to denote a theorem invented by this distinguished mathematician, for the solution of certain binomial equations. We have seen, in the article RECIPROCAL *Equations*, in what manner the roots of binomial equations may be obtained by means of a table of sines and cosines; but Gauss's theorem is the converse of this, and shews in what manner the sines and cosines of certain angles may be obtained, by the numerical solution of such equations. See POLYGON.

Guldin's Theorem is the same as the CENTROBARYC *Method;* which see.

Lagrange's Theorem is commonly used to denote the general formula assumed by Lagrange as the foundation of his theory of functions; which may be thus enunciated.

"If ϕx be any function whatever of a variable quantity x, and if x changes its value, and becomes $x + i$, then the $\phi(x + i)$ may be represented or resolved into a series of the form

$$\phi(x+i) = \phi x + P i + Q i^2 + R i^3 + \&c.$$

in which the co-efficients of the powers of i are new functions of x, derived from the primitive function x, independent of i; and, moreover, that every co-efficient is derived from the preceding one, in the same manner as the first is derived from the original function." See FUNCTIONS.

Leibnitz's Theorem is a theorem proposed by this author for differencing under the sign $\int$, and it may be exhibited under the form $\frac{d \int M\,dx}{dy} = \int \frac{dM}{dy} dx$, where $M = \frac{du}{dx}$, u being any function of x and y.

Since $\frac{du}{dx\,dy} = \frac{du}{dy\,dx}$ by the known principles of the differential calculus; if we make $u = \int M\,dx$, we shall have $\frac{du}{dx} = M$, $\frac{d^2u}{dx\,dy} = \frac{dM}{dy}$; and integrating with regard to x, we shall find

$$\int \frac{d^2u}{dx\,dy} dx = \int \frac{d^2u}{dy\,dx} dx = \frac{du}{dy} = \int \frac{dM}{dy} dx.$$

This is called by Leibnitz *differentiatio de curva in curvam*, because in the question which he proposed to resolve, he passed from one curve to another of the same species, by making one of the constant quantities variable. See La Croix "Calcul Integral."

Maclaurin's Theorem is a formula which we owe to this author for expressing any function y, of a variable quantity x; *viz.* adopting the differential notation,

$$y = (y) + \left(\frac{dy}{dx}\right) x + \tfrac{1}{2}\left(\frac{d^2y}{dx^2}\right) x^2 + \frac{1}{2 \cdot 3}\left(\frac{d^3y}{dx^3}\right) x^3 + \&c.$$

where (y), $\left(\frac{dy}{dx}\right)$, $\left(\frac{d^2y}{dx^2}\right)$, &c. represent what these several quantities become when $x = 0$.

Let $\quad y = A + Bx + Cx^2 + Dx^3 + \&c.$

differencing, and dividing by dx, we have

$$\frac{dy}{dx} = B + 2Cx + 3Dx^2 + \&c.$$

$$\frac{d^2y}{dx^2} = 2C + 2 \cdot 3Dx + \&c.$$

$$\frac{d^3y}{dx^3} = + 2 \cdot 3D + \&c.$$

conseconfequently, when x in each of thefe $= 0$, we have

$$(y) = \mathrm{A}, \left(\frac{d\,y}{d\,x}\right) = \mathrm{B}\,; \left(\frac{d^2 y}{2\,.\,d\,x^2}\right) = \mathrm{C}\,; \frac{1\,d^3 y}{2\,.\,3\,d\,x^3} = \mathrm{D}\,;$$

therefore,

$$y = (y) + \left(\frac{d\,y}{d\,x}\right) x + \tfrac{1}{2}\left(\frac{d^2 y}{d\,x^2}\right) x^2 + \frac{1}{2\,.\,3}\left(\frac{d^3 y}{d\,x^3}\right) x^3 + \&c.$$

See Maclaurin's "Fluxions," and Boucharlat's "Calcul Differentiel, &c."

Moivre's Theorem. See the next article.

Multinomial Theorem, fometimes called Moivre's theorem, having been firft difcovered by that author, is a general expreffion or formula for determining any power or root of a given quantity confifting of any number of terms. This theorem was firft publifhed by its author in N° 230. of the Phil. Tranf. 1697; but it was afterwards fimplified by Euler in his "Calcul Differentiel," and the fame has alfo been done by Arhogaft in his "Calcul des Derivations."

The general form of this theorem, as given in Bonnycaftle's Algebra, is as follows:

$$(\mathrm{A}_0 + \mathrm{A}_1 x + \mathrm{A}_2 x^2 + \mathrm{A}_3 x^3 + \;.\;.\;.\;.\; \mathrm{A}_n x^n)^m = \mathrm{A}^m +$$

$$m\,\mathrm{A}_1 \mathrm{B}_0 \,.\, \frac{x}{\mathrm{A}} + \left.\begin{matrix} 2m\,\mathrm{A}_2 \mathrm{B}_0 \\ + (m-1)\,\mathrm{A}_1 \mathrm{B}_1 \end{matrix}\right\} . \frac{x^2}{2\,\mathrm{A}_0} + \left.\begin{matrix} 3m\,\mathrm{A}_3 \mathrm{B}_0 \\ + (2m-1)\,\mathrm{A}_2 \mathrm{B}_1 \\ + (m-2)\,\mathrm{A}_1 \mathrm{B}_2 \end{matrix}\right\} \frac{x^3}{3\,\mathrm{A}_0} + \left.\begin{matrix} 4m\,\mathrm{A}_4 \mathrm{B}_0 \\ + (3m-1)\,\mathrm{A}_3 \mathrm{B}_1 \\ + (2m-2)\,\mathrm{A}_2 \mathrm{B}_2 \\ + (m-3)\,\mathrm{A}_1 \mathrm{B}_3 \end{matrix}\right\} \frac{x^4}{4\,\mathrm{A}_0} + \&c.$$

Where $\mathrm{B}_0 = \mathrm{A}_0^m$, and B_1, B_2, B_3, &c. are the co-efficients of the terms immediately preceding thofe in which they firft appear; and the manner of applying this theorem to any particular cafe, is by fubftituting the numbers or letters in the given example for A_0, A_1, A_2, &c. and the numerical value of m for m. It would lead us too far to attempt the demonftration of this theorem in this place, we muft, therefore, refer the reader for fuch information to the works above-mentioned.

Newtonian Theorem. See Binomial *Theorem.*

Taylor's Theorem, an elegant and highly valuable formula, which was firft publifhed by Dr. Brook Taylor in his "Methodus Incrementorum," which is as follows; *viz.*

"If Y reprefent any function whatever of the variable quantity x, and if x be increafed by any difference $\Delta\,x$, the value of Y, *viz.* $\mathrm{Y} + \Delta\,\mathrm{Y}$, becomes (employing the differential notation)

$$\mathrm{Y} + \Delta\,\mathrm{Y} = \mathrm{Y} + \frac{\Delta\,x\,d\,\mathrm{Y}}{1\,.\,d\,x} + \frac{\Delta\,x^2\,d^2\,\mathrm{Y}}{1\,.\,2\,.\,d\,x^2} + \frac{\Delta\,x^3\,d^3\,\mathrm{Y}}{1\,.\,2\,.\,3\,d\,x^3} + \&c.$$

$$\text{or } \Delta\,\mathrm{Y} = \frac{\Delta\,x\,d\,\mathrm{Y}}{1\,.\,d\,x} + \frac{\Delta\,x^2\,d^2\,\mathrm{Y}}{1\,.\,2\,.\,d\,x^2} + \frac{\Delta\,x^3\,d^3\,\mathrm{Y}}{1\,.\,2\,.\,3\,d\,x^3} + \&c.$$

The demonftration of this celebrated theorem is given very concifely by La Croix, on the following principles.

Let Y be any function of x, and let Y′ denote what this function becomes, when x becomes $x + h$, we may write

$$\mathrm{Y}' = \mathrm{A} + \mathrm{B}\,h + \mathrm{C}\,h^2 + \mathrm{D}\,h^3 + \&c.$$

in which developement, it is obvious that A, B, C, &c. are functions of x.

If now we difference this equation with h variable and x conftant, we obtain, dividing by $d\,h$,

$$\frac{\mathrm{Y}'}{d\,h} = \mathrm{B} + 2\,\mathrm{C}\,h + 3\,\mathrm{D}\,h^2 + \&c.$$

Again, differencing with x variable and h conftant, we have

$$\frac{\mathrm{Y}'}{d\,x} = \frac{d\,\mathrm{A}}{d\,x} + \frac{d\,\mathrm{B}}{d\,x}\,h + \frac{d\,\mathrm{C}}{d\,x}\,h^2 + \frac{d\,\mathrm{D}}{d\,x}\,h^3 + \&c.$$

But as x and h enter exactly in the fame manner, it follows that $\frac{\mathrm{Y}'}{d\,x} = \frac{\mathrm{Y}'}{d\,h}$, whence the firft of thefe feries is equal to the fecond; equating, therefore, the co-efficients of the like powers of h, we have

$$\mathrm{B} = \frac{d\,\mathrm{A}}{d\,x},\quad \mathrm{C} = \frac{d\,\mathrm{B}}{2\,d\,x},\quad \mathrm{D} = \frac{d\,\mathrm{C}}{3\,d\,x},\ \&c.$$

Now

$$\mathrm{A} = \mathrm{Y},\ \mathrm{B} = \frac{d\,\mathrm{Y}}{d\,x},\ \mathrm{C} = \frac{d^2\,\mathrm{Y}}{1\,.\,2\,.\,d\,x^2},\ \mathrm{D} = \frac{d^3\,\mathrm{Y}}{1\,.\,2\,.\,3\,d\,x^3};$$

whence

$$\mathrm{Y}' = \mathrm{Y} + \frac{d\,\mathrm{Y}}{1\,.\,d\,x}\,h + \frac{d^2\,\mathrm{Y}}{1\,.\,2\,.\,d\,x^2}\,h^2 + \frac{d^3\,\mathrm{Y}}{1\,.\,2\,.\,3\,d\,x^3}\,h^3 + \&c.$$

Or writing

$$\mathrm{Y}' = \mathrm{Y} + \Delta\,\mathrm{Y}, \text{ and } x + h = x + \Delta\,x,$$

we have

$$\Delta\,\mathrm{Y} = \frac{\Delta\,x\,d\,\mathrm{Y}}{1\,.\,d\,x} + \frac{\Delta\,x^2\,d^2\,\mathrm{Y}}{1\,.\,2\,.\,d\,x^2} + \frac{\Delta\,x^3\,d^3\,\mathrm{Y}}{1\,.\,2\,.\,3\,d\,x^3} + \&c.$$

See La Croix "Calcul Differentiel," p. 21.

Trinomial Theorem is only a particular cafe of the *Multinomial Theorem*, which fee.

Wilfon's Theorem is a curious formula relative to prime numbers, publifhed firft by Waring in his "Meditationes Algebraicæ," which is as follows.

"If n be any prime number, then will

$$1\,.\,2\,.\,3\,.\,4,\ \&c.\ (n-1) + 1$$

be divifible by n."

This curious theorem was not demonftrated by fir John Wilfon, who firft difcovered it, nor by Waring, by whom it was firft made public; it has, however, fince received different demonftrations from Lagrange, Gaufs, &c. the latter of which is very fimple, and has been adopted by Barlow in his "Theory of Numbers," to which work we beg to refer our readers, as it would require more room than we can allow ourfelves to give it at full length in this place.

The above include, we believe, all thofe theorems which are known by any particular defignation; there are, doubtlefs, many others equally important, and which are equally entitled to bear the names of their refpective authors, but cuftom has not fanctioned the adoption; and we have, therefore, not introduced them.

THEORETIC, Theoretical, or *Theoric*, formed from θεωρεω, *I ſee or contemplate*, ſomething relating to theory, or that terminates in ſpeculation. In which ſenſe it ſtands oppoſed to *practical*.

The ſciences are ordinarily divided into *theoretical*, as theology, philoſophy, &c.; and *practical*, as medicine, law, &c. See Science.

Theoretic, *Theoreticus*, is an appellation peculiarly given to an ancient ſect of phyſicians, contradiſtinguiſhed by it from the empirics. See Empiric.

Theoretic phyſicians were ſuch as applied themſelves to a careful ſtudy and conſideration of what relates to health and diſeaſes; the principles of the human body, and its ſtructure and parts, with their actions and uſes; whatever befals it, either naturally or preternaturally; the differences of diſeaſes, their nature, cauſes, ſigns, indications, &c.; the textures, properties, &c. of plants, and other medicines, &c. In a word, the theoretic phyſicians were ſuch as proceeded in their judgment and practice on the foot of reaſon, in oppoſition to the empirical phyſicians, who proceeded wholly on experience. See Medicine.

Theoretical *Arithmetic* and *Philoſophy*. See the ſubſtantives.

THEORI, θεωροι, in *Antiquity*, an appellation given to thoſe Athenians who performed the ſolemnity called *theoria*.

THEORIA, θεωρια, a ſolemn annual voyage to Apollo's temple, in the iſland of Delos, performed by the Athenians always in the ſame ſhip in which Theſeus went. For the particularities of this naval proceſſion, ſee Potter Archæol. Græc. lib. ii. cap. 9. tom. i. p. 284, ſeq.

THEORIC Money, in *Ancient Authors*, was what was raiſed, by way of tax on the people, to defray the expences of theatrical repreſentations, and other ſpectacles.

There were particular queſtors and treaſurers of the theoric money. By a law of Eubulus, it was made a capital crime to pervert the theoric money to any other uſe; even to employ it in the occaſions of war.

THEORICAL Astronomy, is that part of aſtronomy which conſiders the true ſtructure and diſpoſition of the heavens, and heavenly bodies; and accounts for their various phenomena therefrom. See Astronomy.

It is thus called, in oppoſition to that part which conſiders their apparent ſtructure, or their diſpoſition as viewed by the eye, which is called *ſpherical* aſtronomy.

The ſeveral parts of theorical aſtonomy, ſee under System, Sun, Star, Planet, Earth, Moon, Satellite, and Comet.

THEORY, a doctrine which terminates in the ſole ſpeculation, or conſideration, of its object, without any view to the practice or application of it.

To be learned in an art, &c. the theory ſuffices; to be a maſter of it, both the theory and practice are required. Machines, many times, promiſe very well in the theory, yet fail in the practice.

We ſay, theory of the moon, theory of the rainbow, of the microſcope, the camera obſcura, the motion of the heart, the operation of purgatives, &c.

Theories *of the Planets*, &c. are ſyſtems or hypotheſes, according to which the aſtronomers explain the reaſons of the phenomena or appearances of them. See System.

Theory, in *Muſic*, in the hands of a mere mathematician is confined only to ratios and the philoſophy of ſound. (See Harmonics.) But among *practical* muſicians, the theory of harmony or compoſition is connected with the combination of agreeable ſounds, and the practice and performance of real muſic.

Theory, *Atomic*, in *Chemiſtry*, the means of explaining the compoſition and decompoſition of chemical bodies, by conſidering their ultimate atoms or particles as peculiar and diſtinct elementary ſolids, never changing in their figure, weight, or volume, under any circumſtances.

It would be difficult to conceive the exiſtence of any compound, without ſuppoſing it to have originated by union, in ſome way or other, of particles of its elementary conſtituents: but the prevalence of a doctrine, which has been generally advanced by mathematicians, *viz.* the infinite diviſibility of matter, has never allowed philoſophers to conclude that the circumſtance of compounds being made up of particles, muſt neceſſarily limit the proportions in which the elements combine. If the elementary bodies be conceived infinitely diviſible, the molecules, or compound particles, may be conceived infinitely ſmall, and the number of mean compounds exiſting between any two given extremes may be alſo conſidered infinite.

If ſuch were the nature of elementary matter, and no other cauſes interfered, there could be no limitation to the proportions in which ſimple matter would combine. This, however, is contrary to fact; as it is a fact known from the earlieſt dawnings of chemical knowledge, that bodies are limited in the proportions of their elements; the moſt ſtriking of theſe facts being the mutual ſaturation which takes place between an acid and an alkali, and the uniform proportions afforded in the analyſis of many native compounds.

Philoſophers were always ſatisfied to conſider this fact of the limitation of the proportions of bodies as one of the hidden ſecrets of nature, as difficult to conceive as the nature of the attraction by which their elements were held together. Berthollet appears to have been the firſt to attempt this arduous taſk, in his ingenious work, entitled "Chemical Statics." He ſuppoſes that the particles of bodies, when brought within the ſphere of attraction, combine without controul till the compound aſſumes ſome definite form, by which it is withdrawn from the ſituation in which it was formed. He ſuppoſes the chemical affinity of bodies to be diſtinct from that power on which their coheſion depends, and alſo that power by which they tend to an elaſtic ſtate.

Hence he concludes, that every ſolid compound is determined by the coheſion which takes place at ſome limit in the proportion of its elements: ſuch he ſuppoſes to be the caſe with ſalts and other cryſtallizable compounds. On the other hand, he ſuppoſes the limitations of the proportions of the elements of gaſeous compounds to ariſe from the elaſtic form which they aſſume in certain ſtages of combination. This hypotheſis was ſupported by ſo many ſtriking facts, that it was thought by ſome to explain in general the cauſe of limited proportions. All agreed, that whatever might be the true theory, the cauſes pointed out by Berthollet had conſiderable influence in the compoſition and decompoſition of bodies, but they ſaw at the ſame time numerous caſes in which this hypotheſis failed to explain the facts.

Chemiſts have, from the earlieſt times, been acquainted with thoſe points of limitation which we call mutual ſaturation, and have been long familiar with thoſe limited augmentations of their proportions, called by ſome doſes and by others particles. Among the oxyds of metals, which had been little examined before the time of Lavoiſier, it was found, that inſtead of having an infinite number of means between the loweſt and higheſt ſtages of oxydation, only a certain number of oxyds of each metal could be formed, in which the ratio of the metal to the oxygen is uniform. Many of the ſalts in the ſame way are formed by limited doſes of acid. Some of the facts in the latter have been explained on Berthollet's hypotheſis, while its application to to the former facts is totally insufficient. Long previous to the true cause of these limited doses, the facts were so conspicuous, that a decided nomenclature was adopted for the purpose of expressing these different stages of combination. The oxyds have been distinguished by the Greek numerals *prot*, *deut*, *trit*, &c. The salts containing two doses of acid have been called *super-salts;* and those containing an extra dose of base, have been called *sub-salts*.

Although chemists have frequently used a language which appeared to shew their acquaintance with the real cause of the definite proportions, such as one compound being forced by one proportion, dose, or particle of one of its elements, and another with two proportions, doses, or particles: on the other hand, we find expressions which would favour the idea of indefinite proportions; such as bodies losing a small portion of their oxygen, or absorbing a little oxygen from the atmosphere. Salts are sometimes said to contain a slight excess of acid, or a small excess of base.

The most decided language used in any chemical work before the discoveries of Mr. John Dalton, giving any idea that the doses are limited by distinct atoms, will be found in a work by Mr. Higgins, entitled "A Comparative View of the Phlogistic and Antiphlogistic Theories." We beg leave to correct a mistake in a former article, in which we have entitled this work a Treatise on Phlogiston.

This work was written for the express purpose of combatting the phlogistic theory, and principally in answer to Mr. Kirwan's treatise of phlogiston. In order to shew the contradictions and absurdities of the phlogistic doctrine, which, under the name of phlogiston, confounded a number of bodies which were very different, he exhibited by diagrams a number of chemical operations, in which he supposed the elementary bodies concerned to be ultimate particles, and their immediate compounds molecules. He in the same diagrams also used numbers, which he supposed to be estimates of the strength of affinity of the combining particles. By this means he very successfully shewed many of the inconsistencies which must be admitted to explain the phenomena on the phlogistic theory. In this mode of proceeding, however, the numbers expressing the relative attractions, served his purpose much more than the consideration of the proportions being caused by distinct atoms; and the language which would induce the belief that he had such a conception of the nature of elementary matter, occurs only in a very few parts of his work.

After concluding that it is unnecessary to admit the existence of the imaginary substance phlogiston in sulphur, he concludes, in page 36, that sulphurous acid is compounded of one ultimate particle of sulphur with one of oxygen, and that sulphuric acid consists of one of sulphur and two of oxygen.

In the same page he also observes, that water is formed by one ultimate particle of water united to one of oxygen.

In page 81, he supposes sulphuretted hydrogen to consist of nine ultimate particles of sulphur with five of hydrogen. Previous, however, to this conclusion, he believes that the sulphur and hydrogen are not chemically combined, but that the sulphur is dissolved in hydrogen, as a salt dissolves in water.

After using arguments to shew, in answer to Mr. Kirwan, that the nitric acid does not contain what was thought to be phlogiston, he concludes, in page 132, with giving what he conceives to be its constituents, *viz.* that the nitrous oxyd consists of one ultimate particle of azote and one of oxygen; nitrous gas, of one of azote and two of oxygen; red nitrous vapour, one of azote and three of oxygen; straw-coloured nitrous acid, one of azote to four of oxygen; and lastly, that the nitric acid is constituted by one of azote and five of oxygen. These facts are certainly very remarkable, as they agree with the conclusions in the present time, and give a strong proof of Mr. Higgins's genius at the time he wrote.

He does not, however, lay any stress upon these remarks, and was not probably aware that they would be confirmed by future research. We are induced to think so, from the manner in which he expresses himself in other parts of his work, in which he frequently speaks of the absorption of small portions of oxygen, and of bodies having a small portion of oxygen more than they can retain. This vague manner of speaking, and others which we do not immediately recollect, is sufficient to shew that Mr. Higgins had no fixed notions of the cause of definite proportions, and that the language in which he has used the words ultimate particles and molecules, was employed rather with a view to illustrate his examples, than to broach any new theory to explain indefinite proportions. Indeed it would have been inconsistent to have treated two subjects, so very different in their objects, in the same pages.

As a proof that there was nothing striking in the remarks in which the words ultimate atoms and molecules are mentioned, we only need refer to the article which Mr. Higgins himself quotes from the Analytical Review, written soon after the appearance of the work in question. The reviewer gives him the highest praise for the able manner in which he has refuted the doctrine of phlogiston, but does not even hint at his diagrams or the ultimate particles. Indeed we can venture to assert, that if no more had been said on the subject of definite proportions than is to be found in this work, we might yet have been as much in the dark as we were twenty years after the publication of Mr. Higgins's "Comparative View."

It was not enough to know that compound bodies were formed of particles, to enable us to explain the cause of definite proportions; and we want no greater proof of this, than the fact of the true cause not being known till twenty-eight years after Mr. Higgins had told us that one particle of sulphur and one of oxygen formed sulphurous acid, and that one to two formed sulphuric acid. These loose expressions were but a small step indeed towards the discovery of the atomic theory in its present form, which has placed chemistry on the same ground with that on which the discovery of the laws of gravity placed the science of astronomy.

We are inclined to believe that the first step towards this important discovery was given by Richter. He found, in the double decomposition of salts, that the acid of one salt was always just sufficient to saturate the base of the other, and *vice versâ*. He also ascertained, that when one metal was precipitated by another, the oxygen of the precipitated metal was just what was required by the precipitating metal.

The inference to be drawn from these facts was, that if A combine with x to saturation, and B with y to the same; then, if A should be found to saturate y, B would also saturate x. This inference may be still further extended; for if A be a body capable of combining with B, they will mutually saturate each other.

It is the means of drawing these inferences arising from the mutual fitness of those parts of bodies which combine, that constitutes the importance of the atomic theory, and it is for the establishment of this new principle that we are indebted to Mr. John Dalton. When Mr. Higgins can shew, from the data given in his work, that similar inferences

ences could be drawn, he then will be entitled to ſhare in the merit of the diſcovery of the atomic theory. We lay ſhare with him, for we are firmly convinced that Mr. Dalton had never read Mr. Higgins's book previous to the publication of his own work.

We perfectly recollect the time, not more than four or five years ago, even when Mr. Dalton's book was before the public, very few chemiſts underſtood the true ſpirit of the atomic theory; and thoſe who conceived they did underſtand it, in general diſcarded it. All knew that he conſidered compounds to be formed of atoms united 1 to 1, 1 to 2, 1 to 3, &c.: but it was not till the reciprocal fitneſs of theſe atoms with each other was found to agree with analyſis, that it was generally received. When they ſaw that the numbers, which Dalton called the weights of the atoms, expreſſed the ſimple proportions in which bodies combine, they knew it could not be the effect of chance, and have willingly joined in the reſearch. It is for this part of the diſcovery that Mr. Dalton juſtly merits the fame he has acquired.

We have given all the facts on which Mr. Higgins could poſſibly found his claim to the diſcovery; and we muſt leave it to our readers to judge, whether they contain the ſmalleſt data on which to eſtabliſh what in the preſent time we call the atomic theory.

In all the chemical articles ſince the article Iron, we have had the greateſt confidence in the atomic theory; and we have never failed to compare the analyſes of different authorities with the reſults given by theory. We have in general found, that theſe reſults have been nearer to the beſt of theſe authorities, than they have been to each other.

We have already given an outline of the atomic theory, with a table of the weights of the ſimple atoms, and another of ſome of the moſt conſpicuous compounds, in our articles *Definite* Proportions, and Simple *Bodies*.

The French chemiſts have adopted the atomic theory under another form, which will be found to agree with the language given by Berzelius, who uſes the word *volume* for atom, as we have already explained in the article above alluded to.

Gay Luſſac ſeveral years ago publiſhed a new law reſpecting the combination of gaſeous bodies. He held that gaſes which combine chemically, either unite in equal volumes, or 1 to 2, or ſome multiple of 1, by a whole number. Although a number of facts ſeemed to agree with this law, the truth of it was doubted by ſome chemiſts, and principally becauſe no apparent reaſon appeared for ſuch a law.

In ſtating (under the article Proportions) the notion of Berzelius reſpecting volumes, we have pointed out a curious coincidence between the ſpecific gravity and the weight of atoms of the gaſes, which has ſince been confirmed by Dr. Prout in Dr. Thomſon's Annals. In order that the weights of the atoms may be equal to their ſpecific gravities, we have there ſtated, that the number of particles in equal volumes of all gaſes muſt be equal, and the diſtance between the centres of the particles of all gaſes the ſame, ſo that the weights of equal volumes of different gaſes, would be as the weights of the atoms.

This would alſo require, that the attraction between the particles ſhould either be the ſame in all, or that it ſhould be nothing; and the diſtance of the particles be at points where the repulſion of the calorific atmoſphere is balanced by the incumbent preſſure.

The ſtate here ſuppoſed, however, is not the caſe, ſince we find that the weights of the atoms of the gaſes generally are not equal to the ſpecific gravity, when reduced to the ſame ſtandard, although it is ſtrictly the caſe with a great proportion of them. And in thoſe caſes where they are not equal, the one is ſaid to be ſome multiple of the other, by a whole number.

This circumſtance favours the hope that ſome general law exiſts, by which the weights of the atoms of bodies are intimately connected with their ſpecific gravities in the elaſtic form. When the ſpecific gravity is double the weight of the atom, as is the caſe with oxygen, we have to ſuppoſe, that the particles are nearer each other in the proportion of 2 to 1, or that two particles come together, and are ſurrounded by the caloric, which belongs to one of them in their ſingle ſtate.

It would appear that the oxygen puts on this ſingle ſtate of exiſtence in the formation of carbonic oxyd, becauſe that gaſeous body contains only one atom of oxygen; hence its ſpecific gravity is the ſame as if it were formed from a gaſeous oxygen of half the real ſpecific gravity united to an atom of carbon without any change of volume, the ſame as takes place when ſulphur or carbon is burned in oxygen gas. Hence we may explain the great tendency that oxygen has to combine in double doſes with bodies, as is the caſe with carbon, ſulphur, phoſphorus, iron, and many other bodies.

We have alſo an inſtance of a compound gaſeous body becoming of double the ſpecific gravity which would be expected in olefacient gas, which is compoſed of an atom of carbon and an atom of hydrogen. The ſpecific gravity (hydrogen being 1) ought to be $1 + 5.4 = 6.4$; but in fact it is about the double of this. Hence we ſhould conclude, that the repulſion between the particles is halved, or that the compound atoms have united in pairs, by which the denſity is doubled.

Theory *of the Manufacture and Production of Bread*, in *Rural Economy*, the explanation of the principles and practices on which it depends in different caſes. The means which are employed in ſuch caſes are moſtly well underſtood; but the principles upon which they depend are far from being ſo well known. The writer of a late work on the "Elements of Agricultural Chemiſtry," has, however, thrown ſome light on this hitherto intricate ſubject. He has noticed, that a number of the changes taking place in the vegetable principles, depend upon the ſeparation of oxygen and hydrogen as water from the compound; but that there is one of very great importance, in which a new combination of the elements of water is the principal operation: this is in the manufacture of bread. When any kind of flour, which conſiſts principally of ſtarch, is made into a paſte with water, and immediately and gradually heated to about 440°, it increaſes, it is ſaid, in weight, and is found entirely altered in its properties; it has loſt its ſolubility in water, and its power of being converted into ſugar. In this ſtate it is unleavened bread.

And when the flour of corn, or the ſtarch of potatoes, mixed with boiled roots of the ſame kind, is made into a paſte with water, kept warm, and ſuffered to remain thirty or forty hours, it ferments, carbonic acid gas is diſengaged from it, and it becomes filled with globules of elaſtic fluid. In this ſtate it is raiſed dough, and affords by baking leavened bread; but this bread, it is ſaid, is ſour and diſagreeable to the taſte; and that leavened bread for uſe is made by mixing a little dough that has fermented, with new dough, and kneading them together, or by kneading the materials for the bread with a ſmall quantity of yeaſt.

It is ſtated, that in the formation of wheaten bread, more than one-fourth of the elements of water combine with the flour;

flour; that more water in proportion is consolidated in the formation of bread from barley, and still a larger quantity in that from oats; but that the gluten in wheat, being in much larger quantity than in other grain, seems to form a combination with the starch and water, which renders wheaten bread more digestible than other species or kinds of bread.

On this principle too it is probable, that this sort of bread may be more suitable and proper for the less laborious classes of society, though the other kinds may be equally or more nourishing and lasting for those who are engaged in hard work.

THEOSOPHISTS, the denomination of a class of philosophers, who profess to derive their knowledge of nature from divine revelation. Not contented with the natural light of human reason, nor with the simple doctrines of scripture understood in their literal sense, these persons have recourse to an internal supernatural light, superior to all other illuminations, from which they pretend to derive a mysterious and divine philosophy, manifested only to the chosen favourites of heaven. They boast, that, by means of this celestial light, they are not only admitted to the intimate knowledge of God, and of all divine truth, but have access to the most sublime secrets of nature. They ascribe it to the singular manifestation of divine benevolence, that they are able to make such an use of the element of fire, in the chemical art, as enables them to discover the essential principle of bodies, and to disclose stupendous mysteries in the physical world. (See Fire *Philosophers*.) They even pretend to an acquaintance with those celestial beings, which form the medium of intercourse between God and man, and to a power of obtaining from them, by the aid of magic, astrology, and other similar arts, various kinds of information and assistance. This they affirm to have been the ancient secret wisdom, first revealed to the Jews under the name of Cabbala, and transmitted by tradition to posterity. Philosophers of this class have no common system; but every one follows the impulse of his own imagination, and constructs an edifice of fanaticism for himself. They only agree in abandoning human reason, and pretending to divine illumination. Many traces of the spirit of Theosophism are to be found in the whole history of philosophy, in which fanatical and hypocritical pretensions to divine illumination frequently occur. Among moderns, the first name that is mentioned with any distinction in this class of philosophers is Paracelsus. (See his biographical article.) He was succeeded by Robert Fludd, who compounded into a new mass of absurdity all the mysterious and incomprehensible dreams of the Cabbalists and Paracelsians. He supposed two universal principles, the northern or condensing power, and the southern or rarefying power; and over these he placed innumerable intelligences and geniuses, and called together whole troops of spirits from the four winds, to which he committed the charge of diseases. (See his article.) Another dazzling luminary in the constellation of Theosophists was Jacob Bœhmen. See Behmen.

A more scientific Theosophist than Bœhmen was Van Helmont. (See Helmont.) The most elegant and philosophical of all the Theosophists was Peter Poiret, who was born at Metz in the year 1646, and educated in the academy of Basil. In 1668 he became a student in the university of Heidelberg, with a view of qualifying himself for the clerical profession, and in 1672 he assumed the character of an ecclesiastic in the principality of Deux-Ponts. After a severe fit of illness, he wrote his "Cogitationes Rationales de Deo, Anima, et Malo," in which he mostly followed the principles of Des Cartes, having in his youth studied the Cartesian philosophy; a work which he defended against the censures of Bayle. Being obliged by the public tumults to withdraw from his clerical cure, he removed to Holland, and afterwards to Hamburgh, where he became acquainted with the celebrated mystic Mad. Bourignon, and enlisted himself in the number of her disciples. Abandoning Cartesianism, and fascinated with Bourignonian mysticism, he rejected the light of reason as useless and dangerous, and inveighed against every kind of philosophy that was not the effect of divine illumination. Towards the close of his life he settled at Rheinsburg, in Holland, and employed himself in writing mystical books; such were his treatises "De Œconomia Divina," "De Eruditione Triplici," and the last edition of his "Cogitationes Rationales." He died in the year 1719. Some of his mystical notions may be collected from the preliminary dissertation prefixed to his works: they are such as these: "It hath pleased God, in order that he may enjoy a vivid and delightful contemplation of himself, beyond that solitude which belongs to the divine essence, to create external beings in whom he may produce an image of himself. The essence of the human mind is 'thought,' capable and desirous of light, and joyful complacence; the properties in which it bears a resemblance of the divine essence. Nothing is more intimate or essential to the mind than this desire; by which it is borne always towards the true and infinite good. In order to satisfy this desire, the illumination of faith is necessary; by means of which the mind, conscious of its weakness and impotence, disclaims all the fictions of human reason, and directs itself towards God with an intense and ineffable ardour, till, by the silent contemplation of him, it is filled with tranquillizing light and joyful complacence; although, whilst oppressed with the load of mortality, it cannot behold his unveiled face. From this divine illumination proceeds the most pacific serenity of mind, the most ardent love of God, and the most intimate union with him."

To the class of Theosophists it has been usual to refer the entire society of *Rosycrucians*; which see.

It will be sufficient to observe, at the close of this article, that the whole system of Theosophism is founded in delusion, and that it is injurious both to philosophy and religion. These supposed illuminations are to be ascribed either to fanaticism or to imposture. The fastidious contempt, with which these pretenders to divine wisdom have treated those who are contented to follow the plain dictates of common sense, and the simple doctrine of scriptures, has unquestionably imposed upon the credulous vulgar, and produced an indifference to rational enquiry, which has obstructed the progress of knowledge. And their example has encouraged others to traduce philosophy and theology in general, by representing them as resting upon no better foundation than enthusiasm and absurdity. It is to be charitably presumed, that these deluded visionaries have not been themselves aware of the injury which they have been doing to the interests of science and religion. Nevertheless, it must be regretted, both on their own account, and on account of the multitudes they have misled, that whilst they have thought themselves following a bright and steady luminary, they have been led astray by wandering meteors. Brucker by Enfield.

THEOTOCUS, Deipara. See Mother *of God*.

THEOXENIA, Θεοξενια, in *Antiquity*, a festival in honour of all the gods, and celebrated in many cities of Greece, but especially Athens.

THEOXINI Malagma, the name of a sort of cataplasm, good against pains of the feet.

THERA, in *Ancient Geography*, one of the islands called *Sporades*,

Sporades, in the Ægean ſea, between the iſland of Crete and the Cyclades. It is ſaid to have taken its name from Theras, a prince of the race of Cadmus, who removed from Lacedæmon into this iſland, which was occupied by the deſcendants of the Membliarii, who had poſſeſſion of it 1550 years before our era; whereas Pliny ſays that it firſt appeared in the fourth year of the 135th olympiad. This iſland is now called *Santorin;* which ſee.—Alſo, a town of the iſland of the ſame name.—Alſo, a town of Aſia Minor, in Caria, between Idymus and Pyſtus.—Alſo, a town of Aſia, in Sogdiana.

THERAMBUS, a town of Macedonia, in the peninſula of Pallené.

THERAMNÆ, a town of Aſia Minor, in Lycia; conſecrated to Apollo.

THERAPEUTÆ, θεραπευται, a Greek term ſignifying ſervants, more eſpecially thoſe employed in the ſervice of God. The Greeks gave the appellation *therapeutæ* to ſuch as applied themſelves to a contemplative life, whether it were from the great concern they had for their ſouls, or from the particular mode and manner of their religion; the word θεραπευειν, whence *therapeutæ*, ſignifying the care a phyſician takes of his patient, or the ſervice any one renders another.

Philo, in his firſt book of the Contemplative Life, relates, that there were a people ſpread throughout moſt of the known world, but particularly throughout Egypt, and about Alexandria, who renounced their friends, their goods, &c. and who, after diſcharging themſelves of all temporal concerns, retired into ſolitary places, where they had each their ſeparate manſion, called *ſemneium*, or *monaſtery*, and placed their whole felicity in the contemplation of the divine nature.

The principal ſociety of this kind was formed near Alexandria, where they lived, not far from each other, in ſeparate cottages, each of which had its own ſacred apartment, to which the inhabitant retired for the purpoſes of devotion. After their morning prayers, they ſpent the day in ſtudying the law and the prophets, endeavouring, by the commentaries of their anceſtors, to diſcover ſome allegorical meaning in every part. They alſo amuſed themſelves with compoſing ſacred hymns in various kinds of metre. Six days of the week were thus paſſed in ſolitude. On the ſeventh day they met, decently clothed, in a public aſſembly, where, ſeated according to their age, they held the right hand between the breaſt and the chin, and the left at the ſide. Then one of the elders, ſtepping to the middle of the aſſembly, diſcourſed, gravely and calmly, on the doctrines of the ſect; the audience remaining ſilent and occaſionally expreſſing their approbation by a nod. The chapel in which they aſſembled was ſeparated into two apartments, one for the men, the other for the women. At the cloſe, the ſpeaker ſung a hymn of praiſe to God, in the laſt verſe of which the whole aſſembly joined. On great feſtivals, ſacred muſic was performed, accompanied with ſolemn dancing; and theſe vigils were continued till morning, when the aſſembly, after a morning prayer, in which their faces were directed towards the riſing ſun, was broken up. Such was their abſtemiouſneſs, that they commonly ate nothing before the ſetting ſun, and often faſted two or three days. They wholly abſtained from wine, and their ordinary food was bread and herbs.

There are two points relating to theſe therapeutæ exceedingly controverted among critics, *viz.* 1. Whether they were Jews or Chriſtians; and, 2. If they were the latter, whether they were monks or ſeculars?

Moſheim affirms, that the therapeutæ were neither Chriſtians nor Egyptians, as ſome have erroneouſly imagined; they were undoubtedly Jews; nay, they gloried in that title, and ſtyled themſelves, with particular affectation, the true diſciples of Moſes, though their manner of life was equally repugnant to the inſtitutions of that great lawgiver, and to the dictates of right reaſon, and ſhewed them to be a tribe of melancholy and wrong-headed enthuſiaſts.

Calmet alſo, in his Dictionary of the Bible, alleges a variety of reaſons to prove, that the therapeutæ were Jews and not Chriſtians; and that they were not monks in the ſenſe which eccleſiaſtical writers affix to this term. Some have imagined that they were judaizing Gentiles; but Philo, by claſſing them with the Eſſenes, evidently ſuppoſes them to be Jews. Others have maintained, that they were an Alexandrian ſect of Jewiſh converts to the Chriſtian faith, who devoted themſelves to a monaſtic life. But this is impoſſible; for Philo, who wrote before Chriſtianity appeared in Egypt, ſpeaks of this as an eſtabliſhed ſect. From a compariſon of Philo's account of this ſect with the ſtate of philoſophy in the country where it flouriſhed, we may reaſonably conclude, that the therapeutæ were a body of Jewiſh fanatics, who ſuffered themſelves to be drawn aſide from the ſimplicity of their ancient religion by the example of the Egyptians and Pythagoreans. It is uncertain how long this ſect continued; but it is thought not improbable, that, after the appearance of Chriſtianity in Egypt, it ſoon became extinct. See Essenes.

THERAPEUTICE, Therapeutics, θεραπευτικη, formed from θεραπευειν, *to attend, to nurſe, cure,* &c. that part of medicine which is employed in ſeeking out remedies againſt diſeaſes, and in preſcribing and applying them to effect a cure.

Therapeutice teaches the uſe of diet, pharmacy, ſurgery, and the *methodus medendi.*

Therapeutice is alſo uſed figuratively, in ſpeaking of the mind, and of diſcourſes made to correct the errors and defects of it.

Such is the Therapeutice or Therapeutics of Theodoret; being a treatiſe againſt the errors of unwholeſome opinions of the Greeks, *i. e.* the heathens.

THERAPHIM, or Teraphim, an Hebrew term, which has given great exerciſe to the critics. We meet with it thirteen or fourteen times in Scripture, where it is commonly interpreted *idols:* but the rabbins are not contented to have them ſimply ſignify idols, but will have it denote a peculiar ſort of idols or images intended for the knowledge of futurity, *i. e.* oracles.

R. David de Pomis obſerves, that they were called theraphim, from רפה, *raphah, to leave,* becauſe people quitted every thing to conſult them.

Others hold, that the theraphim were brazen inſtruments which pointed out the hours and minutes of future events, as directed by the ſtars.

R. Eliezer tells us the reaſon why the rabbins will have the theraphim to ſpeak, and render oracles: it is, ſays he, becauſe it is written in the prophet Zechariah, x. 2. "The theraphim have ſpoken vain things."

The ſame rabbin adds, that to make the theraphim, they killed a firſt-born child, clove his head, and ſeaſoned it with ſalt and oil: that they wrote on a plate of gold the name of ſome impure ſpirit, laid it under the tongue of the dead, placed the head againſt the wall, lighted lamps before it, and prayed to it, and that it then talked with them.

Vorſtius alſo obſerves, that, beſide the paſſage of Zechariah, juſt quoted, it appears likewiſe from Ezekiel, xxi. 21. that the theraphim were conſulted as oracles.

F. Kircher directs us to ſeek the origin of the theraphim in in Egypt; adding, that the word is Egyptian. Spencer, in his diſſertation on the *urim* and *thummim*, maintains the word to be Chaldee, and to ſignify the ſame with ſeraphim: the Chaldeans being frequently known to change the ש into ת, that is *ſ* into *t*. He adds, that thoſe images were borrowed from the Amorites, Chaldeans, or Syrians; and that the *Serapis* of the Egyptians is the ſame thing with the theraphim of the Chaldeans. See Selden de Diis Syris, ſynt. i. cap. 2.

Calmet obſerves, that the figure of a winged ſerpent, called *ſeraph*, whence the name ſeraphim, has given riſe to the appellation theraphim, becauſe in the abraxas and other taliſmans of the ancients, which are real theraphims, we find the figures of ſerpents both with and without wings; whence he infers, that the theraphims of Laban, which were ſtolen by Rachael, were real taliſmans. Jurieu conjectures, that theſe theraphims were the penates, or houſhold gods of Laban, which, he ſays, were the ſouls of the heroes of families, deified and worſhipped; and he adds, that the theraphims of Laban were the images of Noah, the reſtorer of the human race, and of Shem, the chief of the family of Laban. But Calmet, in reply to this conjecture, obſerves, that it is by no means credible, that the worſhip of the penates and lares was known in the time of Laban; and that it is not likely, that Laban ſhould have ranked among the gods Noah and Shem, who had died ſo near his own time: for Noah died A.M. 2006, and Shem A.M. 2158, about eighty-ſeven years before Jacob came to Meſopotamia after Laban.

THERAPIDION, in *Botany*, a name given by ſome authors to the common oyſter-green, or ſea-laver, a ſubſtance of the tremella kind.

THERASIA, in *Geography*, a ſmall rocky iſland in the Grecian Archipelago, ſeparated from the N.W. coaſt of Santorin (the ancient Thera) by a narrow channel, which forms a ſecure harbour for boats; 3 miles N. of St. Nicolo. Theraſia is ſaid by Tournefort and Sonnini to be the preſent *Aſpronisi* (which ſee); but Olivier mentions them as diſtinct iſlands. Theraſia, ſays this laſt-mentioned traveller, on which Ptolemy places a town, and which Pliny conjectures, with reaſon, to have been detached from Thera, cannot be taken for Aſpronisi, nor the latter for the former, as Tournefort imagines. Aſpronisi is not large enough to have had upon it the ſmalleſt village, or the ſmalleſt habitation; whereas Theraſia has ſufficient extent, and its territory is ſufficiently good, to have been always the ſcite of a town, as one is ſtill to be ſeen there at the preſent day.

THERESA, a river of Africa, which runs into the Atlantic, S. lat. 13°.

THERESA, *Order of Maria*, a military order inſtituted by the empreſs-queen in Germany, on the 18th of June, 1757, and compoſed of two claſſes, *viz.* grand croſſes and knights. To theſe the emperor Joſeph II., in the year 1765, added an intermediate claſs, under the appellation of commanders. The number of knights is not fixed, and the emperor is grand-maſter. The badge of the order is, "a croſs of gold, enamelled white, edged with gold;" on the centre are the arms of Auſtria, *viz.* "gules, a feſſe-argent, encircled with the word *Fortitudini*;" on the reverſe is "a cipher of the letters M. L. F. in gold, on an enamelled green ground." The badge is worn pendant to a ſtriped crimſon and white ribbon.

THERGUBIS, in *Ancient Geography*, a town of Aſia, in the interior of Meſopotamia, ſituated on the bank and towards the ſource of the river Chaborras.

THERIACA, ϑηριακα, *Treacle*, in *Medicine*, a name given by the ancients to various compoſitions eſteemed good againſt poiſons; but afterwards chiefly reſtrained to what, by way of diſtinction, has been called *theriaca Andromachi*, or *Venice treacle*: but now altogether out of uſe.

This is a compound of no leſs than ſixty-four drugs, prepared, pulverized, and reduced, by means of honey, into an electuary. The baſis or foundation of the compoſition is viper's fleſh. M. Charas has written a particular hiſtory of the animals, plants, and minerals, which enter the compoſition of this famed remedy.

It is ſaid to be ſovereign againſt the bites of venomous beaſts, and in the wind-colic; and was alſo uſed in intermitting fevers, and in caſes requiring perſpiratives and diaphoretics; alſo in continual fevers, eſpecially ſuch as are malignant, and where the pulſe is low and ticking; and in the ſmall-pox and meaſles: and, as moſt of the ingredients of it are very hot, in all diſeaſes where the natural heat is weak and languid.

Andromachus, Nero's phyſician, paſſes for the inventor of the theriaca; at leaſt, it was he who gave the firſt deſcription of it in elegiac verſes; his ſon did the ſame in proſe, and Damocrates in iambics.

Anciently, the treacle made at Venice had all the vogue: and many ſtill retain the ancient prejudice; but it has been ſince prepared at Montpellier, at Paris, and at London, with as much advantage as at Venice.

There is another vulgar kind of theriaca, called *diateſſaron*, becauſe it only conſiſts of four ingredients.

Treacle-water and treacle-vinegar are found good preſervatives againſt putrid air, whether by only being ſmelt at, or by rubbing the wriſts, temples, and noſe with them.

THERIACA *Ruſticorum*, a name given to garlic, from its uſe as an antidote againſt the contagion of peſtilential and other putrid diſorders.

THERIOMA, from θηριοω, *to rage*, in *Surgery*, a malignant ulcer.

THERMA, in *Ancient Geography*, a town of Cappadocia, on the route from Tavia to Cæſarea, between Tavia and Soanda. Anton. Itin.—Alſo, a town ſituated on the confines of Macedonia, or rather of Theſſaly, towards Thermopylæ. This town was ſituated on the gulf called Thermæus, whence its name.

THERMA *Pythia*, baths of Aſia Minor, in Bithynia. Procopius mentions this place, and ſays that Juſtinian conſtructed here a bath for public uſe, and a canal to conduct into it freſh water, and that he alſo provided others, which indicated a magnificence truly royal.

THERMÆ, θερμαι, in *Architecture*, ancient buildings, furniſhed with baths, eſpecially of the hot kind.

Among the nobleſt monuments of ancient Rome, are reckoned the thermæ, or baths of Diocleſian. See BATHS.

Thermæ, or hot ſprings, it is commonly argued, owe heat to a colluctation, or efferveſcence, of the minerals in them. Though Dr. Woodward aſcribes it to the ſubterraneous heat, or fire, which communicates with them by ſome ſpiracle, or canal, whereby a greater quantity of heat is derived thither, than to ordinary ſprings. See BATH.

THERMÆ, in *Ancient Geography*, a place on the ſouthern coaſt of Sicily. Pliny denominates this place a Roman colony; and Antonine calls the ſources of the hot water which gave the name of Thermæ to this place "Aquæ Larodæ." There were alſo baths at Selinonti in Sicily, called Thermæ Selinuntiæ. The name *thermæ* was alſo given to thoſe highly ſaline warm waters that were found in the neighbourhood of Corinth.

THERMÆUS SINUS, a gulf of the Ægean ſea, on the coaſt of Macedonia.

THERMASMA, a word uſed by ſome of the ancients

 to

to exprefs any thing that warms the body, and by others particularly for a warm fomentation, prefcribed by Hippocrates for removing pains in the fide, and giving eafe in pleurifies.

THERMES, in *Ancient Geography*, a town of Hifpania Citerior, S. of Numantia.

THERMI, in *Geography*, a town of Afiatic Turkey, in the province of Natolia; 24 miles N. of Burfa.

THERMIA, an ifland in the Grecian Archipelago, fo called from its abounding with hot fprings. It is not fo mountainous as fome of the other iflands, and the foil, when well cultivated, produces very large quantities of barley, wine, and figs. The ifland alfo affords plenty of honey, wax, partridges, a great quantity of fine filk, and as much cotton as the inhabitants require for their own ufe. The Greek Chriftians in this ifland are computed at 16,000. Thermia is the fee of a bifhop, and contains fifteen or fixteen churches, and feveral convents. On the ifland are ftill vifible the ruins of two cities; one of which, on the fouth coaft, muft have been of extraordinary fplendour. N. lat. 37° 20′. E. long. 24° 32′.

THERMIA, a town and capital of the ifland of Thermia. N. lat. 37° 24′. E. long. 24° 26′.

THERMOMETER, THERMOMETRUM, derived from θερμος, *heat*, and μετρον, *to meafure*, an inftrument fhewing, or rather meafuring, the increafe and decreafe of the heat and cold of the air.

The degree of heat, as afcertained by a thermometer, is only to be confidered in relation to the furrounding bodies, by virtue of which a body fupports the equilibrium of temperature, when it is in the neighbourhood of bodies equally heated: thus, if a thermometer ftands at 60°, both in a veffel of water and in another of mercury, we may infer that the water and the mercury may be mixed without any change of their temperature; but the abfolute quantity of heat contained in equal weights, or in equal bulks, of any two bodies at the fame temperature, is by no means the fame. See HEAT.

The general principles upon which the conftruction and ufe of thermometers, or meafurers of heat depend, are ftated and explained under the articles CALORIC, COLD, CONGELATION, FREEZING, HEAT, &c.

It will be fufficient to obferve in this place, that the well-known and moft general effect of heat, whether it be obtained by compreffing a certain fubftance into a narrower fpace, fo that a quantity of heat may come out of it and be communicated to certain bodies, or by expanding a certain fubftance into a larger fpace, fo that it may abforb a quantity of heat from furrounding bodies, and thus cool thefe bodies, or in whatever other way it be procured, is a dilatation of bodies, or an augmentation of their bulks. The contrary effect is produced by cold, *i. e.* by a diminution of the free caloric. It muft, however, be obferved, that bodies of equal bulks, but of different kinds, are not expanded alike by being heated to the fame degree; nor are the increments of bulk in the fame body always proportional to the quantities of heat which are communicated to it. *E. gr.* if a given quantity of water, by being heated to a certain degree, be increafed in bulk one cubic inch, the addition of double or treble that quantity of heat will not increafe its bulk two or three cubic inches refpectively; therefore the expanfions of water are not proportional to the increments of heat.

The only practicable method of meafuring the expanfions of fluids, is by inclofing them in certain veffels, and by meafuring that part of the cavity of each veffel which is occupied by the particular fluid which fills it in different temperatures. It is evident, that the fubftance of the veffel is alfo expanded by the heat, and of courfe its cavity is enlarged. Therefore, when we find that the bulk of the fluid is increafed, that apparent increment is only the difference between the enlarged capacity of the veffel and the increafed bulk of the fluid. For this reafon thofe veffels muft be made of fuch fubftances as are leaft expanfible by heat. Indeed glafs is the fubftance which is univerfally ufed for fuch purpofes, both on account of its little expanfibility, and of its tranfparency, befides its having other remarkably ufeful properties.

A glafs veffel filled to a certain degree with a liquid, for the purpofe of fhewing the expanfion of that liquid in different temperatures, or for the purpofe of fhewing the temperature by the correfponding expanfion of that liquid, is called a *thermometer*.

The thermometer and thermofcope are ordinarily accounted the fame thing: Wolfius, however, makes a difference; but fhews, at the fame time, that what we call thermometers are, in reality, no more than thermofcopes.

The invention of the thermometer is attributed to feveral perfons by different authors, *viz.* to Sanctorio, Galileo, Father Paul, and Drebbel. The invention is afcribed to Cornelius Drebbelius of Alcmaer, about the beginning of the feventeenth century, by his countrymen Boerhaave (Chem. i. p. 152. 156.) and Mufchenbroeck, Introd. ad Phil. Nat. vol. ii. p. 625.

Fulgenzio, in his life of Father Paul, gives him the honour of the firft difcovery. Vincenzio Viviani (Vit. de l'Galil. p. 67. See too Oper. di Galil. pref. p. 47.) fpeaks of Galileo as the inventor of thermometers. But Sanctorio himfelf (Com. in Galen. Art. Med. p. 736—842. Com. in Avicen. Can. Fen. i. p. 22. 78. 219.) exprefsly affumes this invention; and Borelli (De Mot. Animal. ii. prop. 175.) and Malpighi (Oper. Pofth. p. 30.) afcribe it to him without referve. Upon which Dr. Martine remarks, that thefe Florentine academicians are not to be fufpected of partiality in favour of one of the Patavinian fchool. But whoever was the firft inventor of this inftrument, it was very rude and imperfect; and as the various degrees of heat were indicated by the different contraction or expanfion of air, it was afterwards found to be an uncertain and fometimes a deceiving meafure of heat, becaufe the bulk of air was affected, not only by the difference of heat, but likewife by the variable weight of the atmofphere.

There are various kinds of thermometers; the conftruction, defects, theory, &c. of which, are as follow:

Conftruction of the Thermometer, depending on the Rarefaction of the Air.—This *aerial* thermometer, which was that firft invented by Drebbel, confifts of a glafs tube B E (*Plate* XVI. *Pneumatics, fig.* 1.), connected at one end with a large glafs ball A, and at the other end immerfed in an open veffel, or terminating in a ball D E, with a narrow orifice at D; which veffel, or ball, contains any coloured liquor that will not eafily freeze. Aqua fortis tinged of a fine blue colour with folution of vitriol or copper, or fpirit of wine tinged with cochineal, or Brafil wood, will anfwer this purpofe. But the ball, A, muft be firft moderately warmed, fo that a part of the air contained in it may be expelled through the orifice D; and then the liquor preffed by the weight of the atmofphere will enter the ball D E, and rife, *e. g.* to the middle of the tube at C, at a mean temperature of the weather; and in this ftate the liquor by its weight, and the air included in the ball A, &c. by its elafticity, will counterbalance the weight of the atmofphere. As the furrounding air becomes warmer, the air in the ball and upper part of the tube, expanding by heat, will drive the liquor into the lower

lower ball, and consequently its surface will descend; on the contrary, as the ambient air becomes colder, that in the ball is condensed, and the liquor pressed by the weight of the atmosphere will ascend: so that the liquor in the tube will ascend or descend more or less, according to the state of the air contiguous to the instrument. To the tube is affixed a scale of the same length, divided upwards and downwards from the middle, C, into one hundred equal parts, by means of which the ascent and descent of the liquor in the tube, and consequently the variations in the cold or heat of the atmosphere, may be observed.

It must be acknowledged, that the expansion of elastic fluids affords, in some cases, a test of heat, which is very convenient from its great delicacy, and because a very small quantity of heat is sufficient to raise their temperature very considerably.

A similar thermometer may be constructed by putting a small quantity of mercury, not exceeding the bulk of a pea, into the tube B C (*fig.* 2.) thus bent in wreaths, that taking up the less height, it may be the more manageable and less liable to harm; divide this tube into any number of equal parts to serve for a scale.

Here the approaches of the mercury towards the ball, A, will shew the increase of the degree of heat. The reason is the same as in the former.

The defect of both these instruments consists in this, that they are liable to be acted on by a double cause: for, not only a decrease of heat, but also an increase of weight of the atmosphere, will make the liquor rise in the one, and the mercury in the other; and, on the contrary, either an increase of heat, or decrease of weight of the atmosphere, will make it descend.

In winter, for example, the liquor would rise and sink too much; for a frost condensing the internal air, the liquor would ascend, but as the air is heavier in frosty weather, its pressure on the liquor in the vessel D E (*fig.* 1.) being increased, would raise the liquor still higher in the tube, and thus indicate a degree of cold greater than it really is. On the other hand, if the weather grows warm, as it does in rainy weather in winter, the air in the ball will expand, and the liquor descend in the tube; but as the weight of the atmosphere is less in foul weather, the liquor in D E will be less pressed than it was, and suffer the liquor to descend more than it should do, and shew a greater degree of warmth than that of the ambient air. The reverse of this will happen in summer: for warm weather being fair weather, and the atmosphere being then heavier than usual, the liquor will be made to stand higher in the tube than it should do, and shew the degree of heat to be less than it really is. And as in summer, the weather becomes cold with rain; but the weight of the atmosphere being diminished, the liquor will not ascend so far as it ought to ascend by the condensation of the internal air, and therefore indicate the cold to be less than it really is: and when the two causes, thus contributing to the rise and fall of the liquor, act equally in opposite directions, the liquor would appear neither to ascend nor descend, whatever might be the changes in the temperature of the atmosphere, on account of equal corresponding variations in its gravity. Besides, the air in the ball, &c. is liable to be affected more or less in its elastic quality by the vapours that detach themselves from the included liquor according to the degree in which it is heated or cooled. For these and other measures, thermometers of this kind have been long disused.

Instruments of this kind, when they are subject to the variations of the pressure of the atmosphere, as well as to those of its temperature, are properly called manometers, and require, for enabling us to employ them as thermometers, a comparison with the barometer; while, on the other hand, they may be used as barometers if the temperature be otherwise ascertained. They are, however, very useful without this comparison, in delicate experiments of short duration; besides, the changes of the barometer are seldom very rapid, and they may also be wholly freed from the effects of the pressure of the atmosphere in various ways.

Bernouilli's method consists in closing the tube of a common barometer so as to leave the column of mercury in equilibrium with the air contained in the bulb at its actual temperature, and capable of indicating, by the changes of its height and of its pressure, any subsequent changes in the temperature of the air, which must affect both its bulk and its elasticity. (See *fig.* 3.) Mr. Leslie's photometer, or *Differential* THERMOMETER (which see), has some advantages which render it better than this instrument; but it can only be employed when the changes of the temperature can be confined only to a part of the instrument. The elasticity of the air contained in the bulb is here counteracted, not by the pressure of a column of mercury, but by the elasticity of another portion of air in a second bulb, which is not to be exposed to the heat or cold that is to be examined; and the difference of the temperatures of the two bulbs is indicated by the place of a drop of a liquid, moving freely in the tube which joins them.

M. Amontons, in 1702, with a view of perfecting the *aerial* thermometer, contrived his *universal* thermometer. Finding that the changes produced by heat and cold in the bulk of the air were subject to invincible irregularities, he substituted for these the variations produced by heat in the elastic force of this fluid. This thermometer consisted of a long tube of glass (see *fig.* 4.) open at one end, and recurved at the other end, which terminated in a ball. A certain quantity of air was compressed into this ball by the weight of a column of mercury, and also by the weight of the atmosphere. The effect of heat on this included air was to make it sustain a greater or less weight; and this effect was measured by the variation of the column of mercury in the tube, corrected by that of the barometer, with respect to the changes of the weight of the external air. This instrument, though much more perfect than those in the room of which it was substituted by its inventor, is nevertheless subject to very considerable defects and inconveniences. Its length of four feet renders it unfit for a variety of experiments, and its construction is difficult and complex: it is extremely inconvenient for carriage, as a very small inclination of the tube would suffer the included air to escape: and the friction of the mercury in the tube, and the compressibility of the air, contribute to render the indications of this instrument extremely uncertain. Besides, the dilatation of the air is not so regularly proportional to its heat, nor is its dilatation by a given heat nearly so uniform as he supposed. This depends, as the abbé Nollet has suggested, much on its moisture; for dry air does not expand near so much by a given heat, as air stored with watery particles; which by being converted into steam, very much increase the seeming volume of the air. For these and other reasons enumerated by M. de Luc, (Récherches sur les Mod. de l'Atm. tom. i. p. 278, &c.) this instrument was imitated by very few, and never came to be of general use.

Construction of the Florentine Thermometer.—The academists del Cimento, about the middle of the seventeenth century, considering the inconveniences of the air-thermometers above described, attempted another, that should measure heat and cold by the rarefaction and condensation of spirit of wine; though much less than those of air, and consequently to express any thing that warms the body, and by others particularly for a warm fomentation, prescribed by Hippocrates for removing pains in the side, and giving ease in pleurisies.

THERMES, in *Ancient Geography*, a town of Hispania Citerior, S. of Numantia.

THERMI, in *Geography*, a town of Asiatic Turkey, in the province of Natolia; 24 miles N. of Bursa.

THERMIA, an island in the Grecian Archipelago, so called from its abounding with hot springs. It is not so mountainous as some of the other islands, and the soil, when well cultivated, produces very large quantities of barley, wine, and figs. The island also affords plenty of honey, wax, partridges, a great quantity of fine silk, and as much cotton as the inhabitants require for their own use. The Greek Christians in this island are computed at 16,000. Thermia is the see of a bishop, and contains fifteen or sixteen churches, and several convents. On the island are still visible the ruins of two cities; one of which, on the south coast, must have been of extraordinary splendour. N. lat. 37° 20'. E. long. 24° 32'.

THERMIA, a town and capital of the island of Thermia. N. lat. 37° 24'. E. long. 24° 26'.

THERMOMETER, THERMOMETRUM, derived from θερμος, *heat*, and μετρον, *to measure*, an instrument shewing, or rather measuring, the increase and decrease of the heat and cold of the air.

The degree of heat, as ascertained by a thermometer, is only to be considered in relation to the surrounding bodies, by virtue of which a body supports the equilibrium of temperature, when it is in the neighbourhood of bodies equally heated: thus, if a thermometer stands at 60°, both in a vessel of water and in another of mercury, we may infer that the water and the mercury may be mixed without any change of their temperature; but the absolute quantity of heat contained in equal weights, or in equal bulks, of any two bodies at the same temperature, is by no means the same. See HEAT.

The general principles upon which the construction and use of thermometers, or measurers of heat depend, are stated and explained under the articles CALORIC, COLD, CONGELATION, FREEZING, HEAT, &c.

It will be sufficient to observe in this place, that the well-known and most general effect of heat, whether it be obtained by compressing a certain substance into a narrower space, so that a quantity of heat may come out of it and be communicated to certain bodies, or by expanding a certain substance into a larger space, so that it may absorb a quantity of heat from surrounding bodies, and thus cool these bodies, or in whatever other way it be procured, is a dilatation of bodies, or an augmentation of their bulks. The contrary effect is produced by cold, *i. e.* by a diminution of the free caloric. It must, however, be observed, that bodies of equal bulks, but of different kinds, are not expanded alike by being heated to the same degree; nor are the increments of bulk in the same body always proportional to the quantities of heat which are communicated to it. *E. gr.* if a given quantity of water, by being heated to a certain degree, be increased in bulk one cubic inch, the addition of double or treble that quantity of heat will not increase its bulk two or three cubic inches respectively; therefore the expansions of water are not proportional to the increments of heat.

The only practicable method of measuring the expansions of fluids, is by inclosing them in certain vessels, and by measuring that part of the cavity of each vessel which is occupied by the particular fluid which fills it in different temperatures. It is evident, that the substance of the vessel is also expanded by the heat, and of course its cavity is enlarged. Therefore, when we find that the bulk of the fluid is increased, that apparent increment is only the difference between the enlarged capacity of the vessel and the increased bulk of the fluid. For this reason those vessels must be made of such substances as are least expansible by heat. Indeed glass is the substance which is universally used for such purposes, both on account of its little expansibility, and of its transparency, besides its having other remarkably useful properties.

A glass vessel filled to a certain degree with a liquid, for the purpose of shewing the expansion of that liquid in different temperatures, or for the purpose of shewing the temperature by the corresponding expansion of that liquid, is called a *thermometer*.

The thermometer and thermoscope are ordinarily accounted the same thing: Wolfius, however, makes a difference; but shews, at the same time, that what we call thermometers are, in reality, no more than thermoscopes.

The invention of the thermometer is attributed to several persons by different authors, *viz.* to Sanctorio, Galileo, Father Paul, and Drebbel. The invention is ascribed to Cornelius Drebbelius of Alcmaer, about the beginning of the seventeenth century, by his countrymen Boerhaave (Chem. i. p. 152. 156.) and Muschenbroeck, Introd. ad Phil. Nat. vol. ii. p. 625.

Fulgenzio, in his life of Father Paul, gives him the honour of the first discovery. Vincenzio Viviani (Vit. de l'Galil. p. 67. See too Oper. di Galil. pref. p. 47.) speaks of Galileo as the inventor of thermometers. But Sanctorio himself (Com. in Galen. Art. Med. p. 736—842. Com. in Avicen. Can. Fen. i. p. 22. 78. 219.) expressly assumes this invention; and Borelli (De Mot. Animal. ii. prop. 175.) and Malpighi (Oper. Posth. p. 30.) ascribe it to him without reserve. Upon which Dr. Martine remarks, that these Florentine academicians are not to be suspected of partiality in favour of one of the Patavinian school. But whoever was the first inventor of this instrument, it was very rude and imperfect; and as the various degrees of heat were indicated by the different contraction or expansion of air, it was afterwards found to be an uncertain and sometimes a deceiving measure of heat, because the bulk of air was affected, not only by the difference of heat, but likewise by the variable weight of the atmosphere.

There are various kinds of thermometers; the construction, defects, theory, &c. of which, are as follow:

Construction of the Thermometer, depending on the Rarefaction of the Air.—This *aerial* thermometer, which was that first invented by Drebbel, consists of a glass tube B E (*Plate* XVI. *Pneumatics, fig.* 1.), connected at one end with a large glass ball A, and at the other end immersed in an open vessel, or terminating in a ball D E, with a narrow orifice at D; which vessel, or ball, contains any coloured liquor that will not easily freeze. Aqua fortis tinged of a fine blue colour with solution of vitriol or copper, or spirit of wine tinged with cochineal, or Brasil wood, will answer this purpose. But the ball, A, must be first moderately warmed, so that a part of the air contained in it may be expelled through the orifice D; and then the liquor pressed by the weight of the atmosphere will enter the ball D E, and rise, *e. g.* to the middle of the tube at C, at a mean temperature of the weather; and in this state the liquor by its weight, and the air included in the ball A, &c. by its elasticity, will counterbalance the weight of the atmosphere. As the surrounding air becomes warmer, the air in the ball and upper part of the tube, expanding by heat, will drive the liquor into the lower

lower ball, and consequently its surface will descend; on the contrary, as the ambient air becomes colder, that in the ball is condensed, and the liquor pressed by the weight of the atmosphere will ascend: so that the liquor in the tube will ascend or descend more or less, according to the state of the air contiguous to the instrument. To the tube is affixed a scale of the same length, divided upwards and downwards from the middle, C, into one hundred equal parts, by means of which the ascent and descent of the liquor in the tube, and consequently the variations in the cold or heat of the atmosphere, may be observed.

It must be acknowledged, that the expansion of elastic fluids affords, in some cases, a test of heat, which is very convenient from its great delicacy, and because a very small quantity of heat is sufficient to raise their temperature very considerably.

A similar thermometer may be constructed by putting a small quantity of mercury, not exceeding the bulk of a pea, into the tube B C (*fig.* 2.) thus bent in wreaths, that taking up the less height, it may be the more manageable and less liable to harm; divide this tube into any number of equal parts to serve for a scale.

Here the approaches of the mercury towards the ball, A, will shew the increase of the degree of heat. The reason is the same as in the former.

The defect of both these instruments consists in this, that they are liable to be acted on by a double cause: for, not only a decrease of heat, but also an increase of weight of the atmosphere, will make the liquor rise in the one, and the mercury in the other; and, on the contrary, either an increase of heat, or decrease of weight of the atmosphere, will make it descend.

In winter, for example, the liquor would rise and sink too much; for a frost condensing the internal air, the liquor would ascend, but as the air is heavier in frosty weather, its pressure on the liquor in the vessel D E (*fig.* 1.) being increased, would raise the liquor still higher in the tube, and thus indicate a degree of cold greater than it really is. On the other hand, if the weather grows warm, as it does in rainy weather in winter, the air in the ball will expand, and the liquor descend in the tube; but as the weight of the atmosphere is less in foul weather, the liquor in D E will be less pressed than it was, and suffer the liquor to descend more than it should do, and shew a greater degree of warmth than that of the ambient air. The reverse of this will happen in summer: for warm weather being fair weather, and the atmosphere being then heavier than usual, the liquor will be made to stand higher in the tube than it should do, and shew the degree of heat to be less than it really is. And as in summer, the weather becomes cold with rain; but the weight of the atmosphere being diminished, the liquor will not ascend so far as it ought to ascend by the condensation of the internal air, and therefore indicate the cold to be less than it really is: and when the two causes, thus contributing to the rise and fall of the liquor, act equally in opposite directions, the liquor would appear neither to ascend nor descend, whatever might be the changes in the temperature of the atmosphere, on account of equal corresponding variations in its gravity. Besides, the air in the ball, &c. is liable to be affected more or less in its elastic quality by the vapours that detach themselves from the included liquor according to the degree in which it is heated or cooled. For these and other measures, thermometers of this kind have been long disused.

Instruments of this kind, when they are subject to the variations of the pressure of the atmosphere, as well as to those of its temperature, are properly called manometers, and require, for enabling us to employ them as thermometers, a comparison with the barometer; while, on the other hand, they may be used as barometers if the temperature be otherwise ascertained. They are, however, very useful without this comparison, in delicate experiments of short duration; besides, the changes of the barometer are seldom very rapid, and they may also be wholly freed from the effects of the pressure of the atmosphere in various ways.

Bernouilli's method consists in closing the tube of a common barometer so as to leave the column of mercury in equilibrium with the air contained in the bulb at its actual temperature, and capable of indicating, by the changes of its height and of its pressure, any subsequent changes in the temperature of the air, which must affect both its bulk and its elasticity. (See *fig.* 3.) Mr. Leslie's photometer, or *Differential* THERMOMETER (which see), has some advantages which render it better than this instrument; but it can only be employed when the changes of the temperature can be confined only to a part of the instrument. The elasticity of the air contained in the bulb is here counteracted, not by the pressure of a column of mercury, but by the elasticity of another portion of air in a second bulb, which is not to be exposed to the heat or cold that is to be examined; and the difference of the temperatures of the two bulbs is indicated by the place of a drop of a liquid, moving freely in the tube which joins them.

M. Amontons, in 1702, with a view of perfecting the *aerial* thermometer, contrived his *universal* thermometer. Finding that the changes produced by heat and cold in the bulk of the air were subject to invincible irregularities, he substituted for these the variations produced by heat in the elastic force of this fluid. This thermometer consisted of a long tube of glass (see *fig.* 4.) open at one end, and recurved at the other end, which terminated in a ball. A certain quantity of air was compressed into this ball by the weight of a column of mercury, and also by the weight of the atmosphere. The effect of heat on this included air was to make it sustain a greater or less weight; and this effect was measured by the variation of the column of mercury in the tube, corrected by that of the barometer, with respect to the changes of the weight of the external air. This instrument, though much more perfect than those in the room of which it was substituted by its inventor, is nevertheless subject to very considerable defects and inconveniences. Its length of four feet renders it unfit for a variety of experiments, and its construction is difficult and complex: it is extremely inconvenient for carriage, as a very small inclination of the tube would suffer the included air to escape: and the friction of the mercury in the tube, and the compressibility of the air, contribute to render the indications of this instrument extremely uncertain. Besides, the dilatation of the air is not so regularly proportional to its heat, nor is its dilatation by a given heat nearly so uniform as he supposed. This depends, as the abbé Nollet has suggested, much on its moisture; for dry air does not expand near so much by a given heat, as air stored with watery particles; which by being converted into steam, very much increase the seeming volume of the air. For these and other reasons enumerated by M. de Luc, (Récherches sur les Mod. de l'Atm. tom. i. p. 278, &c.) this instrument was imitated by very few, and never came to be of general use.

Construction of the Florentine Thermometer.—The academists del Cimento, about the middle of the seventeenth century, considering the inconveniences of the air-thermometers above described, attempted another, that should measure heat and cold by the rarefaction and condensation of spirit of wine; though much less than those of air, and consequently fequently the alterations in the degree of heat likely to be much lefs fenfible.

The fpirit of wine was enclofed in glafs tubes, hermetically fealed; fo that thefe thermometers could be fubject to no inconvenience by the evaporation of the liquor, or the variable gravity of the incumbent atmofphere. Inftruments of this kind were firft introduced into England by Mr. Boyle, and they were foon univerfally ufed among philofophers in other countries. The *Florentine* thermometer confifts of a fmall narrow tube B C D (*fig.* 5.) connected with a glafs ball A. The tube fhould be procured as cylindric as poffible: and it may be tried, by putting into one end of it as much mercury as will fill the length of one inch, and letting this quantity of mercury pafs from one part of the tube to another, through its whole length; meafure with compaffes the length it occupies in every part of the tube; and if it every where takes up an inch, the tube is cylindric, and a fcale of equal divifions will agree with it: otherwife it will be longer where the tube is fmaller, and fhorter than an inch where the tube is larger; and in this cafe, the divifions muft be fuited to the contents of the bore. The glafs ball may then be joined to the tube, and a fmall cavity be made at the other end. Fill the ball and tube with rectified fpirit of wine to a convenient height, as to C, when the weather is of a mean temperature, which may be done by inverting the tube into a veffel of ftagnant coloured fpirit, under a receiver of the air-pump, or by many other ways. The fpirit may be coloured by pouring a quantity of it on fmall pieces of turmeric, which will hereby receive a red tincture; and the fpirit may be repeatedly filtrated through brown paper, in order to feparate from it the coarfer particles of the root. Some perfons, in filling the ball and tube, for preventing the fpirit from wholly defcending into the ball in winter, recommend putting the ball into a lump of fnow, mixed with falt; or if the inftrument be made in fummer, into fpring-water impregnated with falt-petre, that the condenfed fpirit may fhew how far it will retire in extreme cold. If it rifes to too great a height from the ball, part of it is to be taken out; and that the tube may not be made longer than neceffary, it is convenient to immerge the ball, filled with its fpirit in boiling water, and to mark the fartheft point to which it then rifes. When the thermometer is properly filled, with a lamp heat the little bubble left at the end of D red-hot, and feal it hermetically, leaving, as Dr. Defaguliers recommends, in the thermometer only the third part of the air that was in it, which will give room to the dilatation of the fpirit; and this rarefied air will prevent the air left in the fpirit, even after the air-pump has been applied, from dividing the fpirit by its expanfion. To the tube apply a fcale, divided into one hundred equal parts, from C towards D, and alfo from C towards B.

Now, fpirit of wine rarefying and condenfing very confiderably; as the heat of the ambient air increafes, the fpirit will dilate, and confequently will afcend in the tube; and as the heat decreafes, the fpirit will defcend: and the degree or quantity of afcent and defcent will be feen in the fcale. Yet as the ratio of yefterday's heat to to-day's is not hereby difcovered, this inftrument is not ftrictly a thermometer, any more than the former.

It is to be here obferved, 1. That as the natural gravity of the liquor makes it tend downwards, fo it refifts its afcent out of the ball into the tube; and that the more, as it rifes higher; for which reafon, fome have advifed to have the tube horizontal.

2. Since there muft of neceffity be fome air left in the void part of the tube, over the liquor, that air, by its elafticity, will tend downwards, and of confequence will refift the rife of the liquor, and be compreffed by it as it does rife: its elafticity therefore is thus increafed.

3. Since it is found from experience, that a lefs degree of heat is communicated more eafily to the fpirit of wine in the ball than a greater, the rarefactions of the fpirit of wine are not proportionable to their producing caufes; efpecially fince a greater degree of heat finds more liquor in the tube than a lefs does, to which, notwithftanding, the heat may be more eafily communicated than to that ftagnating in the ball.

4. Spirit of wine is incapable of bearing very great heat or very great cold. It boils fooner than any other liquor, and, therefore, the degrees of heat of boiling fluids cannot be determined by this thermometer. And though it retains its fluidity in pretty fevere cold, yet it feems not to condenfe very regularly in them: and at Torneo, near the polar circle, the winter cold was fo fevere, as Maupertuis informs us, that the fpirits were frozen in all their thermometers. So that the latitude of heat and cold, which fpirit of wine is capable of indicating, is much too limited to be of very great or univerfal ufe. On thefe accounts, the Florentine thermometer, though it has been much ufed, is far from being an accurate meafure of heat, &c. to which may be added what Dr. Halley obferves in the Philofophical Tranfactions, that he has learned from thofe who have kept fpirit of wine long, that it always lofes part of its expanfive force in courfe of time.

This objection, fuggefted by Dr. Halley, and often infifted on by others, has, according to Dr. Martine, no great weight. Well rectified fpirit of wine, if fealed up in a glafs, is in a confiderable degree unalterable. It cannot evaporate; and by many years experience its force of expanfion has continued the fame; as, befide other obfervations, we know efpecially from the Annual Regifters of M. de la Hire's fpirit thermometer, that have been kept in the Obfervatory for many years.

Another great defect of thefe, and other thermometers, is, that their degrees are not comparable with each other. They mark, indeed, the different degrees of heat and cold; but each marks only for itfelf, and after its own manner; becaufe they do not proceed from any point of heat, or cold, that is common to them all. It is with them as with two clocks, which for want of having been firft fet to the fame hour by the fun, will, indeed, mark that one, two, or more hours are paffed, but not what hour it is by the day. Nor can we be affured, that when the liquor is rifen a degree in two different thermometers, they have both fuffered the fame impreffion of an equal additional heat: fince the fpirit of wine may not be the fame in both; and, in proportion as the fpirit is more or lefs rectified, it will rife more or lefs high by the fame heat. Nor is this all; for in graduating thermometers, they often take equal lengths of the tube for equal afcents of the fpirit: whereas, fuppofing the diameters of the tube equal throughout, which very rarely happens, there are fo many irregularities withinfide, that a certain length of tube fometimes requires double the quantity of liquor to fill it, that the fame length in another tube of the fame diameter requires. All which arifes from the unequal thickneffes of the parietes of tubes in different places; and from accidental prominences and cavities, always found in the inner furfaces of tubes; and efpecially from their being always bigger at one end than the other.

Befides, the divifions of the fcale cannot accurately indicate the quantity of rarefaction, unlefs the proportion of the cavity of the tube D B to that of the ball A were known. Hence it is, that the comparifon of thermometers becomes fo precarious and defective. Yet the moft curious and interefting ufe of thermometers is, what ought to arife from fuch ſuch compariſon. It is by this we ſhould know the heat or cold of another ſeaſon, of another year, another climate, &c. and what is the greateſt degree of heat or cold in which men and other animals can ſubſiſt.

M. de Reaumur contrived a new thermometer for the purpoſe; wherein the inconveniences above recited are propoſed to be remedied. He took a large ball and tube, and knowing the content of the ball as well as that of the tube in every part, he graduated the tube, ſo that the ſpace from one diviſion to another might contain a thouſandth part of the liquor, which liquor would contain one thouſand parts when it ſtood at the freezing point: then putting the ball of his thermometer, and part of the tube, into boiling water, he obſerved whether it roſe eighty diviſions; and if it exceeded theſe, he changed his liquor, and by adding water lowered it, ſo that on the next trial from the freezing point to the point of boiling water, it ſhould only riſe eighty diviſions: but if the liquor, being too low, fell ſhort of eighty diviſions, he raiſed it by adding rectified ſpirit to it. The liquor thus prepared ſuited his purpoſe, and ſerved for making a thermometer of any ſize, whoſe ſcale would agree with his ſtandard. Such liquor, or ſpirits, being about the ſtrength of common brandy, may eaſily be had any where, or made of a proper degree of denſity by raiſing or lowering it.

The abbé Nollet made many excellent thermometers upon M. de Reaumur's principle. Dr. Martine, however, expreſſes his apprehenſions that thermometers of this kind are conſtructed on principles, that will by no means be found ſo accurate as were to be wiſhed and expected. The balls, or bulbs, being large, as three or four inches in diameter, are neither heated nor cooled ſoon enough to ſhew the variations in the heat of bodies, and in the weather. Small bulbs and ſmall tubes, he ſays, are much more convenient, and may be conſtructed with ſufficient accuracy. Though it muſt be allowed, that Reaumur, by his excellent ſcale, and by depriving the ſpirit of wine of its air, and expelling the air by means of heat from the ball and tube of his thermometer, has brought it to as great a degree of perfection as it may poſſibly admit; yet it is liable to ſome of the inconveniences of *ſpirit* thermometers, and much inferior to the *mercurial* thermometers. Thermometers of this kind, and thoſe of mercury, do not agree in indicating the ſame degrees of extreme cold; for when the mercury has ſtood at 22° below 0, the ſpirit indicated only 18°; and when the mercury ſtood at 28° or 37° below 0, the ſpirit reſted at 25° or 29°. See the deſcription of Reaumur's thermometer at large in Mem. de l'Acad. R. des Scienc. an. 1730, p. 645. Hiſt. p. 15. Ibid. an. 1731, p. 354. Hiſt. p. 7.

In 1740, M. Micheli du Creſt conſtructed a ſpirit thermometer, to which he annexes four ſcales beſides its own, *viz.* that of the old thermometer in the Obſervatory at Paris, Reaumur's, de l'Iſle's, and Fahrenheit's. See *Fixed Points of* THERMOMETERS.

THERMOMETER, *Mercurial.* It is a circumſtance of principal importance in the conſtruction of thermometers, to procure a fluid that meaſures equal variations of heat by correſponding equal variations in its own bulk or volume: and the fluid which poſſeſſes this eſſential requiſite in the moſt perfect degree is mercury: the variations in its bulk approaching nearer to a proportion with the correſponding variations of its heat than any other fluid. This general propoſition M. de Luc has very elaborately evinced, by ſhewing that the condenſations of fluids, which increaſe in bulk when they freeze, are not proportional to the diminutions of heat; and that the dilatations of fluids, which are eaſily converted into vapour by heat, are not proportional to the augmentations of heat: whereas the bulk of mercury is not enlarged when it freezes, and it reſiſts evaporation more than every other liquid that has been uſed in the conſtruction of thermometers. Beſides, it is of all liquids the moſt eaſily purged of its air. It is alſo the moſt proper for meaſuring very conſiderable variations of heat; for, if a ſcale be graduated with 0 at the point of melting ice, and 80 at that of boiling water, mercury well purged of its air will indicate ſeven times this difference of heat, or 561 degrees in ſuch a ſcale; as it will condenſe without freezing to — 261 of this ſcale, and expand without boiling to 300 of the ſame ſcale. Mercury is alſo more ſenſible than any other fluid, air excepted, and conforms more readily to the ſeveral variations of heat. Moreover, as mercury is an homogeneous fluid, it will in every thermometer exhibit the ſame dilatation or condenſation by the ſame variations of heat. The expanſion of mercury is ſcarcely leſs regular than that of ſolids, which probably approaches the neareſt to the ſteps of the natural ſcale, though not without ſome inequality; and therefore a portion of mercury incloſed in a bulb of glaſs, having a fine tube connected with it, forms a thermometer the moſt convenient and probably the moſt accurate of any, for common uſe; the degrees correſponding very nearly with thoſe of the natural ſcale, although, according to the moſt accurate experiments, they appear to indicate, towards the middle of the common ſcale of Fahrenheit, a temperature two or three degrees too low. There is an inequality of the ſame kind, but ſtill greater, in the degrees of the ſpirit thermometer; and this inſtrument has alſo the diſadvantage of being liable to burſt in a heat below that of boiling water; nevertheleſs, it is well calculated for the meaſurement of very low temperatures, ſince pure alcohol has never yet been frozen, while mercury has been reduced to a ſolid by the cold of Siberia and of Hudſon's Bay; but both mercury and linſeed oil ſupport a heat of between 500° and 600°, without ebullition.

In order to render thermometers uniform and comparable, it is deſirable that mercury, ſo excellently adapted for this purpoſe, ſhould be the only fluid uſed in the conſtruction of them, more eſpecially as a thermometer with mercury may be more eaſily conſtructed than any others. De Luc's Récherches, &c. vol. i. part ii. cap. 2. paſſim.

Dr. Halley, though appriſed only of ſome of the remarkable properties of mercury above recited, ſeems to have been the firſt who ſuggeſted the application of this fluid to the conſtruction of thermometers. Phil. Tranſ. Abr. vol. ii. p. 34.

Boerhaave (Chem. i. p. 720.) ſays, theſe mercurial thermometers were firſt contrived by Olaus Roemer; but the claims of Fahrenheit of Amſterdam, who gave an account of his invention to the Royal Society in 1724 (Phil. Tranſ. N° 381, or Abr. vol. vii. p. 49.), have been generally allowed. And though Prins and others, in England, Holland, France, and other countries, have made this inſtrument as well as Fahrenheit, moſt of the mercurial thermometers are graduated according to his ſcale, and are called *Fahrenheit's* thermometers. Theſe are made of different lengths, and with ſome variation in the form of the bulb, according to the purpoſes for which they are deſigned. Inſtead of the ball, uſed in the ſpirit thermometer, a cone or cylinder is annexed to the tube, which may be eaſily enlarged or diminiſhed, and made of ſuch a magnitude, that its capacity may have a certain and known proportion to that of the tube; and by this means ſeveral thermometers may be conſtructed to the ſame ſcale: beſides, the heat more eaſily penetrates and reaches the inmoſt parts of the cylindric bulb, and cauſes the whole content to expand uniformly, and the mercury to riſe almoſt immediately; whereas in thermometers with a ſpherical bulb it is ſeen firſt to fall, and then to riſe. This phenomenon has been long ſince noticed both in Florentine and mercurial thermometers, when they are ſuddenly plunged into a heated liquor, the ſpirit of wine or mercury firſt deſcends, and then aſcends; and when they are plunged into a cold fluid, the included liquor firſt aſcends and then deſcends: this is the more remarkable in thermometers whoſe bulb is made of thick glaſs; and the reaſon of the phenomenon is obvious. The bulb of glaſs is ſooner affected by the heat or cold applied to it than the included fluid; and as the glaſs expands by heat, the capacity of the bulb is enlarged, and the liquor deſcends in the tube, but being condenſed by cold, and its capacity diminiſhed, the liquor is preſſed upwards in the tube: and both theſe effects continue till the heat and cold equally affect the incloſed fluid. Hence it follows, that all the variations of aſcent and deſcent, to which the ſpirit or mercury is ſubject in the thermometer, are only the difference of the rarefactions and condenſations of glaſs, and of the contained fluid. Hiſt. Ac. Royal, 1705.

The cone, or cylinder, of the thermometer is made of glaſs of a moderate thickneſs, leſt, when the exhauſted tube is hermetically ſealed, its internal capacity ſhould be diminiſhed by the weight of the ambient atmoſphere. When the mercury is thoroughly purged of its air and moiſture by boiling, the thermometer is filled with a ſufficient quantity of it; and before the tube is hermetically ſealed, the air is wholly expelled by heating the mercury, ſo that it may be rarefied and aſcend to the top of the tube. To the ſide of the tube is annexed a ſcale (ſee *fig.* 4.) which Fahrenheit divided into ſix hundred parts, beginning with that of the ſevere cold which he had obſerved in Iceland in 1709, or that produced by ſurrounding the bulb of the thermometer with a mixture of ſnow or beaten ice and ſal ammoniac or ſea-ſalt. This he apprehended to be the greateſt degree of cold, and accordingly he marked this, as the beginning of his ſcale, with 0; the point at which mercury begins to boil, he conceived to ſhew the greateſt degree of heat, and this he made the limit of his ſcale. The diſtance between theſe two points, he divided into ſix hundred equal parts or degrees; of which 32 reckoned from 0, indicates the degree of cold when ſnow or ice thaws naturally, or water begins to freeze, and this is called the *freezing point:* and he marked the heat of boiling water with 212, &c. In order more particularly to explain the diviſions of this ſcale, and to ſhew how the dilatation and condenſation of the mercury are eſtimated by it, we may obſerve that the bulb is ſuppoſed to contain, according to Boerhaave and Muſchenbroek, 11124 parts of quickſilver, which ſtands at the loweſt mark, or *gr.* 0, in an intenſe cold, &c. as above determined: if the bulb be immerged in ſnow or ice thawing naturally, or in water beginning to freeze, the quickſilver is dilated, and riſes in the tube 32 of theſe 11124 parts; and therefore the ſpace of the tube from *gr.* 0 to the freezing point *gr.* 32, is divided into thirty-two equal parts. When the thermometer is placed in water brought to a ſtrong boiling at a middle ſtate of the atmoſphere in places near the level of the ſea, when the mercury in the barometer ſtands at about 30 inches or a very little under it, the quickſilver is dilated 212 of theſe parts beyond its original bulk of 11124, ſo as now to poſſeſs in the bulb and tube together a ſpace equal to 11336 ſuch parts; and the ſpace from *gr.* 32 to *gr.* 212, is divided into 180 equal parts or degrees of the thermometer; which, if the tube be long enough, may be protracted as far as is convenient. It may extend well enough to *gr.* 600, and not much farther, for with a heat but little greater than that the mercury begins to boil.

Dr. Boerhaave, in one place, makes the number of parts into which the mercury in the bulb is ſuppoſed to be divided to be 10782 inſtead of 11124, and in another place ſtates it at 11520, which Dr. Martine apprehends to be nearer the truth, or about 11790 parts; and he thinks the eaſieſt and ſureſt method is to fill the bulb and tube, without being ſolicitous about the bulk of the quickſilver, ſo that in freezing water, or melting ice, the mercury ſhall ſtand at a convenient height, which muſt be very nicely marked *gr.* 32; and then as accurately to obſerve where it ſtands when dilated by the heat of boiling water to *gr.* 212. The intermediate ſpace is then divided into 180 degrees, which ſcale may be protracted upwards or downwards as far as we ſhall judge convenient. See *Fixed Points of* THERMOMETERS.

In the above method of graduating the ſcale, the bore of the tube is ſuppoſed to be perfectly cylindric, which cannot always be obtained. But though it be tapering or ſomewhat unequal, it is eaſy to manage that matter, in the manner propoſed by the abbé Nollet (Leçons de Phyſ. Exp. tom. iv. p. 376.) by making a ſmall portion of the quickſilver, *e. g.* as much as fills up an inch or half an inch, ſlide backward and forward in the tube; and thus to find the proportions of all its inequalities, and from thence to adjuſt the diviſions to a ſcale of the moſt perfect equality. See *Obſervations on the Conſtruction of* THERMOMETERS.

Other thermometers of a ſimilar conſtruction have been accommodated to common uſe, the ſcale of which is only a part of that above deſcribed. They have been made of a ſmall ſize and portable form, and the tube with its annexed ſcale has been encloſed in another thicker glaſs hermetically ſealed, in order to preſerve it from injury. Mr. Ramſden, at the deſire and for the uſe of Mr. Hunter in his experiments on the heat of animals and vegetables, conſtructed very ſmall thermometers, ſix or ſeven inches long, and not above two twelfths of an inch thick in the ſtem; having the external diameter very little larger than that of the ſtem, on which was marked the freezing point. The ſtem was embraced by a ſmall ivory ſcale, ſo as to ſlide upon it eaſily, and retain any poſition. Upon the hollow ſurface of this ſcale were marked the degrees which were ſeen through the ſtem. Phil. Tranſ. vol. lxviii. part i. p. 8.

Several varieties of thermometers are conſtructed for philoſophical purpoſes. For comprehending the whole range of thermometrical temperature from the moſt intenſe artificial cold to the boiling point of mercury, it is neceſſary to be provided with a very long tube; but for moſt chemical purpoſes, it need only be graduated to about ten degrees above the boiling point, which will reach the temperature of moſt ſaline ſolutions when boiling. For experiments in intenſe cold, a ſpirit thermometer ſhould be graduated about 100 degrees below 0, and the lower extremity of the ſcale ſhould be at ſome diſtance from the bulb, that the temperature may be obſerved without lifting the bulb out of any deep veſſel that may contain the freezing mixture. The moſt delicate and ſenſible thermometers are made with a very ſmall bulb, ſcarcely larger than the ſtem, and a tube of an extremely narrow bore, not larger than a horſe-hair. For chemical purpoſes alſo, the ſcale ſhould either be ſcratched on the glaſs itſelf, or, as this is difficult to be ſeen in a common light, an ivory ſcale ſhould be attached without reaching ſo low as the bulb, that the latter may be ſafely immerſed in acid or corroſive liquors.

In

In 1733, M. de l'Isle of Petersburg constructed a *mercurial* thermometer (see *fig.* 4.) on the principles of Reaumur's *spirit* thermometer. In his thermometer, the whole bulk of quicksilver, when immerged in boiling water, is conceived to be divided into 10,000, or rather 100,000 parts; and from this one fixed point, the various degrees of heat, either above or below it, are marked in these parts on the tube or scale, by the various expansion or contraction of the quicksilver in all the imaginable variety of heat. Dr. Martine apprehends it would have been better if M. de l'Isle had made the integer of 100,000 parts, or fixed point at freezing water, and from thence computed the dilatations or condensations of the quicksilver in those parts. All the common observations of the weather, &c. would have been expressed by numbers increasing as the heat increased, which is the more natural way; nor would there have been any great incongruity, or inconvenience, in expressing, after the manner of Reaumur, the few observations that occur below simple freezing by numbers of contraction below *gr.* 0, or 100,000. However, in practice, it will not be very easy to determine exactly all the divisions from the alteration of the bulk of the contained fluid. And besides, as glass itself is dilated by heat, though in a less proportion than quicksilver, so that it is only the excess of the dilatation of the contained fluid above that of the glass that is observable; if different kinds of glass be differently affected by a given degree of heat, this will make a seeming difference in the dilatation of the quicksilver in the thermometers, constructed in the Newtonian method, either by M. de Reaumur's or M. de l'Isle's rules. Accordingly, it has been found, that the quicksilver in thermometers, constructed in M. de l'Isle's way, has stood at different degrees of the scale when immerged in thawing snow. In some it was at *gr.* 154, in others at 156, and in another at 158: and it appears by M. de l'Isle's own account, that his thermometers disagree considerably from one another. *Celsius's* thermometer has been chiefly used in Sweden, and hence it has been called the *Swedish* thermometer. The French chemists have lately adopted it, under the name of *centigrade* thermometer. See *Fixed Points of* THERMOMETERS, and the table at the close of this article.

THERMOMETER, *Metalline*, is a name given to a machine composed of two metals, which, whilst it indicates the variations of cold and heat, serves to correct the errors that result from hence in the construction of pendulum clocks. Instruments of this kind have been contrived by Graham, Le Roy, in 1738, Ellicot, Harrison, &c. See *Compound* PENDULUM.

We have also an account of instruments of this kind invented by Mortimer, Frotheringham, and Fitzgerald, in the Phil. Trans. vol. xliv. p. 689, vol. xlv. p. 129, and vol. li. p. 823; to which we must refer for a particular description of each, illustrated by figures.

M. de Luc has likewise described two thermometers of metal, which he uses for correcting the effects of heat upon a barometer, and an hygrometer of his construction connected with them. In one of these, a strong rod of well-hardened brass, supports upon an edge, at a convenient distance from the centre of motion, a lever, which holds the scale of the barometer suspended, and makes it rise or fall by the dilatation or condensation of the brass rod, as the quicksilver rises or falls in the barometer, by the corresponding variations of heat. This scale of the barometer, when it moves, draws or loosens a thread of silk-grass, which goes over a small pulley placed upon the same axis with a much larger one, to which the scale of the hygrometer is hung likewise by a similar thread, which thus varies, by the proportion of the diameters of the pulleys, as the heat makes the quicksilver in the hygrometer vary. This instrument is convenient for meteorological observations: because it saves one observation and two corrections for the heat; but it is necessary from time to time to correct an irregularity in it, which is easily perceived by means of an index, carried by the moveable scales of the two instruments, which, going over immoveable scales of the same sort, shews their difference of height. When this difference is no longer conformable to the indication of the thermometer, it is easily rectified by turning small pegs, on which is twisted the thread of silk-grass, which serves for the suspension of the scales. The irregularity just mentioned consists in this, that when the heat, after having varied, returns to the same point of the quicksilver thermometer, the metallic thermometer does not return to it exactly, but varies nearly in the following manner: during the summer, the latter gains constantly on the former, *i. e.* amidst its variations, it always preserves a small part of the lengthening, which is at that time its ordinary state. In winter, on the contrary, it becomes insensibly a little too short. The other metallic thermometer, which is more curious than useful, on account of its greater irregularity, consists of a rod of lead, which, communicating by a thread of silk-grass with a small pulley fixed to the same axis with a greater one, conducts, by means of another pulley, a needle through whose axis, which is bored, passes another axis that carries the needle of a pulley barometer. Thus this instrument marks the heat and weight of the air upon two concentric circles, by means of two needles turning upon the same centre, as in clocks; besides which, the needle of the thermometer points out upon a third circle the correction for the heat, to be made on the barometer. See Phil. Trans. vol. lxviii. part i. p. 437, &c.

THERMOMETERS, *Oil.* To this class belongs sir Isaac Newton's thermometer, constructed in 1701, with linseed oil instead of spirit of wine. This liquor has the advantage of being sufficiently homogeneous, and capable of a considerable rarefaction, not less than fifteen times greater than that of spirit of wine. It has not been observed to freeze even in very great colds, and it is able to bear a great heat, about four times that of water, without boiling. With these advantages it was made use of by sir Isaac Newton, who discovered by it the comparative degree of heat for boiling water, melting wax, boiling spirit of wine, and melting tin; beyond which it does not appear that this thermometer was applied. The method he used for adjusting the scale of this oil-thermometer was as follows: supposing the bulb, when immerged in thawing snow, to contain 10,000 parts, he found the oil expanded by the heat of the human body so as to take up one thirty-ninth more space, or 10256 such parts; and by the heat of water boiling strongly, 10725; and by the heat of melting tin, 11516. So that, reckoning the freezing point as a common limit between heat and cold, he began his scale there, marking it *gr.* 0, and the heat of the human body he made *gr.* 12; and, consequently, the degrees of heat being proportional to the degrees of rarefaction, or 10256 : 10725, *i. e.* 256 : 725 :: 12 : 34, the heat of boiling water was expressed by *gr.* $34 = \frac{725 \times 12}{256}$; and that of the melting tin by *gr.* 72. Phil. Trans. No. 270, or Abr. vol. iv. part ii. p. 3.

Although in this graduation sir Isaac Newton does not specify any degree of cold below that of freezing water, yet it would be easy to protract his scale downward below *gr.* 0, or the freezing point, and thus to adapt it for estimating greater degrees of cold, like other thermometers. But there is another insuperable inconvenience that attends all ther-

thermometers made with oil, or any other viſcid liquor, *viz.* that ſuch a liquor adheres too much to the ſides of the tube. In a ſudden cold or fall of the oil, much of it ſticks by the way, and only ſinks gradually afterwards, ſo that at firſt the ſurface appears really lower than the preſent temperature requires. And beſides, as at all times ſome of the oil muſt continue to ſtick and moiſten the inſide of the tube, in different degrees of heat and cold, the oil, becoming alternately more or leſs viſcid, will adhere ſometimes more and ſometimes leſs; and will, therefore, inevitably diſturb the regularity and uniformity of the thermometer. Martine's Eſſays, Eſſ. iii.

Thermometers, *Fixed Points of.* Various methods have been propoſed by various authors, for finding a fixed point, or degree, of heat and cold, from which to reckon the other degrees, and adjuſt the ſcale; ſo that obſervations made at the ſame or different times, in different places, might be compared together. For want of this, notwithſtanding all the numerous regiſters of the weather, &c. that have been kept and publiſhed by different authors, we are much at a loſs to determine the comparative differences of heat and cold in different countries and climates, and the reſult of many other obſervations. If all the weather-glaſſes in the world had been made according to one determined ſcale, theſe inconveniences and uncertainties would have been prevented; which, indeed, are now unavoidable, and muſt ſtill continue ſo, till all agree to graduate their thermometers in the ſame manner, or at leaſt determine ſome fixed or unalterable points of heat, to which all the different ſcales of thoſe inſtruments may be reduced. The honourable Mr. Boyle was very ſenſible of this inconvenience, and much laments it; and he propoſed the freezing of the eſſential oil of aniſeeds, as a term of heat and cold that might be of uſe in making and judging of thermometers, and ſo to graduate them from this point according to the proportional dilatations or contractions of the included ſpirits. He mentioned alſo the coldneſs requiſite to begin the congelation of diſtilled water as another fixed term that might be adopted; for he was perſuaded, that among the ordinary waters, ſome were apt to freeze more eaſily than others. But he was deterred from proſecuting this ſcheme of fixing a ſtandard for making and graduating all thermometers in the ſame way. Experiments, &c. on cold, in his works abridged by Shaw, vol. i. p. 579.

Dr. Halley (Phil. Tranſ. Abr. vol. ii. p. 36.) ſeems to have been fully apprized of the bad effects of the indefinite method of conſtructing thermometers, and wiſhed to have them adjuſted to ſome determined points. What he ſeems to prefer for this purpoſe is the degree of temperature which is found in ſubterranean places, where the heat in ſummer and cold in winter appears to have no influence. But this degree of temperature is ſhewn by Dr. Martine to be a term for the univerſal conſtruction of thermometers, both inconvenient, as it cannot be eaſily aſcertained; and a precarious one, as the difference of ſoils and depths may occaſion a conſiderable variation. Another term of heat which he thought might be of uſe in a general graduation of thermometers, is that of boiling ſpirit of wine that has been highly rectified: but a much more convenient term of heat, though leſs inſiſted on by Dr. Halley, is that of boiling water. The firſt trace that occurs of the method of actually applying fixed points or terms to the thermometer, and of graduating it, ſo that the unequal diviſions of it might correſpond to equal degrees of heat, is the project of Renaldinus, profeſſor, of Padua, in 1694: it is thus deſcribed in the Acta Erud. Lipſ. "Take a ſlender tube, about four palms long, with a ball faſtened to the ſame; pour into it ſpirit of wine, enough juſt to fill the ball, when ſurrounded with ice, and not a drop over: in this ſtate, ſeal the orifice of the tube hermetically, and provide twelve veſſels, each capable of containing a pound of water, and ſomewhat more; and into the firſt pour eleven ounces of cold water, into the ſecond ten ounces, into the third nine, &c.: this done, immerge the thermometer in the firſt veſſel, and pour into it one ounce of hot water, obſerving how high the ſpirit riſes in the tube, and noting the point with unity: then remove the thermometer into the ſecond veſſel, into which are to be poured two ounces of hot water, and note the place the ſpirit riſes to with 2. By thus proceeding till the whole pound of water is ſpent, the inſtrument will be found divided into twelve parts denoting ſo many terms or degrees of heat; ſo that at 2 the heat is double to that at 1, at 3, triple, &c."

But this method, though plauſible, Wolfius ſhews, is deceitful, and is built on falſe ſuppoſitions; for it takes for granted, that we have one degree of heat, by adding one ounce of hot to eleven of cold water; two degrees, by adding two ounces to ten, &c.: it ſuppoſes, alſo, that a ſingle degree of heat acts on the ſpirit of wine in the ball with a ſingle force; a double with a double force, &c. laſtly, it ſuppoſes, that if the effect be produced in the thermometer by the heat of the ambient air, which is here produced by the hot water, the air has the ſame degree of heat with the water.

Soon after this project of Renaldinus, *viz.* in 1701, ſir Iſaac Newton conſtructed his *oil* thermometer, and fixed the baſe or loweſt fixed point of his ſcale at the temperature of thawing ſnow, and twelve at that of the human body, &c. in the manner explained under the article *Oil* Thermometer.

M. de Luc obſerves, that the ſecond term of his ſcale ſhould have been at a greater diſtance from the firſt, and that the heat of boiling water would have anſwered this purpoſe better than that of the human body.

In 1702, M. Amontons contrived his *univerſal* thermometer, the ſcale of which was graduated in the following manner. He choſe for the firſt term the weight that counterbalanced the air included in his thermometer, when it was heated by boiling water: and in this ſtate he ſo adjuſted the quantity of mercury contained in it, till the ſum of its height in the tube, and of its height in the barometer at the moment of obſervation, was equal to ſeventy-three inches. Fixing this number at the point to which the mercury in the tube roſe by plunging it into boiling water, it is evident, that, if the barometer at this time was twenty-eight inches, the height of the column of mercury in the thermometer above the level of that in the ball was forty-five inches; but if the height of the barometer was leſs by a certain quantity, the column of the thermometer ought to be greater by the ſame quantity, and reciprocally. He formed his ſcale on the ſuppoſition that the weight of the atmoſphere was always equal to that of a column of mercury of twenty-eight inches, and divided it into inches from the point 73 downwards, marking the diviſions with 72, 71, 70, &c. and he ſubdivided the inches into lines.

But as the weight of the atmoſphere is variable, the barometer muſt be obſerved at the ſame time with the thermometer, that the number indicated by this laſt inſtrument may be properly corrected, by adding or ſubtracting the quantity of which the mercury is below or above twenty-eight inches in the barometer. In this ſcale, then, the freezing point is at $51\frac{1}{2}$ inches, correſponding to *gr.* 32 of Fahrenheit, and the heat of boiling water at 73 inches,

inches, anfwering to *gr.* 212 of Fahrenheit's: and thus they may be eafily compared together.

The fixed points of Fahrenheit's thermometer, which is generally ufed in Great Britain, (as we have already obferved under *Mercurial* THERMOMETER,) are the congelation produced by fal ammoniac and the heat of boiling water. The interval between thefe points is divided into 212 equal parts; the firft of thefe points is marked 0, 32 degrees below the freezing point, and the other 212; the diftance of courfe between the freezing and boiling points being 180. The reafon why Fahrenheit fixed his fcale fo far below the water-freezing point was founded on an erroneous hypothefis relative to the real *zero* or point of abfolute privation of heat; neverthelefs it has this advantage, that the diftinction between the pofitive and negative terms, or thofe which exprefs degrees above or below the *zero*, much lefs frequently occurs in any experiments, and fcarcely ever in the regifter of natural cold in temperate climates, by which many accidental errors are avoided. Reaumur, in his thermometer, the conftruction of which he publifhed in 1730, and which is generally ufed in France and other parts of the continent, begins his fcale at an artificial congelation of water in warm weather, which, as he ufes large bulbs for his glaffes, gives the freezing point much higher than it fhould be, and at boiling water he marks *gr.* 80, (the diftance between both points being 80,) which point Dr. Martine apprehends to be more vague and uncertain than his freezing point. The fpirit in the thermometer, he obferves, is abfolutely incapable of fuch a great heat as Reaumur afcribed to it, and that not by a fmall or trifling difference. He finds, that highly rectified fpirit of wine cannot be heated beyond *gr.* 175 in Fahrenheit's thermometer, while boiling water raifes the quickfilver 37 degrees higher; and common brandy was able to conceive a heat no greater than about *gr.* 190. So far, he concludes, was Reaumur in the wrong, when he thought that all fpirits, weak and ftrong, immerged in boiling water, received a given degree of heat, and that equal to the heat of the furrounding water. He fuppofes his ftandard heat could take a heat only of about *gr.* 180; lefs by 32 degrees than what he reckoned. In order to determine the correfpondence of his fcale with that of Fahrenheit, it is to be confidered that his boiling-water heat is really only the boiling heat of weakened fpirit of wine, coinciding nearly, as Dr. Martine apprehends, with Fahrenheit's *gr.* 180. And as his *gr.* $10\frac{1}{4}$ is the conftant heat of the cave of the obfervatory at Paris, or Fahrenheit's *gr.* 53, he thence finds his freezing point, inftead of anfwering juft to *gr.* 32, to be fomething above *gr.* 34.

The thermometer of M. de l'Ifle, of which he prefented an account to the Academy of Sciences at Peterfburg in 1733, has only one fixed point, which is the heat of boiling water, and, contrary to the common order, the feveral degrees are marked downwards from this point or *zero*, according to the condenfations of the contained quickfilver, and confequently by numbers increafing as the heat decreafes to 150, the freezing point. In order to determine the extent of the degrees of this fcale, M. de l'Ifle firft weighed the empty tube, and then weighed it full of mercury; and the difference of thefe two weights gave him that of the mercury. He then expofed the thermometer to the heat of boiling water, and took care to preferve the mercury, which this increafe of heat forced out of it; this he accurately weighed, and deducting its weight from the total weight of the mercury, he made the remainder, or that which was left in the thermometer, equal to 10000: he then found by calculation how many 10000 parts of this refidue that forced out of the tube contained, and thefe parts formed the divifions of the fcale from the point, determined by the condenfation of the mercury to the fame point at which it ftood before it was plunged in boiling water, to the upper end of the tube; and thefe divifions formed the extent of the degrees of M. de l'Ifle's fcale. According to his ftandards, the freezing point, fays Dr. Martine, is near to his *gr.* 150, correfponding to Fahrenheit's *gr.* 32, by which means they may be compared; but M. Ducreft fays, that this point ought to be marked at leaft at *gr.* 154.

M. Ducreft, in his fpirit thermometer, conftructed in 1740, made ufe of two fixed points; the firft, or 0, indicated the temperature of the earth, and was marked on his fcale in the cave of the Royal Obfervatory at Paris; and the other was the heat of boiling water, which the fpirit in his thermometer was made to endure, by leaving the upper part of the tube full of air. He divided the interval between thefe points into 100 equal parts; calling the divifions upwards degrees of heat, and thofe below 0 degrees of cold.

He afterwards regulated his thermometer by the degree of cold indicated by melting ice, which he found to be $10\frac{2}{5}$. In Celfius's, or the centigrade thermometer, the freezing point, like that of Reaumur's, was 0, the boiling point at 100, and the diftance between both 100. See the table at the clofe of the article.

The Florentine thermometers made and ufed by the members of the famous academy *del' Cimento*, being fome of the firft inftruments of the fort, were vaguely graduated, fome of them having many more degrees than others; but thofe of their moft common graduation were of two forts; in one fort the freezing point, determined by the degree at which the fpirit ftood in the ordinary cold of ice or fnow (probably in a thawing ftate), and coinciding with *gr.* 32 of Fahrenheit, fell at *gr.* 20; and in the other fort at *gr.* $13\frac{1}{2}$: and the natural heat of the vifcera of cows and deer, &c. raifed the fpirit in the latter, or lefs fort, to about *gr.* 40, coinciding with their fummer heat, and nearly with *gr.* 102 in Fahrenheit's, and in their other long thermometer, the fpirit, when expofed to the great midfummer heat in their country, rofe to the point at which they marked *gr.* 80. The freezing point of one was 20, the boiling point 174, and the diftance between both was 154: in the other the freezing point was $13\frac{1}{2}$, the boiling point $81\frac{2}{3}$, and the diftance $68\frac{1}{2}$.

In the Parifian thermometer, or the ancient thermometer of the Academy of Sciences, the freezing point was at 25, the boiling point at 239, and the diftance between both 214.

In the thermometer of the obfervatory at Paris, made of fpirit of wine by M. de la Hire, the fpirit always ftands at *gr.* 48, in the cave of the obfervatory, correfponding to *gr.* 53 in Fahrenheit's; and his *gr.* 28 correfponded with 51 inches fix lines in Amontons's thermometer, and confequently with the freezing point, or *gr.* 32 of Fahrenheit's. This thermometer of De la Hire, which ftood in the obfervatory of Paris above 60 years, feems to have been graduated thus; the freezing point 28, the boiling point $199\frac{1}{5}$, and the diftance between both $171\frac{1}{3}$. In Amontons's thermometer the freezing point was $51\frac{1}{2}$, the boiling point 73, and the diftance between them $21\frac{1}{2}$.

In the thermometer of Poleni, made after the manner of Amontons's, but with lefs mercury, 47 inches correfponded, according to Dr. Marfine, with 51 in that of Amontons's, and 53 with $59\frac{1}{2}$. It was graduated thus; the freezing point at $47\frac{3}{10}$, the boiling point at $62\frac{9}{10}$, and the

the diſtance between them $15\frac{1}{10}$. In Crucquius's, the freezing point was 1070, the boiling point 1510, and the diſtance 440.

In the ancient ſtandard thermometer of the Royal Society, after which thermometers were for a long time conſtructed in England, Dr. Martine found that *gr*. $34\frac{1}{2}$, anſwered to *gr*. 64 in Fahrenheit's, and *gr*. 0 to 89 or 88. From that point the numeration aſcended and deſcended thus; the freezing point was $73\frac{1}{4}$, the boiling point $141\frac{1}{4}$, and the diſtance between them $215\frac{1}{2}$. In ſir Iſaac Newton's, the freezing point was 0, the boiling point 34, and the diſtance 34.

In the thermometers graduated for adjuſting the degrees of heat proper for exotic plants, &c. in ſtoves and green houſes, the middle temperature of the air is marked at *gr*. 0, and the degrees of heat and cold are numbered both above and below. Many of theſe are made on no regular and fixed principles. But in that formerly much uſed, called Fowler's regulator, the ſpirit fell, in melting ſnow, to about *gr*. 34 under 0; and Dr. Martine found, that his *gr*. 16 above 0, coincided with nearly *gr*. 64 of Fahrenheit. His 0 ſeems to have coincided with about the 53d or 54th degree of Fahrenheit's, and from that point the numeration aſcended and deſcended thus; the freezing point 34, the boiling point $250\frac{1}{3}$, and the diſtance between them $284\frac{1}{3}$.

Dr. Hales (Statical Eſſays, vol. i. p. 58.) in his thermometer made with ſpirit of wine, and uſed in experiments on vegetation, began his ſcale with the loweſt degree of freezing, or *gr*. 32 of Fahrenheit, and carried it up to *gr*. 100, which he marked where the ſpirit ſtood when the ball was heated in hot water, on which wax ſwimming firſt began to coagulate, and this point Dr. Martine found to correſpond with *gr*. 142 of Fahrenheit. But by experience Hales's *gr*. 100 falls conſiderably above our *gr*. 142. According to others, his freezing point was 0, his boiling point was 163, and the diſtance of courſe 163.

In the Edinburgh thermometer, made with ſpirit of wine, and uſed in the meteorological obſervations publiſhed in the Medical Eſſays, the ſcale is divided into inches and tenths. In melting ſnow the ſpirit ſtood at $8\frac{1}{5}$, and the heat of the human ſkin raiſed to $22\frac{2}{5}$. Dr. Martine found, that the heat of the perſon who graduated it was *gr*. 97 of Fahrenheit. It ſeems to have been graduated thus; the freezing point $8\frac{1}{3}$, the boiling point 47, and the diſtance between them $38\frac{2}{3}$.

As it is often of uſe to compare different thermometers, in order to judge of the reſult of former obſervations, we have annexed from Dr. Martine's Eſſays, the table by which he compared fifteen different thermometers. See *Plate* XVI. *Pneumatics*, *fig*. 4. See alſo the table at the cloſe of this article.

There is a thermometer which was formerly much uſed in London, called the thermometer of Lyons, becauſe M. Criſtin brought it there into uſe, which is made of mercury: the freezing point is marked *gr*. 0, and the interval from that point to the heat of boiling water is divided into 100 equal degrees.

From the above abſtract of the hiſtory of the conſtruction of thermometers, it appears that freezing and boiling water have furniſhed the diſtinguiſhing points that have been marked upon almoſt all thermometers. The inferior fixed point is that of freezing, which ſome have determined by the freezing of water, and others by the melting of ice; and though the difference between theſe two temperatures is not commonly very conſiderable, yet it is not invariable.

It is now well known, that all, or almoſt all bodies, by changing from a fluid to a ſolid ſtate, or from the ſtate of an elaſtic to that of an unelaſtic fluid, generate heat; and that cold is produced by the contrary proceſs.

In order to obtain this fixed point or limit, melting ice, or ice powdered and mixed with water, will produce the ſame temperature. And though there may be ſome trifling difference between the temperature of ice diſpoſed to melt, and that of melted ice or the water produced by it; this difference, however, has no ſenſible effect on the thermometer; conſequently, the temperature of water ſucceſſively produced by ice, and accumulated in its interſtices, or from powdered ice mixed with the water which is produced by it in melting, affords, as De Luc obſerves, a fixed point, which is eaſily obtained, and which ſhould be adopted in the conſtruction of all thermometers.

The ſuperior fixed point of almoſt all thermometers, is the heat of boiling water; but this point cannot be conſidered as fixed, unleſs the heat be produced by the ſame degree of boiling, and under the ſame weight of the atmoſphere. With regard to the firſt circumſtance, it is obſerved, that water, when it begins to boil, has not attained to its greateſt degree of heat, which is known by its bubbling or foaming from the bottom of the veſſel, and over the whole ſurface of the water, with the greateſt violence which it is capable of acquiring; and in this ſtate the water diſcovers an augmentation of heat more than one degree above the heat it had when it began to boil. The temperature of water which boils with vehemence ſhould, therefore, be the ſtandard of the fixed point of thermometers: nevertheleſs it is to be conſidered farther, that this degree of heat with which water violently boils, is invariably the ſame, only under a given preſſure of the atmoſphere; but if the preſſure be diminiſhed or increaſed, the boiling heat is diminiſhed or increaſed. It is well known that water, placed under the exhauſted receiver of an air-pump, will be converted into ſteam with a degree of heat far inferior to that which is neceſſary to its boiling in the open air; and under the preſſure of its own vapour, confined in Papin's digeſter, it is ſaid to ſuſtain a degree of heat, without boiling, far exceeding that which, in the open air, would convert it into ſteam. Hence it follows that, in climates where the preſſure of the atmoſphere is liable to conſiderable change, the heat of boiling water, in open air, will be different at different times. Conſequently thermometers, made in different ſtates of the barometer, will diſagree; unleſs allowance has been made for the effect of the variation of the barometer upon accurate principles. That the heat of boiling was variable, according to the preſſure of the atmoſphere, ſeems to have been known to Fahrenheit as early as the year 1724. See Phil. Tranſ. N° 385.

Some time after this period, Meſſrs. le Monnier and Caſſini (Mem. de l'Acad. des Sc. for 1740) made ſome deciſive obſervations, in order to ſhew that this quantity was very conſiderable.

M. de Luc, in 1762, made a much more complete ſeries of experiments, which he has deſcribed and reduced into a ſyſtem in his Recherches ſur les Mod. de l'Atmoſphere, vol. i. p. 382, &c. vol. ii. p. 338, &c. and theſe have been ſince verified by ſir George Shuckburgh, in 1775 and 1778. See Phil. Tranſ. vol. lxix. part ii. p. 362, &c.

M. de Luc fixes the boiling point of his thermometer when the barometer is at 27 Paris, or 28.75 Engliſh inches, that being its mean height at Geneva. He divides the fundamental interval, *i. e.* the whole extent of the ſcale, between melting ice and boiling water, after the French manner, into eighty equal parts; and by a great number of experiments

periments on the heat of boiling water, at different heights above the level of the ſea, he hath found, that the height of his thermometer, plunged in boiling water, may be expreſſed, in all ſtates of the barometer, by the following formula, *viz.* $\frac{99}{200000}\log. y - a = \mathrm{T}$: in which y denotes the height of the barometer in ſixteenths of a Pariſian line, T the height of a thermometer, plunged in boiling water, above melting ice, in hundredths of a degree of his ſcale; and a the conſtant number 10387.

By logarithms he always means the tabular or Briggian logarithms, and conſiders the ſeven figures given by the tables, beſides the index, as integral figures, *i. e.* he conſiders the eighth figure of the logarithm as ſtanding in the place of units. But as it is more uſual with mathematicians, and, in general, more convenient, to conſider all the figures after the index as decimals, the number which M. de Luc expreſſes by $\frac{99}{200000}\log. y$, would in that caſe be $\frac{99 \times 100}{2}\log. y$; or $\overline{99 \times 50}\log. y$. However, in the ſequel, M. de Luc's notation is retained.

Now if care were taken by the above formula, or in any other way, to adjuſt the boiling point to the main height of the barometer in every country, the inſtruments of the ſame country would always be conſiſtent; but thoſe of different countries would ſtill diſagree; that is, they would expreſs the ſame temperature differently, though their ſimilar intervals ſhould be ſimilarly divided; for in every ſcale, the number of degrees above or below melting ice, by which any given temperature is expreſſed, will be as the value of each degree inverſely; that is, if each be a given part of the fundamental interval, as the value of the fundamental interval inverſely; but if the degrees of different ſcales be different parts of the fundamental intervals, as the value of the fundamental interval inverſely, and the number of degrees contained in it directly.

In order, therefore, to compare the thermometers of different countries, the proportions of their fundamental intervals to each other muſt be aſcertained, or we muſt have ſome means of finding, upon one ſcale, the place of the boiling point of another. For this purpoſe, a general ſolution is requiſite of the following problem, *viz.* the fundamental interval being given for a given height of the barometer, to find the fundamental interval for any other given height of the barometer. The ſolution is furniſhed by M. de Luc's reſearches; and his formula, above given, is reduced to Engliſh meaſures, and adapted to Engliſh inſtruments, by Dr. Horſley. As the ſubject is curious and important, we ſhall ſubjoin the proceſs he has purſued for this purpoſe. It is but ſeldom that the barometer in this country ſtands ſo low as 27 Paris inches. Its main height upon the plain country about London is near 30 Engliſh inches. It may, therefore, be proper for the London workmen to fix their boiling point when the barometer is at 30 inches. Fahrenheit's diviſion of the ſcale, which makes 180 degrees between melting ice and boiling water, and places the point 0 at the 32d degree below melting ice, may be retained: and the thermometer thus conſtructed is called by Dr. Horſley, Bird's Fahrenheit, becauſe Mr. Bird, he apprehends, is the firſt workman who took the pains to attend to the ſtate of the barometer in making thermometers, and has always fixed the boiling point when his barometer has ſtood at 30 inches.

T, then, being put for the height of a thermometer plunged in boiling water, above melting ice, in 100dths of a degree of De Luc's ſcale, in any given ſtate of the barometer; let Θ denote the ſame height in 100dths of a degree of Bird's Fahrenheit; put y for the height of the barometer, in 16ths of a Paris line; v, for its height in Paris lines; x, in 10ths of a Paris inch; z, in 10ths of an Engliſh inch; and for 10387 put a; for 16, b; for 10, c; for 12, d; and let E and F repreſent numbers expreſſing the proportion of the Engliſh foot to the French foot.

M. de Luc hath found that, whatever be the value of y, $\frac{99}{200000}\log. y - a = \mathrm{T}$. But $\log. y = \log. v + \log. b$; and $\log. v = \log. x + \log. d - \log. c$; and $\log. x = \log. z + \log. \mathrm{E} - \log. \mathrm{F}$; therefore $\log. y = \log. z + \log. \mathrm{E} + \log. d + \log. b - \log. \mathrm{F} - \log. c$; and $\frac{99}{200000}\log. z + \frac{99}{200000}\overline{\log. \mathrm{E} + \log. d + \log. b - \log. \mathrm{F} - \log. c} - a = \mathrm{T}$. But $\frac{99}{200000}\overline{\log. \mathrm{E} + \log. d + \log. b - \log. \mathrm{F} - \log. c} - a = -4171.55$; the French foot being to the Engliſh as 2.1315 to 2. Therefore $\frac{99}{200000}\log. z - 4171.55 = \mathrm{T}$; and $\frac{99}{20000000}\log. z - 41.7155 = \frac{\mathrm{T}}{100}$ = the height of the thermometer, plunged in boiling water, above melting ice, in degrees of De Luc's ſcale, when the height of the barometer in tenths of an Engliſh inch, is z. For z write 300: then $\frac{\mathrm{T}}{100} = 80.902$; which is therefore the height of the thermometer, in boiling water, above melting ice, in degrees of De Luc's ſcale, when the barometer is at 30 inches Engliſh. And in the ſame ſtate of the barometer, the height of the thermometer plunged in boiling water, above melting ice, in degrees of Bird's Fahrenheit, or $\frac{\Theta}{100}$, is 180. Hence the numbers T and Θ are in the conſtant proportion of 809 and 1800, whatever be the value of z. For the change produced in the heat of boiling water, by any change of z, being always the ſame for both thermometers, the temperature expreſſed by T in parts of one ſcale is always the ſame, as Θ expreſſes in parts of the other; and therefore putting $\frac{1}{\mathrm{L}}$ and $\frac{1}{\mathrm{B}}$ for the values of the 100dth part of a degree of the ſcales of De Luc and Bird reſpectively, the fractions $\frac{\mathrm{T}}{\mathrm{L}}$, $\frac{\Theta}{\mathrm{B}}$ are always equal, and T, Θ are in the conſtant proportion of the invariable numbers L, B: conſequently, when the proportion of T and Θ is determined for any particular value of z, it is found generally for all: conſequently $\mathrm{T} : \Theta :: 809 : 1800$. And $\mathrm{T} = \frac{809}{1800}\Theta = \frac{899}{2000}\Theta$ very nearly in all values of z: and ſubſtituting this value for T in the equation

equation exhibiting the relation between z and T, we have, for the relation between z and Θ, $\frac{99}{20000000}$ log. z − 41.7155 = $\frac{899}{2000 \times 100}\,\Theta$: or, $\frac{99}{10000 \times 899}$ log. z − 92.804 = $\frac{\Theta}{100}$ = the height of the thermometer in boiling water, above melting ice, in degrees of Bird's Fahrenheit, when the height of the barometer in tenths of an Englifh inch, is z. And thus M. de Luc's formula, for the variation of the boiling point, is adapted to Englifh inftruments, and reduced to Englifh meafures of length.

For z write 287.7525, the length of 27 French inches in tenths of an Englifh inch, and $\frac{\Theta}{100}$, the height of De Luc's boiling point above melting ice, in degrees of Bird's Fahrenheit, comes out 177.989. Hence M. de Luc's boiling point falls upon 209.989 of Bird's fcale, *i. e.* upon 210 very nearly, or infenfibly more than two degrees below Bird's point of boiling. But as 899 is a troublefome divifor, the computation will be more eafy and expeditious, by writing for $\frac{11}{1000000}$ log. z, s. Then $s + \frac{1}{900}s - 92.804 = \frac{\Theta}{100}$ very nearly. Upon thefe principles Dr. Horfley has computed the table following, for finding the heights to which a good Bird's Fahrenheit will rife, when plunged in boiling water, in all ftates of the barometer, from 27 to 31 Englifh inches; which will ferve, among other ufes, to direct inftrument-makers in making a true allowance for the effect of the variation of the barometer, if they are obliged to finifh a thermometer, when the barometer is above or below 30 inches; though it is beft to fix the boiling point when the barometer is at the height prefcribed.

Equation of the Boiling Point.

The numbers in the firft column of this table exprefs heights of the quickfilver in the barometer in Englifh inches and decimal parts: the fecond column fhews the equation to be applied, according to the fign prefixed, to 212° of Bird's Fahrenheit to find the true boiling point for every fuch ftate of the barometer. The boiling point for all intermediate ftates of the barometer may be had with fufficient accuracy by taking proportional parts, by means of the third column of differences of the equations. (See Phil. Tranf. vol. lxiv. part i. art. 30. See alfo an excellent paper on this fubject by Dr. Mafkelyne, in the Phil. Tranf. vol. lxiv. part i. art. 20.) In the following table we have the refult of fifteen different obfervations made by fir George Shuckburgh (ubi fupra) compared with the refult of M. de Luc's rules.

Height of the Barometer reduced to the fame Temperature of 50°.	Mean Boiling Point by Obfervation.	Boiling Point by De Luc's Rules.

The Royal Society, fully apprized of the importance of adjufting the fixed points of thermometers, appointed a committee of feven gentlemen to confider of the beft method for this purpofe; and their report is publifhed in the Phil. Tranf. vol. lxvii. part ii. art. 37. From a variety of experiments and obfervations, relating to this fubject, the committee have deduced the following practical rules, which they recommend in adjufting the fixed points of thermometers. The moft accurate way of adjufting the *boiling point* is, not to dip the thermometer into the water, but to expofe it only to the fteam, in a veffel clofed up in the manner reprefented in *Plate* XVI. *Pneumatics*, *fig.* 6. where A B *b a* is the veffel containing the boiling water, D *d* the cover, E a chimney made in the cover intended to carry off the fteam, and M *m* the thermometer paffed through a hole in the cover. In the purfuit of this method the following particulars muft be regarded: the boiling point muft be adjufted when the barometer is at 29.8 inches; unlefs the operator corrects the obferved point in the manner

manner directed in the ſequel of this article. The ball of the thermometer muſt be placed at ſuch a depth within the pot, that the boiling point may riſe very little above the cover; and the ſurface of the water in the pot ſhould be at leaſt one or two inches below the bottom of the ball. Care muſt be taken to ſtop up the hole in the cover through which the tube is inſerted, and to make the cover fit pretty cloſe, ſo that no air ſhall enter into the pot that way, and that not much ſteam may eſcape. A piece of thin flat tin-plate muſt alſo be laid on the mouth of the chimney, ſo as to leave no more paſſage than what is ſufficient to carry off the ſteam.

If the artiſt pleaſes, he may tie each corner of this plate by a ſtring to prongs fixed to the chimney, and ſtanding on a level with the plate, as it will be thus always kept in its place.

Fig. 7. is a perſpective view of the chimney and tin-plate; A B C D is the plate, E the chimney, F *f*, G *g*, M *m*, and N *n*, the prongs faſtened to the chimney, to which the four corners of the plate are to be tied by the ſtrings A F, B G, C M, and D N; the ends F, G, M, and N, of the prongs muſt be on a level with the plate, and the ſtrings ſhould not be ſtretched tight. The chimney ought not to be leſs than half a ſquare inch in area, and not leſs than two or three inches in length. The cover ſhould be made to take on and off eaſily, and a ring of woollen cloth may be placed under it, ſo as to lie between it and the top of the pot. The hole in the cover may be ſtopped up by a cork, with a hole bored through it, big enough to receive the tube, and then cut into two, parallel to the length of the hole. Another method, more convenient in uſe, but not ſo eaſily made, is repreſented in *fig.* 8. which exhibits a perſpective view of the apparatus: A *a* is the cover, H the hole through which the thermometer is paſſed, B *b* a flat piece of braſs fixed upon the cover, and D *d* E *e* a ſliding piece of braſs, made ſo as either to cover the hole H, or to leave it uncovered, as in the figure, and to be tightened in either poſition by the ſcrew *s* ſliding in the ſlit M *m*; alſo in the edge D *d*, to encloſe the tube of the thermometer: pieces of woollen cloth ſhould alſo be faſtened to the edges B *b* and D *d*, and alſo to the bottom of the ſliding-piece D *d* E *e*, unleſs that piece and the cover are made ſufficiently flat to prevent the eſcape of the ſteam. In order to keep the thermometer ſuſpended at the proper height, a clip may be uſed like that repreſented in *fig.* 9. which, by the ſcrew *s*, muſt be made to embrace the tube tightly, and may reſt on the cover.

Another method, which is rather more convenient, when the top of the tube of the thermometer is bent into a right angle, in the manner often practiſed at preſent for the ſake of more conveniently fixing it to the ſcale, is repreſented in *fig.* 10.: G *g* F *f* is a plate of braſs ſtanding perpendicularly on the cover, and L *l* N *n* a piece of braſs bent at the bottom into the form of a loop, with a notch in it, ſo as to receive the tube of the thermometer, and to ſuffer the bent part to reſt on the bottom of the loop; this piece muſt ſlide in a ſlit K *k*, in the plate L *l* N *n*, and be tightened at any height by the ſcrew T.

Moreover, it is beſt to make the water boil pretty briſkly, as otherwiſe the thermometer is apt to be a great while before it acquires its full heat, eſpecially if the veſſel is very deep; and the obſerver ſhould wait at leaſt one or two minutes after the thermometer appears to be ſtationary, before he concludes that it has acquired its full height.

Another way of adjuſting the boiling point is to try it in a veſſel of the ſame kind as the former, only with the water riſing a little way, *viz.* from one to three or four inches above the ball, taking care that the boiling point ſhall riſe very little above the cover. In this method there is no need to cover the chimney with the tin-plate, and there is leſs need to make the cover fit cloſe, unleſs to prevent the operator from being incommoded with the ſteam. The height of the barometer in this method is $29\frac{1}{2}$ inches.

It will be convenient to have two or three pots of different depths for adjuſting thermometers of different lengths. A third way of adjuſting the boiling point is to wrap ſeveral folds of linen rags or flannel round the tube of the thermometer, and to try it in an open veſſel, taking care to pour boiling water on the rags, in order to keep the quickſilver in the tube as nearly of the heat of boiling water as poſſible. In this method the barometer ſhould be at 29.8 inches; the water ſhould boil faſt, and the thermometer ſhould be held upright, with its ball two or three inches under water, and in that part of the veſſel where the current of water aſcends.

Whichever of theſe methods of adjuſting the boiling point is uſed, it is not neceſſary to wait till the barometer is at the proper height, provided the operator will take care to correct the obſerved height according to the following table.

Height of the Barometer when the Boiling Point is adjuſted according to the		Correction in 1000dths of the Interval between 32° and 212°	Height of the Barometer when the Boiling Point is adjuſted according to the		Correction in 1000dths of the Interval between 32° and 212°.
1ſt or 3d Method.	2d Method.		1ſt or 3d Method.	2d Method.	
	30.60	10	29.69	29.39	1
	53	9	58	28	2
30.71	41	8	47	17	3
59	29	7	36	06	4
48	18	6	25	28.95	5
37	07	5 Lower.	14	84	6 Higher.
25	95	4	03	73	7
14	84	3	28.92	62	8
03	73	2	81	51	9
29.91	61	1	70		10
80	50	0	59		11

In uſing this table, ſeek the height of the barometer in the column anſwering to the method of adjuſting the boiling point, the correſponding number in the third column ſhews how much the point of 212° muſt be placed above or below the obſerved point: *e. gr.* ſuppoſe the boiling point to be adjuſted in them when the barometer is at 29 inches, and that the interval between the boiling and freezing points is 11 inches; the neareſt number to 29 in the left-hand column is 29.03, and the correſponding number in the table is 7 higher, and therefore the mark of 212° muſt be placed higher than the obſerved point by $\frac{7}{1000}$ths of the interval between boiling and freezing, *i. e.* by $\frac{11 \times 7}{1000}$, or .077 of an inch. This method of correcting the boiling point is not ſtrictly juſt, unleſs the tube is of an equal bore in all its parts; but the tube is ſeldom ſo unequal as to cauſe any ſenſible error, where the whole correction is ſo ſmall. The trouble of making the correction will be abridged by a diagonal ſcale, ſuch as is repreſented in *fig.* 10.

Although it is of no great conſequence what kind of water is uſed in adjuſting the boiling point, ſo that it is not ſalt, ſ.lt, or, if it be hard, that it ſhould be kept boiling at leaſt ten minutes before it is uſed; yet the committee recommend, for the adjuſtment of thermometers intended for nice experiments, to employ rain or diſtilled water, and to perform the operation in ſteam.

It is obſerved, that though the boiling point be placed ſo much higher on ſome of the thermometers now made than on others, yet this does not produce any conſiderable error in the obſervations of the weather, at leaſt in this climate: for an error of $1\frac{1}{2}°$ in the poſition of the boiling point. will make an error only of half a degree in the poſition of 92°, and of not more than a quarter of a degree in the point of 62°.

It is only in nice experiments, or in trying the heat of hot liquors, that this error in the boiling point can be of much ſignification.

In adjuſting the freezing, as well as the boiling point, the quickſilver in the tube ought to be kept of the ſame heat as that in the ball. When the freezing point is placed at a conſiderable diſtance from the ball, the pounded ice ſhould be piled to ſuch a height above the ball, that the error which can ariſe from the quickſilver in the remaining part of the tube, not being heated equally with that in the ball, ſhall be very ſmall, or the obſerved point muſt be corrected on that account, according to the following table.

Heat of the Air.	Correction.
42°	.00087
52	.00174
62	.00261
72	.00348
82	.00435

The correction in this table is expreſſed in 1000th parts of the diſtance between the freezing point and the ſurface of the ice: *e. g.* if the freezing point ſtands ſeven inches above the ſurface of the ice, and the heat of the room is 62°, the point of 32° ſhould be placed 7 × .00261, or .018 of an inch lower than the obſerved point. A diagonal ſcale will facilitate this correction.

The committee obſerve, that in trying the heat of liquors, care ſhould be taken that the quickſilver in the tube of the thermometer be heated to the ſame degree as that in the ball; or if this cannot be done conveniently, the obſerved heat ſhould be corrected on that account; for the manner of doing which, and a table calculated for this purpoſe, we muſt refer to their excellent report in the Phil. Tranſ. vol. lxvii. part ii. art. 37.

Several experiments made by governor Hutchins, at Albany Fort, in Hudſon's Bay, in 1782, in purſuance of a method ſuggeſted by Dr. Black and Mr. Cavendiſh, and for which he obtained ſir Godfrey Copley's medal from the Royal Society in 1783, have not only confirmed the obſervations before made, relative to the ſolid ſtate into which quickſilver can be brought by cold, its metalline ſplendour and poliſh when ſmooth, its roughneſs and cryſtallization where the ſurface was unconfined, its malleability, ſoftneſs, and dull ſound when ſtruck; but have alſo clearly demonſtrated, that its point of congelation is no lower than — 40°, or rather — 39°, of Fahrenheit's ſcale; that it will bear, however, to be cooled a few degrees below that point, to which it jumps up again on beginning to congeal; and that its rapid deſcent in a thermometer, through many hundred of degrees, when it has once paſſed the above-mentioned limit, proceeds merely from its great contraction in the act of freezing. See Phil. Tranſ. vol. lxxiii. part ii. art. *20, 20, 21.

THERMOMETERS, *Obſervations on the Conſtruction of.* It is abſolutely neceſſary that thoſe who would derive any advantage from theſe inſtruments, ſhould agree in uſing the ſame liquor, and in determining, according to the ſame method, the two fundamental points. If they agree in theſe fixed points, it is of no great importance whether they divide the interval between them into a greater or leſs number of equal parts. The ſcale of Fahrenheit, in which the fundamental interval between 212°, the point of boiling water, and 32°, that of melting ice, is divided into 180 parts, ſhould be retained in the northern countries, where Fahrenheit's thermometer is uſed: and the ſcale, in which the fundamental interval is divided into 80 parts, will ſerve for thoſe countries where the thermometer of M. de Reaumur is adopted. But no inconvenience is to be apprehended from varying the ſcale for particular uſes, provided care be taken to ſignify into what number of parts the fundamental interval is divided, and the point where 0 is placed.

With regard to the choice of tubes, it is moſt deſirable to have them exactly cylindric through their whole length. See *Mercurial* THERMOMETER.

The capillary tubes are preferable to others, becauſe they require leſs bulbs, and they are alſo leſs brittle, and more ſenſible. Thoſe of the moſt convenient ſize for common experiments are ſuch as have their internal diameter about the fourth of a line: and thoſe made of thin glaſs are better than others, as the riſe and fall of the mercury may be more diſtinctly perceived. The length of nine inches will ſerve for all common occaſions; but for particular purpoſes, the length both of the tubes and of the diviſions ſhould be adapted to the uſes for which they are deſigned.

In determining the beſt ſize of the balls or bulbs, it has been uſual to compare new tubes with ſuch thermometers as are well proportioned. But M. Durand has propoſed a formula for finding the proportion which the balls ought to bear to their reſpective tubes. With this view he expreſſes the length of the tube, meaſured in diameters of itſelf, by a; the whole capacity of the ball and tube by c; the capacity of the fundamental interval, expreſſed in the ſame parts with the whole capacity, by d; the number of degrees of the fundamental interval by m; the number of other degrees which the ſcale is to contain, beſides thoſe of the fundamental interval both above and below it, by n; and the diameter of the ball meaſured in diameters of the tube by b: and $b = \sqrt[3]{\frac{2}{3} a \times \frac{c\,m}{d \times \overline{m+n}}} - 1$. For two cylinders having equal baſes being as their heights, $m : n :: d : \frac{d\,n}{m}$, which is the capacity of that part of the tube which exceeds the fundamental interval, to which adding d, that interval, we have the total capacity of the tube $= \frac{d\,n}{m} + d$, or $\frac{d\,n + d\,m}{m}$. Subtracting this from c, we ſhall have the capacity of the ball $= c - \overline{\frac{d\,n + d\,m}{m}} = \frac{c\,m - d\,m - d\,n}{m}$. If this quantity be divided by the capacity of the tube, the quotient will ſhew how often the capacity of the ball contains that of the tube; and this quotient is =

$c\,m$

$\frac{cm - dm - dn}{dm + dn}$. Conſequently the ball is equal to as many cylinders having *a* diameters of the tube, for their reſpective height, and 1 diameter for the baſe, as are contained in this laſt quotient; and, therefore, its cylindric ſolidity expreſſed in the cylindric ſolidities of the tube will be $= a \times \frac{cm - dm - dn}{dm + dn}$. But the diameter of this ball is equal to the baſe of the cylinder in which it may be inſcribed, and the ſolidity of this cylinder is equal to $\frac{2}{3}$ds the ſolidity of the circumſcribing ſphere. Conſequently the ſolidity of this cylinder will be $= \frac{3}{2} a \times \frac{cm - dm - dn}{dm + dn}$; and the diameter of its baſe equal to the diameter of the ball, will be $= \sqrt[3]{\frac{3}{2} a \times \frac{cm - dm - dn}{dm + dn}}$ or $\sqrt[3]{\frac{3}{2} a \times \frac{cm}{d \times \overline{m + n}} - 1}$.

It is evident that, *cæteris paribus*, the larger the bulb is, in proportion to the diameter of the cavity of the tube, or the narrower the latter is in proportion to the former, the greater will the motion of the ſurface of the fluid be in the tube. But it muſt be obſerved, that when the bulb is very large, the thermometer will not eaſily arrive at the preciſe temperature of any place, wherein it may be ſituated. Some perſons, in order to give the bulb a greater ſurface, and of courſe to render it more capable of readily attaining a given temperature, have made it not globular, but cylindrical (which ſhape was adopted by Fahrenheit), or flat, or bell-like, &c.; but thoſe ſhapes are improper, becauſe they are liable to be altered by the varying gravity of the atmoſphere, conſequently thoſe thermometers cannot be accurate. The bulb ſhould be clean and colourleſs; ſince coloured ſurfaces are apt to be partially heated by a ſtrong light. If you take two equal thermometers, and paint the bulb of one of them black, or of any dark colour, and expoſe them both to the ſun; the mercury in that whoſe bulb is painted will riſe ſeveral degrees higher than in the other: even a ſtrong day-light, independently of the direct rays of the ſun, will affect them differently. The ball of the thermometer ſhould not be in contact with the ſubſtance of the ſcale, leſt it ſhould be influenced by the temperature of that ſubſtance.

When a proper tube and ball are procured, and their proportion aſcertained, the next object which requires peculiar attention is that of filling the thermometer. For this purpoſe the tubes ſhould be clean and dry, and the mercury very pure. (See Mercury and Barometer.) The mercury may be introduced into the tube by means of a kind of reſervoir fixed at the top of it, and proportioned in ſize to the bulk of the ball, or by rolling upon the tube a ſlip of fine paper, about two or three inches broad. In order to clear the tube of its air and moiſture, it ſhould be held over a gentle fire, ſo diſpoſed, as that it may heat at once the whole extent of the tube, till its heat becomes too great for the operator's hand to bear, who therefore uſes a glove or nippers for this purpoſe; care being taken that the ball is not heated at the ſame time. After the incloſed air is thus rarefied, and the particles that might obſtruct the free motion of the mercury are made to float in vapours within the bore of the tube, the tube is to be held upright, and the ball ſuddenly heated, by which means the air contained in it will be dilated, and carry off the impurities of the tube, ſo that it will be rendered clean and free from air. When the ball is heated to a conſiderable degree, the mercury may be poured into the reſervoir fixed at the top of the tube, through a ſmall corner of the paper. When the reſervoir is almoſt full, the ball ſhould be withdrawn from the fire, and the air will then be condenſed, and the ſpace left by it will be ſoon occupied by the mercury. By alternately heating and cooling the ball, it may thus be filled with mercury; but when it is nearly full, the mercury contained in it muſt be made to boil, by placing it over burning coals, in order to purge it of its air. However, as a ſmall quantity of air will be left in the ball after this operation, it will be expedient to remove the mercury, which remains in the reſervoir, immediately after the thermometer is withdrawn from the fire; and thus the whole column, unſupplied with mercury from the reſervoir, will deſcend into the ball by the condenſation of that which is contained in it, and the tube being empty, the ſmall bubble of air will eſcape. Let the tube be again heated ſucceſſively through its whole length, commencing from the bottom, and preſerving the heat of the ball, that the mercury may occupy it entirely, and no air be allowed to enter. During this operation, when the mercury of the thermometer begins to appear in the reſervoir, let the mercury contained in a paper funnel be poured into it in ſuch a quantity as will more than fill the thermometer, which is then to be removed from the fire. The mercury of the tube, and that diſcharged from the funnel, will unite, and paſs together into the thermometer, and thus it will be wholly filled. In this ſtate it may be left for any time at pleaſure, without any apprehenſion of its imbibing either air or moiſture. Nothing now remains but to get rid of the ſuperfluous quickſilver, and to ſeal the tube. For this purpoſe the thermometer is held in the hand and heated, till a drop of mercury falls out of it, and is then left to recover the temperature of the air; by which means there will remain at the top of the tube a ſmall empty ſpace. Then with a blow-pipe and the flame of a candle, let the end of the tube be formed into a fine point, of ſuch a length as will admit of its being properly ſealed. When this preparatory proceſs is completed, let the thermometer be gradually plunged into boiling water, ſo that the ſuperfluous mercury may iſſue from it ſlowly; and when it ceaſes to be diſcharged, withdraw the thermometer from the boiling water; wipe it dry, and as ſoon as poſſible, put the ball of it over a ſmall fire, covered with aſhes, and previouſly prepared for the purpoſe. In this part of the operation, it is neceſſary to be quick, that the mercury may not have time to condenſe, and the air enter into the tube. In this ſtate the thermometer may be left to heat, till it parts with more or fewer drops of the mercury, according to the proportion which the length of the tube bears to that of the ſcale applied to it. The thermometer is then ſealed, by melting only the end of the point above mentioned, and at the ſame inſtant withdrawing it from the fire.

The method of filling the thermometer with a paper tube, or funnel, is as follows. Let the ball be heated, ſo that the mercury may riſe to the top of the tube; whilſt it approaches it, apply the tube of paper to the end of the tube, ſo that it may ſerve for a reſervoir. The thermometer being placed near the fire, ſo that it may always preſerve the ſame degree of dilatation, take ſome well purified mercury in a paper cornet, and communicate a little more heat to the ball. When the mercury riſes, and forms a ſmall drop at the end, pour the mercury of the cornet into the reſervoir of paper, and withdraw the ball from the fire. Having removed the paper reſervoir, place the ball again over the fire, and ſeal the point of the tube at the moment when the mercury riſes to it, and withdraw the thermometer from the fire. This operation will be acquired by uſe.

Thermometers that are defired for meafuring great degrees of heat, require to be filled with particular precautions, which M. de Luc has minutely defcribed.

When the thermometer is filled and fealed, nothing more is neceffary than to mark the two fixed points, graduate the fcale, and attach it to a proper frame. See de Luc's Récherches, &c. vol. i. p. 393, &c.

The frame may be made of any fubftance, or kind of wood, at pleafure: and the degrees may be marked on metal or wood, or paper, or ivory, &c.; but fuch fubftances fhould be preferred for the fcales of thermometers as are not apt to be bent or fhortened, or otherwife altered by the weather, efpecially if the inftruments are not defended by a glafs cafe, or by a box with a glafs face. Thermometers for indicating the temperature of the atmofphere need not have fcales that are much extended; if they go as high as 120° it is fufficient. The lower degrees may be carried down as low as may be neceffary for the cold of any particular climate. The mercurial thermometer need not be graduated lower than 40° below 0, becaufe at about that degree mercury ceafes to be fluid. The fpirit thermometer may be graduated lower, if neceffary.

Thermometers ufed for obfervation, muft be fituated in the open air out of the houfe, and at the diftance of a foot (at leaft) from the wall, and where the light of the fun may not fall directly upon them. For chemical purpofes, the bulbs and part of the tubes of the thermometers fhould project fome way below the fcales, that they may be dipped in liquids, mixtures, &c. For other purpofes, as for botanical obfervations, hot-houfes, brewing manufactories, baths, &c. the thermometers muft be made longer or fhorter, or narrower; and particular directions may be given with regard to the fcales and other appendages.

Great inconvenience has attended the ufe of various kinds of thermometers with different graduations. Kirwan propofed to lay all thefe afide, and to conftruct a general one, beginning at the congelation of mercury, and terminating at the boiling of water, and divided into 250°. Mr. Murray of Edinburgh has fince fuggefted, that it would be convenient to form a fcale whofe extreme points fhould be the temperatures of freezing and boiling mercury, both which are now capable of being accurately afcertained, and to divide this fcale into 1000°.

Thermometers, *Experiments with.* We fhall here infert a table of fome obfervations made with the thermometers of Fahrenheit, Reaumur, fir Ifaac Newton, and Dr. Hales.

Obfervations by Fahrenheit's Thermometer.

	Deg.		
At	600	Mercury boils	According to Mufchenbroeck, the barometer being at 29 Rhinland inches.
	546	Oil of vitriol boils	
	242	Spirit of nitre boils	
	240	Lixivium tartari boils	
	213	Cow's milk boils	
	212	Water boils.	
	206	Frefh human urine boils.	
	190	Brandy boils.	
	174	Alcohol boils.	
	176	————— according to Mufchenbroeck.	
	156	Serum of blood and white of eggs hardens.	
	146	Killing heat for animals, in a few minutes.	
	108	A hen hatching eggs, but feldom fo hot.	
From 107 to 103		Heat of fkin in ducks, geefe, hens, pigeons, partridges and fwallows.	
At	106	Heat of fkin in a common ague and fever.	
From 103 to 100		Heat of fkin in dogs, cats, fheep, oxen, fwine, and other quadrupeds.	
From 99 to 92		Heat of the human fkin in health.	
At	97	Heat of a fwarm of bees.	
	96	A perch died in three minutes, in water fo heated.	
	80	Heat of the air in the fhade, in very hot weather.	
	74	Butter begins to melt.	
	64	Heat of the air in the fhade, in warm weather.	
	48	Temperate air, in England and Holland.	
	43	Oil of olive begins to ftiffen and grow opaque.	
	32	Water juft freezing, or fnow and ice juft thawing.	
	30	Milk freezes.	
	28	Urine and common vinegar freezes.	
	25	Blood out of the body freezes.	
	20	Good Burgundy, ftrong claret, and Madeira freezes.	
	7	One part of fpirit of wine mixed with three parts water freezes.	
	5	Greateft cold in Pennfylvania in 1731–2, 40° lat.	
	4	Greateft cold at Utrecht, in 1728–9.	
	0	A mixture of fnow and falt, which is able to freeze oil of tartar *per deliquium*, but not brandy.	
	— 39	Mercury freezes.	

Martine's Effays, p. 284, &c.

We muft here obferve, that the heat of a hen hatching chickens is placed, by this table, at 108° of Fahrenheit's thermometer: but it appears from M. Reaumur's experiments, that eggs will hatch in a heat no greater than that of the human fkin. See Hatching.

2. *Obfervations by Reaumur's Thermometer.*

	$97\frac{1}{2}$	Anfwers to the heat of boiling water.
	80	Spirit of wine in Reaumur's thermometer boils.
At	$29\frac{2}{3}$	Greateft height of the air in the fhade, obferved at Paris in 1706, 1707, 1724.
	$10\frac{1}{5}$	Conftant heat of the caves of the obfervatory at Paris.
	0	Artificial congelation of water.
	$14\frac{1}{4}$	Lower than (0) greateft cold at Paris, in 1709.

3. *Obfervations by fir Ifaac Newton's Thermometer.*

34	Water boils vehemently.
$28\frac{6}{11}$	Heat between water boiling and wax melting.
24	Heat of water on which floating wax melts.
$20\frac{2}{11}$	Heat of water on which floating melted wax begins, by cooling, to lofe its fluidity and tranfparency.
17	Heat of a bath fupportable to the hand at reft.
$14\frac{3}{11}$	Heat of a bath fupportable to the hand in motion. The heat of blood juft let out is almoft the fame.
12	Heat of thermometer in contact with a human body. The heat of a bird hatching her eggs much the fame.

Deg.	
6 5 4	Heats of the air in ſummer.
4 3 2	Heats of the air in ſpring and autumn.
2 1 0	Heat of the air in the winter.
0	Water begins to freeze.

Phil. Tranſ. Abr. vol. iv. part ii. p. 1.

4. *Obſervations by Dr. Hales's Thermometer.*

$146\frac{1}{3}$	Anſwers to the heat of boiling water.
100	Heat of water on which floating wax begins to melt.
88	Hotteſt ſunſhine in 1727.
85	Scorching heat of a hot-bed of horſe-dung, and alſo the heat of blood in high fevers.
64	Heat of the blood of animals; whence the heat of the blood to that of boiling water is as 14.27 to 33.
58	Heat of urine.
56	Due healthy heat of a hot-bed of horſe-dung in February, that of the open air being 17°, and nearly the boſom heat, and heat for hatching of eggs.
55	Heat of milk from the cow.
54	External heat of the body.
50	Common noon heat in the ſun in July.
38	Mean heat of the air in the ſhade in July.
From 30 to 17	May and June heat; and the moſt genial heat for moſt plants, in which they flouriſh and grow moſt.
From 20 to 10	Autumnal and vernal heat.
From freezing point to 10	Winter heat.
18	Temperate point.
31	The moſt kindly heat for melon-thiſtle.
29	——— ananas or pine-apple.
26	——— pimento.
24	——— euphorbium.
$21\frac{1}{2}$	——— cereus.
19	——— aloe.
$16\frac{1}{2}$	——— Indian fig.
14	——— ficoides.
12	——— oranges.
9	——— myrtle.
0	Freſh water juſt freezing.

Nat. vol. ii. p. 625, &c. ed. 1762. De Luc's Récherches ſur les Modifications de l'Atmoſphere, tom. i. part ii. c. 2. Nollet's Leçons de Phyſique, tom. iv. p. 375, &c.

Thermometers *for particular Uſes*. In 1757, the right hon. the earl of Cavendiſh preſented to the Royal Society an account of a curious conſtruction of thermometers, of two different forms; one contrived to ſhew the greateſt degree of heat, and the other the greateſt cold, that may happen at any time in a perſon's abſence. The firſt conſiſts of a cylinder of glaſs joined to a tube, and differs from the common ſort only in having the top of the ſtem drawn out into a capillary tube, which enters into a glaſs ball C (*Plate* XVI. *Pneumatics*, *fig.* 11.) joined on to the ſtem at the place where it begins to be contracted. The cylinder, and part of the tube, are filled with mercury, the top of which ſhews the common degrees of heat as uſual. The upper part of the tube above the mercury is filled with ſpirit of wine, and ſome of the ſame liquor is left in the ball C, ſo as to fill it almoſt to the top of the capillary tube.

When the thermometer riſes, the ſpirit of wine will be driven out of the tube, and will fall into the ball C. When the thermometer ſinks again, as the ſpirit cannot be returned back from the ball, the top of the tube will remain empty, and the length of the empty part will be proportional to the fall of the thermometer. Conſequently, by means of a proper ſcale, the top of the ſpirit of wine will ſhew how many degrees it has been higher than when obſerved, which being added to the preſent height, will give the greateſt degree of heat it has been at. To fit this thermometer for a new obſervation, it is neceſſary to fill the upper part of the tube with ſpirits, by inclining the inſtrument till the ſpirits in the ball C cover the end of the capillary tube; for if the cylinder is then heated, by applying the hand to it, or by the flame of a lamp held at ſome diſtance, till the ſpirits riſe to the top of the tube, and run over into the ball C, and is then ſuffered to cool in the ſame poſition, the tube will remain full of ſpirits, and the thermometer will be fitted for a new experiment.

The ſcale of degrees at top, which ſhews the deſcent of the thermometer from the higheſt point it has arrived at, ought not, in ſtrictneſs, to be the ſame at all times of the year; for theſe degrees exceed the common degrees of heat pointed out by the top of the mercury, as much as the column of ſpirit of wine expands, and therefore are greateſt when that column is ſo; *i. e.* when the greateſt heat to which the inſtrument has been expoſed is leaſt. A difference of 30 degrees of Fahrenheit's ſcale, in the greateſt riſe of the thermometer, would require the ſcale to be altered one ſixtieth part; and the error ariſing from making uſe of the ſame ſcale, will be about one-ſixth of a degree, if the thermometer is obſerved when it has fallen ten degrees.

In the thermometer here deſcribed, the bore of the tube is about 0.027 inches; and one inch of it contains two grains of mercury, and anſwers to about ten degrees, the cylinder containing about 2280 grains. When the ſcale of degrees is large, the cylinder muſt be of conſiderable ſize. The quickſilver in the ball C ſerves to ſupply the tube, in caſe any of it ſhould be driven into the ball by the thermometer's being expoſed to too great a heat.

If the weight of the mercury be thought inconvenient, it may be avoided by the conſtruction in *fig.* 12. where the bottom of the tube is bent ſo as to point upwards, and is joined to a ball A, which communicates with a cylinder placed above it. It is in all other reſpects the ſame as the former inſtrument. It is filled with ſpirits of wine and mercury; the quantity of the latter being ſufficient to fill the whole tube and the ball A.

The thermometer for ſhewing the greateſt degree of cold that happens in any place during the time the inſtrument is left in it, is repreſented in *fig.* 13. The tube is bent into the ſhape of a ſiphon, of unequal legs, ſtanding parallel to one another; the top of the ſhorter leg is bent to a right angle, and opens into a ball A, which, by means of a ſhort bent tube on the oppoſite ſide, communicates with a cylinder

der ſtanding parallel to the legs of the ſiphon, and pointing downwards. This cylinder contains the greateſt part of the fluid, and is added only to make the thermometer more ſenſible than it would be, if the ball A was made of a ſufficient ſize to contain the proper quantity of fluid. This inſtrument is filled with ſpirit of wine, with the addition of as much mercury as is ſufficient to fill both legs of the ſiphon, and about a fourth or fifth part of the ball A. The common degrees of heat are ſhewn by the top of the mercury in the longeſt leg, or by the top of the ſpirit, in caſe any of it is left above the mercury. When the mercury in the longeſt leg ſinks by cold, that in the ſhorter leg will riſe, and will run over into the ball A; from whence it cannot return back when the thermometer riſes again, as the ſurface of the mercury in the ball is below the orifice of the tube *n*. Therefore the upper part of the ſhorter leg will be filled with a column of ſpirits of a length proportional to the increaſe of heat; the bottom of which, by means of a proper ſcale, will ſhew how much the thermometer has been lower than it is; which being ſubtracted from the preſent height, will give the loweſt point that it has been at. In order to prevent the mercury from falling into the ball A in large drops, which would affect the accuracy of the inſtrument, the top of the ſhorter leg, cloſe to the ball, is contracted, by being held in the flame of a lamp, and the paſſage farther ſtraightened by a ſolid thread of glaſs placed within the tube, and extending from the bottom of the ſhorter leg to the part near the ball A, where it is moſt contracted. By this means, as ſoon as any ſmall portion of mercury is got beyond the thread of glaſs, it breaks off, and falls into the ball in very ſmall drops.

In order to fill the ſhorter leg with mercury, for a new experiment, it muſt be inclined till the mercury in the ball covers the orifice of the tube *n*. The cylinder being then heated, the mercury will be forced into the ſhorter leg, and will run down the thread of glaſs in drops, which will ſoon unite. Thus ſuch a quantity of mercury muſt be got into the ſhorter leg, as, upon the cooling of the inſtrument, will be ſufficient to drive all the ſpirit of wine into the ball, with a leſs degree of cold than what the thermometer is likely to be expoſed to. The ball A muſt always have ſome mercury in it, but never enough to fill it up to the orifice of the tube *n*. It will be beſt to leave a little of the ſpirit above the mercury in the longeſt leg; in which caſe the top of the ſpirit will ſhew the common degrees of heat. The ſcale of degrees on the ſhorter leg will, in different ſeaſons, be liable to an error ſimilar to that which was explained in the firſt mentioned thermometer; but it will be leſs conſiderable, as the ſpace between the two ſcales is filled with mercury, whoſe expanſion is about ſix times leſs than that of the ſpirit of wine. In the thermometer now deſcribed, the bore of the tube is about 0.054 inches; and one inch of it contains eight grains of mercury, and anſwers to ſeven degrees of Fahrenheit's ſcale. The drops of mercury which fall into the ball A, anſwer to about one-eighth of a degree.

Inſtruments of this kind, with ſome alteration in their conſtruction, would ſerve for finding the temperature of the ſea at great depths, and alſo for finding that of the air at conſiderable heights. Lord Charles Cavendiſh has ſhewn how to adapt them for ſuch purpoſes. See Phil. Tranſ. vol. l. art. 38. p. 300, &c.

Since the publication of Mr. Canton's diſcovery of the compreſſibility (ſee Compression) of ſpirits of wine and other fluids, there are two corrections neceſſary to be made in the reſult given by lord Charles Cavendiſh's thermometer. For in eſtimating, *e. g.* the temperature of the ſea at any depth, the thermometer will appear to have been colder than it really was: and beſides, the expanſion of ſpirits of wine by any given number of degrees of Fahrenheit's thermometer is greater in the higher degrees than in the lower. For the method of making theſe two corrections by Mr. Cavendiſh, ſee Phipps's Voyage to the North Pole, p. 145.

Inſtruments of this kind, for determining the degree of heat or cold in the abſence of the obſerver, have been invented and deſcribed by others. Van Swinden (Diſſ. ſur la Compariſon du Therm. p. 253—255.) deſcribes one, which, he ſays, was the firſt of the kind made on a plan communicated by M. Bernouilli to M. Leibnitz. M. Kraft, he alſo tells us, made one nearly like it. Mr. Six, in 1782, propoſed another conſtruction of a thermometer of the ſame kind, which has been well received.

This is properly a ſpirit thermometer, though mercury is employed in it for the purpoſe of ſupporting a certain index: *a b* (*fig.* 14.) is a tube of thin glaſs, about ſixteen inches long, and $\frac{8}{10}$ths of an inch in diameter; *c d e f g h* is a ſmaller tube, with the inner diameter about $\frac{1}{20}$th, joined to a larger at the upper end *b*, and bent down firſt on the left ſide, and then, after deſcending two inches below *a b*, upwards again on the right, in the ſeveral directions *c d e*, *f g h*, parallel to, and one inch diſtant from it. At the end of the ſame tube at *h*, the inner diameter is enlarged to half an inch from *h* to *i*, which is two inches in length. This glaſs is filled with highly rectified ſpirit of wine to within half an inch of the end *i*, excepting that part of the ſmall tube from *d* to *g*, which is filled with mercury. From a view of the inſtrument it will be readily conceived, that when the ſpirit in the large tube is expanded by heat, the mercury in the ſmall tube on the left ſide will be preſſed down, and cauſe that on the right ſide to riſe: on the contrary, when the ſpirit is condenſed by cold, the reverſe will happen. Fahrenheit's ſcale, which begins with 0 at the top of the left ſide, has the degrees numbered downwards, while that at the right ſide, beginning with 0 at the bottom, aſcends. The diviſions are aſcertained by placing the thermometer with a good ſtandard mercurial one in water, gradually heating or cooling, and marking the diviſions of the new ſcale at every five degrees. The diviſions below the freezing point are taken by means of a mixture of ſea-ſalt and ice, as deſcribed by Nollet, De Luc, and others. In order to ſhew how high the mercury has riſen in the obſerver's abſence, there is placed within the ſmall tube of the thermometer, above the ſurface of the mercury on either ſide, immerſed in the ſpirit of wine, a ſmall index, ſo fitted as to paſs up and down as occaſion may require. One of theſe indices is repreſented in *fig.* 15; *a* is a ſmall glaſs tube, three-quarters of an inch long, hermetically ſealed at each end, incloſing a piece of ſteel wire nearly of the ſame length; at each end *c*, *d*, is fixed a ſhort piece of a tube of black glaſs, of ſuch a diameter as to paſs freely up and down within the ſmall tube of the thermometer. The lower end, floating on the ſurface of the mercury, is carried up with it when it riſes, while the piece at the upper end, being of the ſame diameter, keeps the body of the index parallel to the ſides of the thermometrical tube. From the upper end of the body of the index at *c* is drawn a ſpring of glaſs to the fineneſs of a hair, about five-fourths of an inch in length, which being ſet a little oblique, preſſes lightly againſt the ſurface of the tube, and prevents the index from following the mercury when it deſcends, or being moved by the ſpirit paſſing up and down, or by any ſudden motion given to the inſtrument; but at the ſame time the preſſure is ſo adjuſted as to permit this index to be readily carried up by the ſurface of the riſing mercury, and downwards, whenever the inſtrument is rectified for obſervation. This index, by not returning

turning with the mercury when it defcends, fhews diftinctly and accurately how high the mercury has rifen, and confequently what degree of cold or heat has happened. To prevent the fpirit from evaporating, the tube at the end *i* is clofely fealed. The daily rectification of this inftrument is performed, by applying a fmall magnet to that part of the tube againft which the index refts; by the action of which the included piece of fteel wire, and confequently the index, is eafily brought down to the furface of the mercury. When this has been done, the inftrument is rectified for the next day's obfervation, without heating, cooling, feparating, or at all difturbing the mercury, or moving the inftrument. With a thermometer of this fort, Mr. Six obferved the greateft heat and cold that happened every day and night throughout the year 1781. But for the more particular defcription of this inftrument, the illuftration of it by figures, and an account of its advantages, the limits of this work require our referring to Phil. Tranf. vol. lxxii. part i. p. 72, &c.

A fimilar effect to that produced by Six's thermometer is obtained in Rutherford's arrangement of a pair of thermometers, one with mercury, the other with fpirit of wine, placed in a horizontal pofition; one index being without the furface of the mercury, the other within that of the fpirit: the thermometers being in contrary directions, both indices may be brought back to their places, by merely raifing the end of the inftrument. (See *fig.* 16.) Self-regiftering thermometers have alfo fometimes been conftructed for keeping a ftill more accurate account of all the variations of temperature that have occurred, by defcribing a line on a revolving barrel, which fhews the height for every inftant during the whole time of their operation.

M. de Luc has defcribed the beft method of conftructing a thermometer, fit for determining the temperature of the air, in the menfuration of heights by the barometer. He has alfo fhewn how to divide the fcale of a thermometer, fo as to adapt it for aftronomical purpofes in the obfervation of refraction. See Récherches, &c. tom. ii. p. 35, &c. p. 265, &c.

Mr. Cavallo, in 1781, propofed the conftruction of a thermometrical barometer, which, by means of boiling water, might indicate the various gravity of the atmofphere, or the height of the barometer. This thermometer, he fays, with its apparatus, might be packed up into a fmall portable box, and ferve for determining the heights of mountains, &c. with greater facility than with the common portable barometer. The inftrument, in its prefent ftate, confifts of a cylindrical tin veffel, about two inches in diameter, and five inches high, in which veffel the water is contained, which may be made to boil by the flame of a large wax-candle. The thermometer is faftened to the tin veffel in fuch a manner, as that its bulb may be about one inch above the bottom. The fcale of this thermometer, which is of brafs, exhibits on one fide of the glafs tube a few degrees of Fahrenheit's fcale, *viz.* from 200° to 216°. On the other fide of the tube are marked the various barometrical heights, at which the boiling water fhews thofe particular degrees of heat which are fet down in fir G. Shuckburgh's table. With this inftrument the barometrical height is fhewn within one-tenth of an inch. The degrees of this thermometer are fomewhat longer than one-ninth of an inch, and therefore may be divided into many parts, efpecially by a Nonius. But the greateft imperfection of the inftrument arifes from the fmallnefs of the tin veffel, which does not admit a fufficient quantity of water; but when the quantity of water is fufficiently large, *e. g.* 10 or 12 ounces, and is kept boiling in a proper veffel, its degree of heat under the fame preffure of the atmofphere is very fettled; whereas when a thermometer is kept in a fmall quantity of boiling water, the quickfilver in its ftem does not ftand very fteady, fometimes rifing or falling even half a degree. Mr. Cavallo propofes a farther improvement of this inftrument in the Phil. Tranf. vol. lxxi. part ii. p. 524.

The ingenious Mr. Wedgwood, fo well known for his various improvements in the different forts of pottery-ware, has contrived to make a thermometer for meafuring the higher degrees of heat, by means of a diftinguifhing property of argillaceous bodies, *viz.* the diminution of their bulk by fire. This diminution commences in a low red heat, and proceeds regularly, as the heat increafes, till the clay becomes vitrified. The total contraction of fome good clays which he has examined in the ftrongeft of his own fires, is confiderably more than one-fourth part in every dimenfion. If, therefore, we can procure at all times a clay fufficiently apyrous or unvitrefcible, and always of the fame quality in regard to contraction by heat; and if we can find means of meafuring this contraction with eafe and accuracy, we fhall be furnifhed with a meafure of fire fufficient for every purpofe of experiment or bufinefs. Some of the pureft Cornifh porcelain clays (which, by the analyfis of Mr. Wedgwood, appear to contain no calcareous earth nor gypfeous matter, but to confift of pure argillaceous or alum earth, and another indiffoluble earth, which he apprehends to be of the filiceous kind, in the proportion of three parts of the former to two parts of the latter) feem the beft adapted, both for fupporting the intenfity, and meafuring the degrees of fire. This material is prepared for ufe by wafhing it over, and whilft in a diluted ftate paffing it through a fine lawn: it is then dried and put up in boxes. The dry clay is to be foftened for ufe with about two-fifths its weight of water; and formed into fmall pieces, in little moulds of metal, $\frac{6}{10}$ths of an inch broad, with the fides exactly parallel; about $\frac{4}{10}$ths of an inch deep, and an inch long. The moulds are to be oiled and warmed. Thefe pieces, when perfectly dry, are put into another iron mould or gage, confifting only of a bottom, with two fides, $\frac{5}{10}$ths of an inch deep, to the dimenfions of which fides the breadth of the pieces is to be pared down. For meafuring the diminution which they are to fuffer from the action of fire, another gage is made of two pieces of brafs, twenty-four inches long, with the fides exactly ftraight, divided into inches and tenths, fixed five-tenths of an inch afunder at one end, and three-tenths at the other, upon a brafs plate; fo that one of the thermometric pieces, when pared down in the iron gage, will juft fit to the wider end. If this piece be fuppofed to have diminifhed in the fire one-fifth of its bulk, it will then pafs on to half the length of the gage; if diminifhed two-fifths, it will go on to the narroweft end: and in any intermediate degree of contraction, if the piece be flid along till it refts againft the converging fides, the degree at which it ftops will be the meafure of its contraction, and confequently of the degree of heat it has undergone. The thermometric pieces may be formed much more expeditioufly than in the fingle mould by means of an inftrument, confifting of a cylindrical iron veffel, with holes in the bottom, of the form and dimenfions required.—The foft clay, put in the veffel, is forced by a prefs down through thefe apertures, in long rods, which may be cut while moift, or broken when dry, into pieces of convenient lengths. After which, recourfe fhould be had to the paring gage for afcertaining and adjufting their breadth when perfectly dry.

Each divifion of the fcale, though fo large as a tenth of an an inch, anſwers to $\frac{1}{600}$th part of the breadth of the little piece of clay. When one gage is accurately adjuſted to the proportional meaſures above ſtated, two pieces of braſs ſhould be made, one fitting exactly into one end, and the other into the other; which will ſerve as ſtandards for the ready adjuſtment of other gages to the dimenſions of the original, and thus we may be aſſured, that thermometers on this principle, though made by different perſons, and in different countries, will all be equally affected by equal degrees of heat, and all ſpeak the ſame language. The ſcale commences at a red heat fully viſible in day light; and the greateſt heat which Mr. Wedgwood has hitherto obtained in his experiments, is 160°. Swediſh copper has been found to melt at 27°, ſilver at 28°, and gold at 32°, of this thermometer. Braſs is in fuſion at 21°: the welding heat of iron is from 90° to 95°, and the greateſt heat that could be produced in a common ſmith's forge, 125°. Caſt iron melted at 130°; and the heat by which iron is run down among the fuel for caſting is 150°. A Heſſian crucible melted into a ſlag-like ſubſtance at about 150°. The fonding heat of glaſs furnaces, or that by which the perfect vitrifications of the materials is produced, was at one of them 114° for flint-glaſs, and 124° for plate-glaſs. Delft-ware is fired by a heat of 40° or 41°; Queen's-ware by 86°; and ſtone-ware by 102°, which degree of heat changes it to a true porcelain texture. The thermometer pieces begin to acquire a porcelain texture at about 110°. A piece of an Etruſcan vaſe melted completely at 33°; pieces of other vaſe and Roman ware about 36°; Worceſter china vitrified at 94°; Mr. Sprimont's Chelſea china at 105°; the Derby at 112°; the Bow at 121°; but Briſtol china ſhewed no appearance of vitrification at 135°. The common ſort of Chineſe porcelain does not perfectly vitrify by any fire which Mr. Wedgwood could produce: but began to ſoften about 120°, and at 156° became ſo ſoft as to ſink down and apply itſelf cloſe upon an irregular ſurface underneath. The true ſtone Nankeen does not ſoften in the leaſt, by this ſtrong heat; nor even acquire a porcelain texture. The Dreſden porcelain is more refractory than the common Chineſe, but not equally ſo with the ſtone Nankeen. The cream-coloured or Queen's-ware bears the ſame heat as the Dreſden. Mr. Pott ſays, that to melt a mixture of chalk and clay in certain proportions, which appear from his tables to be equal parts, is "among the maſter-pieces of art." This mixture melts into a perfect glaſs at 123° of this thermometer. For other curious particulars, ſee Phil. Tranſ. vol. lxxii. part ii. p. 305, &c.

This thermometer, ſays Dr. Young, (Lect. on Nat. Philoſ. vol. i. 648.) may be extremely uſeful for identifying the degree of heat which is required for a particular purpoſe; but for the compariſon of temperatures by an extenſion of the numerical ſcale, we have not ſufficient evidence of its accuracy to allow us to depend on its indications; and it is ſcarcely credible, that the operation of furnaces of any kind, can produce a heat of ſo many thouſand degrees of a natural ſcale, as Mr. Wedgwood's experiments have led him to ſuppoſe; nor is the ſuppoſition conſiſtent with the obſervations of other philoſophers.

Thermometer, *Differential*, a curious ſort of thermometer invented by profeſſor Leſlie, which expreſſes not the abſolute degree of heat, but the difference, when any exiſts, between the temperatures of the two ſpots where its two bulbs are placed. The method of conſtructing it is as follows. (See *Plate* XVI. *Pneumatics*, *fig.* 17.) Select two thermometer tubes with bores rather wider than uſual, and one a little wider than the other. Let the balls be blown as equal as the eye can judge, and from .4 to .7 of an inch in diameter, and let the open end of the tube alſo be widened in a ſlight degree. The tubes muſt be of unequal length, the longeſt being nearly twice the length of the other. Then introduce into the longer tube a little ſulphuric acid tinged with carmine, ſufficient to fill about an inch of its cavity; join the two tubes together by the blow-pipe, and when joined, bend them in the form of the letter U, with the bulbs about three or four inches aſunder, making one flexure juſt below the juncture of the two tubes, where the ſmall cavity (which is repreſented in the plate) facilitates the adjuſtment of the inſtrument, which by a little dexterity is performed by forcing a few globules of air by the heat of the hand from one bulb to the other. Attach a graduated ſcale to the ſhorter tube, making the zero about the middle of it, and adjuſt to it the quantity of air in each bulb, ſo that when the bulbs are at the ſame temperature, the upper ſurface of the coloured liquor may juſt correſpond with the zero. Sulphuric acid is choſen as the liquor interpoſed between the bulb, on account of its bearing any heat or cold that would be uſed without being evaporated or congealed.

In this inſtrument the air incloſed in the bulbs is the ſubſtance, which, by its expanſion or contraction, cauſes the motion of the coloured liquor up or down the ſcale, and as gaſes are much more expanſible than liquids, the inſtrument is ſooner affected by minute changes of heat. But as the two bulbs are of equal ſize, and both filled with air, and ſeparated from each other by the intervening liquor, it is obvious that when the temperature is the ſame in each bulb, be it high or low, the preſſure on each ſide of the liquor is alſo equal, and it muſt remain ſtationary: ſo that it can only move when one bulb is warmer than the other. Hence the particular and ſole uſe of this inſtrument as a differential thermometer. The lower part of the inſtrument (or the ſpace included between the two bends) is cemented to an upright ſtem, by which it is ſupported.

This inſtrument has been employed by the inventor in a variety of curious experiments on caloric, or the matter of heat. The peculiar advantage which this inſtrument poſſeſſes is, that, beſides its extreme ſenſibility, in uſing it the common temperature of the ſurrounding air may, in general, be diſregarded; this being always the *zero* of the ſcale, whatever be the actual variation of heat in the ſurrounding atmoſphere; and hence a much greater degree of ſimplicity is introduced into the delicate reſearches on this ſubject. For the reflection of heat mirrors were employed, generally of block-tin, highly poliſhed, and hammered to fit a wooden gage, the ſegment of a parabolic curve, by which much of the diſperſion produced by a ſimple concave form was avoided; ſo that when expoſed to the direct rays of the ſun, they collected them into a pretty diſtinct focus, of about half an inch in diameter. The ſubſtance employed to generate the radiant heat was a hollow cubic tin caniſter, placed directly in front of the mirror of its focal point, and when uſed, filled with boiling water, and fitted with a common thermometer, paſſing through a hole in the cover, and immerſed in the water. The cubical form of the caniſter allowed of four ſides, of perfectly equal dimenſions, each of which, when turned to the mirror, afforded a heated ſurface for the tranſmiſſion of radiant caloric, and they were occaſionally coated with various ſubſtances to aſcertain the effect of colour, poliſh, and the like, in retarding or promoting the radiation of the heat within. With this apparatus, and his differential thermometer, Mr. Leſlie performed a variety of intereſting experiments, for

for the general reſults of which we refer to the article Heat; and for a more minute detail to Leſlie's "Inquiry into the Nature of Heat;" and for an extenſive abſtract, to an elaborate article on *Caloric* in Aikin's Dictionary. See alſo our articles Caloric, Radiant *Rays*, &c. &c.

Thermometer, *Balance*, an inſtrument invented by Mr. James Kewley, of the Iſle of Man, and for which he obtained a patent for Scotland, dated Nov. 4, 1816; for England, dated Nov. 21, 1816; and for Ireland, dated Jan. 4, 1817. This inſtrument (beſides anſwering the purpoſe of aſcertaining the temperature) is uſed as a firſt moving power for putting machinery into motion, for the purpoſe of regulating the temperature, by opening or cloſing the flues, windows, or doors of the apartment in which it is placed. This invention muſt therefore be of great importance to the horticulturiſt; as by it the artificial climate of hot-houſes, conſervatories, hot-beds, &c. can be accurately regulated, without the leaſt attention from the gardener, farther than occaſionally to wind up the machine to which it is attached.

In *Plate* XVI. *Pneumatics*, *fig.* 18. is a perſpective repreſentation of Kewley's balance thermometer. A is a glaſs tube, with its bulbs *c* and *d* hermetically ſealed at *e*, and having a very fine aperture at *f*, for the admiſſion of the preſſure of the atmoſphere upon the ſurface of the quickſilver contained in the bulb *d*: *g* is a milled-headed nut, let into a mortiſe in the frame *h*, having a female ſcrew in its centre, through which the ſcrew *i* is made to paſs. This nut ſerves to elevate or depreſs the tube with the two clamping-pieces (between which it is ſcrewed faſt) in the frame *h*, for the purpoſe of adjuſting the inſtrument to its proper centre of gravity: *k* is a milled nut, having a pinion on its arbor, and ſerves the purpoſe of moving the ſcale *i* to the right or left, as may be required: *m* and *n* are the knife-edged centres, on which the inſtrument ſwings in any ornamental frame that the poſſeſſor may chooſe. When the inſtrument is at the mean temperature of its range, the bulbs *c* and *d* ought to be each about half full, and the ſmall tube communicating with the bulbs quite full of quickſilver; and the large tube, and half of the bulb *c*, full of alcohol. Now it is evident, that when the alcohol in the large tube expands by an increaſe of temperature, it muſt preſs upon the ſurface of the quickſilver in the bulb *c*, and force a quantity of quickſilver, equal to its expanſion, into the bulb *d*: the centre of gravity of the inſtrument will thereby be altered, and it will turn upon its centres, like the beam of a pair of ſcales; therefore, when the temperature is deſired to be known, the ſcale is to be moved by turning the nut *k*, in order to bring the inſtrument to a balance; when that is done, the degree is read off at *o*. When this inſtrument is uſed as a firſt moving power, to regulate the temperature of hot-houſes, &c. it has a lever or wheel attached to one of its centres, which communicating with machinery, puts it in motion when the temperature is either higher or lower than the degree deſired, which motion opens or cloſes the windows, flues, &c. as may be neceſſary, until the degree of temperature to which the inſtrument is at be produced.

Comparisons of different Thermometers.

THERMOPOLIUM, formed of θερμος, *hot*, and πωλεω, *I sell*, a name for a sort of public houses among the ancients, in which hot liquors were sold, in the manner of our coffee-houses.

THERMOPSIS, in *Botany*, from θερμος, *a Lupine*, and οψις, *appearance* or *aspect*, indicating a general resemblance to that genus of plants.—Brown in Ait. Hort. Kew. v. 3. 3. lass and order, *Decandria Monogynia*. Nat. Ord. *Papiliona*. Linn. *Leguminosæ*, Juss.

Ch. Calyx oblong, five-cleft half way down, two-li ; convex behind ; tapering at the base. Corolla papilionaceous ; petals nearly of equal length ; standard reflexed at the sides, keel obtuse. Stamens permanent. Legume compressed, linear, with many seeds. *Br.*

1. Th. *lanceolata.* Sharp-leaved Thermopsis. Ait. n. 1. (Podalyria lupinoides ; Willd. Sp. Pl. v. 2. 504. Sophora lupinoides ; Linn. Sp. Pl. 534. "Pallas Astrag. 119. t. 89.")—Leaflets oblong-lanceolate. Stipulas lanceolate, twice as long as the footstalks Flowers whorled.—Native of Siberia ; from whence the late duke of Northumberland is said to have received it in 1776. This is a hardy perennial herbaceous plant, flowering in June and July. The *stems* are spreading or decumbent, about a foot long, branched in an alternate manner, round, hairy, leafy. *Leaves* ternate, light green, hairy, on short stalks ; their *leaflets* about an inch long. *Stipulas* half as large, or more. *Flowers* stalked, about three in each whorl, yellow, much resembling those of a Lupine. *Calyx* hairy.

By Mr. Brown's specific character, we presume there are more species of this genus, though not in our gardens, of which he will one day give an account. For the soundness of the generic distinctions, we rely on him. The compressed *legume* seems the most important difference between *Thermopsis* and the *Baptisia* of Ventenat and Brown ; see Ait. Hort. Kew. v. 3. 5 ; also our articles Sophora and Podalyria.

THERMOPYLÆ, in *Ancient Geography*, a strait or pass, rendered famous by the valour of Leonidas and his companions, who defended it against the army of Xerxes in the year 480 B.C ; and which, long after that celebrated event, was defended against the Gauls. This pass is the only road by which an army can penetrate from Thessaly into Locris, Phocis, Bœotia, Attica, and the adjacent countries. The following succinct description is given of this strait by the abbé Barthelemy, in his "Anacharsis." On quitting Phocis to go into Thessaly, having passed the little country of the Locrians, we arrive, says the abbé, at the town of Alpenus, situated by the sea. As it stands at the entrance of the strait, it has been fortified. The road at first is only wide enough for the passage of a waggon ; but it it afterwards enlarges itſelf between moraſſes formed by the waters of the ſea and almoſt inacceſſible rocks, which terminate the chain of mountains known by the name of Oeta. After leaving Alpenus, a ſtone is diſcovered on the left, conſecrated to Hercules Melanpygus, and a path preſents itſelf that leads to the ſummit of the mountain. Farther on, the traveller croſſes a current of hot water, which gives this place its name of Thermopylæ. Next to this ſtream is the town of Anthela; and in the plain which ſurrounds it are a ſmall eminence and a temple of Ceres, in which the Amphictyons annually held one of their aſſemblies. On coming out of the plain there is a road, or rather cauſeway, only about ſeven or eight feet wide. Here the Phocians had formerly built a wall, to protect their country from the inroads of the Theſſalians. After paſſing the Phœnix, which at laſt falls into the Aſopus, a river that riſes in an adjacent valley, we come to the laſt defile, half a plethrum (15 or 16 yards) in breadth. The road then widens as far as Trachinia, which takes its name from the city of Trachis, that was inhabited by the Malians. This country preſents to the view of the traveller extenſive plains watered by the Sperchius and other rivers. To the E. of Trachis ſtood the city of Heraclea, which did not exiſt in the time of Xerxes. The whole ſtrait, from the defile before we arrive at Alpenus to that which is beyond the Phœnix, may be about 48 ſtadia (about 2 leagues) in length. Its breadth varies almoſt at every ſtep; but through its whole extent it is ſhut in on one ſide by ſteep mountains, and on the other by the ſea, or impenetrable moraſſes. The road is often deſtroyed by the torrents, or by ſtagnant waters. Leonidas poſted his little army near Anthela, rebuilt the wall of the Phocians, and diſpatched a few advanced troops to defend the approaches. But it was not ſufficient to guard the paſſage at the foot of the mountain; on the mountain itſelf there was a path, which, beginning at the plain of Trachis, terminated, after various windings, near the town of Alpenus. Leonidas entruſted the defence of this path to the thouſand Phocians he had with him, and who took poſt on the heights of mount Oeta. As ſoon as theſe arrangements were completed, the army of Xerxes was diſcovered, ſpreading itſelf over Trachinia, and covering the plain with its innumerable tents. The Greeks deliberated on the meaſures proper to be adopted; moſt of the generals were for retiring to the iſthmus; but Leonidas rejected this counſel. A Perſian horſeman was deputed to reconnoitre the advanced poſt of the Greeks, which was compoſed of Spartans; and as the reſt of the army was concealed from him by the wall, he only gave an account to Xerxes of the 300 men he had ſeen at the entrance of the defile. After various meſſages from Xerxes to Leonidas, and the firm and calm replies of the latter, the Perſian king was enraged, and gave orders for an attack. The Medes ruſhed on with fury, and one rank fell after another, while the Greeks, preſſing cloſe againſt each other, and covered with large bucklers, preſented an impenetrable front of long pikes, and a phalanx which freſh troops ſucceſſively in vain attempted to break. At length the Medes were ſeized with a panic, and fled; but they were ſpeedily relieved by the choſen body of the 10,000 immortals, commanded by Hydarnes. The action now became more bloody; but the Greeks had the advantage of ſituation, and ſuperiority of arms. The Perſians loſt many men; and Xerxes, witneſſing their flight, leaped, as it is ſaid, more than once from his chariot, and trembled for their fate. Next day the attack was renewed, but with ſo little ſucceſs, that Xerxes deſpaired of forcing the paſſage. At length Epialtes, an inhabitant of thoſe diſtricts, diſcovered to him the fatal path by which he might turn the Grecians; and ſerved as a guide to Hydarnes and his corps of immortals, under whoſe conduct they arrived near the ſpot where Leonidas had poſted a detachment of his army; and prepared to attack it. When this dreadful news reached the Greeks, their leaders aſſembled. Some were for retreating, and others for remaining; but Leonidas declared for himſelf and his companions, that they were not permitted to quit a poſt which Sparta had confided to their care. In the middle of the night, the Greeks, with Leonidas at their head, iſſued out of the defile, advanced through the plain, overthrew the advanced poſts, and penetrated to the tent of Xerxes, who had already taken flight. They ſpread over the camp, and glutted themſelves with carnage. The Perſians were terrified and confuſed, and many of them periſhed by the hands of one another. At length, with the dawn of day they diſcovered the inconſiderable number of their victors, and rallying, attacked the Greeks on all ſides. Leonidas fell beneath a ſhower of darts; and a conteſt for the honour of carrying off his body, occaſioned a terrible conflict between his companions and the moſt expert and hardy warriors of the Perſian army. The Greeks, however, prevailed, and carried off their general; and having regained the defile, poſted themſelves on an eminence, and for ſome time continued to defend themſelves. When Xerxes offered to Leonidas the empire of Greece, if he ſubmitted to his power, he replied, "I rather chooſe to die free than to enſlave my country." When the king commanded him to ſurrender his arms, he wrote the laconic anſwer, "come and take them." "The Perſians are near us," ſaid one of his ſoldiers to Leonidas: "rather ſay," he coolly replied, "that we are near the Perſians." See Leonidas.

It has been a ſubject of diſpute what was the number of Grecian troops under the command of Leonidas at Thermopylæ. Herodotus ſtates them at 5100, Pauſanias at 11,200, and Diodorus at 7400. The abbé Barthelemy attempts to reconcile theſe different ſtatements, and concludes, upon the whole, that Leonidas had with him about 7000 men. If we may credit Diodorus, he had no more than 500 ſoldiers when he determined to attack the Perſian camp.

On the eminence to which the companions of Leonidas retired after the death of their commander, there were ſeveral monuments erected by order of the Amphyctionic council, in honour of the 300 Spartans, and the other Grecian troops engaged in the combat. On one of theſe cippi is inſcribed, "Here four thouſand Greeks of Peloponneſus fought againſt three millions of Perſians."

THERMOSCOPE, an inſtrument ſhewing the changes happening in the air with reſpect to heat and cold.

The word thermoſcope is generally uſed indifferently with that of thermometer. There is ſome difference, however, in the literal import of the two; the firſt ſignifying an inſtrument that ſhews or exhibits the changes of heat, &c. to the eye; formed from θερμη, *heat*, and σκοπειν, *video, I ſee*; and the latter an inſtrument that meaſures thoſe changes, from θερμη, *heat*, and μετρειν, *to meaſure*, on which foundation the thermometer ſhould be a more accurate thermoſcope, &c. This difference the excellent Wolfius taking hold of, deſcribes all the thermometers in uſe as thermoſcopes; ſhewing that none of them properly meaſure the changes of heat, &c. none of them do more than indicate the ſame. Though their different heights yeſterday and to-day ſhew a difference of heat; yet, ſince they do not diſcover the ratio of yeſterday's heat to to-day's, they are not ſtrictly thermometers.

THERONDELS, in *Geography*, a town of France, in the department of the Aveiron; 3 miles N.E. of Mur.

THEROUANNE, a town of France, in the department of the Straits of Calais, on the Lys. It was anciently the

the capital of the Morini, and afterwards an epifcopal fee, with feveral churches and convents; but being taken in the year 1553 by the emperor Charles V., he demolifhed it. The diftrict belonging to it, however, was ceded by Spain to France, at the treaties of the years 1559 and 1659; 6 miles S. of St. Omer.

THERSA, or Thapsa, in *Ancient Geography*, a royal town of Judea, in the half-tribe of Manaffeh, on this fide of Jordan. Therfa was the feat, capital, and burying-place of the firft kings of Ifrael.

Thersa, or *Thirza*, a town of Paleftine, in the tribe of Ephraim.

THERSARA, a town of Afia, in the interior of Affyria. Ptolemy.

THERSITÆ, a people of Spain, in Iberia; they were of the number of thofe whom Annibal caufed to pafs into Africa.

THERUINGI, a people who inhabited a part of Dacia, on the other fide of the Danube.

THESBON, a town of Paleftine, on the other fide of Jordan, in the tribe of Gad.

THESEA, or Thesæa, Θησεια, in *Antiquity*, feafts celebrated by the Athenians in honour of Thefeus.

In fpite of the important fervices that hero had done his country, in delivering it from a fhameful tribute of fo many youths, of either fex, fent yearly to be devoured by the Minotaur in Crete (as the fable has it), or fent as flaves to Minos, king of Crete, as the hiftories have it, from which he freed them, by overturning Taurus, Minos's general; he was banifhed for fome time, and retired to Scyros, under the protection of Lycomedes, king of that ifland, where he finally loft his life either by accident, or in confequence of the jealoufy of the king.

The gods, it is faid, revenged this treatment Thefeus received from the Athenians, by afflicting them with a famine, which the oracle affured them fhould not ceafe till they had avenged his death. Upon this they flew Lycomedes, brought Thefeus's bones to Athens, placed them in a temple erected to him, and appointed Thefea to be held every eighth day of each month, in which largeffes were diftributed to the people, and the day was fpent, by the rich, in feafting and rejoicing, and with peculiar folemnity on the eighth day of the month Pyanepfion.

Plutarch, however, gives a different account of the origin of this feaft; he fays that the Athenians, imagining they faw Thefeus at the battle of Marathon under the form of a tutelary deity, confulted the oracle on this prodigy: and being ordered to collect his bones in the ifland of Scyros, removed them with great pomp to Athens; and depofited them under a magnificent monument erected in the middle of the city, which became afterwards an afylum for flaves, in commemoration of the fuccour afforded by this prince to the unfortunate during his life. They alfo erected a temple where they offered facrifices, &c. At Rome, Thefeus was held in very different eftimation, for Virgil (Æn. lib. vi.) places him in Tartarus, among thofe who were tormented for their crimes.

THESEUS, in *Biography*, a hero celebrated in the fabulous ages of Greece, and referred by chronologers to the thirteenth century B.C. was the illegitimate fon of Ægeus, king of Athens, by Æthra, daughter of Pittheus, king of Trœzern; and as he advanced towards maturity difcovered a vigorous fpirit in an athletic frame. In his journey to Athens by land he met with many adventures and conflicts, and on his arrival found the city agitated by diffenfions. The fons of Pallas, the brother of Ægeus, fufpecting that the aged and childlefs fovereign would adopt this newly arrived ftranger for his heir, fomented his jealoufies, fo that Ægeus prepared poifon for difpatching him; but before his plan could be accomplifhed, he difcovered by certain tokens that he was his fon. The confequence of this difcovery was a revolt of the Pallantides, which Thefeus fuppreffed.

For an account of the further exploits of Thefeus for the relief of the Athenians, we refer to our article *Hiftory of* Athens. Thefeus having, in the manner there related, eftablifhed a conftitution for the Athenians, yielded to the impulfe of ambition; and quitting his throne, and fometimes in the company of Hercules and fometimes of Pirithous, fon of Ixion, king of Theffaly, whofe friendfhip he had fecured, undertook a variety of enterprizes, the account of which is fo intermixed with the fabulous, that it is impoffible fatisfactorily to develope it. He is faid, however, to have conquered certain Amazons on the banks of the Thermodon, in Afia, taking a queen from among them for his wife; to have affifted Pirithous in overcoming the Centaurs in Theffaly; and to have ftolen away from Sparta the celebrated Helen; and afterwards to have joined the fame friend in a fimilar attempt upon Proferpina, the daughter of Aidoneus, king of the Moloffians, in which Pirithous loft his life, and Thefeus underwent an imprifonment, from which Hercules procured his efcape. Upon his return from this romantic expedition, he found his kingdom and family in confufion. Caftor and Pollux, the brothers of Helen, ravaged Attica by way of revenge for the infult offered to their fifter. His queen Phædra, falling in love with Hippolytus, his fon by the Amazon, and being rejected, calumniated him to his father, and occafioned his death, as his tragedy has recorded. From a variety of circumftances that occurred, Thefeus finding that he had loft the attachment of the Athenians, abandoned the city, and intended to repair to Demetrius, fon of Minos, now reigning in Crete. In his paffage thither he was driven by a ftorm to the ifle of Scyros, where he was kindly received by the king, Lycomedes; but foon afterwards he loft his life by a fall from a rock. (See Thesea.) The refentment of the Athenians afterwards fubfided, and they regarded him only as a hero and benefactor; and Cimon, fon of Miltiades, having conveyed his bones, as they were fuppofed to be, to Athens, in confequence of the injunctions of an oracle, a magnificent temple was erected over them, which was made an afylum for the unfortunate. Its remains ftill fubfift as one of the nobleft relics of ancient art in that famous capital. Plut. in Vit. Thefei. Anc. Univ. Hift. Travels of Anacharfis, vol. i.

THESIN.—*Per Arfin* and *Thefin*. See Per *Arfin*.

THESIS, Θεσις, *pofition*, formed from τιθημι, *I put* or *lay down*, in the *Schools*, a general propofition, which a perfon advances, and offers to maintain.

In the college it is frequent to have placards, containing a number of thefe thefes in theology, in medicine, in philofophy, in law, &c. The maintaining a thefis, is a great part of the exercife a ftudent is to undergo for a degree.

Thesis, in *Logic*, &c.—Every propofition may be divided into thefis and hypothefis; thefis contains the thing affirmed or denied, and hypothefis the conditions of the affirmation or negation.

Thus, in Euclid, if a triangle and parallelogram have equal bafes and altitudes (is the hypothefis), the firft is half of the fecond (the thefis).

Arfis and Thefis. See Arsis.

Thesis, θεσις, *depofitio* or *remiffio*, the beating down the hand or foot at the beginning of a bar in mufic. See Arsis, *tollo*, which is the lifting up the hand or foot in the middle or latter part of a bar.

THESIUM, in *Botany*, an ancient name, adopted from the Greeks, enumerated by Linnæus, Phil. Bot. 174, among

 thofe

thoſe whoſe derivation is extremely difficult, and, after all, doubtful. Pliny has the *Theſium* in two places; book 21. chap. 17, and book 22. chap. 22. In the former, it is mentioned amongſt bulbous plants, as having a harſh taſte: in the latter, it ſtands next to *Picris*, as very bitter, and purgative. This laſt account is copied from Theophraſtus, who, in his book 7. chap. 11, ſpeaks of θησιον in the ſame terms, along with a number of plants of the Sowthiſtle and Dandelion tribe, or *Cichoraceæ*. To theſe indeed ſome of the *Arum* family are ſubjoined, and *Theſium* is placed at the end. All we can hence gather is, that the plant in queſtion may poſſibly be ſome plant of the *Syngeneſia Polygamia-æqualis*, of the ſection *ſemifloſculoſæ*, whoſe root is tuberous. Of this deſcription there are ſeveral natives of Greece; ſee Scorzonera, n. 12 and 13. Ambroſini derives the word from θης, *a ſervant*, or rather *a poor tradeſman*, becauſe, as he thinks, of its being ſerviceable in many reſpects, both for food and medicine. Poſſibly Linnæus, who frequently conſulted this author, may hence have been led to apply the name of *Theſium* to the preſent genus, totally different indeed from all that is recorded of the Greek θησιον, but remarkable for its mean habit and hardy texture.—Linn. Gen. 114. Schreb. 160. Willd. Sp. Pl. v. 1. 1211. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 269. Prodr. Fl. Græc. Sibth. v. 1. 164. Ait. Hort. Kew. v. 2. 63. Purſh 177. Brown Prodr. Nov. Holl. v. 1. 352. Juſſ. 75. Lamarck Illuſtr. t. 142. Gærtn. t. 86.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Vepreculæ*, Linn. *Elæagni*, Juſſ. *Santalaceæ*, Brown.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, tubular, in four or five erect ſegments, internally coloured and hairy, permanent. *Cor.* none. *Stam.* Filaments equal in number to the ſegments of the calyx, but not ſo long, inſerted into their baſe, awl-ſhaped; anthers roundiſh, of two lobes. *Piſt.* Germen inferior, roundiſh, confluent with the baſe of the calyx; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma tumid, cloven. *Peric.* none. *Seed.* Nut oval, angular, coated, crowned with the permanent involute calyx, of one cell, with a ſolitary kernel.

Eſſ. Ch. Calyx ſuperior, of one leaf, bearing the ſtamens. Corolla none. Nut ſolitary, coated, crowned with the calyx.

Obſ. Our learned friend Mr. Brown propoſes to ſeparate the Cape ſpecies of this genus from the reſt, perhaps even into two diſtinct genera; but as we cannot find ſufficient grounds for this meaſure, we ſhall admit the whole here, at leaſt till we can obtain fuller information. *Th. Colpoon*, Linn. Suppl. 161. Willd. n. 18, is of courſe excluded, having a *Drupa*, and a very different habit. This is deſcribed, by ſome one of our coadjutors, under the article Fusanus. See alſo Leptomeria.—We are enabled to add a few in its ſtead to Willdenow's liſt, but cannot adopt ſuch as are merely named by Mr. Brown, unleſs where we happen to have ſpecimens.

The whole genus is of a rigid broom-like habit; ſometimes roughiſh, though ſcarcely pubeſcent; with ſimple, uſually very narrow, ſcattered *leaves;* and inconſpicuous green, whitiſh, or yellowiſh *flowers*, either cluſtered, ſpiked, or ſomewhat capitate.

1. Th. *linophyllum*. Baſtard Toad-flax Theſium. Linn. Sp. Pl. 301. Willd. n. 1. Fl. Brit. n. 1. Prodr. Fl. Græc. n. 1. Engl. Bot. t. 247. Pollich Palat. v. 1. 238. Roth. in Sims and Konig's Ann. of Bot. v. 2. 18. (Th. pratenſe; Ehrh. Herb. n. 12. Th. montanum; ibid. n. 2. Th. intermedium; Schrad. Spicil. 27. Anonymos lini folio; Cluſ. Hiſt. v. 1. 323. Linaria adulterina; Ger. Em. 555.)—Stem erect, ſomewhat branched. Cluſter moſtly compound. Bracteas ternate. Leaves linear-lanceolate. Tube of the calyx cup-ſhaped, very ſhort.—Native of dry chalky hills throughout moſt parts of Europe, though reckoned amongſt our rarer Engliſh plants, flowering in July. The *root* is woody, perennial, branched, crooked, whitiſh, ſending up ſeveral erect or reclining, ſmooth, leafy, more or leſs angular, rigid, branched *ſtems*, from four to twelve inches high. *Leaves* numerous, alternate, linear, entire, in ſome degree ſucculent and glaucous, minutely rough at the edges, as are ſometimes the angles of the ſtem. *Cluſters*, rather than ſpikes, more or leſs branched, or even panicled, each branch bearing one or more *flowers*, either ſolitary at the extremity, accompanied by three lanceolate, leafy, unequal *bracteas*, or without *bracteas*, in the fork of the ſtalk, whoſe diviſions bear other *flowers*, with one or more *bracteas*. The latter is the more luxuriant ſtate of this plant, in which it has been called *intermedium* by Schrader, and *montanum* by Ehrhart; we cannot ſee, by original ſpecimens, that theſe two ſuppoſed ſpecies differ at all, not even ſo as to merit Willdenow's diſtinction of them as varieties. Our Engliſh plant is leſs luxuriant, anſwering to Pollich's excellent deſcription. The *calyx* is turbinate, having hardly any tube: its limb five-cleft, whitiſh, ſpreading, acutely five-cleft, ſometimes with intermediate teeth; cloſely involute after flowering. *Anthers* yellow. *Stigma* white, of two knobs. *Fruit* hard, ſtriated, with five angles. The herb is ſcarcely bitter, a little ſaltiſh. It uſually grows among graſs, which it ſo much reſembles at a little diſtance, as not to be readily diſcernible. The pure air of the open hills about Bury, and ſimilar ſituations, ſeems to ſuit this plant, though the ſoil does not much promote its luxuriance of growth.

2. Th. *ramoſum*. Branched German Theſium. "Hayne in Schrad. Journ. v. 1. 30. t. 7." Roth in Sims and Kon. Ann. of Bot. v. 2. 18. Marſch. von Bieberſt. Caucaſ. v. 1. 175. (T. alpinum; Pollich Palat. v. 1. 239.)—Stem erect, branched. Cluſter elongated. Bracteas ternate. Leaves linear-lanceolate. Flowers three or four-cleft, with a very ſhort, cup-ſhaped tube.—Native of heaths, and ſandy paſtures or woods, in the Palatinate, flowering at the ſame time as the preceding. Not having been able to aſcertain this ſpecies amongſt our ſpecimens, we ſhall copy Pollich's deſcription, having endeavoured to improve our ſpecific character by the aſſiſtance of that faithful and inſtructive writer. "The *root*," ſays he, "is white, fibrous. *Stem* erect, from three inches to a foot high, round, ſtriated, ſmooth, branched from the very baſe; the *branches* alternate, very ſhort. *Leaves* alternate or ſcattered, linear-lanceolate, ſharpiſh, entire, rather fleſhy; convex on one ſide, flat on the other; ſeſſile, above an inch long, three-quarters of a line wide. *Flowers* ſolitary and ſeſſile at the ends of the very ſhort branches, between three leaves, of which the two lateral ones are ſmaller than the third. There is a white roundiſh baſis, or *receptacle*, on which each *flower* ſtands. The *calyx* is two lines in diameter, green without, white within, having but three or four ſegments, which ſpread croſswiſe. *Anthers* pale yellow. *Stigma* white, capitate. Evidently different from the foregoing." *Pollich*. He miſtakes however in his reference to Linnæus, Gerard, and Haller. As to Jacquin's *Enumeratio*, 40 and 213, we have no poſitive means of determining, the tube of the *calyx* not being there deſcribed. Marſchall von Bieberſtein conſiders our Engliſh plant, above deſcribed, as belonging to this ſpecies, and not to *linophyllum*.

3. Th. *alpinum*. Alpine Tubular Theſium. Linn. Sp. Pl. 301. Willd. n. 2. Roth in Sims and Kon. Ann. of Bot. v. 2. 18. (Th. floribus ſubſeſſilibus, pedunculis folioſis, foliis linearibus; Gerard Gallopr. 442. t. 17. f. 1. Th. n. 1574;

n. 1574; Hall. Hift. v. 2. 265.)—Stems procumbent, unbranched. Clufters fimple. Bracteas ternate; the odd one very long. Leaves linear. Flowers three or four-cleft; their tube prifmatic, as long as the limb.—Native of the mountains of Germany, Siberia, Switzerland, and Italy. We received it from Switzerland, and have gathered the fame on mount Cenis. Haller doubted whether his plant were really diftinct from *Th. linophyllum*, not adverting to the oblong angular tube of the *calyx*, which indeed we have not found noticed by any author, except Vahl, nor is it fufficiently indicated in Gerard's plate. That character however clearly diftinguifhes the *alpinum*, which may alfo be recognized by its numerous, fhort, fimple, moftly procumbent, *ftems*; narrower *leaves*; very unequal *bracteas*, the middle one being from three to five times the length of the others, and greatly exceeding the *flower* with its ftalk. The *fruit* is exactly oval, copioufly marked with branching ribs, but not furnifhed with angles. The *flowers*, ufually four-cleft, are faid by Haller to have fometimes but three fegments.

4. Th. *ebracteatum*. Naked-flowered Thefium. "Hayne in Schrad. Journ. v. 1. 33. t. 7. Termin. Bot. n. 6. t. 26. f. 4." Roth in Sims and Kon. Ann. of Bot. v. 2. 18.)—Stem erect, unbranched. Clufter fimple. Flowers without lateral bracteas; their tube cup-fhaped, very fhort.—Found near Berlin, by Mr. Hayne, author of an elegant German and Latin work on botanical terminology. We have an authentic fpecimen from profeffor Schrader, though we accidentally are deficient in that fafciculus of his Journal, which contains the defcription of the prefent fpecies. No difpute can arife as to its difference from all the foregoing. The wide fhallow form of the *calyx* is like the two firft, but the narrow *foliage*, and the long narrow terminal *bracteas*, agree with *Th. alpinum*. The total abfence of the pair of fmaller lateral *bracteas*, effentially diftinguifhes it from all three.

5. Th. *humile*. Dwarf Thefium. Vahl Symb. v. 3. 43. Willd. n. 3. (Alchimilla linariæ folio, floribus et vafculis in foliorum alis feffilibus; Shaw Afric. n. 14.)—Stem erect, branched. Flowers axillary, feffile, five-cleft; their tube very fhort. Gathered in cultivated ground near Tunis, by Vahl, who refers hither the fynonym of Shaw, applied by Linnæus, not without fcruple, to his *alpinum*; from which therefore it muft of courfe be erafed. The prefent is faid to be annual, with an herbaceous *ftem* hardly three inches high, branched from the bafe; *branches* fmooth, angular, fomewhat divided, as tall as the main ftem. *Leaves* linear, thick, numerous, acute, an inch and half long. Tube of the *calyx* fcarcely any; not elongated as in *Th. alpinum*. *Fruit* globofe, rugofe, the fize of Coriander-feed. *Vahl.*

6. Th. *auftrale*. Auftralian Thefium. Br. n. 1.—"Clufter fimple, elongated, fomewhat fpiked. Partial-ftalks fhorter than the flower. Calyx four or five-cleft; its fegments bordered longitudinally, rather longer than the tube."—Gathered by Mr. Brown, at Port Jackfon, as well as in Van Diemen's ifland, and on the fouth coaft of New Holland. We have feen no fpecimens.

7. Th. *lineatum*. Lineated Thefium. Linn. Suppl. 162. Thunb. Prodr. 45. Willd. n. 4.—"Leaves linear. Stem round, fomewhat angular; leaflefs in the lower part: branches ftraight, divaricated. Flowers axillary, ftalked." *Linn.*—Gathered at the Cape of Good Hope, by Thunberg, who, in his *Prodromus*, defines it, "leaves lanceolate, remote; branches ftriated, erect." We have not feen the plant, nor does Mr. Brown mention its name.

8. Th. *fquarrofum*. Recurve-leaved Thefium. Linn. Suppl. 162. Thunb. Prodr. 46. Willd. n. 5.—Leaves linear-awlfhaped, recurved. Stem round. Flowers axillary, feffile.—From the fame country. Thunberg fays the *flowers* are ftalked. The younger Linnæus remarks that the recurved, or reflexed, *foliage* gives this plant a very fquarrofe afpect. It does not appear that he poffeffed any fpecimen.

9. Th. *Frifea*. Little Trailing Thefium. Linn. Mant. 213. Willd. n. 6. Thunb. Prodr. 46.—Stem decumbent. Leaves awl-fhaped. Flowers fpiked; denfely woolly within. Fruit globofe, wrinkled.—Found at the Cape of Good Hope by Koenig, who fent fpecimens to his preceptor Linnæus, under the new generic name of *Frifea*, by which, we prefume, he meant to commemorate his own countryman Chriftian Friis Rottböll; but Linnæus reduced the plant to *Thefium*. It is one of thofe fpecies whofe *calyx* is denfely lined with reflexed pubefcence, and of which Mr. Brown has, juftifiably perhaps, made a diftinct genus, on that account. Yet it has all the habit of an European *Thefium*. The little woody knobbed *root* fends forth numerous decumbent, fimple, leafy, roundifh, fmooth *ftems*, two or three inches in length. *Leaves* not an inch long, linear, acutely pointed; channelled above. *Flowers* feffile, each accompanied by two fmall acute *bracteas*. *Calyx* in five deep, lanceolate, acute fegments, with fcarcely any tube; their denfe internal white woollinefs did not efcape Linnæus. *Fruit* nearly globofe, much wrinkled, not fo large as Coriander-feed.

10. Th. *funale*. Stringy Thefium. Linn. Sp. Pl. 302. Willd. n. 7. Thunb. Prodr. 45.—Stem with numerous long, nearly naked, branches. Leaves, and lateral bracteas, awl-fhaped, very fhort. Flowers fpiked; their fegments lanceolate, denfely woolly within.—Native of the Cape. The fhrubby round fmooth *ftem*, with its numerous crowded upright *branches*, has a very rufhy afpect. The little *leaves* are diftantly fcattered. The *fpikes* are terminal, folitary, fcarcely an inch long, compofed of feveral fmall, crowded, not quite feffile, *flowers*, in ftructure like the laft; each accompanied by one ovate, pointed, keeled *bractea*, and a pair of minute, lateral, awl-fhaped ones.

11. Th. *fpicatum*. Large-fpiked Thefium. Linn. Mant. 214. Willd. n. 8.—Stem erect, repeatedly branched. Leaves awl-fhaped, minute, fcattered. Flowers fpiked; their fegments linear, denfely woolly within. Lateral bracteas lanceolate.—From the fame country, growing on hills. Allied to the laft, but thrice as large in almoft every part, with a ftout, round, ftraight, determinately branched *ftem*. The *leaves* however are even more minute than in that fpecies. The *fpikes* are thick, of numerous, very denfely crowded, *flowers*, which Linnæus defines *læves*, fmooth, apparently in contradiftinction to thofe of *Th. funale*; but however fmooth, or even, like that, externally, their fegments, which are linear, narrow, and parallel, are full as hairy or woolly within. The outer *bracteas* are much dilated and rounded in their lower half; the lateral ones alfo are broadly lanceolate, very different from thofe of *funale*.

12. Th. *capitatum*. Capitate Thefium. Linn. Sp. Pl. 302. Willd. n. 9. Thunb. Prodr. 46.—Flowers capitate, feffile, terminal. Leaves three-edged, pointed, fmooth. Bracteas ovate. Segments of the calyx ftrongly pointed; denfely woolly within.—Native of the fame country. The *ftem* is hard and fhrubby, with alternate diftant *branches*; the upper ones gradually longer. *Leaves* alternate, fmall, awl-fhaped, pointed. Heads of *flowers* terminal, a frefh branch fhooting out from beneath each. Segments of the *calyx* very much pointed, and internally villous throughout their whole length. *Linnæus*. In his herbarium are fpecimens which anfwer to this defcription, though left by him with-

out

out any specific name, he having originally described the present species in Van Royen's *Prodromus*. The younger Linnæus took these specimens for *scabrum*, with which they agree only so far as to confirm their being the *capitatum*, contrasted therewith in Sp. Pl. Their *leaves* however can hardly be termed small, measuring near an inch in length. The *bracteas* have dilated membranous edges; fringed, as Thunberg describes them. *Calyx* with an oblong, five-angled tube. We cannot so blindly follow Willdenow, as to insert any species between this and *scabrum*.

13. Th. *scabrum*. Rough Thesium. Linn. Sp. Pl. 302. Willd. n. 13. Thunb. Prodr. 45.—Heads of flowers stalked. Leaves three-edged, pointed; their edges very rough with cartilaginous teeth.—Native likewise of the Cape. Nearly allied to the last, though undoubtedly a very distinct species. The *leaves* are but half as large, and remarkable for the cartilaginous teeth of their three edges. *Flower-stalks* sometimes two or three inches long, naked. *Calyx* with hardly any tube; its segments, according to Linnæus, internally villous at the tips only, but of this we are not perfectly convinced.

14. Th. *strictum*. Wand-like Thesium. Berg. Cap. 73. Linn. Mant. 214. Willd. n. 10. Thunb. Prodr. 45.—Leaves lanceolate, with a decurrent keel. Cymes terminal. Calyx obtuse, smooth, except at the back of each stamen.—Found at the Cape, and first described by Bergius. Linnæus originally referred the description of this author to his own *Th. capitatum*, from which scarcely any species can be more distinct. In general dimensions, and shrubby habit, indeed they are not unlike; but the *leaves* of the present plant are much fewer, and more distant, and the *inflorescence* totally different, being a sort of compound irregular *umbel*, or *cyme*. The *calyx* being smooth both within and without, except a slender tuft of hairs at the back of each *stamen*, as observed by Mr. Brown, reduces this species to a different section, according to that author, along with *squarrosum*, n. 8, *fragile*, n. 16, and some others. A note at the back of one of the Linnæan specimens of *Th. strictum*, gathered by Sparrmann, says "the fruit is a *drupa*, like that of *Prunus Padus*." If so, this species should seem referrible to some other genus, as *Fusanus*; yet their habits are too dissimilar.

15. Th. *umbellatum*. Umbel'd Thesium. Linn. Sp. Pl. 302. Willd. n. 11. Ait. n. 2. Pursh n. 1. (Centaurium luteum ascyroides virginianum; Pluk. Mant. 43. Phyt. t. 342. f. 1.)—Flowers umbellate. Leaves elliptic-oblong.—On dry hills and fields, from New York to Carolina. Perennial, flowering in June and July.—*Flowers* white. *Pursh*. Mr. Aiton records its having first been introduced into the British gardens in 1782, by the late Dr. Hope, professor of botany at Edinburgh. This is an herbaceous species, about a foot high, erect, scarcely branched, except at the top, and having more of the aspect of some annual *Euphorbiæ*, than of the genus of which we are treating. The *leaves* are scattered, on short stalks, erect, smooth, nearly oval, about an inch long. *Flowers* three or four together in small *umbels*, on slender, solitary *stalks*, either axillary or terminal. *Bracteas* three or four under each umbel, pale, lanceolate, deflexed. Mr. Brown says the character of the *flower* of this, the only American species, is between *Fusanus* and *Santalum*. Of the *fruit* nothing is known.

16. Th. *fragile*. Brittle Thesium. Linn. Suppl. 162. Willd. n. 12. Thunb. Prodr. 45. — Leaves three-edged, somewhat ovate, keeled, decurrent. Stem angular. Flowers axillary, sessile.—Discovered by Thunberg at the Cape of Good Hope. We have seen no specimen of this species. It is said to have the habit of a *Salsola*, and to be extremely brittle. The *leaves* are so very short, that at first sight they seem to be altogether wanting.

17. Th. *paniculatum*. Panicled Thesium. Linn. Mant. 51. Willd. n. 14. Thunb. Prodr. 45. — Stem much branched; branches diffuse, panicled, angular, many-flowered. Flowers solitary, stalked. Leaves awl-shaped.—From the Cape of Good Hope.—The *stem* is round, shrubby, with several round primary *branches*, subdivided throughout into many lateral and terminal, slender, angular ones, repeatedly and irregularly cloven and forked, bearing innumerable, small, terminal, stalked, solitary *flowers*, each of which is subtended by four or five sharp awl-shaped *bracteas*, which Linnæus describes as an inferior, but not a proper, *calyx*. The real *calyx* is obtuse and five-cleft. *Fruit* like Coriander-seed. Many of the *flowers* are abortive. The *leaves* are scattered, and for the most part very minute. Mr. Brown does not mention this species, perhaps from not having been able to examine the inside of the *flowers*.

18. Th. *ericoides*. Heath-like Thesium. Herb. Banks. Brown Prodr. Nov. Holl. v. 1. 353.—Stem much branched, panicled; branches erect, many-flowered. Flowers capitate. Leaves lanceolate, channelled, decurrent, acute.—Native of the Cape of Good Hope. This has a round shrubby *stem*, with the panicled habit, and innumerable small *flowers*, of many *Ericæ*. The younger Linnæus confounded it very negligently with the last, and it seems to have passed undescribed, being only mentioned in Mr. Brown's work, by the apt name it bears in the Banksian herbarium. The *leaves* are pretty numerous, minute, spreading, concave, broad at the base; decurrent at the margins and keel. *Flowers* sessile, two, three, or four, in each little terminal head, accompanied by several imbricated, ovate, keeled, sheathing *bracteas*, partly jagged or fringed at the edges. These *bracteas* evince the true nature of what Linnæus terms, in the foregoing, an inferior *calyx*.

19. Th. *amplexicaule*. Heart-leaved Thesium. Linn. Mant 213. Willd. n. 15. Ait. n. 3.—"Clusters terminal. Leaves heart-shaped, sessile."—Native of lofty hills at the Cape of Good Hope.—*Stem* rather woody, erect, somewhat angular, four feet high, smooth. *Leaves* alternate, sessile, clasping the stem, heart-shaped, entire, rather acute, smooth, thickish, an inch long. *Clusters* terminal, consisting of minute *flowers*, intermixed with large ovate *bracteas*. *Linnæus*. Neither Mr. Brown nor professor Thunberg mention this species. There is no authentic specimen of it in the Linnæan collection, and we are almost convinced of its being the same plant as the following. Willdenow has made a singular mistake in copying the specific character of *Th. Frisea*, see n. 9, over again, for the *amplexicaule*, which stands above it in the *Mantissa*.

20. Th. *euphorbioides*. Spurge-like Thesium. Berg. Cap. 74. Linn. Mant. 214. Willd. n. 17. Thunb. Prodr. 46. (Planta africana frutescens, portulacæ foliis, Morgsani Syrorum, ex brevi pediculo binis, similis; Pluk. Amalth. 173.) — Stalks three-flowered, terminal. Leaves roundish-ovate, acute, fleshy. Stem shrubby, with alternate corymbose branches.—Native of the Cape of Good Hope. This was adopted from Bergius by Linnæus, without seeing a specimen, at least from that author. One is preserved in his own herbarium, on which he had written *Thesium capense*, which his son altered to *euphorbioides*, considering it as the same with the plant of Bergius. A similar specimen lies in the Banksian collection for *Th. amplexicaule*. Both names are excellent, but perhaps *euphorbioides*, as the original

original one, ought to be preferred. The plant is of a ftout fhrubby habit, turning black in drying. *Leaves* about the fize of the finger-nail, alternate, feffile, ovate or rather heart-fhaped, clafping the ftem, acute, entire, flefhy, fmooth, without rib or veins. *Flowers* about the tops of the alternate corymbofe upper branches, enveloped in *bracteas*, like the leaves, but fmaller. Tube of the *calyx* very fhort, and ftrongly angular; limb fmooth within, except perhaps a few minute hairs behind the *ftamens*, indicated by Mr. Brown. *Fruit* globofe, chiefly angular at the top.

21. Th. *triflorum*. Three-flowered Thefium. Linn. Suppl. 162. Willd. n. 16. Thunb. Prodr. 46.—"Leaves lanceolate. Stem angular. Flower-ftalks axillary, three-forked, compound."—Gathered by Thunberg at the Cape. The *flower-ftalks* are three-flowered, fometimes divided, or three-cleft, greatly divaricated. *Linn.* We have met with no fpecimen anfwering to this fpecies, nor does Mr. Brown advert to it.

22. Th. *fpinofum*. Spinous Thefium. Linn. Suppl. 161. Willd. n. 19. Thunb. Prodr. 45. — Leaves awl-fhaped, fpinous-pointed, fpreading, flefhy, decurrent. Flowers axillary, ftalked, folitary. — Gathered by Thunberg at the Cape. A very fingular fpecies, whofe woody decumbent *ftem* is befet with numerous, afcending, fimple *branches*, two or three inches long, clothed with alternate, horizontally projecting, pungent *leaves*, one-third of an inch in length, giving the plant the afpect of an *Ulex*. *Flower-ftalks* about as long as the leaves. — Mr. Brown places this in his fection of fuch Cape fpecies as have the *calyx* internally naked, except a flender tuft of hairs behind each *ftamen*. With it ranges *fquarrofum*, *fragile*, *ftrictum*, *fpinofum*, *ericoides*, *euphorbioides*, and one unknown to us, called *fparteum*. The fection whofe *calyx* is lined with a denfe deflexed beard, confifts of *Frifca*, *funale*, *fpicatum*, *capitatum*, and *fcabrum*, befides five fpecies unknown to us, called *craffifolium*, *teretifolium*, *debile*, *ciliatum*, and *divaricatum*.

THESMOPHORIA, Θεσμοφορια, in *Antiquity*, a feftival in honour of Ceres, which was celebrated by many cities of Greece; but efpecially the Athenians obferved it with great devotion and pomp. For the ceremonies of this folemnity, fee Potter, Archæol. Græc. tom. i. p. 403, feq. See CEREALIA and ELEUSINIA.

THESMOTHETÆ, Θεσμοθεται, an appellation given to fix of the nine Athenian archons; the firft and chief of the nine was called, by way of eminence, *archon;* the fecond in dignity was called *bafileus;* the third, *polemarchus;* and the other fix, *thefmothetæ:* for an account of whofe power and jurifdiction, fee Potter, Archæol. Græc. tom. i. p. 77.

THESPANIS, in *Ancient Geography*, a river of Afiatic Sarmatia; the mouth of which, according to Ptolemy, lay between that of Rhembitus and the town of Azara.

THESPHATA, Θεσφατα, in *Antiquity*, an appellation given to oracles. See ORACLE.

THESPIA, or THESPIÆ, in *Ancient Geography*, a town of Bœotia, fituated at the foot of mount Helicon, about 50 ftadia from the city of Thebes. The Thebans, who deftroyed this city, fpared nothing but the facred monuments, among which were the temple of Hercules, which was ferved by a prieftefs reftricted to celibacy during her whole life, and the ftatue of that Cupid (or Cupidon), fometimes confounded with the god of love, which was only a fhapelefs ftone as it was dug in the quarry, for thus the objects of public worfhip were reprefented in ancient times. Praxiteles is faid to have formed a ftatue of Cupidon of Penthelic marble; and Lyfippus made one of bronze. The Thefpians reported, that the ftatue of Praxiteles was taken away by Caius, the Roman emperor; but others fay, that it was returned by Claudius, and that Nero removed it to Rome, where it was confumed by fire. This ftatue was fo beautiful, that, according to Cicero, Thefpia was vifited merely for the fake of feeing it. The Cupidon that exifted in the time of Paufanias was an imitation of that of Praxiteles by Menodorus, the Athenian; but here were a Venus and Phryné in marble, executed by Praxiteles himfelf. In one quarter of the city was a temple confecrated to Venus Melenis. The theatre was a beautiful ftructure, ornamented with a ftatue of Hefiod in bronze. Near it was a Victory in bronze, and a chapel confecrated to the Mufes, each of which had a fmall ftatue in marble. At Thefpia there was a ftatute of Venus in marble, made by Praxiteles.

THESPIADES, in *Mythology*, an appellation given to the Mufes from the city of Thefpia, where they were honoured.

THESPIÆ, in *Ancient Geography*, a town of Theffaly, in Magnefia.

THESPIANA, the name of an antidote intended for internal abfceffes.

THESPIS, in *Biography*, an ancient poet, and the fuppofed inventor of tragedy, was born in a fmall borough of Attica, named Icaria, and he, as well as Sufarion, a native of the fame place, appeared each at the head of a company of actors, one on a kind of ftage and the other in a cart. Sufarion attacked the vices and abfurdities of his time, and reprefented his firft pieces towards the year 580 B.C. Thefpis treated nobler fubjects, which he drew from hiftory: he appeared fome years after Sufarion, made his firft attempts in tragedy, and acted his Alceftis in the year 536 B.C. He was followed in this fpecies of drama by Æfchylus, Sophocles, and Euripides. Thefpis having obferved at the feftivals, in which before his time hymns only were fung, one of the fingers, mounted on a table, forming a kind of dialogue with the chorus, took the hint of introducing into his tragedies an actor, who by fimple recitals, introduced at intervals, fhould relieve the chorus, divide the action, and render it more interefting. This innovation, together with fome other liberties in which he indulged himfelf, alarmed Solon, the legiflator of Athens, who condemned a fpecies of compofition, in which the ancient traditions were difguifed by fiction. "If we applaud falfehood in our public exhibitions," faid he to Thefpis, "we fhall foon find that it will infinuate itfelf into our moft facred engagements."

The exceffive approbation and delight with which both the city and country received the pieces of Thefpis and Sufarion, at once juftified and rendered ufelefs the fufpicious forefight of Solon; the poets, who till that time had only exercifed their genius in dithyrambics and licentious fatire, ftruck with the elegant forms which thefe fpecies of compofition began to affume, dedicated their talents to tragedy and comedy. See TRAGEDY.

Thefpis, according to the defcription of Horace, extended his plan farther than the introduction of a fingle actor in the intervals between the fongs of the chorus, to the reprefentation of fome fable by actors on a kind of moveable ftage, who alternately fung and played, with their faces ftained by the lees of wine.

> "Ignotum tragicæ genus inveniffe Camœnæ
> Dicitur, et plauftris vexiffe poemata Thefpis,
> Quæ canerent agerentque peruncti fæcibus ora."
>
> Art. Poet.

Some writers have mentioned three pieces of Thefpis, *viz.*

viz. "The Conteft of Pelias or Phorbas;" "The Sacred Youths;" and "Pentheus." Socrates fays that he reprefented tragedies in the 61ft Olympiad, long after Solon's death. Travels of Anacharfis, vol. vi. 8vo.

THESPIUS, in *Ancient Geography*, a river of Greece, in Bœotia.

THESPROTI, a people of Epirus, who inhabited Thefprotia, in the vicinity of the Ambraciates; and formed one nation with the Chaonians. They derived their name from Thefprotus, the fon of Pelafgus, who was the fon of Lycaon, and who was the firft that conducted the Pelafgi into Epirus.

THESPROTIA, or THESPROTIS, a fmall country of Epirus, S. of Chaonia, having to the E. the lake Ambracius and Ambracia, and to the S. the fea. This country was watered by three rivers, which ran from W. to E, viz. Thiamis, Cocytus, and Acheron.

THESSALIA, THESSALY, a celebrated country of Greece. This country, comprifing Magnefia and other fmall diftricts which have particular denominations, is bounded to the E. by the fea, to the N. by mount Olympus, to the W. by mount Pindus, and to the S. by mount Oeta. From thefe permanent boundaries branch out other chains of mountains and hills, that wind through the country, occafionally embracing fertile plains, which, from their form, and the manner in which they are inclofed, refemble vaft amphitheatres. Opulent cities are feated on the heights that encircle thefe plains; and the whole country is watered by rivers falling in general into the Peneus, which, before it lofes itfelf in the fea, flows through the famous valley of Tempé. The Aphidanus, or Apidanus, proceeded from the S. where was Dolopia, afcended northward (fee PENEUS), traverfed the plains of Pharfalia in the Theffaliotide, and difcharged itfelf into the Alpheus, W. of Lariffa. (See APIDANO.) The Oncheftus, or Onfchones, took its rife S. of Lariffa, paffed by the Palus Bœbeis, and after having received the Naurus, difcharged itfelf into the Pelafgic gulf, between Demetrius on the left and Pagafæ on the right. The Sperchius commenced S.W. in an angle which was formed by the chains of Pindus with thofe of mount Oeta, afcended N.E., watered Sperchium, turned to the E., and having paffed Hypata, received the Achelous of Theffaly, which proceeded from mount Othrys, and being joined by the Lamina, difcharged itfelf into the Maliac or Lamiac gulf. The country was marfhy, and abounded with a variety of plants, fome of which were medicinal and fanative, and others venomous and pernicious. The knowledge of their different properties caufed the Theffalians to be regarded as a clafs of forcerers, who poffeffed the art of producing fupernatural effects. The principal people of Theffaly were the Æthices, fituated towards the N.W., whofe chief town was Oxinia, near a lake that lay between fmall chains of mountains:—the Pelagoni Tripoliti, in a kind of hollow territory, feparated from Macedonia by a chain of mountains, called Cambrunii montes; denominated Tripolitans on account of their three towns, Dolicha, Pythium, and Azorus: in the eaftern part of this territory was the Afcuris palus, or marfh Afcuri:—the Perrhæbi, lying S. of the mountains which formed this territory, and extending from W. to E., the N. of the Peneus:—S. of the Peneus, towards the W., was the Eftiæotis, watered by the rivers Ion and Thœus, and bounded W. and S. by mount Pindus: its moft confiderable towns being Gomphi, Trica, Pellinæum, and Pharcadon:—the Pelafgiotis, towards the E., having the Peneus to the N. and commencing W. from the Apidanus, which received the Enipeus, that paffed to Pharfala: the principal towns of this part of Theffaly were Lariffa, reckoned the capital of Theffaly; Pharfala, one of the largeft and moft opulent towns, now Pharfalia, Scotuffa, Cranon, &c.:—the Theffaliotis being to the S. and watered by the Enipeus in the lower part of its courfe, and having to the S. mount Othrys, and to the S.W. Dolopia; its principal town was Melitæa upon the Enipeus:—the Phthiotis, towards the S.E., terminating in a peninfula, and watered by the Sperchius and Achelous; its principal towns were Pheræ, to the N.; Thaumaci, to the W., commanding one of the fineft profpects in Greece; Alos and Lamia, towards the middle; Phalara, at the bottom of the Amaliac gulf; in the peninfula, Thebæ, Lariffa, Cremafta and Echinus: at the extremity the port of Aphetæ, and S.E. Heraclea Trachina, the road from which led to the ftraits of *Thermopylæ;* which fee. Magnefia was feparated from the fea by mount Pelion: here were the towns of Demetrias and Iolcos, and S.E., on the eaftern coaft, the town of Magnefia, and at the extremity of the peninfula to the S.W. the town of Antium. At the bottom of the Pelafgiotic gulf were the two fmall iflands of Deucalion and Pyrrha. Dolopia lay towards Ætolia, and contained no confiderable towns. The extremity of the S.E. of Magnefia was terminated by the promontory Sepias, where the fleet of Xerxes was battered by a tempeft. The town of Gonnus, at the entrance of the valley of Tempé, was the key of Theffaly on the fide of Macedonia, as the poft of Thermopylæ was on the fide of Phocis. See THESSALY.

The feveral nations which we have recounted, as properly Theffalian, were formerly governed by kings, but after various revolutions became for the moft part fubject to an oligarchy. The ftates and the towns were independent of each other. The confederacy of the Theffalians, properly fo called, was the moft powerful of all, both from the number of towns pertaining to it, and from the acceffion of the Magnefians and Perrhæbians which were brought almoft under complete fubjection. There were fome free cities, unconnected with any of the ftates. The Theffalians could bring into the field an army of 6000 horfe and 10,000 infantry, exclufively of their archers, who were excellent, and who from their infancy were accuftomed to draw the bow. The Theffalians are faid to have been the firft who managed horfes with the bit, and ufed them in battle; and hence, it is faid, originated the tradition that a race of creatures, called centaurs, half horfe and half man, formerly exifted in Theffaly. This country produced wine, oil, and fruit of different kinds. The land has been reprefented to be fo rich, that the corn grew too faft, if it were not cut, or fheep turned in to graze upon it. They carried on a confiderable commerce in corn. The Theffalians, though they boafted of their liberty, were the firft to reduce Greeks to flavery. Amongft them they had a prodigious number of flaves, known by the name of Peneftæ. Thefe people are very hofpitable to ftrangers, and treat them magnificently. In their drefs and houfes luxury is confpicuous; and at their entertainments they hire dancing girls to amufe them. They are reckoned paffionate and turbulent, and very difficult to be governed; and they are reproached with infincerity and falfehood. They have cultivated poetry from their moft early ages, and pretend that Theffaly gave birth to Thamyris, Orpheus, Linus, and many others who lived in the heroic age; but fince that period, they have produced no writer nor any celebrated artift. They were much addicted to dancing; and in fome places generals or magiftrates were called chiefs of the dance. Their mufic obferves a medium between the Doric and Ionic, and accordingly harmonizes with the character and manners of the country,

country. They have never on any occaſion killed ſtorks, and the ſame puniſhment was inflicted on a perſon who killed one of theſe birds as if he had taken away the life of a man. This law, it is ſaid, was founded on the circumſtance, that ſtorks had freed Theſſaly from the enormous ſerpents which formerly infeſted it.

THESSALICUM Sedile, the Theſſalian chair, ſo called from Theſſaly, where chairs of this figure were moſt in uſe: it is recommended by Hippocrates, Lib. de Art. in place of a machine for reducing a recent luxation of the ſhoulder-bone. The back of this chair is perpendicular to the ſeat, as Galen tells us, by which conſtruction it is diſtinguiſhed, and accommodated to the operation.

THESSALIOTIS. See Thessalia.

THESSALON, in *Geography*, a river of Canada, which runs into lake Huron, N. lat. 49° 6′. W. long. 82° 8′.

THESSALONIANS, *Epiſtles to*, in *Scripture Hiſtory*. See Epistle.

THESSALONICA, in *Ancient Geography*, a town of Macedonia, ſituated on the Thermaic gulf; and built on the declivity of a mountain in the form of an amphitheatre, the ſummit of which was defended by a caſtle of great extent. Strabo ſays that it was named "Therma," and that it was only a village; that Caſſander augmented it conſiderably, and tranſported hither the inhabitants of ſome neighbouring cities, and gave it the name of Theſſalonica, that of his wife, the ſiſter of Alexander the Great. In the year 168 B.C., Macedonia was divided into four parts, and Theſſalonica was the capital of the ſecond part. Its government was regulated by magiſtrates, called "Political." Under the Greek empire it continued to be governed by a ſenate. Cicero, during his exile, paſſed ſome time at Theſſalonica. This city had ſeveral divinities, and alſo emperors, who were objects of public worſhip. Jupiter was the principal; Apollo was alſo repreſented on its monuments; and the Cabiri had a temple in Theſſalonica. The Cabirian and Pyrrhic games were exhibited in this city in honour of the Cabiri, and the Olympic games were celebrated in honour of Jupiter. That rich and powerful city had, for its ſpectacles and the amuſement of the citizens, an amphitheatre for the combats of gladiators, and a circus for the public games. The emperors Valerian and Gallienus gave it the title of a colony. It had alſo the title of Neocorus, The modern name of Theſſalonica is *Salonica* or *Saloniki*. (which ſee.) Although there are different routes by which goods are tranſported from Macedonia into the Auſtrian dominions, the beſt, ſays Dr. Holland in his Travels into Albania, &c. is through Bulgaria, by Widin and Offovo, where it enters the Auſtrian territory, and is thence continued through the Bannat by Temeſwar, Peſt, Raab to Vienna. The goods landed at Salonica are made up in packages of 1½ hundred weight, and two of theſe are the load of a horſe. The cavalcades for this inland journey conſiſt often of 200 or 300, and ſometimes of 1000 horſes. The property ſo tranſported, at a moderate eſtimate, might be worth 30,000*l.* on its arrival in Germany. The time occupied between Salonica and Vienna was in general thirty-five days, excluſive of the quarantine at Offovo, which ſometimes took place. The cavalcades uſually travel eight hours in the twenty-four.

THESSALY, or Janna, in *Geography*, a province of European Turkey, bounded on the N. by Macedonia, on the E. by the Archipelago, on the S. by Livadia, and on the W. by Livadia and Epire, anciently called *Theſſalia*, *Pelaſgia*, and *Pyrrhæa*, (ſee Thessalia,) and now by the Turks *Janna*. It was ſometimes annexed to Macedonia, and ſometimes ſeparated from it. The celebrated mount Pindus, now Meſſova, or Meſſo Novo, ſeparated it from Epirus, or a part of the preſent Albania. Amongſt its once celebrated twenty-four mountains, the moſt remarkable are Olympus, Pelion, and Oſſa. Here are alſo ſituated the plains of Pharſalia, and the delightful valley of Tempé. The country is extremely fertile, and retains its ancient character in this reſpect. It produces oranges, citrons, lemons, pomegranates, very ſweet grapes, excellent figs and melons, almonds, olives, cotton, and cheſnuts, which take their name from Caſtanea in Magneſia. The modern Theſſalians are a well-made ſpirited people. The moſt remarkable places in the country are Lariſſa and Janna. See Thessalia.

THESTIA, in *Ancient Geography*, a town of Epirus, in Acarnania.—Alſo, a river of the Peloponneſus, in Laconia.

THESTIDION, a town of Greece, in Theſſaly.

THESTIS, a town which belonged to the Arabs.—Alſo, a town of Africa, in Libya.—Alſo, a fountain of Africa, in the Cyrenaica, near Iraſa.

THETA, Θ, among the *Ancients*, one of the Greek letters. It was uſed as a mark on the ballots of judges, by which they condemned the perſon to death, it being the firſt letter of the word Θανατος, *death*. Whence it had the epithet of *niger* and *infelix*, thus:

"O multum ante alias infelix litera theta."

THETES, Θητες, in *Antiquity*, the loweſt claſs of people at Athens. Ariſtides repealed Solon's law by which the thetes were made incapable of bearing any office in the government.

THETFORD, in *Geography*, an ancient borough and market-town, partly in the hundred of Shropham, and county of Norfolk, and partly in the hundred of Lackford, in the county of Suffolk, England, is ſituated at the diſtance of 28 miles S.W. from Norwich, and 80 miles N.N.E. from London. It was a place of conſiderable conſequence at an early period.

Thetford, called in the Saxon Chronicle *Theodford*, has an acknowledged claim of having been once the ſeat of the Eaſt Anglian kings. Being the metropolis of that portion of the heptarchy, it became ſubject to the ravages of the Danes, by whom it was repeatedly laid in aſhes. From numerous coins, it is evident that there was a mint at Thetford from the time of Athelſtan to the reign of king John. At the eaſtern extremity of the town are ſome extenſive remains of fortifications, conſiſting of a large artificial mount, or keep, with lofty banks and deep ditches. Theſe fortifications were probably firſt formed by the early kings of Eaſt Anglia, and the keep an addition, made ſubſequent to the Norman conqueſt. Eaſt of the mount is a large area, or place of arms, three hundred feet ſquare. The mount is about one hundred feet in height, and nine hundred and eighty-four feet in circumference, at the baſe. The ſlope is extremely ſteep; and yet no traces remain of any path or ſteps for the purpoſe of carrying up machines or weighty ammunition.

In the Conqueror's time, Herfaſt having removed the epiſcopal ſee from North Elmham to Thetford, the latter became the head of the Eaſt Anglian dioceſe; but in the ſucceeding reign, the ſee was transferred to Norwich. The ruins of eccleſiaſtical and other buildings ſtrongly point out the ancient ſplendour of this town. At one period it is ſaid to have had twenty churches, anſwerable to the number of pariſhes, and eight monaſteries, beſides other religious and charitable foundations. But of theſe, the names only of ſome remain; and of others, a few dilapidated walls ſerve to to mark their fcites. Of the twenty churches, three only are preferved; St. Peter's, and St. Cuthbert's, on the Norfolk fide of the river; and St. Mary the Lefs on the Suffolk fide. St. Peter's, commonly called the Black church, from its being conftructed chiefly of flint, confifts of a chancel, nave, two aifles, and a tower. The latter was rebuilt in 1789, when a great part of the church was alfo re-edified. The battlements on the fouth fide, and the buttreffes, are decorated with allufive ornaments and large letters inlaid in the flint work.

The *Nunnery* was founded by Uvius, the firft abbot of St. Edmund's Bury, in the reign of king Canute; in commemoration of the number of perfons who fell at Snarefhill, near this town, in the fanguinary conflict between king Edmund's army and the forces under the Danifh leaders Ingwar and Ubba. A few monks were placed in this monaftery, which was then confidered as a cell to Bury Abbey. In the year 1176, the monks, being reduced to two, refigned, by the requeft of the abbot of Bury, who placed in their ftead a convent of nuns, who had previoufly refided at Lynn. At the diffolution, the revenues and fcite were granted to fir Richard Fulmerfton, who made this houfe his refidence. It was afterwards let to a farmer, and fome years fince the greater part was taken down: a new farm-houfe was built of the materials, and the conventual church converted into a barn. Some of the walls, with buttreffes, windows, &c. ftill remain.

The *Priory* or *Abbey* was founded by Roger Bigod, in the year 1104, for monks of the Cluniac order. This was a peculiarly privileged houfe; for other Cluniac monafteries were fubject to have their revenues feized, on a war breaking out between England and France, becaufe being dependant on the abbey of Clugny, in Burgundy, the monks were confidered as foreigners; but the religious perfons of this monaftery were naturalized, and treated as other fubjects of the realm. At the fuppreffion the revenues were granted to the duke of Norfolk, and are now the property of lord Petre. The ancient gateway, conftructed with freeftone and black flint, with parts of the church, &c. ftill remain. This monaftery had been the burial-place of the feveral noble families who had fucceffively borne the title of earls of Norfolk.

St. Auftin's Friary was founded by John of Gaunt, duke of Lancafter, in the year 1387, for friars mendicant of the Auguftine order. The fcite, granted to fir Richard Fulmerfton, is ftill called the Friar's Clofe.

The *Monaftery of St. Sepulchre* was founded in 1109, by William, earl of Warren and Surrey, for canons of the Auguftine order, and additionally endowed by king Henry II. The fcite is ftill called Canons: part of the conventual church, yet ftanding, has long fince been ufed as a barn. The gate of the porter's lodge, and fome other parts of the buildings, remain. Of the other four religious houfes, no veftiges are now left. In the Suffolk part of the town, near St. Mary's church, is a free grammar-fchool. In the year 1566, fir Richard Fulmerfton bequeathed property for the erection of a free-fchool, with dwelling-houfes and falaries for a mafter and ufher; and alfo habitations and weekly penfions for two poor men and two poor women. The benevolent defign of the donor, however, was not carried into effect till the time of James I., when it was enacted by authority of parliament, that there fhould be for ever a free grammar-fchool and hofpital; and that the mafter, ufher, and the four poor people, fhould be a body politic, under the title of "The mafter and fellows of the fchool and hofpital at Thetford, founded by king James the Firft, according to the will of fir Richard Fulmerfton, knt."

Thetford, though a very ancient burgh, is comparatively a modern corporation. In the time of the Conqueror, the town was governed by a conful and other inferior officers. Not being a free burgh, it fuffered greatly at times by the oppreffion of the officers nominated by the crown. But in the year 1573, queen Elizabeth granted a charter, by which a mayor, ten aldermen, twenty common-councilmen, a recorder, town-clerk, fword-bearer, and two ferjeants at mace, conftitute the corporation. The mayor for the time being is clerk of the market, and in the year after his mayoralty officiates as coroner. The corporation had alfo permiffion to fend two burgeffes to parliament, "provided they were difcreet and honeft men, and were elected at the expence of the borough." This charter was furrendered to the crown in the thirty-fourth year of Charles II., and a very imperfect one obtained in its ftead. But in 1692 an order was procured from the court of chancery for cancelling the furrender, and procuring a tranfcript of the charter granted by Elizabeth, under which the town is at prefent governed. Thetford has been honoured with the prefence of many of our fovereigns, particularly Henry I. and II. Several charters, granted by the former, bear date from this town. When the manor fell with the duchy of Lancafter, of which it formed a parcel, to the crown, the ancient feat of the earls Warren became the royal palace. This was rebuilt in the time of queen Elizabeth, who occafionally refided here. King James I. made it one of his hunting feats; but being difgufted with the abrupt remonftrance of a farmer, over whofe lands he had been hunting, he gave the palace to fir Philip Wodehoufe: it has been rebuilt, and is now the property of a private gentleman; but ftill bears the appellation of the "King's Houfe." The old guildhall or council-houfe being in a dilapidated condition, fir Jofeph Williamfon, fecretary of ftate to king Charles II., erected at his own expence the prefent council-chamber, and the apartment for the juries. Thetford has been much improved within the laft twenty years. A new bridge has been built, the principal ftreet paved, and feveral handfome houfes have been erected. The navigation of the river has been attended to, and by this communication fome mercantile bufinefs is tranfacted in the corn and coal trade. Five fairs are held annually, and a market weekly on Saturdays; but, compared with its former greatnefs, it is now a very inconfiderable place. The population in the return of the year 1811, was ftated to be 2450, occupying 530 houfes.

Near to Thetford is a mineral fpring, the waters of which poffefs confiderable virtues, though their celebrity has by no means been commenfurate with their acknowledged efficacy. Thomas Paine, well known for his political and theological tracts, was a native of this town, and received his education in the grammar-fchool.—Blomefield's Effay towards a Topographical Hiftory of Norfolk, vol. ii. Beauties of England and Wales, vol. xi. by John Britton, F.S.A. Hiftory, &c. of Thetford, by Thomas Martin, 4to.

THETFORD, a town of the United States, in the county of Orange, Vermont; 10 miles N. of Hanover; containing 1735 inhabitants.

THETIS, in *Mythology*, the name of the moft beautiful of the Nereids.

THEVACOURCHY, in *Geography*, a town of Hindooftan, in the Carnatic; 20 miles W.S.W. of Tiagar.

THEUDORIA, in *Ancient Geography*, a town of Achaia, from which the Macedonians were driven by the Romans.

THEUDURUM, a town of Lower Germany, on the route

route from Colonia Trajana to Colonia Agrippina, between Mederiacum and Coriovallum. Anton. Itin.

THEVEN, in *Geography*, a town of Perfia, in the province of Lariftan; 40 miles E. of Lar.

THEVENARD, Gabriel Vincent, of Paris, in *Biography*, born in 1669, became in the operas of Lulli the firft finger and actor of his time. He had a tenor voice, which made the public forget that of Beaumavielle; it was fonorous, mellow, and extenfive in compafs. He fung a little through the throat, but by dint of art, he found the means of rendering this little defect even agreeable. His appearance on the ftage was dignified, and his performance wonderful! It was to him that the prefent manner (1780) of fpeaking recitative is due. He excelled above all in finging at table; nor has he ever been furpaffed in that talent, except by De Chaffé and Jeliote, who fo many years delighted their friends.

He fung more than forty years at the Opera, and only retired in the year 1730. He was more than fixty years old, when, feeing a beautiful female flipper in a fhoemaker's fhop, he fell violently in love, unfight, unfeen, with the perfon for whom it was made; and having difcovered the lady, married her, after obtaining the confent of an uncle on whom fhe was dependent, with the affiftance of many bottles of wine which they cracked together with the utmoft cordiality, and which Thevenard meliorated with the charms of his voice.

He died at Paris in 1741, at the age of 72. Thevenard was the caufe of the duke d'Antin quitting the management of the opera. This finger having a penfion offered him for his fervices, found it fo inconfiderable, that he refufed to accept of it, faying it was only fit for his footman. The duke, piqued at this infolence, would have fent him to prifon; but it having been reprefented to him that the public would fuffer by his abfence, he facrificed to this confideration his refentment; but determining to have nothing more to do with fuch people, he quitted the fuperintendance of the opera. Laborde.

THEVENOT, John, a traveller in the Levant, was born in Lorraine, and after repeated journies, died in Perfia in 1667. He is faid to have introduced the ufe of coffee into France. His "Voyage in Afia" was publifhed in 1664, which is a work confiderably efteemed, and has been often re-edited. The Amfterdam edition in 12mo., 1727, is comprifed in 5 vols. Nouv. Dict. Hiftor.

Thevenot, Nicholas Melchisedec, a writer of travels, was born in 1621, probably at Paris, and having finifhed his ftudies, indulged his propenfity for vifiting foreign countries, confining himfelf chiefly to various parts of Europe. Some perfons have given him the credit of being a great linguift, but this is difputed by Huet, who was perfonally acquainted with him. The refult of his obfervations and inquiries was publifhed in a "Collection of Voyages and Travels," comprifed in 4 vols. fol. from 1663 to 1672. Thevenot was a great collector of books, confifting of more than 2000 volumes, in which the royal library, of which he was keeper, was deficient. Nointel, on returning from his embaffy to Conftantinople, enriched this collection by a prefent of his marbles, infcriptions, and bas-reliefs. He died in 1692. From various MSS. in the royal library, he had compiled "The Works of Ancient Mathematicians," an edition of which was publifhed after his death. Moreri. Huet.

THEVET, Andrew, a traveller and writer, was born at Angouleme in 1502; and being defirous of vifiting foreign countries, he obtained, by the intereft of the cardinal of Lorraine, an opportunity of going to Jerufalem. His travels in the Levant occupied him from 1549 to 1554; and after his return to France, he accompanied the fieur de Villegaignon, in 1555, to found a colony in Brazil. In 1556 he took the habit of an ecclefiaftic, and was appointed almoner to queen Catharine de Medicis. He alfo obtained the titles of hiftoriographer and cofmographer royal, and died at Paris in 1590, at the advanced age of 88 years. Befides other works, he publifhed "Cofmographie du Levant," 1554, 4to.; "Les Singularités de la France Antarctique," 1588, 4to.; and "Cofmographie Univerfelle," 2 vols. fol. 1575; but unfortunately his veracity is queftionable. Moreri.

THEVESTE, Tiffeste, in *Ancient Geography*, a town of Africa, fituated on a delightful plain in the interior of the country, on the banks of a river, E. of Sigus, and E.S.E. of Cirta. In Anton. Itin. this town has the title of a Roman colony, and is placed on the route from Carthage to Cæfarea, between Ammedara Colonia and Attaba.

THEVET. See Tebet.

THEVETIA, in *Botany*, a name given by Linnæus, in his *Hortus Cliffortianus* 75, to a genus diftinguifhed by Plumier, and other authors, under the American appellation of *Ahouai*. The perfon commemorated by the above name was André Thevet, a French monk, who travelled to Brafil, of which he publifhed an account in 1554, under the title of *Les Singularitez de la France Antarctique, autrement nommée Amerique*, &c. Of this book there are feveral editions, with rude wooden cuts, and fome accounts of plants, amongft which the *Ahouai* is, for the firft time, defcribed. The author, according to De Theis, died in 1590, about the age of eighty-eight. Haller fays he has injudicioufly applied paffages in the writings of the ancients to the productions of the new world; and that he has defcribed many countries which he never vifited. Linnæus himfelf appears not to have been fatisfied with the honour he was conferring, for he fays he fhould not be difpleafed with any perfon who might change this name for another. He fubfequently retained it as a fpecific name only, when the genus in queftion was funk in his own Cerbera. See that article.

THEU-PROSOPON, in *Ancient Geography*, a promontory of Phœnicia, between Tripolis and Botrys. Mela calls it Euprofopon.

THEURGY, θεουργια, a name which the ancients gave to that facred part of magic which we fometimes call *white magic*, or the *white art*.

The word is formed from Θεος, *God*, and εργον, *work*; *q. d.* the art of doing divine things, or things which God alone can do: or the power of working extraordinary and fupernatural things, by invoking the names of God, faints, angels, &c.

Accordingly, thofe who have written of magic in the general, divide it into three parts: the firft of which is called *theurgy*, as operating by divine or celeftial means; the fecond, *natural magic*, performed by the powers of nature; and the third, *necromancy*, which proceeds by invoking dæmons.

This theurgy, or pretended art of fo purging and refining that faculty of the mind, which receives the images of things, as to render it capable of perceiving the dæmons, and of performing many marvellous things by their affiftance, was adopted by the difciples of Ammonius towards the clofe of the fecond century. Ammonius, the founder of the fect of modern Platonics (fee Platonism), with a view of reconciling the popular religions of different countries, and particularly the Chriftian, with his own fyftem, turned into mere allegory the whole hiftory of the gods, and maintained that thofe beings, whom the priefts and people dignified with this title,

title, were no more than celestial ministers, to whom a certain kind of inferior worship was due. He acknowledged Christ to be a most excellent man, the friend of God, and the admirable theurge; but denied that it was his intention entirely to abolish the worship of dæmons, and of the other ministers of divine providence; affirming, on the contrary, that he merely purified the ancient religion, and that his followers had manifestly corrupted the doctrine of their divine master. Mosh. Eccl. Hist. vol. i. 8vo.

THEUTIS, in *Ancient Geography*, a small town of Arcadia, S. of the river Lodon, and near that of Tuthoa.

THEUX, in *Geography*, a town of France, in the department of the Ourthe; 5 miles N.W. of Spa.

THEXIS, a word used by the old medical writers, sometimes for wounds made by puncture with small instruments, and sometimes for the operation of the suture, or the sewing together the lips of a wound, to make it heal with a less scar.

THEYA, in *Geography*. See TEYA.

THEYE-CHEEKE LAKE, a lake of North America. N. lat. 65°. W. long. 109°.

THEYE-NOYE-KYED LAKE, a lake of North America. N. lat. 64° 10′. W. long. 108°.

THEYHOLEKYED LAKE, a lake of North America. N. lat. 62°. W. long. 102° 5′.

THEYSSE, a river which rises in the E. part of Hungary, on the borders of Poland, and runs into the Danube; 19 miles N.W. of Belgrade.

THEZE, a town of France, in the department of the Lower Pyrenees; 12 miles N. of Pau.

THIA, or DIVINE, in *Ancient Geography*, an island which, A.D. 46, was under the empire of Claudius. It was one of the Cyclades, situated between Thera and Therasia. It either disappeared, or was reunited to that of Hiera towards the year 726, on occasion of a violent eruption which took place at that time.

THIA, a town of Cappadocian Pontus, upon the route from Trapezunte to Satala, between Zigana and Sedisscapisonti. Anton. Itin.

THIACAR, in *Geography*, a town of Thibet; 75 miles S.E. of Lassa.

THIAGOLA, in *Ancient Geography*, a name given to the most northerly mouth of the Danube, and to the marsh which it forms before it runs into the Euxine sea.

THIAN, in *Geography*, a town of the county of Tyrol; 13 miles W. of Bolzano.

THIAR, in *Ancient Geography*, a town of Spain, upon the route from Tarragona to Castula, between Illicis and Carthage. Anton. Itin.

THIAUCOURT, in *Geography*, a town of France, in the department of the Meurthe; 7 miles W. of Pont-à-Mousson.

THIAUMA, in *Ancient Geography*, a town of Albania, between the rivers Cæsius and Gerrus.

THIBAULT VI., in *Biography*, count of Champagne and king of Navarre, deserves to be recorded as one of the earliest French song-writers. In 1234 he succeeded to the crown of Navarre on the death of his maternal uncle. Upon his return from the East, whither he went as one of the crusaders, he cultivated literature, and particularly poetry. He died at Pampelona in 1253, having acquired the somewhat inconsistent titles of the Great and the Song-maker. Under the latter character he obtained permanent reputation, degraded, however, by the occasional licentiousness of his imagery. He was the first, it is said, who blended masculine with feminine rhymes:—a capital invention in French versification. Moreri. Nouv. Dict. Hist.

The songs of this prince are placed by some at the head of those that have been preserved in the French language, as those by Guillaume IX., duke of Aquitaine, are in that of Provence. There were indeed songs written in both languages before these princes had done poetry the honour to make it their favourite amusement; but the chief part of those of higher antiquity than the time of these patriarchs of Provençal and French versification are either lost, or thought of little value.

This prince was contemporary with Philip Augustus, and Lewis VIII. and IX., which last prince he accompanied to the Holy War. It has been said by several historians that he was much captivated by the charms of queen Blanche of Castile, mother of St. Lewis, to whom many of his songs were addressed; but this point of history has been disputed with great zeal by M. l'Eveque de la Ravalliere, editor of Thibault's poems, which he published in 1742, with notes, in 2 vols. 12mo. and a history of the revolutions, in the French language, from the time of Charlemagne to that of St. Lewis, together with an Essay on the Antiquity of French Songs. This learned prelate has defended the honour of queen Blanche with his pen, five hundred years after her decease, with as much prowess and true chivalry, as the most valiant champion of injured innocence could have done with his sword and lance, had he been animated by the presence of that princess, and the heroism of the times in which she lived.

"Les Grandes Chroniques de France" tell us that Thibault, at the age of thirty-five, having conceived a violent and hopeless passion for queen Blanche, was advised by wise and prudent counsellors to apply himself to music and poetry, which he did with such success, that he produced "the most beautiful songs and melodies that have ever been heard." Fauchet Des Anciens Poetes François.

Two airs by Thibault may be seen in Burney's General History of Music, from the Vatican collection of Provençal songs in Gregorian notes, without bars or base; and given afterwards in modern notation, with a base, and an English version of the words.

THIBERVILLE, in *Geography*, a town of France, in the department of the Eure; 9 miles E. of Lisieux.

THIBET, or TIBET, pronounced *Tibbet* and *Tibt* in Bengal, and called by its own inhabitants *Puë*, or *Puëkoachim*, *puë* signifying *northern*, and *koachim*, *snow*, that is, the snowy region of the North, is a country of Asia, of which our knowledge, principally obtained at a very recent period, is still very imperfect. We have no evidence that the ancients ever penetrated the snowy mountains of Tibet. It seems to have been in some measure disclosed to the Portuguese, in their commercial intercourse with the East Indies; and the name of it was known to Marco Paolo and other travellers of the 12th and 13th centuries. Accordingly, Tibet seems to have been the southern part of their Tangut. Paolo indeed describes the province of "Tebeth," as containing eight kingdoms, with many cities and villages, and as being a mountainous country, which produced some gold and spices, a large breed of dogs, and excellent falcons. But we have no geographical nor statistical account of this conntry upon which we can depend previously to the last century; and even now our knowledge of it is very partial and defective. About the year 1715, the emperor of China, as we learn from Du Halde, being desirous of obtaining a map of Tibet, sent two lamas, who had studied geometry, for this purpose. These lamas drew a map, from Sining, in the province of Shen-si, to the sources of the Ganges, which was afterwards examined by the Jesuits, and improved. This map is published in the Atlas of Du Halde, and has been followed, with few variations, by our modern geographers.

Its

Its authority is doubtful, its accuracy very fufpicious, and the information it affords concerning kingdoms, ftates, and provinces, as well as particular places, very limited and unfatisfactory. According to our moft recent maps, Tibet extends from about the 75th to the 101ft degree of longitude, which, in the latitude of 30°, may be about 1350 geographical miles. The breadth may be regarded as extending from the 27th to the 35th degree of latitude, or about 480 geographical miles. It appears, however, from the teftimonies of two intelligent travellers, Mr. Forfter and Tieffenthaler, that the northern boundary of Tibet may be fafely extended two degrees farther than it appears in our beft maps, in which there is no portion of Great Tibet to the N.E. of Cafhmir. Major Rennell moved it one degree farther to the north than D'Anville's boundary in lat. 34°, and Pinkerton thinks that he might fafely have extended it at leaft 3°. The northern boundary of Tibet, according to the Ruffians, is Mus Tag, and they place that range in 38°. By adding 2° to 35°, we obtain an addition of 120 geographical miles to the number of 480 above ftated.

Thibet, according to Mr. Bogle's account (Phil. Tranf.) begins properly from the top of the great ridge of the Caucafus, and extends from thence in breadth to the confines of Great Tartary, and perhaps to the dominions of the Ruffian empire. He fays, that having once attained the fummit of the Bootan mountains, you do not defcend in an equal proportion on the fide of Thibet; but continuing ftill on a very elevated bafe, you traverfe vallies which are wider and not fo deep as the former, and mountains that are neither fo fteep, nor apparently fo high. On the other hand, he reprefents it as the moft bare and defolate country he ever faw; and the climate as extremely fevere. According to Mr. Turner, the boundaries of Tibet and Bootan are feparated by the lofty range of mountains called Soomoonang, and are marked by a long row of little infcribed flags, fixed in rude heaps of ftones, and fluttering in the wind. Thefe, at the fame time, are fuppofed to operate as a charm over the Dewtas, or "genii loci," who are paramount here. No mountain is thought to be wholly exempt from their influence; and they range chiefly in the moft elevated regions, where, drenched with dews, and worried with tempeftuous weather, they are fuppofed to deal around them, in ill humour, their moft baneful fpells, to harafs and annoy the traveller.

Tibet is fometimes divided into three parts, *viz.* Upper, Middle, and Lower. Upper Tibet comprifes chiefly the province of Nagari, abounding with tremendous rocks and mountains, always covered with fnow. The countries of Lata or Ladak (Latac) and Breguiong or Bramafcion (perhaps Sirinagur) probably conftitute a portion of Upper Tibet, as well as Nagari. Middle Tibet contains the provinces of Shang, Ou, and Kiang; and thofe of Lower Tibet are Takbo, Congbo, and Kahang. Many of thefe provinces are again fubdivided: *e. g.* Nagari, which is confidered as a kingdom confifting of three departments, Sanghar, Pourang, and Tamo (Dam or Daum). Shang is on the W. bounded by Nipal. The province of Ou contains Lahaffa or Laffa, the capital of Tibet. Kiang lies to the N. (or N.E.) of Ou, and is inhabited by a mixture of Tibetians and Monguls in tents. Kahang is on the S.E. bordering on the Birmans, and is divided into twelve departments. To thefe we muft add the wide region of Amdoa, if it be not the fame with Kahang, the natives of which fpeak the Chinefe language. The country of Hor lies between Tartary and the provinces of Nagari and Kiang, and feems to be the Hohonor of our maps. Our *Bootan* (which fee) is called by the natives Decpo or Takbo; and the countries W. of it, *viz.* Moringa or Morung, Mocampour, Nipal, Gorca, and Kamaoon, are not confidered as parts of Tibet. On the weftern fide, high mountains, covered with perpetual fnow, and terrible avalanches, have prevented the accefs and invafions of the Perfians and the conquerors of Bucharia; while the deferts on the N.E. have proved ineffectual barriers againft the Monguls and Eluts. Travellers have alfo been prevented from exploring this quarter by the weftern mountains, fo that it is even now little known.

According to the topography, compiled from the papers of Pinnabilla, a Capuchin friar, who died in 1747, and was buried at Patan, by father Giorgi, in a work publifhed at Rome in 1762, Tibet is bounded on the E. by China and Tarcenton, a province abounding with tea, and, fince the year 1720, incorporated with the Chinefe empire; on the S. by Bengal, Lotenke, Altibary, Mon, Brukpa, Lhoba, Lhokhaptra, Sciapado, and Bha; on the W. by Cafhmir, Nekpal, and Moronga; and on the N. by Great Tartary, the Ufbeks, Cafhur, and Jonkar, as far as Jerkend and Cokonor or Kokonor. The kingdoms and provinces in this topography are enumerated by Pinkerton, *ubi infra.*

The government of Tibet has been confidered as ecclefiaftical or fpiritual; though the lamas were accuftomed to appoint a "tipa," or fecular regent, a right which has been probably transferred to the Chinefe emperor. This officer refides at Laffa the capital, and he is invefted with the government and fupreme controul over the whole country. Mr. Turner, however, is of opinion, that the temporal authority of the lamas may again recover its former dignity and fplendour. Bootan, which is generally confidered as a feudatory province of Tibet, has a raja or prince called Daab, of no very permanent or extenfive authority. The laws muft, like the religion, bear fome affinity to thofe of the Hindoos.

The lama of Tibet was the Prefter John of the middle ages, if he were not fome Neftorian khan; and the appellation was unaccountably transferred by Portuguefe ignorance to the emperor of Abyffinia. (See Prester John.) In the time of Marco Paolo, Tibet, having been ravaged by the Monguls, was almoft defolate. For fome time this country had been fubject to fecular kings, called Tfan Pa; and the lama refided at Laffa, with a power refembling that of the fpiritual prince of Japan. According to Giorgi, the fucceffion of kings and lamas commences about 1340 years B.C. but about 1100 years after Chrift the Chinefe emperor gave to a celebrated lama the regal power. Thofe Monguls, called Eluts, conquered the fecular prince, and transferred the whole power to the lama. (See Du Halde, iv. 50.) In 1792, the Nipalefe, having committed great ravages in Tibet, the Chinefe emperor fent an army to protect the lama; in confequence of which the Chinefe eftablifhed military pofts on the frontiers, fo that the intercourfe between their country and Bengal is now precluded. The revenues of the lama and of the fecular princes are trifling; nor is it likely that Tibet can ever afpire to any political importance.

Some have faid, that the religion of Tibet is a corrupted Chriftianity; and even father Difiderii, a Jefuit, who vifited the country about the beginning of the laft century, thinks he can refolve all their myfteries into ours; and he afferts that they have a good notion of the Trinity, fince, in their addrefs to the Deity, they fay as often koneiok-oik in the plural, as koneiok in the fingular, and with their rofaries pronounce thefe words, Om, Ha, Hum. Of thefe whimfical conjectures we fhall fay no more, but pafs on to obferve, that the religion of the Tibetians feems to have derived its origin, fays Turner, (*ubi infra,*) from a difciple of Budh, who firft broached the doctrine which now prevails over the wide extent of Tartary. It is reported to have received its earlieft admiffion admiſſion in that part of Tibet bordering upon India, (which from hence became the ſeat of the ſovereign lamas,) to have traverſed over Mantchew Tartary, and to have been ultimately diſſeminated over China and Japan. Though it differs from the Hindoo in many of its outward forms, yet it ſtill bears a very cloſe affinity with the religion of Brahma in many important particulars. The principal idol in the temples of Tibet is Mahamoonie, the Budha of Bengal, who is worſhipped under theſe and various other epithets throughout the great extent of Tartary, and among all the nations to the eaſtward of the Berhampooter. In the wide extended ſpace over which this faith prevails, the ſame object of veneration is acknowledged under numerous titles; among others, he is ſtyled Godama or Gowtama, in Aſſam and Ava; Samana, in Siam; Amida Buth, in Japan; Fohi, in China; Budha and Shakamuna, in Bengal and Hindooſtan; Dherma Raja and Mahamoonie, in Bootan and Tibet. Durga and Kali; Ganeiſh, the emblem of wiſdom; and Cartikeäh, with his numerous heads and arms, as well as many other deities of the Hindoo mythology, have alſo a place in their aſſemblage of gods.

The ſame places of popular eſteem or religious reſort, are equally reſpected in Tibet and in Bengal; Praag, Caſhi, Durgeedin, Saugor, and Jagarnaut, are objects of devout pilgrimage; and loads of the ſacred water taken from the Ganges, have been ſeen travelling over theſe mountains, (which, by the bye, contribute largely to its increaſe,) upon the ſhoulders of men, whom enthuſiaſts have deemed it worth their while to hire at a conſiderable expence for ſo pious a purpoſe.

As far as can be judged reſpecting their ritual or ceremonial worſhip, it differs materially from the Hindoo. The Tibetians aſſemble in chapels, and unite together in prodigious numbers, to perform their religious ſervice, which they chant in alternate recitative and chorus, accompanied by an extenſive band of loud and powerful inſtruments. So that, whenever theſe congregations were heard, they forcibly recalled to remembrance, both the ſolemnity and ſound of the Roman Catholic maſs.

The inſtruments made uſe of were all of an enormous ſize. Trumpets above ſix feet long; drums ſtretched over a copper cauldron, ſuch as are termed *nowbut* in Hindooſtan; the gong, a circular Chineſe inſtrument of thin hammered bell-metal, capable of producing a ſurpriſing ſound; cymbals, hautboys; and a double drum, ſhallow, but of great circumference, mounted upon a tall, ſlender pedeſtal, which the performer turns with great facility, ſtriking either ſide with a long curved iron, as the piece requires a higher or a lower tone: theſe, together with the human tibia, and ſea-conch, a large ſpecies of the buccinum, compoſe, for the moſt part, their religious band. Harſh as theſe inſtruments, individually taken, might ſound to a muſical ear, yet when joined together in uniſon with the voices of two or three hundred boys and men, managed with varying modulation, from the loweſt and ſofteſt cadence to the loudeſt ſwell, they produce to the ear an effect extremely grand.

Other muſical inſtruments are in the hands of the people of Tibet.

Among the Tibetians, ſays Mr. Turner, all is ſyſtem and order. The mind readily obeys the ſuperiority it has been accuſtomed to acknowledge. A ſovereign lama, immaculate, immortal, omnipreſent, and omniſcient, is placed at the ſummit of their fabric. He is eſteemed the vicegerent of the only God, the mediator between mortals and the ſupreme. They view him only in the moſt amiable light, as perpetually abſorbed in religious duty; and, when called to beſtow attention on mortal beings, as employed only in the benign office of diſtributing comfort and conſolation by his bleſſing, and in exerciſing the firſt of all attributes, forgiveneſs and mercy. He is alſo the centre of all civil government, which derives from his authority all its influence and power. At the ſame time that he is the ſoul which animates their whole ſyſtem, a regular gradation, from the moſt venerated lama, through the whole order of Gylongs to the young noviciate, is obſerved with rigid ſeverity.

The inferior gradations from the preſident of a monaſtery, who is always ſtyled lama, in addition to the name of the ſtation to which he belongs, are Gylong, Tohba, and Tuppa. See Gylong, Teshoo-Loomboo, Tohba, and Tuppa.

The nation is divided into two diſtinct and ſeparate claſſes, thoſe who carry on the buſineſs of the world, and thoſe who hold intercourſe with heaven. No interference of the laity ever interrupts the regulated duties of the clergy. The latter, by mutual compact, take charge of all their ſpiritual concerns; and the former, by their labours enrich and populate the ſtate.

In Tibet there are two ſects, diſtinguiſhed by the appellations of Gyllookpa and Shammar, but the external appearance, or dreſs of both, is ſimilar, except the diſtinction in the colour of the cap; the Gylloopka having adopted yellow, the Shammar red; a circumſtance which is ſtrictly attended to, on all occaſions of ceremony. Three lamas are placed at the head of each ſect; Dalai lama, Teſhoo lama, and Taranaut lama, preſide over the Gyllookpa, who have their reſidence at Pootalah, Teſhoo-Loomboo, and Kharka. This ſect prevails over the greateſt part of Tibet, and a diviſion of the ſame is ſaid to be eſtabliſhed in a province of the Decan, called Seurra or Serrora.

In like manner, three lamas alſo, lam' Rimbochay, lam' Sobroo Nawangnamghi, and lam'Ghaſſatoo, preſide over the Shammar; theſe have their reſidence in Bootan, in ſeparate monaſteries, but, from the limited extent of that country, at no great diſtance from each other. The principal of the Shammar ſect in Tibet is ſtyled Gongſo Rimbochay, and has his reſidence at Sakia.

The Tibetians are actuated by an ardent ſpirit of devotion; and they attribute the merit of every thing great, or ſingularly beneficial, to the agency of ſome ſupernatural being. It is the cuſtom in Tibet to preſerve entire the mortal remains of their ſovereign Lama only; every other corpſe is either conſumed by fire, or given to be the promiſcuous food of beaſts and birds of prey. As ſoon as life has left the body of the Lama, it is placed upright, ſitting in an attitude of devotion, the legs being folded before him, with the inſtep reaching upon each thigh, and the ſoles of the feet turned upwards. It is the practice here to cover the bodies of men, found dead in the fields, with clods of earth, which the rains gradually diſſolve and incorporate, forming the looſe maſs into a compact hillock. This always attracts the ſame reſpect, and paſſengers continue to add to the heap, long after all traces of the body are loſt, and its exiſtence forgotten. Thus alſo the piety of the Tibetians offers a ſimilar rite to the bodies of thoſe whom chance may have led to the ſpot, where the fragment lay at the inſtant of its fall, though the fatal effects of it may not have been certainly known.

A tribute of reſpect is paid, in this region, to the manes of the dead in various ways. The ſovereign lamas are depoſited entire, in ſhrines prepared for their remains, which ever after are looked upon as ſacred, and viſited with religious awe. The bodies of inferior lamas are uſually burnt, and their aſhes preſerved with great care in little metallic idols, which have places aſſigned them in their ſacred cabinets. Common ſubjects are treated with leſs ceremony;

mony; fome of them are carried to lofty eminences, where, after having been disjointed, and the limbs divided, they are left a prey for ravens, kites, and other carnivorous birds. Others, with lefs refpect, are committed to the ufual receptacle of the dead. The laft, but lefs frequent, mode of difpofing of the dead, is committing them to the waters of the river. Burial, that is, inhuming the corpfe entire in the earth, is altogether unpractifed.

On one fide of the monaftery of Teshoo-Loomboo is the place to which they convey their dead. It is a fpacious area, inclofed on one part by a perpendicular rock, and on the others by lofty walls, raifed probably with a view to feclude from public obfervation, the difgufting objects contained within them. At the top it was totally uncovered, fo as to be perfectly open to the birds; and at the bottom a narrow paffage was left through the walls, near their foundation, for the fole purpofe of admitting dogs, or other beafts of prey. On the rock above, a platform overhung the inclofure, which had been conftructed for the conveniency of precipitating the dead bodies with greater eafe over the walls, into the area. And here, the only rites performed, in honour of the dead, were merely fuch as tended to facilitate the deftruction of the body by dogs or birds of prey. But though this was the general receptacle, yet there were fome who declined the ufe of it, and conveyed their friends to the fummit of fome neighbouring hill, where they disjointed and mangled the dead body, that it might become a more eafy prey to carnivorous birds. Hence it was concluded that there was a ftrong prejudice in their minds of fome idea of pollution attached to "being given to the dogs," which was fufficient to create a preference of the contrary practice. In Tibet, as well as in Bengal, an annual feftival is kept in honour of the dead.

The Tibetians are much addicted to fuperftition; and accordingly they lay great ftrefs on lucky and unlucky days. They alfo pay great refpect to the profeffors of aftrology. Hence we find no prudent traveller ever attempting to undertake a journey, without previoufly appealing to this authority, and endeavouring to obtain an aufpicious prefage. The fame fignal of favour is deemed indifpenfably requifite in every important enterprife, and the fame wary circumfpection enters equally into all the more minute concerns of domeftic life. The union of the fexes, and the giving names to infants, are neither of them events to be accomplifhed without a regular appeal to the fame decifive oracle. This fcience is alfo regarded in the conftruction of their almanacs. Their year, which is lunar, confifts of 12 months, each month having 29 days; and the days are reckoned from the appearance of the new moon, in regular fucceffion, till it fhews itfelf again. The parts of the days are, evening, night, morning, and noon: and their computation of time is conformable to the general practice of the Eaft, by a cycle of 12 years. The art of printing is faid to have been very anciently practifed in Tibet; but it has hitherto been principally appropriated to facred works, and to the fervice of learning and religion. Their books are printed with blocks of wood, on narrow flips of thin paper, fabricated from the fibrous root of a fmall fhrub. The printed and written letters appropriated to works of learning and religion, are called "uchen;" and thofe of bufinefs and correfpondence are called "umin." The Gylongs, or priefts, pafs through a regular education. As for the language of Tibet, its origin is not fatisfactorily afcertained. Du Halde reports, that it is the fame with that fpoken by the people of Sifan, on the frontiers of China; but as this province is fometimes included in Tibet, this information is vague and indeterminate. Their characters, fays fir William Jones, are apparently Indian, but their language has now the difadvantage of being written with more letters than are ever pronounced; for, although it was anciently Sanfcrit and polyfyllabic, it feems at prefent, from the influence of Chinefe manners, to confift of monofyllables, to form which, with fome regard to grammatical derivation, it has become neceffary to fupprefs, in common difcourfe, many letters which we fee in their books; and thus we are enabled to trace in their writings a number of Sanfcrit words and phrafes, which, in their fpoken dialect, are quite undiftinguifhable.

A fingular cuftom prevails in this country, which may be called polyandry. One female affociates her fate and fortune with all the brethren of a family, without any reftriction of age or of numbers. The choice of a wife is the privilege of the elder brother; and it is faid, that a Tibetian wife is as jealous of her connubial rites, though thus joined to a numerous party of hufbands, as the defpot of an Indian zennana is of the favours of his imprifoned fair. The bufinefs of propagating the fpecies is abandoned to mere plebeians; and marriage feems to be confidered rather as an odium and a burden. The influence of this cuftom on the manners of the people is not found to be unfavourable. Humanity and gentlenefs of difpofition are the conftant inheritance of a Tibetian. Mr. Turner fays that he never faw thefe qualities poffeffed by any people in a more eminent degree. Without being fervilely officious, they are always obliging; the higher ranks are unaffuming; the inferior, refpectful in their behaviour; nor are they at all deficient in attention to the female fex; but, as we find them moderate in all their paffions in this refpect, alfo their conduct is equally remote from rudenefs and adulation. Comparatively with their fouthern neighbours, the women of Tibet enjoy an elevated ftation in fociety. To the privileges of unbounded liberty, the wife here adds the character of miftrefs of the family, and companion of her hufbands. The company of all, indeed, fhe is not at all times entitled to expect. Different purfuits, either agricultural employments or mercantile fpeculations, may occafionally caufe the temporary abfence of each; yet whatever be the refult, the profit of the labourer flows into the common ftore; and when he returns, whatever may have been his fortune, he is fecure of a grateful welcome to a focial home. The men are generally ftout, having in a degree the Tataric features, and the women are of a ruddy brown complexion, heightened like the fruits by the proximity of the fun, while the mountain breezes beftow health and vigour.

The ceremonies of marriage are neither tedious nor intricate in Tibet. Their courtfhips are carried on with little art, and quickly brought to a conclufion. The elder brother of a family, to whom the choice belongs, when enamoured of a damfel, makes his propofal to the parents. If his fuit is approved, and the offer accepted, the parents, with their daughter, repair to the fuitor's houfe, where the male and female acquaintance of both parties meet and caroufe for the fpace of three days, with mufic, dancing, and every kind of feftivity. At the expiration of this time the marriage is complete.

Tibet is thinly fcattered with inhabitants, on account of its mountainous furface and the feverity of its climate; nor can any accurate eftimate be made of its population. From fome circumftances it has been conjectured, that upon the whole it cannot be lefs than half a million. Giorgi, indeed, or rather Pinnabilla, from whom he deduces his ftatement, computes the number of inhabitants in 1730 at 33 millions, and the foldiers at 690,000; but both thefe numbers are moft extravagantly exaggerated; for Tibet has been

been often conquered by the Chinefe with armies not exceeding 40,000 men. The fingular cuftom of polyandry, already mentioned, feems adapted to check the progrefs of population, the fuperabundance of which, in an infertile country like Tibet, would be one of the greateft calamities, as it muft produce eternal warfare or internal want.

Bootan and Tibet exhibit a very remarkable contraft in their external appearance. Bootan prefents to the view nothing but the moft mis-fhapen irregularities; mountains covered with eternal verdure, and rich with abundant forefts of large and lofty trees. Almoft every favourable afpect of them, coated with the fmalleft quantity of foil, is cleared and adapted to cultivation, by being fhelved into horizontal beds: not a flope or narrow flip of land between the ridges lies unimproved. There is fcarcely a mountain, whofe bafe is not wafhed by fome rapid torrent, and many of the loftieft bear populous villages, amidft orchards and other plantations, on their fummits and on their fides. It combines in its extent the moft extravagant traits of rude nature and laborious art.

Tibet, on the other hand, ftrikes a traveller, at firft fight, as one of the leaft favoured countries under heaven, and appears to be in a great meafure incapable of culture. It exhibits only low rocky hills, without any vifible vegetation, or extenfive arid plains, both of the moft ftern and ftubborn afpect, promifing full as little as they produce. Its climate is cold and bleak in the extreme, from the fevere effects of which the inhabitants are obliged to feek refuge in fheltered valleys and hollows, or amidft the warmeft afpects of the rocks. Yet perhaps Providence, in its impartial diftribution of bleffings, has beftowed on each country a tolerably equal fhare. The advantages that one poffeffes in fertility, and in the richnefs of its forefts and its fruits, are amply counterbalanced in the other by its multitudinous flocks and invaluable mines. As one feems to poffefs the pabulum of vegetable, in the other we find a fuperabundance of animal, life. The variety and quantity of wild fowl, game, and beafts of prey, flocks, droves, and herds in Tibet, are aftonifhing. In Bootan, except domeftic creatures, nothing of the fort is feen. It has been afferted that Tibet was, in remote times, almoft totally inundated; and the removal of the waters that covered its furface is afcribed to the miraculous interpofition of fome object of their worfhip, whofe chief temple is reported to be at Dungeedin, Gya. In this traditionary belief we may poffibly difcover fome traces of the univerfal deluge; though the tradition be obfcured by fable and disfigured by a mixture of abfurdity. In the temperature of the feafons in Tibet, a remarkable uniformity prevails, as well as in their periodical duration and return. The fame divifion of them takes place here, as in the more fouthern region of Bengal. The fpring is marked from March to May, by a variable atmofphere; heat, thunder-ftorms, and occafionally with refrefhing fhowers. From June to September is the feafon of humidity, when heavy and continued rains fill the rivers to their brim, which run off from hence with rapidity, to affift in inundating Bengal. From October to March, a clear and uniform fky fucceeds, feldom obfcured either by fogs or clouds. For three months of this feafon, a degree of cold is felt, far greater perhaps than is known to prevail in Europe. Its extreme feverity is more particularly confined to the fouthern boundary of Tibet, near that elevated range of mountains which divides it from Affam, Bootan, and Nipal. The fummits of thefe are covered all the year with fnow, and their vicinity is remarkable, at all feafons, for the drynefs of the winds. The range is confined between the twenty-fixth and twenty-feventh degrees of northern latitude. During the winter, a practice is adopted in the neighbourhood of thefe mountains, fimilar to that in ufe in the coldeft parts of North America, but in fome refpects more complete. It is that of preparing meat and fifh for carriage, by the action of extreme cold. This practice, however, feems to be confined to the prefervation of mutton alone, which is a very fimple procefs, and requiring no ufe of falt. The Tibetians generally ufe that which is recently killed in a raw ftate, without any previous cookery.

Among the valuable and ufeful animals of Tibet, which are mufk-deer, horfes of a fmall fize, goats yielding the hair that is manufactured into fhawls, and cattle that are diminutive, to which we may refer the yak of the Tartars, their breed of fheep claims a diftinguifhed rank. Of thefe the flocks are numerous, and upon them they chiefly depend for their winter food. A peculiar fpecies, thought to be indigenous to this climate, is marked almoft invariably by black heads and legs. Their fize is fmall, their wool is foft, and their flefh, fays Mr. Turner, is the fineft mutton in the world. The wool affords material for one of their principal manufactures. (See IJHANSA-JEUNG.) Their fkins and thofe of the lambs are cured with the wool on, and conftitute a valuable article for winter garments, and for foreign traffic.

The foil and climate of Tibet are very unfavourable to any kind of exertion and activity that have for their object the cultivation of the land, but from time immemorial it has been the refort of merchants. Commerce, however, has been very languidly encouraged. The form of government, which is arbitrary, is inimical to induftry and enterprife. In Tibet, and alfo in Bootan, the firft member of the ftate is the chief merchant; and his ftation and power of controul give him great advantages over the common adventurer; and of courfe by this monopoly of the fovereign, emulation is reftrained and fuppreffed.

Although, as we have faid, the nature of the foil prohibits agriculture; yet the vales on the approach of winter being laid under water, they are ploughed and fown in fpring, and the crops are matured by frequent fhowers and a powerful fun. The autumn being clear and tranquil, the harveft is long left to dry on the ground; and when fufficiently hardened is trod out by cattle. The courfe of cultivation is wheat, peas, and barley; rice being confined to a more fouthern foil. Neverthelefs, the country abounds with commodities, which in different circumftances would give fpirit and extent to commercial tranfactions, whilft they are languifhing in floth, or exhibiting every indication of poverty. The trade with Bengal was formerly not inconfiderable; but this has been interrupted and diminifhed by the commotions which have long diftracted the kingdom of Nipal, which was the only known channel of communication. Bengal tranfmitted to Tibet, broad cloth, chiefly of inferior quality, and of yellow and fcarlet colours; fome few trinkets, fuch as fnuff-boxes, fmelling-bottles, knives, fciffars, and optic-glaffes; and fpices, particularly cloves and nutmegs; fandal wood, pearls, emeralds, fapphires, lapis lazuli, coral, jet, amber, fhells, cloths, leather, tobacco, indigo, and otter-fkins; and it received from Tibet, gold-duft, mufk, and tincal. The articles of trade next in importance, amongft the natural productions of Tibet, are goats' hair and rock-falt. Bootan, Nipal, Bengal, and Hindooftan, are fupplied with tincal from Tibet. The hair of the goats is carried to Cafhmire, where it is manufactured into fhawls. The demand for falt is in the confumption of Nipal and Bootan.

The trade from Tibet to Bootan confifts of gold-duft, tea,

tea, woollen cloths, and falt; from Bootan to Tibet, the articles are Englifh broad cloth, Rungpore leather, tobacco, coarfe cotton cloths, &c. paper, rice, fandal wood, indigo. Tibet fends to Luddauk, the mart between Cafhmire and Tefhoo-Loomboo, the fine hair of goats, and receives in return gamboge, fhawls, dried fruits, as apricots, raifins, currants, dates, almonds, and faffron. Khumbauk fends to Tibet, horfes, dromedaries, and Balgar hides. In Tibet there are feveral mines of lead; and as lead-ore contains filver, it might be feparated from it to great advantage, if the method of doing it were known. Here are alfo mines of cinnabar, which contains a great proportion of mercury, if the Tibetians knew how to extract it. The copper-mines furnifh materials for the manufacture of idols, and all the ornaments difpofed about monafteries, on which gilding is beftowed, for which there is a great demand in Tibet.

A very fmall quantity of fpecie is current in Tibet, and that is of a bafe ftandard. It is the filver coin of Nipal, here denominated *indermillee*, and worth about one-third of a ficca rupee; and it is cut into halves, third parts, and quarters. In all mercantile tranfactions, however, the equivalent is made in bullion, *i. e.* talents of gold and filver, valued in proportion to the purity and fpecific gravity of the metal.

The commerce between Tibet and China is carried on principally at a garrifon town, on the weftern frontier of China, named Sinning, or Silling: thither merchants refort from Tibet with their manufacture; *viz.* a thin cloth refembling frieze, but rather of a more open texture, gold-duft, and fome other commodities procured from Bengal; which they exchange for tea, filver bullion, brocades, and fruit. In thefe articles an extenfive trade is carried on; and Mr. Turner has been affured that, on the territory of Tefhoo-Loomboo alone, tea, to the amount of five or fix lacs of rupees, is annually confumed. From hence, too, Bootan is fupplied with tea, which is in the fame general ufe there.

Tibet exports to China, gold-duft, diamonds, pearls, coral, mufk, woollen cloths of its own manufacture, lamb-fkins and otter-fkins, called *ood*, brought from Bengal; and China returns to Tibet, gold and filver brocades, plain filks, fatins, black teas of four or five different forts, tobacco, filver bullion, quickfilver, cinnabar, china ware, trumpets, cymbals, and other mufical inftruments; furs, *viz.* fable, ermine, black fox; and dried fruits of various forts.

The regulations for carrying the commerce of the Englifh Eaft India Company through the dominions of Bootan, by means of the agency of native merchants, were fettled by the treaty entered into by Mr. Bogle, in the year 1775.

The cities and towns of Tibet are little known: the capital is *Laffa;* which fee. Among the edifices, the monafteries occupy the firft clafs. (See Teshoo-Loomboo.) The chief river of Tibet is *Berhampooter;* which fee. The Hoan-ho and Kian-ku of the Chinefe alfo derive their origin from the eaftern boundaries of Tibet. The great Japanefe river of Cambodia, or Maykaung of Laos, that of Nou Kia, fuppofed to pafs near Martaban, into the gulf of Pegu, and the Irawaddy of the eaft country, are fuppofed to have their fources from the mountains of Tibet, which may be ftyled the Alps of Afia. Another large river, called the Sardjoo or Gagra, which, after a courfe of about 600 miles, nearly parallel on the E. with that of the Ganges, joins it near Chupra, and derives its fpring from the lofty weftern mountains of Tibet. In thefe Alpine regions are many lakes, fuch as *Terkiri*, and Jamdro or *Pelté;* which fee. The ranges of Tibetian mountains in the W. and S. feem to bend in the form of a crefcent, from the fources of the Ganges to the frontiers of Afam, in a N.W. and S.E. direction. To the N. of Sampoo a parallel and higher ridge feems to extend, the northern extremities abounding with large frozen lakes. The chief elevation of mountains appears to be central, S. of the lake Terkiri, and is called Koiran, the weftern part being denominated Kantel. The fouthern range prefents many names of diftinct mountains, comprehended under the Hindoo name of Himmela. From thefe ranges many branches extend N. and S. This country poffeffes many mineral waters, the falutary ufe of which is not unknown to the natives. Among its natural curiofities we may reckon a fingular rock, N. of Taffifudon, defcribed by Mr. Saunders in the Appendix to Turner's Travels, and forming in front fix or feven angular femi-pillars of large circumference, and fome one hundred feet in height. This natural curiofity is partly detached from the mountains, and projects over a confiderable fall of water, which heightens the picturefque appearance of the whole. The rock is laminated, and might be formed into flate; and as iron-ftones are found in the vicinity, thefe pilafters probably, like thofe of bafalt, arife from the influence of that metal. Phil. Tranf. vol. lxvii. Sir W. Jones's Works, vol. iii. Turner's Travels. Pinkerton's Geography.

Thibet or Tibet, *Little*, a diftrict N.W. of Cafhmire, which is fuppofed to contain the chief fource of the Indus. The fituation of this country is doubtful; it probably lies on the N. and N.W. of Cafhmire, and is divided from Great Tibet by a high mountainous ridge, and by a higher chain, that of Belur, from Great Bucharia. It is defcribed as a very mountainous and poor country, pervaded by the Indus, and towards the N. full of forefts. The capital is Afcardu, and further to the N. is Schekar. Temir-kand, or the fortrefs of iron, feems to command the pafs between Great and Little Tibet; and the two Ganges of the Chinefe maps (fuppofed fources of the Ganges) are probably rivers which join the Indus from the Eaft. Pinkerton.

The delineation of the country of the Sacæ, by Ptolemy and Strabo, (fee Sacæ,) will be found to correfpond, fays Hugh Murray, efq. in his "Ancient Geography of Central and Eaftern Afia," in every refpect, with that given by Mr. Elphinftone of the Plain of Pamera and Little Thibet. It was bounded on the S. by Hindooftan, from which it was feparated by the ridge of Imaus. On the N. it was bounded by the next parallel chain, "Mons Afcataneas," which cannot poffibly be any other than the Mooz-Taugh, to whofe name, indeed, it bears a rude refemblance. It extended E. from the Montes Comedorun, (the Beloor or Belur,) to fomewhat beyond the head of the Ganges; precifely the dimenfions of Little Thibet. Great and Little Thibet form a table land of extraordinary elevation, bordering on Hindooftan to the S.: and two parallel chains, running from E. to W., prop this mighty bulwark of Afia. The northern barrier is formed by an immenfe chain, known under the name of Hindoo Coofh, and Himmela or Himalaya, which forms the northern limit of India. The whole extent of it is covered, to a great depth, with perpetual fnow; and every meafurement yet made, from Pefhaur to Nepaul, has made it exceed 20,000 feet above the level of the plain, being higher than the higheft peaks of the Andes. The whole is recognized by Ptolemy under the name of Imaus. The northern range, known by the uncouth appellation of Mooz-Taugh, *taugh* being merely the generic name of mountain, or Karrakorum, Mr. H. Murray apprehends to be defcribed by him under the name of Mons Afcataneas. Its abfolute elevation feems to exceed that of Himalaya, and yet from the high level of its bafe, it does not prefent fo formidable an afpect. At right angles to both, connecting them, and shutting in the western side of the table land, is another chain, called the Beloor-Taugh; forming the eastern limit of Shognaun, the ancient Sogdiana, and thus coinciding with the Montes Comedorum. According to the writer now cited, the "Scythia extra Imaum" of Ptolemy must be Great Thibet, with an extent of Tartary stretching indefinitely northwards. After Scythia, he says, comes the famous Serica; and if Great Thibet be Scythia extra Imaum, the next great country must be China, which he concludes from a variety of circumstances to be Serica. This writer thinks Pinkerton's hypothesis, mentioned under SERICA, of its being Little Bucharia, altogether inadmissible. See Murray's Ancient Geography of Central and Eastern Asia.

THICKET, a close knot or tuft of trees; a close wood, &c. in any field or inclosure of any kind.

THICKETS, in *Gardening*, a sort of close plantations of trees and shrubs, in pleasure-grounds, parks, &c. They are designed for different purposes, as sometimes to repel the force of tempestuous and cold cutting winds, either from the habitation, or some particular part of the garden; or to form places of shade and retirement in summer, having spaces for walks, recesses, &c. under the umbrage of the trees, and occasionally to conceal from view any unsightly or disagreeable object, and also sometimes to form a screen or blind arranged towards some outward boundary.

They are sometimes planted wholly of the large tree kinds, five or six to eight or ten feet asunder, some in regular lines, like a close grove, or more generally in a sort of promiscuous planting, but with some degree of order in the distances: they are also often composed of various trees and shrubs together, to effect a more full, close growth below and above, and to display a greater diversity in the plantation, by disposing the various shrubs properly between the larger trees, in some order of gradation, the lowest towards the front, and the taller growths backward, so as to form a sort of close underwood thicket below, while the trees run up and form a thicketty growth above; and sometimes they are formed wholly of shrubs of different sorts and degrees of growth, from the lowest placed forward, to the tallest behind.

They are sometimes, too, formed wholly of particular sorts of trees disposed separately in distinct plantations, as of elm, ash, beech, poplar, alder, willow, &c.

The planting of thicket plantations should be effected with young trees of from four, five, or six, to eight or ten feet growth, and the shrub kinds proportionally; in all of which the planting may be performed in the common seasons of autumn, winter, and spring.

In the culture of thicket plantations, little is required but that of keeping them clear from large overbearing weeds, while the trees and shrubs are in young small growth.

Thickets are now much less in use than was formerly the case in ornamental gardening, and pleasure-ground planting; they may, however, on some occasions, be introduced with good effect.

THICKON, in *Geography*, a river of Pennsylvania, which runs into the Delaware, N. lat. 40° 25′. W. long. 75° 8′.

THICKSTUFF, a name for sided timber exceeding four inches in thickness, but not being more than twelve inches in thickness.

THIEBLEMONT, in *Geography*, a town of France, in the department of the Marne; 8 miles E.S.E. of Vitry le François.

THIEL, or TIEL, a city or town of Holland, in the department of Guelderland, situated on the north side of the Wahal, in a small island called *Tieler-Weert*. In one of its fauxbourgs, called *Santwyck*; which is well fortified, is a strong citadel: the fortifications were destroyed in the year 1674, by the French, who had made themselves masters of the place about two years before, and have been since repaired. In the year 1528, it was besieged by the Spaniards, when Charles V. was at war with the duke of Gueldres; but they were compelled to raise the siege, through the brave resistance of the citizens. The country about it is marshy, and the air reckoned unwholesome. The fortifications are destroyed; 18 miles N.N.E. of Bois-le-Duc.

THIELLE, a town of the county of Neufchâtel, between the lake of Bienne and the lake of Neufchâtel; 5 miles N.E. of Neufchâtel.—Also, a river of Switzerland, which rises in the Vaudois, passes through the lakes of Neufchâtel and Bienne, and runs into the Aar, 3 miles below Buren.

THIELLEN, a town of Switzerland, in the canton of Uri; 2 miles N.W. of Altorff.

THIELT, a town of France, in the department of the Lys; 10 miles N. of Courtray.

THIENE, a town of Italy, in the Vicentin; 9 miles N.W. of Vicenza.

THIERS, JOHN BAPTIST, in *Biography*, a divine, was born at Chartres about the year 1636, and became a batchelor of the Sorbonne, professor in the college of Du Plessis at Paris, and curé of Chauprend, in the diocese of Chartres. Being arrested in consequence of a dispute with the clergy of Chartres, and a satire against one of them, he escaped by a stratagem, and found refuge with the bishop of Mans, who gave him the cure of Vibraie, where he died in February, 1703. His works are numerous, freely written, and on singular subjects; but we refer for an account of them to Moreri, the Nouv. Dict. Histor. and Gen. Biog.

THIERS, in *Geography*, a town of France, and principal place of a district, in the department of the Puy-de-Dôme; here are manufactures of cutlery, playing-cards, paper, thread, &c.; 21 miles S.E. of Gannat. N. lat. 45° 52′. E. long. 3° 38′.

THIERSHEIM, a town of Germany, in the principality of Culmbach; 6 miles N.E. of Wonsiedel.

THIERSTEIN, a town of Germany, in the principality of Culmbach, on the Eger; 5 miles N.E. of Wonsiedel.

THIE-WEY-ARA-YETH LAKE, a lake of North America. N. lat. 61° 20′. W. long. 106° 30′.

THIGH, FEMUR, a part of the body of men, quadrupeds, and birds, between the leg and the trunk. See EXTREMITIES.

We have an account in the Philosophical Transactions of a large piece of a young man's thigh-bone being taken out, and the place so well supplied by a callus, that he walked straight. See N° 461. sect. 2.

THIGH-*Bone*, *Fractured*. See FRACTURE.

THIGH, *Luxation of*. See LUXATION.

THIGH, in the *Manege*. The effect of the horseman's thigh is one of the aids that serves to make a horse work vigorously. See AID.

Fore-thigh, or arm of a horse, is that part of the fore-leg that runs between the shoulder and the knee: though the fore-thigh does not bend or bow, yet we commonly say, a horse goes fine, that bends well the fore-thigh, importing by it, that he bends well his leg.

Horses should always be full and well made in the thick parts of the thigh, especially in horses of the working kinds.

THIGHT, in *Agriculture*, a term provincially applied to turnip, or other crops which are thick or closely set. It also signifies impervious, when applied to roofs or vessels in some districts.

THILACHIUM, in *Botany*, so named by Loureiro, from

from θυλακιον, *a little bag*, alluding to the form of the calyx. It ought rather therefore to have been *Thylachium*.—Loureir. Cochinch. 342.—Clafs and order, *Polyandria Monogynia*. Nat. Ord. *Capparides*, Juff.

Gen. Ch. *Cal.* Perianth inferior, oblong-turbinate, ribbed, pointed, undivided, clofe, at length burfting all round. *Cor.* none. *Stam.* Filaments numerous, about feventy, awl-fhaped, long, erect, inferted into the receptacle; anthers oblong, upright. *Pift.* Germen fuperior, on a ftalk the length of the filaments, oblong, ftriated; ftyle none; ftigma roundifh. *Peric.* Berry oblong, with ten fides, of one cell. *Seeds* numerous, kidney-fhaped, imbedded in pulp.

Eff. Ch. Calyx of one leaf, oblong, burfting all round. Corolla none. Berry ftalked, with ten angles, one cell, and many feeds.

1. Th. *africanum*. African Pouch-flower.—Obferved by Loureiro on the eaftern coaft of Africa, near Mozambique, where it is called by the Portuguefe *Mangueiro*. The *tree* is fmall, with fpreading *branches*. *Leaves* alternate, ftalked, ovate, entire, fmooth. *Stalks* terminal, bearing feveral *flowers*, whofe long *ftamens* are of a faffron colour. The author obferves that this genus approaches *Capparis*, in its *ftamens* and the ftalk of its *berry*, but differs widely in the unufual form of the *calyx*, as well as the want of a *corolla*, and the figure of the *feed-veffel*. De Theis thinks it allied to MARCGRAVIA, fee that article. As far as it is related to *Capparis*, he is right; but between the *corolla* of *Marcgravia*, and the *calyx* of *Thilachium*, which he feems to have had in view, there can be no affinity; any more than between the latter and the pouch in the outer *calyx* of RUYSCHIA, which article the reader may likewife confult. We muft be content to leave the matter as we find it, there being great probability, confidering how little we know of the botany of its native country, that the plant, and even its genus, are entirely new to Europeans.

THILAY, in *Geography*, a town of France, in the department of the Ardennes; 7 miles N.N.E. of Charleville.

THILCHATEL, a town of France, in the department of the Cote d'Or; 14 miles N. of Dijon.

THILCO, or rather T'HILCO, in *Botany*. See FUSCHIA, n. 9.

THILL, in *Rural Economy*, the name of the framed fhafts of carts and waggons, between which the horfe draws and moves. The thills of thefe kinds of carriages fhould always, as much as poffible, be made of tough afh-wood, and light in proportion to the nature and ufes of them.

THILL-*Horfe*, the laft horfe in a team, or the horfe that goes between the thills or fhafts; which often fuftains much undue weight and preffure on the back, in confequence of the load which is drawn. This is capable of being relieved in various ways and by different contrivances, but the two which are noticed below would feem to be the moft fimple and eafy. It is well known to be almoft univerfally the practice to hook or attach the fecond horfes, in cart or waggon teams, on at the end of the fhafts. The confequence of which is obvioufly this: whenever the cart or carriage afcends a hill, and the fore part of the team comes to level ground, which not unfrequently happens, while the thill-horfe or horfes are ftill on the declivity, from their force being exerted in a right line to the ends of the fhafts, all the powers of the whole of the leading horfes muft, in fuch cafes, inevitably load and opprefs the thill-horfe or horfes, when fo directed, as they tend to deprefs the fhafts, in their exertion to draw at the proper point of draught; that is, in the line with the axle. The thill-horfe or horfes are often feen, in fuch inftances, nearly borne down, where the afcents are fteep, and the levels rather fuddenly regained. The back, or backs, of fuch horfes become a fort of fulcrum, on which the ftrength of all the preceding horfes acts as a kind of lever; which, if fufficiently forcible, and the thill-horfe or horfes' backs were ftrong enough to bear the preffure, muft lift the carriage off the ground, until it fhould come to a level with the line of their pull.

In order to remedy this great preffure and inconvenience, it is advifed that a looped iron, of about a foot in depth, in the whole, be faftened to the end of the fhaft; nailing and rivetting it firmly, by means of expanded flats. The looped part will then reach about eight or nine inches under or below the fhafts. Each trace is to be carried through thefe loops inftead of hooking on there, and be faftened at the bottom of the fhaft, near to where it hitches on to the frame of the carriage. This will give play to the traces, and wholly relieve the thill-horfe or horfes from the undue preffure to which they are expofed.

The principle here laid down is neceffary, whatever other method may be had recourfe to in removing the inconvenience.

At Hinton-Houfe, in Berkfhire, S. Nicolls, efq. is faid to effect this in a fomewhat different manner, the aim of which is the prevention of the draught of the trace-horfes pulling down the thill-horfe or thiller, which is always found to be the cafe, when they draw from a *drail*, as it is termed, in the fore part of the fhaft, if the thill-horfe be taller than the trace-horfes, or if the latter are going down a declivity, before the former has paffed its fummit, as feen above.

The preventive practice or mode in this cafe is by inferting a chain to the hinder part of the fhafts, which is alfo attached, and confined in fome meafure, to the fore part of the fhaft (where the drail is generally placed) by a piece of chain, which allows it to move freely to a certain diftance from the fhaft, in order that the draught may be conftantly kept in a horizontal direction.

THILYPTERIS, in *Botany*, a term ufed by Dillenius to exprefs the common female fern or brakes.

THIMA, in *Geography*. See TIMA.

THIMBLE, a cover for the finger, made of brafs, fteel, or filver, and ufed by all people who few, as taylors, milliners, &c.

THIMBLE, in *Sea Language*, an iron ring with a groove round the outfide, to receive the rope it is fpliced into. Thimbles are fpliced into the rigging and fails for blocks to be hooked to, or ropes to reeve through where blocks would appear too heavy.

THIMBLE *Iflands*, in *Geography*, fmall iflands near the coaft of Connecticut. N. lat. 41° 11'. W. long. 72° 42'.

THIMBRIC-KEUY, a village of Afiatic Turkey, in the province of Natolia, on the fcite of an ancient town called "Thymbra," built by Dardanus, king of Phrygia. Here are fome confiderable ruins, fuppofed of a temple of Apollo.

THIMDA, a town of Tunis; 8 miles S.W. of Bizerta.

THIMIO, in the *Materia Medica*, a name ufed by fome authors for a peculiar fort of lignum aloes, which is blackifh and very heavy, and extremely fweet.

THIN, a name given by the Arabian writers to earth of any kind.

Thus the bole armenic of Galen is called by Avicenna *thin Armeni*; and hence the word *muthin*, an adjective fignifying earthy, or approaching to the nature of earth; a term applied to many medicines of this kind.

THINA, in *Botany*, a name by which fome authors have called the larix, or larch-tree.

THINGAU, in *Geography*. See TINGAU.

THINGVALLA, a place of Iceland, about 26 miles distant from Reikiavik, and 24 miles from Skalholt; in which is a small, mean, and dirty church. The scenery about it is romantic; but the want of wood, and the effects of subterraneous heat, combine to give it a dreary aspect. The adjoining lake of the same name is a fine sheet of water, reckoned to be about ten miles long and from three to seven in breadth. In the lakes are two pretty large islands, called Sandey and Nesey, composed entirely of volcanic matter. The depth of the lake is said to be very great; a line of 100 fathoms having been sunk without reaching the bottom. It receives the waters of the surrounding bogs, and near it in different places vapours are seen to ascend from hot springs. It abounds with trout. At the S. end the mountains are very picturesque, and the ascending vapours contribute to the solemnity of the whole scene, as they arise from springs that have been produced by the most dreadful commotions, and the destruction of a country that may once have been beautiful and fertile. Near Thingvalla is a building, where the courts of justice were formerly held; but as Reikiavik is now the seat of government, the courts are held there. It does not appear why this place was originally selected for the seat of justice; but a town being once established, and trade carried on freely, and to a greater extent than in former times, ready recourse to the law became necessary. Although not more than fifteen years have elapsed (1817) since the judicial courts were transferred to Reikiavik, few remains are left to mark a spot so famous in the history of Iceland. The only building is a small wooden house, in which the consultations were held and sentence pronounced by the stiftantment or governor. The magistrates and people assembled on the occasion lived in tents. The culprits who were condemned to die were beheaded on a small island in the river Oxeran, which here flows into the lake. The females were drowned in a deep pool below the lava, a little farther up the valley. An ecclesiastical court used to be held at Thingvalla by the bishop of Skalholt, attended by the provosts and two ministers from each Syssel. It is suggested, that Tingwall in Shetland, and Dingwall in Rossshire, are evidently the same names as Thingvalla; and were probably, in ancient times, places where justice was administered. Towards the N. are several ranges of mountains, which, from the account received, and the appearances observed, are volcanic. Among these, the principal seems to be Skalbreidé, a lofty Jokul, of which description of mountains others were seen at a distance. Although the transference of the superior court from Thingvalla to Reikiavik has, probably, been attended with advantage, the Icelanders, as a people, have some reasons for regarding this change with regret. The annual meeting at Thingvalla was not merely that of a tribunal of justice, but an assembly of the nation; and though the importance of this assembly was diminished, and its dignity degraded, by the subjection of the island to a foreign power, yet on the spot where the greatest among his ancestors so often stood, the mind of the Icelander must ever have been awake to enthusiasm and patriotic pride. "Hic sacra, hic genus, hic majorum multa vestigia!" Mackenzie's Iceland.

THINKING, COGITATION, a general name for any act or operation of the mind.

Chauvin, with the Cartesians, will have thinking to consist in a certain native, inherent motion or agitation of the human mind, of which itself is conscious.—*Native* and *inherent*, since he conceives it no other than the very essence of the mind itself, or, at least, its principal and fundamental property: an *agitation*, since there is a new modification or change made in the mind, which we scarcely know how to conceive without motion; add, that the origin and etymology of the word *cogitation*, according to Varro and Festus, implies as much; *cogito* being used for *coagito*.

When the mind turns its view inwards, upon itself, the first idea that offers, says Mr. Locke, is thinking; in which it observes a great variety of modifications, and of them frames to itself distinct ideas: thus the perception annexed to any impression on the body, made by an external object, is called *sensation*.

When an idea recurs without the presence of the object, it is called *remembrance*.

When sought after by the mind, and brought again into view, it is called *recollection*.

When held there long under attentive consideration, it is called *contemplation*.

When ideas float in the mind without regard or reflection, it is called a *revery*; when they are taken express notice of, and, as it were, registered in the memory, it is *attention*; and when the mind fixes its view on any one idea, and considers it on all sides, it is *study* and *attention*.

These are the most obvious modes of thinking; but there are several others which we know of; and, doubtless, the mind is capable of infinite others, of which we have no notion at all.

The school-philosophers usually divide thinking, with regard to the object it is employed about, into understanding, *intellectio*; and willing, *volitio*.

And hence, those are said to be the two powers or faculties of the human mind.

Intellectual thinking is farther subdivided into divers kinds; the first, when the mind merely apprehends or takes notice of a thing, called *perception*; the second, when it affirms or denies a thing, called *judgment*; the third, when it gathers or infers a thing from others given, called *reasoning*; the fourth, when the mind disposes its own thoughts or ideas in order, called *method*.

Volitive thinking, or volition, admits of infinite different modifications, or new determinations.

Some authors extend the idea of thinking farther; and consider it in God, angels, brutes, &c. whence results a new division of thinking, into divine, angelical, human, and animal or sensitive.

But the two first we know little or nothing of: the third is that of which we have already been treating.—As to the last, *viz.* animal or sensitive thought, it is defined to be, an action of the soul attending to an external object, affected by means of the animal spirits duly agitated in the brain, to excite an idea.

The Cartesians maintain, that thinking is essential to the human soul; and, consequently, that there is no time when the soul does not think: but this doctrine has been very vigorously attacked by Mr. Locke; who labours to shew, that in sleep, without dreaming, there is an entire cessation of the modes of thinking.

I think, *cogito*, according to Des Cartes, is the first, and most certain, of all truths; from which, alone, we draw this consequence, *therefore I am*, or exist, *sum*.—One might also say, *cogito, ergo Deus est*; *I think, therefore there is a God.*—Logic is defined, the art of thinking methodically.

THINNING *of Plantations and Woods*, in *Agriculture*. The practice of thinning plantations of trees and woods, so as to let the plants of them have more room as they advance in growth, is mostly an operation of considerable importance; as upon it, perhaps, more than upon any other point of the after-management in such cases, depends the nature, quantity,

tity, and modification of the timber which is raiſed and produced.

Woods of the natural kinds, the ſeeds of which are ſown by birds or the winds on ſoils and ſurfaces of very different deſcriptions and ſorts, riſe and ſpring up at different times, and of very different degrees of thickneſs, ſtrength, and vigour in themſelves and their different parts; conſequently it is eaſy to ſuppoſe, that thoſe which are placed in favourable ſituations and circumſtances, will quickly overtop the others; and if they do not wholly deſtroy, will at leaſt weaken them in ſuch a way as not to be affected or inconvenienced by them, until the ſtrongeſt trees ultimately find ample and ſufficient room for their growth. In this way, although nature may be ſlow in her operations, ſhe effects her purpoſe in a very complete manner. Beſides theſe obſervations, Mr. Loudon has noticed that artificial thinning is only aſſiſting nature; and that hence even leaving natural woods to be thinned by time, would not be economical.

It is ſuggeſted with regard to artificial plantations, that in theſe the ſoil is equally cultivated, and the plants are put into the ground much about the ſame ſize, and at the ſame time, and that hence they of courſe ruſh up together all nearly of the ſame height, producing neither ornament nor timber; and none being produced ſo ſtrong as to take the lead and deſtroy the reſt, they grow in this manner until they are ſo crowded as to exclude air and moiſture. At which period, unleſs aſſiſtance has been previouſly given by thinning, the whole of the plantation dies together, and is deſtroyed.

Where thinning is neceſſary in old natural woods, or ſuch as have been planted, it ſhould conſtantly be performed by degrees in a regular manner, well conſidering the ſtate, qualities, and habits of the trees, as well as the nature of the ſoil on which they grow, the ſituation and expoſure in which they are placed, and other ſimilar matters. The outſides of them ſhould commonly be leſs thinned than the other parts, and the trees on the richer parts of the land be more thinned than thoſe on the other deſcriptions of it. The thinning of the ſide ſhoots and branches of the trees ſhould likewiſe, in ſome meaſure, accompany the other thinnings, and be performed in a ſuitable manner to their natures, ſtates, and purpoſes for which they are intended.

It is, however, moſtly the cuſtom to begin to thin them out at about ſeven years from the time of planting them, or that of their firſt growing up, and to repeat it every ſeven years afterwards. When the planting has been performed in the proportion of from ſix to eight hundred trees to the acre, they may be made to ſtand, in the firſt thinning, at about one tree to each rod of ground, or nine trees to eight rods. But in the ſecond thinning, a rather larger proportion of trees ſhould be taken out, as rather more than one to each rod; and in the third thinning, the proportion may be made ſtill in a larger ratio, ſo as to leave the trees about a rod ſquare each. Much muſt, however, always depend upon the nature, ſituation, and circumſtances of the particular plantations and woods.

In all theſe thinnings the worſt trees ſhould be removed, ſo as to leave the ſtraighteſt and beſt plants to ſtand for timber or other purpoſes.

It is ſuggeſted, that as in moſt plantations the fir tribe of trees has been introduced either for the purpoſe of ornament or ſhelter; where thinning is practiſed, in ſuch caſes, too large a proportion of theſe firs are moſtly left. Hence, from their comparatively quick growth, it is concluded that ſuch plantations have a diſagreeable ſameneſs throughout; and that, as moſt of them are made in the ſame manner, this appearance extends itſelf over the whole country.

The plantations in which thinnings in the way of ornament is moſt particularly required, are thoſe which are deſigned for groves. In many woods and copſes no plants require to be taken out but the nurſe ones, where any ſuch have been planted. Plantations of the fir kind, Mr. Loudon adviſes to be thinned ſomewhat gradually, beginning the work after they have been five or ſix years planted, and continuing it for ten or twelve years: after which time, thinning, he thinks, becomes pernicious. And that the trees which are to be thinned out ſhould conſtantly be grubbed up by the roots; for that when theſe are ſuffered to remain, they check the progreſs of the trees which are left. But theſe ſorts of plantations are ſometimes, and very properly, left altogether without thinning, being cut down wholly as a crop when fifteen or twenty years old, or of about that ſtanding. This is conceived to be in general the moſt profitable mode of planting and after-management on thin, bare ſoils in the vicinity of mines and pits, where wood of this ſort is greatly in demand by the proprietors for the ſupport of the upper ſtrata. Where ſome of the fir tribe have been planted as nurſes, they are recommended to be thinned out in a gradual manner, by being grubbed up as they begin to injure and inconvenience the principal trees. And groves, where the trees are of the deciduous kinds, ſhould be thinned out after the ſame manner; only, the work in theſe caſes may proceed until the trees have arrived at nearly their full growths.

Woods, where under-growth is always the object intended when they are properly planted, require, as has been ſeen above, no ſort of thinning, unleſs in caſes where nurſes have been planted, or when the timber-trees are too much crowded by the low growths; the whole ſhould be ſuffered to grow for twelve, fourteen, or more years, or until the under-growth is in a ſuitable ſtate to be cut over; when at that period the ſtrongeſt trees ſhould be fixed upon, and left as ſtandards in a properly thin ſtate. As copſe-woods uſually grow a certain length of time in proportion to their natures and kinds, and are then wholly cut over by the ſurface of the ground; they, of courſe, demand leſs thinning than others, or none at all, except when nurſes have been planted among them; and in the caſe of both woods and copſes, theſe, as they are thinned out, ſhould conſtantly be replaced by the principal trees at ſuitable diſtances.

In all caſes where ornament is in any way conſidered, the above writer thinks the trees or copſe left in thinning ſhould not be equidiſtant from each other, but in groups of irregular thickneſs; and it is ſuppoſed that the ſame may be had recourſe to even in woods where utility is the chief conſideration; as it will make no material difference in the produce of timber, and is ſo much more natural. See Plantation and Planting. See alſo Timber and Wood.

Thinning *out Crops*, the practice of thinning out ſuch plants among them as are too thickly or cloſely placed together, as in the caſe of turnips or other ſimilar crops. In the different ſorts of turnips, the thinnings may be made in ſuch a manner as that the plants may ſtand ultimately at the diſtance of from ſeven or eight to nine or ten inches every way from each other, in proportion as the land is more poor or rich in its quality. But in carrot crops, the thinning them out to the diſtance of about eight or twelve inches, according to the richneſs of the ſoil, may probably be the moſt proper practice. And the ſame will moſtly be the caſe for thoſe of the parſnip and beet kinds.

Where cabbage, borecole, or other ſimilar crops, are ſown, fown, they fhould always be thinned out to the diftance of a foot and a half, two feet or more, as the foil may be of a lefs or more rich quality. And lettuces, when put in by fowing, fhould be thinned to the diftance of from eight to twelve inches, according to the nature of the foil.

The thinning out of any other forts of field-crops of thefe kinds muft alfo be performed according to their natures and particular habits of growth.

Some of thefe forts of crops are beft thinned out in a gradual manner, as the turnip, carrot, beet, &c.; while in others it may be done all at once, as for the cabbage, and fome other kinds.

There are feveral different methods practifed in accomplifhing this bufinefs, as by means of the hand fimply, the ufe of the hand-hoe of different fuitable fizes, according to the ftates and circumftances of the crops, and lately in the row kinds, by an implement invented for the purpofe. This laft is by much the cheapeft and moft expeditious manner of performing the work; if it fhould be found, on further trial, to be equally accurate and effectual in the execution of the bufinefs. This fort of tool or machinery was invented and conftructed on the farm of Charles Gibfon, efq. at Quarmer Park, near Lancafter, and a reprefentation of it is given in the Corrected Agricultural Survey of that county, lately publifhed. See THINNING *and Hoeing Machine for Turnips, &c.*

The other modes of effecting and completing this kind of work, are a great deal more troublefome, laborious, and expenfive than the above, efpecially the firft of them, as many hands and much time are required for doing it in the moft proper and effectual manner by fuch means. Where the hand-hoe is employed, two or three different fized hoes are moftly made ufe of for the purpofe in the different fucceffive thinning hoeings, which, when in the hands of experienced workmen, do the bufinefs in a pretty quick, eafy, and complete manner, as the fupernumerary plants are ftruck and cut out with much exactnefs and regularity. It is conftantly neceffary in fuch cafes to keep the hoes in a pretty fharp ftate, in order to perform the work well, and with neatnefs. The principal objections to doing this fort of labour by the hand, are its tedioufnefs, and the treading which takes place during the operation.

THINNING *out Plants*, in *Gardening*, the pulling or drawing out fuch as are too clofe and thick in fome crops of the general and other kinds, as well as in fome other cafes, fo as that the remaining ones may ftand at proper and fuitable diftances for producing the moft favourable crops, plants, or other productions. This is moftly practifed in the cafes of the main crops of onion, carrots, parfnips, beets, fpinach, and feveral other fimilar kinds, which are fown in the broad-caft manner; in different fmall feed crops, for raifing plants to be afterwards fet out, fuch, for inftance, as the cauliflower, brocoli, cabbage, borecole, lettuce, endive, and many others; and in the producing and bringing forward young tree plants of moft forts in nurfery grounds and other places.

Onion crops are, for the moft part, thinned out at different times, as the demands of the markets, or in other ways may be, fo as to leave the remaining plants at the diftances of four or five inches or more from each other, according to their nature, kinds, and other circumftances; always, however, allowing fufficient room for their full and complete growths. Much advantage is often made in this way by the young onions which are thinned out, which would otherwife be loft and thrown away.

The carrot, parfnip, and beet crops are commonly thinned out at one or two thinnings, the ftanding plants being left at the diftances of about fix or eight inches apart, as the nature of the foil and crops may be. The young plants of the carrot kind, thus drawn, are in fome cafes bunched and made ufe of, efpecially when the crops are late in being thinned out, which fhould always be avoided as much as poffible.

Lettuce and fpinach crops may be thinned out at once to the diftances of fix, eight, or more inches between the plants, in the different kinds, as the nature of them may be, when put in upon the broad-caft plan. The thinnings are of little ufe or value, except for wafte purpofes, fuch as being thrown to the hogs, &c. in thefe inftances. Moft other fimilar forts of crops may be thinned out in the fame manner.

The fmall feed crops of the different kinds fhould conftantly be kept fo thinned out as to prevent the plants of them from being drawn up in a weak manner, and unfit for being fet out; as where the contrary is the cafe, there is always great wafte, and the plants feldom fucceed fo well. They fhould be gradually thinned out by planting, as well as in other ways.

Young tree plants, in moft cafes, require frequently thinning out in their early growths, in order to raife and bring them forward in the beft and moft perfect manner. They fhould therefore, in general, be fo kept thinned out as never to want fufficient room for rifing in the manner which is the moft natural and proper for them, and for preventing the injury they may fuftain by ftanding too clofe in the rows or otherways.

Due, early, and proper thinning out of crops and plants, is of courfe a matter of confiderable importance and utility in the garden culture of different forts of vegetables, trees, and other productions of the fame kinds.

THINNING *and Hoeing Machine for Turnips*, that fort of implement or machine which is contrived for the purpofe of thinning or fetting out this as well as other fimilar kinds of crops that ftand in rows. It is made light, and conftructed fomewhat in the form of the plough, having a fuitable apparatus fo attached to it behind as to be put in motion, and ftrike out the fupernumerary plants as the horfe proceeds regularly along the intervals of the ridges. The horfe is driven by the perfon who holds and directs the tool while at work. It is capable of going over a very confiderable fpace of ground in a fhort time, and if found, on the refult of further trials, to perform the work with due accuracy and correctnefs, will be a very great acquifition to the drill turnip hufbandry, and for different other purpofes of the fame nature.

THIONVILLE, in *Geography*, a town of France, and principal place of a diftrict, in the department of the Mofelle. The place contains 5014, and the canton 13,988 inhabitants, on a territory of 175 kiliometres, in 27 communes; formerly belonging to the duchy of Luxemburgh, and ceded to France by the treaty of the Pyrenées in 1659. N. lat. 49° 21′. E. long. 6° 15′.

THIORSAA, a large turbid river of Iceland, on the road from Skalholt to mount Hetla, the courfe of which is nearly from N.E. to S.W. In its paffage over rugged maffes of lava rifing abruptly from its bed, this river dafhes among the rocks, and forms impetuous rapids and falls.

THIR, in *Chronology*, the name of the fifth month of the Ethiopians, which correfponds, according to Ludolf, to the month of January.

THIRD, TERTIUS. See NUMBER and NUMERATION.

THIRD, in *Mufic*. The 3d is the moft agreeable and neceffary

neceffary concord in counterpoint, throughout the whole fyftem of practical harmony.

There are two kinds of thirds; the major or fharp 3d, which is four femitones or half notes above the bafe; and the minor or flat 3d, which is three.

Very agreeable mufic in two parts may be compofed, and often is compofed, of thirds only. The 3d is wanted with every other concord, and even difcord, except the 4th, when it is ufed as fuch with the 2d inftead of the 9th.

Dr. Pepufch, in his "Treatife on Harmony," has given curious and ample inftructions for the ufe of thirds in compofition.

It would be a curious inquiry, why a 3d was regarded by the ancients as a *difcord;* and why it is called by the moderns an *imperfect concord.* We cannot afford fpace for long difquifitions on every fubject of vain and frivolous curiofity, among which this would probably be numbered. But it feems as if the ancients eftimated the perfection of confonances by the fimplicity of ratios in the divifion of the monochord; regarding the *octave* as the moft perfect concord next to the unifon, as it was produced by a fimple divifion of a ftring into halves, expreffed by - - - $\frac{1}{2}$

The next in perfection was the 5th, produced by a third part of a ftring - - - - $\frac{2}{3}$

After this, the 4th, which was reckoned by the ancients not only a concord, but a *perfect concord,* expreffed by the ratio of - - - - $\frac{3}{4}$

A fourth part of a ftring gives the 15th, or double octave - - - - - $\frac{2}{4}$

The fifth part of a ftring produces the major 3d to the 15th, which, though in the organ the ftop called the *tierce,* it is a major 17th to the diapafon: its ratio is expreffed by - - - $\frac{4}{5}$

The minor 3d is expreffed by - - - $\frac{5}{6}$

The major 6th, compofed of four tones and a femitone major, as $\frac{E}{G}$: its ratio is - - $\frac{3}{5}$

The minor 6th, compofed of three tones and two major femitones, as $\frac{C}{E}$: its ratio is - - $\frac{5}{8}$

The extreme fharp, or, as the French call it, the fuperfluous 6th, compofed of four tones, a femitone major, and a femitone minor, as $\frac{G\sharp}{B\flat}$: the ratio of this 6th is - - - - - - $\frac{72}{125}$

We believe that the triple progreffion of a feries of perfect 5ths made the major 3ds fo extremely harfh, that no natural good ear could admit them among the concords. And in the firft attempts at counterpoint, it was a long time before a 3d was admitted in *difcant,* in which *diateffaronare* and *quintoier,* or a diatonic feries of 4ths and 5ths, now prohibited, was preferred to 3ds and 6ths in fucceeffion.

Third *Borough,* in our *Ancient Law-Books,* denotes a conftable.

Third *Earing,* in *Hufbandry,* the tilling or ploughing of the ground a *third* time.

Third *Eftate.* See Estate, Commons, &c.

Third *Night-awn-hynd.* By the laws of Edward the Confeffor, a gueft, who had lain three nights in an inn, was reputed a domeftic, and his hoft was anfwerable for what offence he fhould commit.

For one night he was accounted *uncuth;* for two nights, *gueft;* and the *third, awn-hynd,* or *hogen-hyne.* "Prima nocte incognitus, fecunda hofpes, tertia domefticus cenfetur."

Third *Order,* a fort of religious order, that obferves the fame rule, and the fame manner of life, in proportion as fome other two orders inftituted before.

The third orders are not originally religious orders, but affociations of fecular, and even married perfons, who conform, as far as their condition will allow them, to the defign, intention, and rules of a religious order, which affociates and directs them.

The Præmonftrantes, Carmelites, Auguftines, and Francifcans, difpute among themfelves the honour of having firft introduced third orders; but the pretenfions of the laft appear to be the beft founded.

The firft contend, that the third order of Præmonftrantes began in the life-time of their founder St. Norbert, who died in 1134.

F. Diego de Coria Maldonado, a Spanifh Carmelite, who has a particular treatife on the third order of Carmelites, derives them immediately, as well as the Carmelites themfelves, from the prophet Elijah.

The third order of Auguftines, if we credit F. Bruno, was inftituted by St. Auguftine himfelf; but the arguments he produces are fo frivolous, that F. Helyot obferves, they are not worth refuting.

The third order of Francifcans was inftituted by St. Francis in 1221, in favour of people of both fexes; who being fmitten with the preachings of that faint, demanded of him an eafy manner of living a Chriftian life; upon which he gave them a rule, the conftitutions of which are not now extant, as written by himfelf, but only as reduced and confirmed by pope Nicholas IV. fixty-eight years afterwards.

Thofe of the firft order of this faint are the monks called *Minor Friars,* comprehending the Cordeliers, Capuchins, and Recollects; the fecond comprehends the nuns of St. Claré; and the third, feveral perfons of both fexes, who live at liberty: and thefe are what we call the *third order.* See Franciscans, &c.

Of this order, which was only eftablifhed for fecular perfons, feveral of both fexes, to attain the greater perfection, have afterwards commenced religious, and formed various congregations, under various names; as "Religious Penitents of the Third Order," &c.

Third *Point,* or *Tierce-point,* in *Architecture,* the point of fection in the vertex of an equilateral triangle.

Arches or vaults of the third point, called by the Italians *diterzo acuto,* are thofe confifting of two arcs of a circle meeting in an angle at top. See Arch.

Third *Point,* in *Perfpective.* See Point.

Third *Rate.* See Rate.

Third *Subfidy Duty.* See Duty.

Third *Sound,* in *Mufic.* See Terzo *Suono,* Tartini, and Stillingfleet.

Third *Year, Tithe of the.* See Tithe.

THIRDENDALE, a liquid meafure ufed at Salifbury, containing three pints.

THIRDINGS, the third year of the corn or grain growing on the ground at the tenant's death, due to the lord for an heriot, within the manor of Turfat, in Herefordfhire.

THIRLAGE, or *Thirlage to Mills,* in *Rural Economy,* a contract or power authorized by law, to prevent the tenants of certain diftricts from carrying their corn to be ground any where elfe than at a particular mill. It was a practice which formerly prevailed much; and it was too often ufed as an engine of oppreffion, that proved extremely galling to thofe who were obliged to fubmit to it, but which at prefent is nearly, if not wholly done away, except in certain places.

The account of the origin and nature of this oppreffive practice,

practice, which has been given by the author of the original Agricultural Survey of Eaft Lothian, in the latter diftrict of country, may not be uninterefting to the curious inquirer. It is conceived that there, in former times, corn was reduced into meal, as in ancient Rome, by a hand mill, which was called a *quern*; and which was ufed in the remote parts of the Highlands of Scotland long after the year 1745.

It is certain, however, that the water machine called the mill, for the grinding of oats into meal, is of high antiquity in the fame country; and as it was introduced before the period of record, it may be fairly faid "caput inter nubilia condit." But from the ancient name of one of the duties, *knavefhip*, which will be afterwards explained, the mill would feem to be of Saxon original.

It feems alfo natural, that a perfon who poffeffed a ftream of water upon his eftate, fhould be invited by his neighbours to be at the expence of erecting a mill upon this ftream; and that they, on the other hand, fhould *thirle*, that is, aftrict and bind their lands, in all time coming, to ufe and frequent this mill with their corns, and to pay a certain proportion of the meal according to the univerfal mode then practifed of paying in kind for the grinding of it.

Anciently, it is contended, there is reafon to believe, the mills were at firft erected upon ecclefiaftical lands, and belonged to the clergy.

It is ftated, that there are three different fpecies of this fort of fervitude known and acknowledged in the law of the above country; but of thefe, two only belong properly to rural economy; however, in order more thoroughly to underftand the fubject, the whole may be fhortly explained.

It is noticed, that the firft and the lighteft fpecies of thirlage, is called the *thirlage of grindable grain*, and it means that the tenants and poffeffors of the aftricted lands (in the law of the above country the *fervient tenement*) fhall be obliged to refort to the mill (the *dominant tenement*) to which thefe lands have been aftricted, with all the oats and barley they fhall ufe for food, and there pay certain dues for the grinding of them.

The fecond, and the oppreffive thirlage, is, it is faid, called the *thirlage of growing corn*. By this covenant of thirlage, it is ftated, that every ounce of corn produced upon the fervient lands, let the quantity be ever fo great, muft be brought to the dominant mill, and there manufactured into meal, and the covenanted or accuftomed duties paid.

It is fuggefted, that the only limitation that this fevere thirlage admitted of, was in favour of feed and of horfe corn.

Sometimes a fpecial covenant was made, by which the poffeffors of the fervient lands paid what was called *dry multure*; that is, they paid a quantity of corn to purchafe the freedom of going to market with the remainder in the fame ftate; and where conftant immemorial ufage has fanctioned this cuftom, the courts of law generally, it is faid, have fo far mitigated the feverity of this fpecies of thirlage, as to find, that the proprietor of the dominant mill can demand no more than that quantity of *dry multure*, which the immemorial ufage has eftablifhed. Such decifions are afferted to be grounded upon the principle of a prefumed contract, of which the record or memory has been loft betwixt thefe parties, whereby the one agreed to pay, and the other to receive, the commutation fixed by the ufage.

The third and laft fpecies of thirlage is, it is obferved, called the *thirlage of invecta et illata*, and belongs properly to *urban* tenements: the meaning of it is, that corn, wherever produced, if brought for confumption within the boundaries of the dominant mill, muft be carried to the mill and manufactured there, and pay the accuftomed duties.

It is ftated that this fpecies of thirlage exifted in moft of the boroughs of the above country; and that the mill generally belongs to the incorporation, where the borough holds directly of the crown, or what are called royal boroughs. But where a borough holds of a fubject fuperior (the lord of the manor), the mill generally belongs to the fuperior, and the accuftomed duties are paid to him, or to his tenant in the mill.

It is to be obferved, the writer fays, that in all thefe thirlages, it was the land of the fervient tenement that was bound; and that although it fhould pafs by purchafe through twenty different hands, every purchafer, and all his people upon thefe lands, were equally bound to frequent the dominant mill.

It is further noticed, that there were alfo three different fpecies of duties paid at the dominant mill; as, firft, the *multure* (*multura*, grinding); fecondly, the *bannock* (loaf); and, thirdly, the *knavefhip*.

It is remarked, that the firft of thefe duties belonged to the heritor and proprietor of the mill; and feems evidently to have been the fine or *premium*, originally fettled, as the inducement for his being at the expence of erecting the mill, and for fupporting the machinery of it in future. The *bannock* was the duty paid to the miller; and the *knavefhip* the duty paid to the under fervants in the mill.

It is ftated, that the quantity of meal paid under the name of multure, varied confiderably in different counties, and even at different mills. It has been known as high as the eleventh boll, and fometimes as low as the twenty-fecond boll; and in one particular inftance fo fmall as the thirty-fecond: but it may be taken, on the average, at nearly the feventeenth boll.

The other duties were alfo various; but they may, it is fuppofed, be taken jointly as equal to the half, or from that to three-fourths of the multure.

But wholly independent of thefe feveral duties, the poffeffors of the fervient tenement were, it is faid, bound to perform certain perfonal fervices to the mill and its appendages: for inftance, when the dam-dyke, or the rampart that directs the ftream of water from the river to the mill wanted repair, or when the aqueducts to and from the mill required to be fcoured, the people of the fervient tenement muft turn out and perform thefe works. When the roof of the houfe in which the mill ftood decayed, they muft find thatch for making that repair, and they muft put it on. When grind-ftones were wanted, or an axle, or any other part of the machinery that required a heavy carriage, they muft go with their horfes and carriage to the neareft place (whatever might be the diftance) to bring thefe articles to the mill.

But this fpecies of thirlage, it is believed, never was known in the above county; or that at leaft, if it was, it has long fince been forgot. Befides, it is noticed, that there was another circumftance peculiarly fortunate, which put it in the power of moft of the landed proprietors of that county, without difficulty, to emancipate their tenants from the thirlage even of *grindable* grain, namely, that the landlord almoft univerfally was proprietor both of the dominant and fervient tenement; and that as he aftricted his tenants to his own mill by a covenant in the leafe, progreffively as the leafes of the mills expired, the landlords in general emancipated their tenants from every fpecies of thirlage, at a converfion of twenty fhillings *per* plough, which was paid by the tenant; and he and his fervants were left at perfect freedom to refort to any mill, where they could get their work beft done, and at the loweft rate.

The cafe, however, it is remarked, was widely different

in

in many parts of the north of the above country; and it is known, from what has already been mentioned, that there were many estates, or *servient tenements*, belonging to one proprietor, which were astricted to mills, or the *dominant tenements*, belonging to another proprietor, and that not a few of these thirlages were the severe one of *growing corns*.

The writer does not think it here necessary to inquire whether these mills were originally erected by the clergy, and since the reformation in religion, have passed into the hands of laymen; or whether, perhaps, if mills are truly of Saxon origin, they were generally, and at once introduced into the above country, when under the Saxons, who certainly were, it is thought, a more enlightened people than the Scottish and Pictish inhabitants of the North, whose ignorance, of course, may have led them more generally to subject themselves in the servitude of thirlage, to invite their clergy, or a few of the more wealthy among them, to undertake the arduous task of erecting mills.

From the near analogy betwixt tithes and thirlage, it has appeared to the writer a matter of just surprise, that the parliament of the above country, which, in the course of a preceding century, first authorised the valuing of tithes for the purpose of fixing a *modus* of payment, and afterwards compelled the lay titulars (proprietors) to sell their tithes at nine, and in some cases at six years' purchase, to the proprietors of the lands, did not introduce a fixed modus for thirlage, which certainly operated like tithes, as a tax upon industry, to bar, or at least to retard agricultural improvement in its progress. See TITHE.

THIRLBY, STYAN, LL.D. in *Biography*, a learned critic, was born about the year 1692 at Leicester, and finished his education at Jesus college, Cambridge, blending promising talents with self-conceit, litigiousness of temper, and a habit of intemperance. He appeared at an early age as a writer of controversial pamphlets, and thus acquiring some degree of reputation, obtained the fellowship of his college at the age of about 21 years. In maturer life he probably applied to study with greater diligence, for his edition of Justin Martyr, to which he was indebted for literary reputation, was published in 1722. Versatile in his disposition, he diverted his attention at this time from divinity to physic, and accepted the post of librarian to the duke of Chandos. In this station he continued for a short time, and being under a necessity of quitting it, he became first a student in civil law, and afterwards in common law. Weary of these pursuits, he resided in the house of his former pupil, sir Edward Walpole, by whose interest he obtained a sinecure place in the port of London, of the value of about 100*l*. a-year. Upon leaving this asylum, he took private lodgings; but continued to indulge his habit of sotting and intoxication. He is said to have contributed some notes to Theobald's edition of Shakspeare; but his self-indulgence and indolence rendered him unfit for mental exertion, and he closed his career in December 1753. His edition of Justin Martyr, censured by some, but regarded upon the whole as a valuable performance, contains Justin's two apologies, and his dialogue with Tryphon the Jew, Greek and Latin, with notes and emendations by the editor, and select notes by former editors. Nichols's Lit. Anecd. Gen. Biog.

THIRLWAL CASTLE, in *Geography*, a boundary fortress between England and Scotland, on the Picts' Wall; 3 miles N.W. of Haltwesel.

THIRON *de Gardais*, a town of France, in the department of the Eure and Loire, 21 miles S.W. of Chartres.

THIRSK, or THRUSK, a borough and market-town in the wapentake of Birdforth, North Riding of the county of York, England; is 23 miles N.W. by N. from the city of York, and 223 miles N.N.W. from London. It is situated in a plain, nearly surrounded by hills, on the banks of a rivulet called Cod-beck, which divides the town into two parts, respectively named the Old Town and the New, which are connected by two small stone bridges. The two towns are distinct, as far as relates to the election of members; but in all other respects are considered as one. The civil government is vested in a bailiff, annually chosen by the burgage holders. The New Town stands within the precincts of the ancient castle of the Mowbrays. In the centre of the town is the market-place; which would be one of the finest in the county, were it not for the tolbooth and shambles, now in a ruinous condition. The market is held on Mondays, and is well supplied with all kinds of provisions. Five fairs are held annually for horned cattle, sheep, leather, and woollen cloth. These fairs attract a considerable number of dealers, and, with the advantage of the great North road from York, are very beneficial to the town, and in some degree supply the want of manufactures, of which here are only a small quantity of coarse linens and sacking, and a few bridles and saddles. The population, as returned to parliament in the year 1811, consisted of 2155 persons, occupying 549 houses. The parish church stands on a rising ground at the northern extremity of the town. The roof, which is elliptical, and of oak, ornamented with carving, is supported by a double row of pillars and pointed arches. In the south wall of the chancel, near the altar, are three ornamented stone seats. The church is generally supposed to have been built out of the ruins of the ancient castle, which was demolished in the reign of Henry II. A moat and rampart are still to be seen, but no vestige of the building remains; and in Camden's time, it was nearly in the same state. It had once, however, been a place of great strength, when held by the potent Mowbray family. It was here that Roger de Mowbray began his rebellion against Henry II. and joined the king of Scotland against his own sovereign. The revolt was suppressed, and the castle of Thirsk, as well as several others belonging to the rebellious lords, were by the king's order destroyed. Besides the parish church, the Calvinists, the Quakers, and the Methodists, have their respective meeting-houses. Here is also a School of Industry for poor girls, who are clothed and taught reading, writing, and arithmetic, plain work, knitting, &c.

That division of the town called *Old Thirsk*, is a borough by prescription, and returns two members to parliament. The right of election is in the occupiers of burgage tenements, now only fifty in number, of which forty-nine are the property of sir Thomas Frankland, bart. Old Thirsk consists of a range of cottages on each side of the turnpike road leading from York to Stockton, and of two squares surrounded by the same kind of buildings. In one of these squares, called St. James's Green, the cattle fairs are held; the other is the scite of an ancient church, of which, time has long since swept away every vestige. In the latter of these squares is an elm-tree of venerable antiquity, from which the place takes its name, Hawm (that is Elm) Green; and under the shade of whose branches the members of parliament are elected. One of the chief inconveniences of Thirsk and the adjacent country, is the scarcity and high price of coal, which is brought from the county of Durham in small carts, containing from eighteen to twenty-two bushels, varying in price according to the season.

In the vicinity of the town is Byland abbey, which was founded

founded in the year 1177, by Roger de Mowbray, when a ftately monaftery and church were erected, and dedicated to the Virgin Mary. This abbey continued to flourifh till the general diffolution in 1540, when the feite and moft of the demefnes were granted to fir William Pickering. At prefent, the ruins and feite belong to the honourable family of Stapylton.

Near the bafe of the Hambleton hills, within four miles of Thirfk, is Thirkleby-Hall, the feat of fir Thomas Frankland, bart. The walks and pleafure-grounds are extenfive and well laid out; and the houfe is an elegant modern ftructure.—Beauties of England and Wales, vol. xvi. Yorkfhire; by J. Bigland.

THIRST, a painful fenfation, occafioned by a vellication of the nerves of the throat or fauces, and producing a defire of drinking. See DIGESTION.

Thirft may be fometimes eluded by rolling a clean bullet or a pebble in the mouth, which occafions an extraordinary iffue of faliva to moiften the throat, &c.

Mr. Boyle mentions a man who could eafily abftain from drinking for nine days, and yet have his diet nothing more liquid than ufual; the fecretions of urine, fweat, &c. being performed all the while regularly, and in the fame quantity as ufual.

In dropfical cafes, where there is not a right fecretion of the urine by the renal glands, and the veffels and parts of the body are loaded with too great a quantity of ferous humours, a great moderation in drink might be attended with good fuccefs, provided fome liquor could be found out to allay that uneafy fenfation. Probably this would be beft performed by mucilages acidulated with fpirit of vitriol or fulphur, or jellies with juice of lemon, &c. and that a fmall quantity of fuch a compofition, now and then ufed, might be of as much real fervice, in quenching thirft, as draughts of liquors, which increafe the fymptoms.

In feverifh diforders, the patient is frequently tormented with a violent thirft, which is moderated by acidulating the barley-water, or fage-tea, with fpirit of vitriol, or with lemon-juice: but by nothing fo much, as allowing the patient fome flices of an orange. Pringle, Obferv. on Difeafes of the Army, p. 135.

THIRSTY SOUND, in *Geography*, an inlet or bay on the N.E. coaft of New Holland, fo called by Cook in 1770, becaufe it afforded no frefh water. It lies in S. lat. 22° 10′, and W. long. 210° 18′; and may be known by a group of fmall iflands lying under the fhore, from two to five leagues diftant, in the direction of N.W., and by another group of iflands that lie right before it, between three and four leagues out at fea. In this inlet is good anchorage in 7, 6, 5, and 4 fathom; and here are places very convenient for laying a fhip down, where, at fpring-tides, the water does not rife lefs than 16 or 18 feet. The N.W. point of Thirfty Sound was called "Pier-Head."

THIRTEEN ISLANDS, a clufter of iflands in the Pacific ocean, among the New Carolinas, fo named by Capt. Wilfon. N. lat. of the moft foutherly 7° 16′. E. long. 144° 30′.

THISATON, a river of Canada, which runs into lake Huron, N. lat. 46°. W. long. 84°.

THISMA, a name ufed by fome for any fubterranean vein, or bed of a mineral.

THISTLE, in *Agriculture*, a well-known prickly troublefome weed, common in corn and other fields. It has been obferved, that wherever thiftles grow naturally, it is a fure fign that the land is ftrong, and of a tolerable good quality; but that they are at the fame time a great annoyance to every plant intended to be cultivated. And it has alfo been well remarked, that there are no weed-plants over which the economical farmer ought to keep a more watchful eye than the thiftle tribe, as they are not only wholly ufelefs, but occupy much ground, and being furnifhed with downy feeds, are capable of being multiplied and carried almoft to any diftance. Befides, they do much mifchief by impeding the work both in handling hay and corn crops. It is of courfe a matter of much confequence to be well acquainted with the qualities of each kind, in order to enable the farmer to judge with certainty how far and by what means their deftruction may be effected in the moft certain and ready manner.

There are a great many forts of thiftles; and thofe which chiefly deferve the attention of the farmer, are the *annual*, *biennial*, and *perennial* kinds.

There are four of thefe plants belonging to the firft divifion or fort, namely, the *mufk-thiftle*, which grows to the height of two or three feet; the heads hang down, and the flowers fmell fomewhat like mufk. It is frequently found occupying whole fields, particularly where the lands are of a chalky or barren quality; and fending forth flowers in July and the following month in great abundance. The *milk-thiftle*, which is found plentiful in moft wafte places, and upon old banks, being well known by its beautiful large leaves, which are variegated with white fpots and veins, as if they had been fprinkled with milk. The flowering feafon of this plant is in Auguft, or thereabouts. The *welted* or *curled* thiftle, which is frequently met with on banks, and by road-fides, but feldom intruding itfelf into fields or paftures. Its time of flowering is June and the following month. See CARDUUS.

And the *common fow-thiftle*, which is a very troublefome weed in fields and gardens; it is found in fome fituations that the plant is fmooth, but in others that it is rough, being prickly on the margins and mid-ribs of the leaves, and alfo on the peduncles and calyces of the flowers, and the ftems or ftalks abound with a lactefcent or milky juice. See SONCHUS.

But in the fecond divifion, or biennial kind, there are not more than three, as the *fpear* or *bull-thiftle*, which rifes about three or four feet in height, the extremity of each leaf running out into a long fharp point, remarkably prickly: hence, in fome places it is called by the name of the bull-thiftle. It has large heads of flowers, and commonly grows by the fides of roads, near dunghills, and not unfrequently in fields and paftures, flowering in June and the following month: the *marfh-thiftle*, which grows very tall and prickly, having numerous heads of flowers, fmall and of a red colour, growing abundantly in wet meadows and in woods, flowering in July and the month which fucceeds it. See CARDUUS.

And the *cotton-thiftle*, which is found plentifully in uncultivated places in many parts. The roots are long and fibrous, and fend forth feveral oblong fharp-pointed whitifh-green finuated leaves, covered with a cottony down, and fet with fpines on their edges. In the middle of thefe fhoots up a ftalk, to the height of five or fix feet, divided towards the top into diverfe branches, fet with leaves at their joints, and having jagged, leafy borders running along them, edged with fpires, as has the main ftalk alfo. Each branch terminates with a fcaly head of reddifh purple florets, having narrow tubes, and cut at their brim into five teeth. They contain flowers, which are fucceeded by fmall oblong feeds crowned with down. The time of its flowering is about July, for the moft part. See ONOPORDUM.

And in the third divifion or fort there are only two; as the

the *corn sow-thistle*, which is a very troublesome weed in arable land, flowering in July and the succeeding month. See SONCHUS.

And the *common* or *field-thistle*, which has many provincial names in different places, as the *horse-thistle*, the *cursed thistle*, &c. This is a thistle which is more general in its growth than any of the others, being found not only by the sides of roads, but also in arable and pasture lands, and it is remarkably prickly, growing from two to three feet in height, but the heads of the flowers are small, and of a purplish colour, though sometimes white; it flowers in July, or about that period. See CARDUUS and SERRATULA.

It is obvious, from what has been said, that the annual and biennial sorts of thistles may be readily removed, by preventing their running to seed and disseminating themselves over the land; which is best effected probably by carefully eradicating them, or frequently mowing them over closely by the surface, and rolling. But in the perennial sorts, from their roots continuing in the earth, increasing and throwing out new shoots or stems every year, there is much more difficulty in extirpating them, and they, perhaps, can be no other way completely destroyed than by rooting them out on arable land by trench or deep ploughing and frequent harrowings, or by fallowing or laying the land down to pasture; for the first of these sorts seldom appears in pasture lands. But for destroying the common thistles, the best method is perhaps by cutting them over in the bleeding season frequently by proper implements. The writer of the Berkshire Agricultural Report, who thinks them particularly noxious, troublesome, and inconvenient among the corn and grass crops, proposes drawing them up by an implement of the forceps kind, somewhat similar to that described under the head noticed below, especially the sort which is termed *serratula arvensis;* or if they be cut over about an inch above the surface of the ground, it is believed they will be liable to rot, on account of the stem being filled with water. They also frequently bleed to death when cut over in this way about the month of August, as hinted at above. See THISTLE-*Drawer*.

Others suggest that thistles might probably be destroyed in arable land by continued fallowing for one or two summers; with such repeated ploughing and hoeing as wholly to prevent their vegetating: but as such a progress would be tedious and expensive, an easy, expeditious, and effectual mode of eradicating them in this case, seems equally wanting and desirable, as in that of grass lands. Thistles are likewise very troublesome in hedges, especially those of the sow and the large rough kinds, and should constantly be rooted out and removed as soon as possible, as no hedge can go on well that is much infested with them. See THISTLE-*Cutter*, WEED, and WEEDING.

It may be noticed, that by an excellent regulation in France, a farmer may sue his neighbour who neglects to thistle his land at the proper seasons, or may employ people to do it at the other's expence. And it were to be wished that a similar law was enacted here, to prevent the wide-spreading mischief occasioned by the seeding of this pernicious weed; among which may be reckoned, besides its choaking the young corn, that if wheat in particular be not well thistled, the reapers take up the grips so tenderly, lest they should prick themselves, that by their loose handling of them, they sometimes leave upon the ground corn enough to sow the whole field. There is much inconvenience often experienced too in working hay from them.

Something in the same way as above has also lately been done here, especially in regard to the removal of them from the sides of highways and roads.

Though the sow-thistle has commonly been considered as a troublesome and injurious weed in tillage lands, it has lately been conceived by some to possess no small degree of nutrient power; and on this ground it has been suggested by the writer of the "Experienced Farmer," that it may be a plant of considerable fattening properties when properly raised and cultivated. When taken young, and cut or broken, it produces something, it is said, like cream; and he has noticed that many animals eat it in preference to every other plant now in vogue. Sheep, when in clover, &c. will feed upon it so greedily as to eat the very roots. Pigs likewise prefer it to almost any other green food. Rabbits will breed more speedily when fed with sow-thistles, than with any other food he knows of, except dandelion; which is of the same nature: and is now sold in Covent Garden market to the breeders of tame rabbits, to make the does take buck more readily. A man of his acquaintance, who was allowed better skill with stallions than the generality of people, used to search for sow-thistles, and give them to his horses to make them serve mares more readily and effectually. When he could not get sow-thistles, he fed them, it is said, with new laid eggs and milk, or cream, if he could get it; but he preferred sow-thistles or dandelion to any thing.

And there is, he contends, a well-known and remarkable proof of the nourishing and feeding quality of the sow-thistle, in the fat wether sheep fed to such an amazing size by Mr. Trimnel, of Bicker-fen, near Boston, upon fen-land. This sheep, it is said, was bred by Mr. Hutchinson, in Hail-fen, from a ram bred by Mr. Robinson of Kirby, near Sleaford. He never ate any corn, oil-cake, or other similar dry food, but fed wholly on grass and herbage. Being turned with many other sheep into a field of clover, he was observed first to search for the sow-thistles, and would eat no other food while any of these could be found in the parts of the field that were burdled off successively, a little at a time. None of the other sheep that fed with him, however, shewed any extraordinary liking for the sow-thistle. A small hut was built for him in the field to repose under in hot weather: and when the part that was hurdled off became bare of food, his attendants, on account of his liking for sow-thistles, gathered a quantity of them for him, which they gave him at particular hours, three times a day, from two to five pounds at a meal.

It is added, that when standing on his feet, he measured only two feet six inches high: he was weighed once a month, and weighed alive twenty-six stone, at fourteen pounds to the stone. He gained only one pound the last month: and as it was judged, therefore, that he was quite ripe, and would not increase any more, but might possibly lose weight the next month, he was killed on the 13th of October 1791, by Mr. Isaac Lumby, of Bicker, being then a four-shear, or four-year-old sheep.

The writer further states, that the skin, hung up by the nose part, measured ten feet two inches from the point of the nose to the tip of the tail, and was sold for 7*s.* 6*d.* in the common course of business. And that the carcase measured five feet from the nose to the tail; the rump or cushion eight inches and a half in depth; plate or fore-flank the same thickness; breast end seven inches; and was one yard five inches and a half round the collar. That the legs were reckoned at 40lbs. each; but if cut haunch of venison fashion, they would, it is said, have weighed 50lbs. each. Mr. Lumby was offered 2*s.* a pound for them; so that he could have sold the two legs alone for 10*l.* when so cut.

 This

This is certainly a remarkable inftance of fatnefs, but it might probably depend more on the difpofition of the animal to take on fat, than the fattening quality of the thiftle or food on which the fheep was fed. Many further trials are neceffary to fully afcertain the point.

Thistle, *Bleffed, carduus benedictus, vel cnicus.* See Centaurea.

As an article of the *Materia Medica*, the bleffed thiftle, which is the hairy wild *cnicus* of Miller, and the *centaurea benedicta* of Linnæus, was formerly much ufed in infufion, as a gentle emetic, in fevers and certain naufeas.

Dr. Lewis has often obferved excellent effects from a light infufion of carduus, in weaknefs of appetite and indigeftion, where the ftomach was injured by irregularities, or oppreffed by vifcid phlegm: nor has he found any one medicine of the bitter kind to fit fo eafily on weak ftomachs, or to heat fo little. Thefe infufions, taken freely, promote the natural fecretions. Drank warm in bed, they commonly increafe perfpiration or excite fweat; and as they act with great mildnefs, not heating or irritating confiderably, they have been ufed, in this intention, in acute as well as chronical cafes. The feeds, which, as well as the leaves, have a confiderably bitter tafte, have fometimes been ufed as fudorifics or diaphoretics, in the form of an emulfion. Cold water poured on the leaves, extracts, in an hour or two, a light grateful bitternefs; by ftanding long upon the plant, the liquor becomes difagreeable: a ftrong decoction is very naufeous and offenfive to the ftomach. The extracts, obtained by infpiffating both the cold infufion and decoction, have the fame differences as the liquors themfelves. Rectified fpirit extracts, in a fhort time, the light bitter part of this plant, but does not take up the naufeous near fo eafily as water. On keeping the watery extracts for fome months, a confiderable quantity of faline matter was formed on the furface, in fmall cryftals, refembling in fhape thofe of nitre, in the tafte bitterifh, with an impreffion of coolnefs. Lewis's Mat. Med. See Centaurea *Benedicta*.

Some diftil a water from it, which they ufe in cordial and fudorific potions.

Thistle, *Carline*. See Carlina.

The root of the *carlina acaulis* of Linnæus, is fuppofed to be diaphoretic, antihyfteric, and anthelmintic. It has been greatly efteemed by fome foreign phyficians, in acute malignant as well as in chronical difeafes, and given in fubftance from a fcruple to a drachm, and in infufion from one to two drachms and more. It is rarely to be met with in our fhops. See Carlina *Caulefcens*.

Thistle, *Diftaff*. See Atractylis.

The roots of the *atractylis gummifera* of Linnæus, or pine-thiftle, which is a native of Italy and the ifland of Candy, yield, if wounded when frefh, a vifcous milky juice, which concretes into tenacious maffes, at firft whitifh and refembling wax, but when much handled growing black; fuppofed to be the *ixion*, and *acanthina maftiche* of the ancients. The juice is faid to have been formerly chewed for the fame purpofes as maftich, and the root itfelf of the fame virtue with that of the carline thiftle. Lewis.

Thistle, *Fifh*, a fpecies of *Carduus;* which fee.

Thistle, *Fuller's*. See Dipsacus and Teasel.

Thistle, *Gentle*, a fpecies of *Carduus;* which fee.

Thistle, *Globe*. See Echinops.

Thistle, *Golden*. See Scolymus.

Thistle, *Hedge-hog*, a fpecies of *Cactus;* which fee.

Thistle, *Ladies*, or *Milk*, a fpecies of *Carduus;* which fee.

Thistle, *Melon*. See Cactus.

Thistle, *Sow*. See Sonchus.

Thistle, *Downy Sow*. See Andryala.

Thistle, *Star*. See Centaurea.

Thistle, *Torch*. See Cactus.

Thistle, *Woolly*. See Onopordum.

Thistle-*Cutter*, in *Agriculture*, a tool of the fward-dreffing kind, for cutting up thiftles and other coarfe weeds and plants.

An effective implement of this fort has lately been invented, delineated, and defcribed by Mr. Amos, in his work on "Agriculture and Planting."

The plan of the whole machine, when complete, is that of a fort of fquare, in which the leading fhare is made of caft-fteel, in the form of an ifofceles triangle, whofe equal fides are fourteen inches long, and its bafe twelve inches, being about one-eighth of an inch thick in the middle, tapering to a very fine edge on the outfides. There are four pieces of afh-wood, three inches fquare, and two feet four inches long, to which the fcythes are fixed, and which are called the fcythe-handles. There are alfo four fcythes, three feet long from point to point, four inches broad at the wideft part, made of caft-fteel, and which, the inventor fays, are manufactured by Meffrs. Hunt and Company, at their caft-fteel manufactory, Brades, Birmingham. There are likewife four other pieces of afh-wood, three inches fquare and two feet five inches long, for throwing the two hindmoft fcythes to their proper diftance, and which are braced two and two together by four bars, which are one by two inches fquare, and eighteen inches and one-fourth long. And there is a main piece of afh-wood, three by four inches fquare, and five and a half feet long, to which all the other pieces are fixed by hooks, and eye-bolts, by means of which the fcythe-handles act as it were upon hinges, and the fcythes are thereby made to form the fame parallel line with the furface of the land, whether it be concave, convex, or level. For this purpofe, it is fuggefted that it might be ufeful to make a joint in the middle of this piece, where the land is uneven. And in the fore part of this piece a fawgate is to be made, three-fourths of an inch from the under fide, at the hind part of the fhare, and one inch from the under fide at the front of the wood, which gives an elevation to the point of the fhare, to receive the fhare where it is fixed.

There are four iron braces, one of the ends of which are fixed in the fcythe-handles, and the other ends to the under fides of the fcythes by a fcrew. There is a ftaple, to which the chain and fwinging-tree is fixed, and by which the machine is drawn. There are two mortife-holes on the fides, which receive the tenons of two upright ftuds, to which pullies are fixed for lifting the fcythes off the ground, where there is any thing to obftruct them or retard their progrefs. Each of thefe ftuds is one and a half by four inches fquare, and three feet long. Two fmall pullies are fixed on each fide of thefe upright ftuds. Through the pullies of the foremoft ftud, a fmall rope paffes (one end of which is fixed to the outfides of the iron braces), and likewife through the pullies of the hindmoft ftud, and then the two ropes unite at about two or three feet behind the whole machine; and through the pullies of the hindmoft ftud pafs two other fmall ropes (one end of each being fixed to the outfide of the hindmoft iron braces), and then the four ropes unite together, where the manager holds them as a coachman does the reins of four horfes. By means of thefe ropes the fcythes may be lifted to any degree of elevation, by which contrivance any unevennefs of the ground, or other obftructions on its furface, fuch as ftones, roots, ant-hills, &c. &c. may be eafily avoided and paffed by.

The fwinging-tree is thirty-three inches long, and the chain

chain which hooks into the ftaple for drawing the machine by, is thirty inches long.

The whole of the fcythes, when properly fixed, projects beyond the wood, and cut the thiftles three-quarters of an inch above the furface of the ground.

In cafes where the fcythes want fharpening, it is obferved that they may be reared perpendicularly up, or taken off entirely; and that, at the fame time, the horfes fhould be ungeared and taken away.

In ufing the machine, it is advifed by the ingenious inventor, that as foon as the thiftles are in full flower it fhould be fet to work, the length way of the ridges; and that if the fcythes are kept very fharp, it will make excellent work. And when the thiftles have been cut, they fhould lie a day or two, it is faid, to perifh by the lofs of their fap-juice: the ground muft then be cleared, and the clofe or field rolled, the crofs way of the ridges, with a very heavy roller, which fo crufhes the hollow ftumps, and renders them fo pervious to water, that their roots foon rot and are deftroyed. But to expedite the operation of the implement, and the deftruction of the weeds and plants, the land fhould be cleaned of all kinds of rubbifh, the latter end of March or beginning of April, being dreffed with the fward-dreffer, and then rolled the crofs way of the land, or ridges, with a weighty roller, as juft mentioned. See SWARD-*Dreffer*.

THISTLE-*Drawer*, an ufeful implement of the forceps kind, which is extremely beneficial in drawing up the common field-thiftle and fome other ftrong forts of weeds. It may be conftructed either of wood or iron, in the latter cafe having fockets for receiving wooden handles. When made of wood, it fhould be of the hard and lefs brittle kind, as good tough afh. It is ufually formed from two to three feet in length, having fix notches or blunt teeth cut in each blade, at the bottom part, where it bites or feizes the plants, and each arm well fitted to the other, turning upon a ftrong pivot or pin. In its operation the thiftle is feized clofe to the ground and firmly held, fo as to be drawn out with confiderable length of root. It has been long in ufe in the northern parts of Lancafhire; and is faid to be lately introduced from Wiltfhire into the county of Gloucefterfhire, in the agriculture report of that diftrict. It is an ufeful and effective tool for the above purpofe, and only cofts about two fhillings when made of wood, and three or four when of iron. It has long been known in the firft of the above counties by the provincial name of *Gripes*.

THISTLE-*Fly*, in *Natural Hiftory*, a fmall fly produced from a fly-worm hatching in the protuberances of the carduus hæmorrhoidalis. In the protuberances of this thiftle, while they are clofed in all parts, the worm of this fly, from whofe injuring it, at the time of depofiting the egg from which it was hatched, the protuberances arofe, undergoes its laft transformation. It here makes of its own fkin a fhell in form of an egg, within which it puts on the nymph ftate. When this nymph becomes a living fly, the leaft part of its difficulty is the finding its way out of this fhell; it has a ftronger prifon than that, and before it can obtain its liberty, muft force its way through the much more clofely compacted fibres of the protuberance of the vegetable. It has, however, no other means of doing this difficult work, but that of inflating its head, and throwing out the bladder or muzzle with which all thefe creatures are provided in this ftate. See THISTLE-*Galls*.

This is a difficult operation, and many of the creatures perifh in the attempt; but what much forwards the fuccefs of it, in many cafes is, that the ftalk of the thiftle often becomes naturally half rotten before the time of the fly's egrefs. Reaumur, Hift. Inf. vol. iv. p. 338.

THISTLE-*Galls*, a name given by the more accurate authors to the protuberances on the ftalk of a fpecies of thiftle, called by authors *carduus hæmorrhoidalis*, from thofe tubercles, which are fuppofed to refemble thofe of the hæmorrhoidal veins in perfons fubject to the piles. Thefe have been fuppofed a natural production of the plant; but they are far otherwife. The whole hiftory of them is, that a certain fpecies of fly always depofits its eggs on the ftalks; and the young ones, when hatched, gnaw their way into the fubftance of the ftalks, and the copious derivation of the juice, occafioned by their fucking, produces the tubercles which are found on it.

Thefe tubercles are of a roundifh or oblong figure, and are of various fizes, from that of a pea to the bignefs of a nutmeg; they are much harder than the reft of the ftalk, approaching to a woody ftructure; when cut open, they are found to contain each feveral oblong and narrow cells; thefe have no communication with one another, and are each inhabited by a fmall white worm, which has two hooks at the head; with thefe it breaks the fibres of the plant, in order to get at its juices. When it has arrived at the time of its change into the nymph ftate, it ceafes to eat, and drawing up its body much fhorter than ufual, its fkin hardens, and forms a fhell, under which it changes into a very beautiful two-winged fly; the wings are whitifh and tranfparent in the middle; and at the edges furrounded with black in the form of a chain of figures like the letter Z; the body and breaft of this fly are of a beautiful black, with fome flight variations of yellow, with which the fhoulders are ftreaked; the anterior part of the head is white, and its back-part edged with a yellow down; the antennæ are reddifh, and the legs are partly black, and partly of a fine clear brown.

In obferving the changes of the worms of thefe galls, there are often obferved fome which go through them in a different manner from the reft, and finally produce a very different fpecies of fly. Thefe are the progeny of the eggs of fome other fpecies of fly, whofe worm being carnivorous, is lodged by the art of its parents, while it is yet in the egg ftate, in the fubftance of this gall, there to prey upon the defencelefs inhabitants.

There are many fpecies of galls the inhabitants of which are expofed to enemies. In thofe it is common to find the proper inhabitant and the devourer in the fame cell; the one feeding on the juices of the plant, the other on its juices; but this is not the cafe here, thefe worms immediately deftroying the proper inhabitants, and being found always alone in their cells. Reaumur, Hift. Inf. vol. vi. p. 221.

THISTLE, *Order of*. See ANDREW.

THISTLE, *our Lady of the*, was alfo a military order, inftituted in 1370, by Louis II. duke of Bourbon. It confifted of twenty-fix knights, of which that prince and his fucceffors were the chiefs. Their badge was a fky-blue girdle; and, on folemn occafions, a mantle of the fame colour, with a gold collar, interwoven with flower-de-luces; among which was the word *efperance*, *hope*, in capitals.

THISTLE-TAKE, a cuftom in the hundred of Halton, in the county of Chefter, whereby, if in driving beafts over the common, the driver permits them to graze, or take but a thiftle, he fhall pay a halfpenny a beaft to the lord of the fee.

At Fifkerton, in Nottinghamfhire, by ancient cuftom, if a native, or cottager, killed a fwine above a year old, he paid the lord one penny, which was alfo called thiftle-take.

THIVA, or STIBES, in *Geography*, a town of European Turkey,

Turkey, in the province of Livadia, anciently called "Thebes," and the capital of Bœotia, situated on a rising ground between two small rivers, supposed to be the Ismenus and Dirce of the ancients. (See THEBÆ.) The town is of an oval form, about three miles in circumference, and the houses are higher and better built than is usual in most parts of Greece. It contains four or five thousand inhabitants, about half Turks and half Christians, which latter have several churches, not remarkable for any thing except some few inscriptions to be seen upon the pavement of the cathedral. The air of the country about Thebes is thick and foggy, whence the ancient inhabitants of Bœotia were accounted dull and phlegmatic, and were neither famous for their wit nor valour. (See BŒOTIA.) Epaminondas raised Thebes to its highest pitch of grandeur; after whose death it was not remarkable for its virtues, but misfortunes, till it sunk into its original obscurity; so that its glory took birth with this great man, and with him expired; 28 miles W.N.W. of Athens. N. lat. 38° 25′. E. long. 23° 34′.

THIVIERS, a town of France, in the department of the Dordogne; 7 miles N.W. of Exideuil.

THIULETIS-TSKALI, a river of Georgia, which runs into the Kur.

THIZY, a town of France, in the department of the Rhone and Loire; 27 miles N.W. of Lyons.

THLASIAS, a term used by the ancients to express an eunuch made by a compression or contusion of the testicles, not by the cutting them out.

THLASIS, a word used by the ancients to express either a contusion without a wound, or a wound made by some blunt instrument, which contused the parts.

THLASMA, a word sometimes used like *thlasis*, to express a contusion either with or without a wound; sometimes applied particularly to a recess of the cranium inward without a fracture, an accident principally affecting children.

THLASPEOS SEMEN, in the *Materia Medica*, the name of a seed produced by the common *thlaspi arvense siliquis latis*, or common treacle-mustard. It used to be an ingredient in several of our shop compositions, and was esteemed attenuating, detersive, and aperient, and is said to promote urine and the menses, and to expel the after-birth.

THLASPI, in *Botany*, θλασπι, an ancient name, which Dioscorides tells us, in his book 2. chap. 186, originated in the broken, or pounded, appearance of the seed, alluding, we suppose, to its smallness. The word therefore is derived from θλαω, *to bruise*, or *beat*. He compares this seed to that of his καρδαμον, our *Lepidium sativum*, or Garden Cress, adding that the seed-vessel is moderately dilated upwards, the flower white, and the plant found about paths, walls, and banks. Every other part of his description, respecting the leaves and stems, is so apposite, that no doubt can remain of his θλασπι being our Shepherd's Purse, which Dr. Sibthorp found common in Greece and the Archipelago, in the early spring. Linnæus might surely have spared his mark of uncertainty concerning the etymology of the above name, in *Phil. Bot.* 183. But as he translates θλαω by the Latin word *comprimo*, to compress, he, most likely, had in view the *Th. arvense*, which several old writers have taken for the plant of Dioscorides, and whose seed-vessel is very remarkably compressed.—Linn. Gen. 334. Schreb. 437. Willd. Sp. Pl. v. 3. 442. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 683. Compend. ed. 2. 98. Prodr. Fl. Græc. Sibth. v. 2. 7. Brown in Ait. Hort. Kew. v. 4. 80. Juss. 241. Lamarck Illustr. t. 557. Gærtn. t. 141.—Class and order, *Tetradynamia Siliculosa*. Nat. Ord. *Siliquosæ*, Linn. *Cruciferæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of four ovate, concave, somewhat spreading, deciduous leaves. *Cor.* cruciform, equal, of four obovate petals, twice the length of the calyx, with narrow claws. *Stam.* Filaments six, but half the length of the corolla, the two opposite ones still shorter; anthers pointed. *Pist.* Germen superior, roundish, compressed, emarginate; style simple, the length of the stamens; stigma obtuse. *Peric.* Pouch compressed, inversely heart-shaped, emarginate, the style being mostly the length of the notch in which it stands, of two cells, the partition lanceolate, and the valves boat-like, with more or less of a dilated keel. *Seeds* several in each cell, pendulous, inserted into the sutures, roundish, compressed.

Ess. Ch. Pouch compressed, emarginate, inversely heart-shaped; its valves boat-like, keeled. Seeds several.

Obs. Mr. Brown has very happily separated from this genus the Linnæan *Th. campestre*. That species, on account of its solitary seeds, properly belongs to *Lepidium*, to which genus it, as well as *Th. hirtum*, is removed in the new edition of our *Compendium Fl. Brit.* The same ingenious botanist, of whose elucidation and reformation of the cruciform genera we have spoken under the article TETRADYNAMIA, has founded a new genus, called *Aethionema*, upon *Th. saxatile*, with another species, whose pouch has no valves, and only a single seed. With this latter, a Spanish plant, we are unacquainted; but as the *saxatile* has two cells, and many seeds, we can hardly either disjoin it from *Thlaspi*, or unite it with this, though, it seems, they agree in having an unequal insertion of their calyx-leaves, which in *Thlaspi* is equal; and their longer filaments are either combined, or else toothed near the top. As there are but two species, we presume one of these last characters belongs to each. The question seems at least doubtful, and therefore, without presuming to form an opinion respecting Mr. Brown's *Aethionema monospermum*, we prefer keeping his *saxatile* where it is.

The plants of this genus are herbaceous, and most of them annual, with simple *leaves*, and numerous corymbose *flowers*; their surface more frequently smooth, and somewhat glaucous, than pubescent; *stem* leafy and branched.

1. Th. *peregrinum*. Red Penny-Cress. Linn. Sp. Pl. 901. Willd. n. 1. Scop. Carn. v. 2. 17. (Th. capsulâ cordatâ, peregrinum; Bauh. Hist. v. 2. 927, badly copied in Moris. sect. 3. t. 18. f. 30.)—Pouches roundish-heartshaped. Leaves lanceolate, entire.—Native of dry hills, above Heidenschaft in Carniola. *Scopoli*. Of this very rare plant we have never seen a certain specimen. Scopoli says the *stems* are a span high, hard, branched, turning reddish, as well as the *leaves*, as they advance in age. The *leaves* grow on short stalks. *Flowers* small, red, with entire ovate *petals*, and reddish *stamens*. *Anthers* yellow, as well as the short *style*, and the *stigma*, which last is flat at the top. *Seeds* two in each cell, ovate, yellowish, slightly rugged, shining, attached to the falcate *partition*.

2. Th. *arabicum*. Purple Arabian Penny-Cress. Vahl Symb. v. 2. 76. Willd. n. 2. (Th. humile, spicâ purpureâ; Buxb. Cent. 1. 2. t. 2. f. 1. Iberis arabica; Linn. Sp. Pl. 906. Am. Acad. v. 4. Subularia purpurea; Forsk. Ægypt.-Arab. 117.)—Pouch nearly orbicular, compressed, with a notch at each extremity. Lower leaves wedge-shaped; upper oblong-heartshaped, entire, clasping the stem.—Native of Arabia and Cappadocia.—The *root* is tapering, fibrous, annual. *Stem* more or less branched, round, smooth, from three to six inches high, leafy, corymbose. *Leaves* an inch long, acute, entire, smooth, rather succulent, slightly stalked. *Flowers* small, purple or reddish. *Pouch* light green, with a very broad striated border, much exceeding the *style*, and notched at the base as well as summit.

fummit. *Seeds* two in each cell. This fpecies appears nearly related to the foregoing, nor fhould we be greatly furprifed if they proved one and the fame. If Bauhin's delineation of the *pouch* of the former be correct, they muft be diftinct.

3. Th. *arvenfe*. Common Penny-Crefs, or Smooth Mithridate Muftard. Linn. Sp. Pl. 901. Willd. n. 3. Fl. Brit. n. 1. Prodr. Fl. Græc. n. 1. Engl. Bot. t. 1659. Curt. Lond. fafc. 6. t. 43. Fl. Dan. t. 793. (Th. Diofcoridis; Ger. Em. 262. Th. fecundum; Matth. Valgr. v. 1. 519. Camer. Epit. 337.)—Pouch orbicular, compreffed, entire at the bafe. Leaves oblong, toothed, fmooth.—Native of cultivated fields, in moft parts of Europe, but not frequent in England. It is annual, flowering in June and July. Dr. Sibthorp met with it in the countries north of Greece. The *root* is fmall, and tapering. Whole *plant* fmooth, about a foot high, branched; the *ftem* leafy, angular upwards. *Leaves* two or three inches long, clafping the ftem with their arrow-fhaped bafe; their edges wavy and toothed. *Flowers* numerous, fmall, white. *Pouch* large, erect, almoft perfectly orbicular. *Style* much fhorter than the notch in which it ftands. *Seeds* numerous. The warm pungent tafte of this plant is combined with a difagreeable garlick flavour. The *feeds*, as obferved in Engl. Bot. "make an ingredient in that naufeous opprobrium of pharmacy, the Mithridate Confection, the receipt for which may be found, with many excellent critical remarks, in Lewis's Difpenfatory." See MITHRIDATE.

4. Th. *alliaceum*. Garlick Baftard-Crefs. Linn. Sp. Pl. 901. Willd. n. 4. Ait. n. 2. Jacq. Ic. Rar. t. 121. (Th. allium redolens; Morif. fect. 3. t. 18. f. 28.)—Pouch nearly obovate, tumid, with a narrow border. Leaves oblong, obtufe, fmooth, fomewhat toothed.—Native of the fouth of Europe. An annual herb, much refembling the laft, but the *leaves* are blunter, and lefs toothed. The *pouches* are very different, having but a flight border at their upper part only, their bafe being wedge-fhaped.

5. Th. *Pfychine*. Long-ftyled Baftard-Crefs. Willd. n. 5. (Pfychine ftylofa; Desfont. Atlant. v. 2. 69. t. 148. Burfa paftoris hirfuta, erucæ flore, ftilo prominente; Shaw Afric. n. 91. f. 91.)—Pouch abrupt. Style prominent. Leaves heartfhaped-oblong, toothed, downy, clafping the ftem.—Native of the borders of fields in Barbary. *Root* annual. *Herb* larger than the foregoing, and clothed with hoary hairs. *Leaves* rounded, not acute, at the bafe. *Flowers* pale yellow, as large as the Common Muftard. *Pouch* wedge-fhaped, or triangular, being quite abrupt at the end; the *ftyle*, which is as long as the whole pouch, ftanding prominent at the fummit. Willdenow is certainly correct as to the genus.

6. Th. *faxatile*. Rock Baftard-Crefs. Linn. Sp. Pl. 901. Willd. n. 6. Jacq. Auftr. t. 236. (Lithothlafpi quartum, carnofo rotundo folio; Column. Ecphr. 279. t. 277. f. 2. Aethionema faxatile; Br. in Ait. Hort. Kew. v. 4. 80.)—Pouch nearly orbicular; concave above; convex below. Stems moftly fimple. Leaves linear-lanceolate, flefhy, obtufe.—Native of dry hills, and the clefts of rocks, in Italy, Auftria, Switzerland, Greece, and the fouth of France, flowering in April and May. The *root* is perennial, and in fome degree woody, though generally marked as annual. *Stems* annual, afcending, fix or eight inches high, round, leafy, rarely fubdivided. *Leaves* numerous, fcattered, on fhort ftalks, glaucous, fmooth, entire, three quarters of an inch long; the lower ones rather elliptical. *Flowers* fmall, pink, numerous, in denfe terminal *corymbs*, foon elongated into lax *clufters* of glaucous *pouches*, tinged with pink, each on a flender, fpreading, partial ftalk; their border broad, ftriated, fomewhat crenate, emarginate at the top only, where the minute *ftyle* is fituated. The fhrubby habit, glaucous hue, and very pretty little red *flowers* with a pale-green *calyx*, render this one of the moft elegant plants of its natural order. *Iberis faxatilis*, Linn. Sp. Pl. 905, diftinguifhed from this by the accurate Fabius Columna, and figured in the fame plate of his work, is fo like it, that they are hardly to be known afunder, except by the unequal *petals*, proper to *Iberis*, and the downinefs of this latter plant. On a clofe comparifon, the fhapes and furfaces of their *feed-veffels* will be found effentially different.

7. Th. *montanum*. Mountain Baftard-Crefs. Linn. Sp. Pl. 902. Willd. n. 9. Ait. n. 7. Jacq. Auftr. t. 237. (Th. montanum, burfæ paftoris fructu; Column. Ecphr. 275. t. 276. f. 1. Th. præcox; Wulf. in Jacq. Coll. v. 2. 124. t. 9. Lepidium n. 518; Hall. Hift. v. 1. 223.

β. Th. alpinum; Jacq. Auftr. t. 238. Willd. n. 10. Crantz Auftr. fafc. 1. 25. t. 3. f. 1. (Th. minimum; Arduin. Spec. 2. 33. t. 15. f. 2.)

Pouch inverfely heart-fhaped. Leaves fmooth, nearly entire; radical ones obovate, ftalked; the reft feffile, clafping the ftem. Petals thrice as long as the calyx. Stems fimple.—Native of ftony places, on the lofty mountains of Switzerland, Auftria, Dauphiny, and Italy, flowering in April or May. The *roots* are perennial, long, fubdivided at the fummit, each trailing fhoot crowned with a tuft of obovate *leaves*, rarely a little ferrated, their fize, and the length of their *footftalks*, varying according to luxuriance of foil, or a more or lefs elevated place of growth. From the centre of each tuft arifes a folitary, fimple, afcending or upright *ftem*, from three inches to a fpan long, round, fmooth, clothed with numerous, alternate, feffile, cordate or arrow-fhaped, very rarely toothed, *leaves*, whofe bafe is more or lefs elongated and acute; their length three quarters of an inch. *Flowers* in folitary terminal *corymbs*, numerous, large, white and handfome; their broad, obovate, fpreading *petals* at leaft thrice as long as the fmooth, often purplifh, *calyx*. *Pouch* tapering at the bafe; more or lefs deeply lobed at the end, with a *ftyle* almoft as long as itfelf, projecting far beyond the lobes. *Seeds* naturally two in each cell, as Jacquin defcribes them. Haller found one only. This may be accounted for from their being often abortive, as indeed are generally moft of the *pouches* themfelves, the plant increafing much by root. Having had occafion to ftudy this and the neighbouring fpecies very minutely, in our inveftigation of Swifs and Britifh plants, we can with confidence maintain the correctnefs of our fynonyms, on the authority of original fpecimens. Our β alone is entitled to be diftinguifhed as a variety, and that an infignificant one, being merely rendered fmall in fize by its very elevated or expofed fituation. The faithful Jacquin himfelf evidently miftrufted this fuppofed fpecies, though he fays it retained the fame habit when cultivated.

8. Th. *alpeftre*. Alpine Shepherd's Purfe. Linn. Sp. Pl. 903. Willd. n. 12. Fl. Brit. n. 5. Engl. Bot. t. 81. Ait. n. 6. (Th. foliis globulariæ; Raii Syn. ed. 2. 175. ed. 3. 305. Bauh. Hift. v. 2. 926. Th. montanum fecundum badenfe; Cluf. Hift. v. 2. 131. Th. albi fupini varietas; Ger. Em. 268. f. 2. Lepidium n. 519; Hall. Hift. v. 1. 223, on the authority of fpecimens from Davall and Du Cros.)—Pouch obovate, abrupt, fomewhat heartfhaped, with many feeds. Stem-leaves arrow-fhaped. Stems fimple. Style prominent.—Native of mountainous paftures in Switzerland and England, flowering in June and July. It abounds on limeftone rocks, and about lead-mines, in Yorkfhire and Derbyfhire. Many authors have confounded this

T H L

[illegible] with the laſt, from which it differs in having a tufted *root*, not throwing out ſcyons, or runners; uſually taller and more numerous *ſtems*; more glaucous herbage; much ſmaller *flowers*, whoſe *petals* are erect, and though variable in dimenſions, never a quarter ſo large as in *montanum*; but above all, in having at leaſt three or four *ſeeds* in each cell. The *pouches* moreover are always numerous, and all perfect. Their terminal lobes are variable in length or dilatation, but conſtantly much ſhorter than the *ſtyle*. (See the following.) We have often been inclined to remove from this ſpecies to the foregoing the ſynonyms of Bauhin, Cluſius, and Gerarde, cited in *Fl. Brit.* on account of the large ſpreading *petals* of their figures. But this appears to be an inaccuracy on their part. The habit of their plant; ſeveral *ſtems* from the ſimple crown of the *root*; and the copious *pouches* in long continued *cluſters*, all properly belong to our *alpeſtre*, by no means to *montanum*. We have ſome ſuſpicion that the *alpeſtre* is rather biennial than perennial. It never remains long in gardens, but that is no proof, nor have we had an opportunity of watching the plant through a ſeaſon, on its own native hills. Hudſon miſtook the *perfoliatum*, next deſcribed, for *alpeſtre*.

9. Th. *perfoliatum*. Perfoliate Shepherd's Purſe. Linn. Sp. Pl. 902. Willd. n. 11. Fl. Brit. n. 4. Engl. Bot. t. 2354. Jacq. Auſtr. t. 337; not. 237, as in Willdenow. (Th. alterum mitius rotundifolium, burſæ paſtoris fructu; Column. Ecphr. 278. t. 276. f. 2. Th. rotundifolium; Ger. Em. 266. Th. cordatum minus, flore albo, inſipidum; Barrel. Ic. t. 815. Th. tertium pumilum; Cluſ. Hiſt. v. 2. 131. Th. minus Cluſii; Ger. Em. 268. Naſturtium n. 510; Hall. Hiſt. v. 1. 220. Piloſella ſiliquata; Thal. Harcyn. t. 7. f. C, at the end of Camer. Hort.)—Pouch exactly inverſely heart-ſhaped. Stem-leaves heart-ſhaped, ſharpiſh at the baſe, claſping the branched ſtem. Style very ſhort.—Native of calcareous paſtures or rocks, walls, and dry places, in Switzerland, Germany, France, Italy, Greece, and England, flowering in the ſpring. In the laſt-mentioned country it is hardly known any where but in the limeſtone part of Oxfordſhire, about Witney and Burford. We have gathered it at Caſerta, near Naples. The *root* is fibrous and annual. *Stem* branched from the bottom, except on poor ground, uſually from four to ſix inches high, round, ſmooth, leafy. *Leaves* glaucous, ſmooth, various in ſize, entire, or now and then ſlightly toothed; the radical ones ſtalked, ovate, obtuſe; the reſt ſeſſile, alternate. *Flowers* white, ſmall, with narrow, erect *petals*. *Style* ſo ſhort as to be ſcarcely diſcernible between the rounded lobes of the *pouch*. *Seeds* three or four, at leaſt, in each cell. The ſmall annual *root*, uſually branched *ſtem*, and minute *ſtyle*, are quite ſufficient to diſtinguiſh this ſpecies from the laſt, with which it has been confounded; nor is it difficult, with a moderate degree of obſervation, to avoid the error of thoſe old botaniſts, who deſcribed its ſtarved and luxuriant ſtates for diſtinct ſpecies. Ray ſuſpected this, and has adverted to it in his own ſecond edition of the *Synopſis*, by far the moſt exact, p. 176.

10. Th. *luteum*. Yellow Sicilian Shepherd's Purſe. Bivon. Cent. 1. 78. (" Th. montanum, glaſti folio, parvum, perfoliatum, nonnihil ſerratum, ſilicula cordatâ; Cupan. Panphyt. v. 2. t. 256. Th. montanum luteum, glaſti folio, parvum, perfoliatum, nonnihil ſerratum, ſiliculâ cordiformi; Cupan. Hort. Cathol. 212.")—Pouch inverſely heart-ſhaped, nearly orbicular. Leaves toothed, the lowermoſt ſtalked; the reſt claſping the ſtem. Style almoſt equal to the lobes of the ſeed-veſſel.—Native of dry mountainous places near Palermo, flowering in April and May, and ſent us by the baron Bivona. This is a ſmall, ſmooth, glaucous, annual *plant*, from one to three inches high. *Stem* erect, either ſimple, or branched from the baſe. *Leaves* half an inch, more or leſs, in length; the lower ones ſpatulate; the others ovate-oblong, bluntiſh, with a heart-ſhaped baſe; all having one or two large teeth at each ſide. *Flowers* remarkable for being yellow. They are ſmall, not many together, in ſhort terminal *corymbs*, becoming elongated *cluſters* of rather large, rounded, reticulated *pouches*, with a few *ſeeds* in each cell. The *petals* are emarginate, erect, longer than the *calyx*. *Stigma* large, on a level with the lobes of the pouch.

11. Th. *Burſa Paſtoris*. Common Shepherd's Purſe. Linn. Sp. Pl. 903. Willd. n. 13. Fl. Brit. n. 6. Prodr. Fl. Græc. n. 1499. Engl. Bot. t. 1485. Curt. Lond. faſc. 1. t. 50. (Burſa Paſtoris; Ger. Em. 276. Matth. Valgr. v. 1. 521.)—Hairy. Pouch inverſely heart-ſhaped, ſomewhat triangular, ſcarcely bordered. Radical leaves pinnatifid.—A very common weed in cultivated and waſte ground, throughout Europe, as well as in North America, and in moſt countries where European merchandiſe or cultivation has reached. We have already mentioned that this ſpecies is indubitably the θλασπι of Dioſcorides. It flowers at all times, from the beginning of ſpring to the end of autumn. The white tapering annual *root* is diſtinguiſhed by a very peculiar nauſeous ſmoke-like ſcent, when pulled out of the ground. Whole *herb* rough with ſtarry as well as prominent hairs. *Stem* various in height, erect, round, with alternate ſpreading *branches*, though ſometimes ſo ſtarved as to be quite ſimple and ſlender, with all the *leaves* of the plant undivided; in which ſtate the ſpecies is difficult to be recognized. The radical *leaves* are numerous, cloſe to the ground, variouſly pinnatifid, moſtly toothed, ſomewhat lyrate, about two or three inches long; the reſt linear-oblong, acute, ſeſſile, entire or toothed, embracing the ſtem with their elongated heart-ſhaped baſe. *Flowers* ſmall, white, in denſe *corymbs*, often tinged with purpliſh-brown. *Pouches* ſmooth, ſatchel-ſhaped, whence the modern name, diſpoſed in very long, lax, upright *cluſters*. *Style* rather prominent. *Seeds* numerous, ſmall, oval, a favourite food of ſmall birds, as well as the flower-buds. The flavour of both is warm and pungent.

12. Th. *ceratocarpon*. Horned Shepherd's Purſe. Murray in Comm. Goett. v. 5. 21. t. 1. Linn. Suppl. 295. Willd. n. 14. Ait. n. 3. Scop. Inſub. v. 1. 10. t. 4.)—Very ſmooth. Pouch obovate, tumid, with a terminal, double horn-like, compreſſed border. Leaves lanceolate, ſomewhat toothed; arrow-ſhaped at the baſe.—Native of Siberia, from whence Pallas brought the ſeeds. The *root* is annual, tapering. *Stem* ſolitary, erect, twelve or eighteen inches high, leafy, moſtly quite ſimple. *Leaves* all ſmooth, ſlightly toothed, or wavy; the radical ones obovate, on long ſtalks; the reſt ſeſſile. *Flowers* numerous, white, very ſmall. *Pouches* compoſing a long *cluſter*, very conſpicuous for their two ſharp prominent horns, between which ſtands the very ſhort *ſtyle*. *Seeds* large, about two in each cell.

THLASPIDIUM, θλασπιδιον of Cratevas, according to Tragus; a name whoſe etymology has been miſtaken, like Thlaspi, (ſee that article,) from whence it is manifeſtly derived. Tournefort, who in his *Inſtitutiones* 214, adopts this name, for what Linnæus more aptly termed *Biſcutella*, explains it as meaning that the plants which bore it were allied to *Thlaſpi*; and this, no doubt, is correct. But Ambroſini, who conſiders *Thlaſpi* itſelf as applying to the beaten or flattened form of the ſeed-veſſel, deduces the preſent word from θλαω, *to bruiſe* or *beat*, and ασπιδιον, *a little ſhield*, which is evidently applicable to the flat ſhield-like fruit of *Thlaſpi arvenſe*, and is ſo plauſible an explanation, that

that it feems to have chiefly led the modern expounders of ancient writers to take this fpecies for θλασπι of Diofcorides. We have already, in its proper place, fhewn our Shepherd's Purfe to be what he defcribes; and we can underftand the name, as derived from θλαω, in no other light, than alluding to the minute feeds, which feem as if beaten to powder. This is by no means the firft inftance, in which the moft apparently juft etymology, proves not to be the real one.

THLIBIÆ, in *Antiquity*, a kind of eunuchs. See Thlasias and Castration.

THLIPSIS, θλιψις, is ufed, by anatomifts, for the compreffion of any veffel or aperture, by which its cavity is leffened.

THNETOPSYCHITES, compofed of θνητος, *mortal*, and ψυχη, *foul*, in *Ecclefiaftical Hiftory*; a fect in the ancient church, who believed the foul of man perfectly like that of brutes; and taught that it died with the body. See Soul.

We meet with no account of thefe heretics any where but in J. Damafcenus Hæref. 90, unlefs they be the fame with thofe Eufebius fpeaks of, Hift. Ecclef. lib. ix. c. 38, who relates, that in Origen's time, there were heretics in Arabia, who taught, that the foul of man died with the body; but that it fhould rife again with it at the end of the world. He adds, that Origen refuted them in a numerous council, and reclaimed them from their errors. St. Auguftine and Ifidore call them the Arabian heretics.

Marfhall, in his tables, ufes the word *Thenopfychites* inftead of *Thnetopfychites*.

THOA, in *Botany*, a Guiana name adopted by Aublet, and retained by Juffieu, and even Schreber; fee our article Gnetum, to which genus this plant is there, for the firft time, referred, as a fecond fpecies.

THOALABIAN, in *Geography*, a town of Arabia, in the province of Nedsjed; 260 miles E.N.E. of Hajar.

THOANHOA, a town of Cochinchina, at the bottom of a large bay. N. lat. 16° 45′. E. long. 106° 27′.

THOARD, a town of France, in the department of the Lower Alps; 9 miles E.S.E. of Sifteron.

THOCO, an ifland in the Grecian Archipelago, near the coaft of Greece, about eight miles in circumference. N. lat. 37° 20′. E. long. 23° 21′.

THOCOS, θωκος, in *Antiquity*, the fame with *Thacas*.

THOGRAI, in *Biography*, a Perfian of Ifpahan, who was grand vizier to the fultan Malich Mafhud, is celebrated for his poetical talents, a fpecimen of which is given by Pococke; and for a commentary upon the republic of Plato, to whom the Saracens paid little attention. After a ftrange reverfe of fortune, Thograi was put to death by order of the fultan in the year 1121.

THOIRY, in *Geography*, a town of France, in the department of the Ain; 6 miles S.S.W. of Gex.

THOKES, in our *Old Writers*, fifh with broken bellies, forbid by ftatute to be mixed or packed with tale-fifh. 22 Ed. IV. cap. 2.

THOLEN, in *Geography*. See Tolen.

THOLES, in *Sea Language*, denote fmall pins driven perpendicularly into the upper edge of a boat. In rowing, the oar paffes between the two tholes, in the fpace called the *row-lock*. Sometimes there is only one pin to each oar, as in the boats navigated on the Mediterranean fea: in that cafe the oar is hung upon the pin by means of a ftrop.

THOMÆANS, Thomeans, Thomites, or *Chriftians of St. Thomas*, a people of the Eaft Indies, in Cochin, and upon the coaft of Malabar and Coromandel, who, according to tradition, received the Gofpel from the apoftle St. Thomas.

It appears by the teftimony of Cofmas, who wrote about A.D. 547, and whofe work is tranflated by F. Montfaucon, that Chriftianity was eftablifhed in India in the fixth century. We alfo find in the fubfcriptions of the council of Nice, that of a prelate, who calls himfelf bifhop of Perfia. Moreover, an ancient author, cited by Suidas, fays, that the inhabitants of Interior India, (a name which Cofmas gives to the coaft of Malabar,) the Iberians and Armenians, were baptized under the reign of Conftantine.

The princes of the country, and particularly Serant Peroumal, emperor of Malabar, the founder of the city of Calicut, A.D. 825, granted extraordinary privileges to thefe Chriftians.

When Vafco de Gama, the Portuguefe admiral, arrived at Cochin with a fleet, in the year 1502, thefe Chriftians fent deputies to him, imploring his protection, and that of the king his mafter. The admiral treated them kindly, but was in no condition to afford them any effectual affiftance, in relieving them from the yoke of the Pagan kings, to which they were then fubject. The language they ufe *in facris*, is the Syriac, or, as fome fay, the Chaldee; but their ordinary language is the fame with that of their neighbours. The firft miffionaries, who attempted to profelyte them to the church of Rome, were Cordeliers, but their endeavours proved ineffectual. The diftinguifhing opinions and religious rites of thefe Chriftians are as follow.

They are charged with an invincible attachment to the doctrine of Neftorius, and with an obftinate refufal to acknowledge, that the Virgin is the mother of God: they have no images in their churches: they believe that the fouls of the bleffed are not admitted into the prefence of God till after the day of univerfal judgment: they allow only of three facraments, *viz.* baptifm, orders, and the euchariſt: they defer the baptifm of infants for fome time, as for a month, or even for feven, eight, or ten years, after they are born: they make no ufe of holy oil, neither in baptifm, nor in the adminiftration of the other facraments; but after baptizing their infants, they fprinkle the oil of a fpecies of Indian faffron all over their bodies: they allow of no auricular confeffion, treat purgatory as a fable, and their priefts are permitted to marry: they entertain an extraordinary affection for the Neftorian patriarch of Babylon, but will not fuffer any mention of the pope, or of the Romifh churches in their affemblies. Their days of abftinence are Wednefday and Friday, and their faft is very fevere in Lent, during which time they go to church three times a day. They alfo faft in the fame manner during the time of Advent. Befides thefe two greater fafts, which are enjoined on pain of excommunication, they have feveral others of a religious nature. Their women do not enter a church for forty days after their delivery of a male child, nor for eighty days after the birth of a daughter.

Thefe Chriftians are in general poorly inftructed, knowing only the Lord's prayer and the angelical falutation. Their churches are mean and unadorned buildings, and conftructed after the manner of the pagodas. They appear to maintain many of the religious opinions and practices received among Proteftants, and reject either wholly, or in a very great meafure, thofe of the church of Rome. They deny the fupremacy of the pope, and tranfubftantiation, and exclude from the number of facraments, confirmation, extreme unction, and marriage. Such are the errors profcribed by the fynod of Diamper, held in 1599, by Aleixo de Menefes, archbifhop of Goa, in order to unite the Thomæans to the Romifh church. However, notwithftanding the temporary fuccefs that attended the vigorous exertions of the archbifhop, for which he was recompenfed after his return to Europe, with the archbifhopric of Braga, the viceroyfhip of of Portugal, and the presidency of the council of state at Madrid, these Christians, oppressed and abused by the Jesuits, relapsed from the church of Rome soon after the death of the archbishop; and notwithstanding the endeavours of Alexander VII. to conciliate them by the mission of four bare-footed Carmelites, they could no more be reduced to submission. At length, when the Dutch took Cochin, in 1663, the Christians of St. Thomas recovered the liberty which they had formerly enjoyed; but they derived little advantage besides from their new masters. Encyclopédie, and Geddes's History of the Church of Malabar and Synod of Diamper, in his Tracts, vol. v. For a further account of this sect, see CHRISTIANS *of St. Thomas*.

THOMAR, in *Geography*, a town of Portugal, in Estremadura, containing two churches, an hospital, four convents, and about 3600 inhabitants; 63 miles N.E. of Lisbon. N. lat. 39° 34'. W. long. 8° 8'.

THOMAS, surnamed *Didymus*, or the *Twin*, in *Scripture Biography*, one of our Lord's twelve apostles, of whom the evangelist John has given a short account in the 20th chapter of his Gospel. John Chrysostom informs us, that Thomas preached the gospel to the Ethiopians, Parthians, Persians, and Medes, and even, according to tradition, to the Indians, and in the island of Taprobana; and the Christians called after his name in the East, regard him as the founder of their church. See CHRISTIANS *of St. Thomas*, and THOMÆANS.

For an account of the spurious gospel attributed to St. Thomas, we refer to the article GOSPEL.

THOMAS, ANTONY LEONARD, in *Biography*, a distinguished French writer, was born in the diocese of Clermont, in Auvergne, in the year 1732, and designed for the profession of the law; but his attachment to literature induced him to prefer a professorship in the college of Beauvais. His reputation as a man of letters recommended him to the office of confidential secretary to the duke De Praslin, in which he conducted himself with integrity and honour. When he was advised by the duke to become a candidate for a seat in the French Academy, after having five times gained the prize for his compositions, and discovered that he was put forward as a competitor to Marmontel, who was out of favour with persons in power, he refused to be the instrument of such a design. In consequence of this circumstance, the duke dismissed him his office, but procured for him the place of secretary-interpreter for the Swiss Cantons, to which a very inconsiderable salary was annexed; and yet this was the whole benefit which he obtained from court-favour. His career as a writer commenced in 1756, by "Reflections historical and literary on Voltaire's Poem on Natural Religion;" and on all subsequent occasions he proved himself the friend of virtue, and a lover of mankind. His eulogies, particularly those on Des Cartes and Marcus Aurelius, were highly commended. His "Essai sur les Charactères, les Mœurs, et l'Esprit des Femmes," 1772, is a sprightly performance, in which fine writing and philosophical observation are combined. His "Essai sur les Eloges," in 2 vols. 1775, exhibits striking portraits with just ideas. As a poet, he appears to advantage in his "Epitre au Peuple," his "Ode sur les Temps," and his "Poeme de Jumonville." His epic poem, entitled "Le Petreide," the hero of which was czar Peter, was left unfinished. He was distinguished by his singularities, and also by his sympathy with persons in distress, for whose relief he submitted to personal inconvenience and privation. His death took place at the seat of the archbishop of Lyons, in September 1785, at the age of 53. His works, in prose and verse, were published at Paris, in 7 vols. 8vo. Gen. Biog.

THOMAS, CHRISTIAN, an Eclectic philosopher of the German schools, who deserves notice on account of the boldness with which he threw off the yoke of human authority, and the perseverance with which, against much opposition, and in many vicissitudes of fortune, he maintained and exercised the right of free inquiry. He was born at Leipsic in the year 1655, and finished his course of education in the university of his native city. Upon a perusal of Puffendorf's Apology for rejecting the scholastic principles of morals and law, he renounced implicit deference to all ancient dogmas; and engaged in reading lectures on the subject of natural law, first from the text of Grotius, and afterwards from that of Puffendorf, in the full exercise of his own judgment, with prudent caution while his father lived, but after his death, with a boldness which incurred the violent resentment of theologians and professors. In 1687 he published an "Introduction to Puffendorf," in which he deduced the obligation of morality from natural principles, and thus gave great offence. In the following year he became still more unpopular, by commencing a monthly literary journal, entitled "Free Thoughts; or, Monthly Dialogues on various Books, chiefly new," containing a severe attack upon many of his contemporaries. Complaints of the raillery of this satirical work were lodged before the ecclesiastical court of Dresden; and Thomas with difficulty escaped punishment. Some other sarcastical pieces inflamed the resentment of his enemies, and he was charged before the same court by the clergy of Leipsic with a contempt of religion. Soon after he published another satirical work "On the Divine Right of Kings," "A Defence of the Sect of the Pictists," and some other eccentric works of the same general character, for which he was threatened with imprisonment; but obtaining permission from the elector of Brandenburgh to retire, he became a voluntary exile from Leipsic: and soon after was appointed public professor of jurisprudence, first in Berlin, and afterwards at Halle. In these situations he indulged his satirical humour, and his inclination for controversy, as long as he lived; persevering in his endeavours to correct and subdue the prejudices of mankind, and to improve the state of philosophy. He died at Halle, in the year 1728. Thomas was the author of several treatises on logic, morals, and jurisprudence, in which he deviates from opinions generally received; and his latter publications are, in many respects, inconsistent with the former. His principal philosophical works are, "An Introduction to Aulic Philosophy; or Outlines of the Art of Thinking and Reasoning," Leipf. 1688; "Introduction to Rational Philosophy;" "A Logical Praxis," Hal. 1691; "Introduction to Moral Philosophy," 1692; "A Cure for irregular Passions, and the Doctrine of Self-knowledge," 1696; "The new Art of discovering the secret Thoughts of Men;" "Divine Jurisprudence;" "Foundations of the Law of Nature and Nations;" "Dissertation on the Crime of Magic;" "Essay on the Nature and Essence of Spirit, or Principles of Natural and Moral Science," 1699; and "History of Wisdom and Folly."

As a specimen of the peculiar tenets and maxims of this eccentric philosopher, we shall subjoin the following.

"Thought arises from images impressed upon the brain; and the action of thinking is performed in the whole brain. Brutes are destitute of sensation. Man is a corporeal substance, capable of thinking and moving, or endued with intellect and will. Man does not always think. Truth is the agreement of thought with the nature of things. The senses are not deceitful, but all fallacy is the effect of precipitation and prejudice. From perceptions arise ideas, and their relations; and from these, reasonings. It is impossible to to difcover truth by the fyllogiftic art. No other rule is neceffary in reafoning, than that of following the natural order of inveftigation; beginning from thofe things which are beft known, and proceeding, by eafy fteps, to thofe which are more difficult.

"Perception is a paffive affection, produced by fome external object, either in the intellectual fenfe, or in the inclination of the will. Effence is that without which a thing cannot be perceived. God is not perceived by the intellectual fenfe, but by the inclination of the will: for creatures affect the brain; but God, the heart. All creatures are in God: nothing is exterior to him. Creation i extenfion produced from nothing by the divine power. Creatures are of two kinds, paffive and active; the former is matter; the latter, fpirit. Matter is dark and cold, and capable of being acted upon by fpirit, which is light, warm, and active. Spirit may fubfift without matter, but defires a union with it. All bodies confift of matter and fpirit, and have therefore fome kind of life. Spirit attracts fpirit, and thus fenfibly operates upon matter united to fpirit. This attraction in man is called love; in other bodies, fympathy. A finite fpirit may be confidered as a limited fphere in which rays, luminous, warm, and active, flow from a centre. Spirit is the region of the body to which it is united. The region of finite fpirits is God. The human foul is a ray from the divine nature; whence it defires union with God, who is love. Since the effence of fpirit confifts in action, and of body in paffion, fpirit may exift without thought: of this kind are light, ether, and other active principles in nature.

"Good confifts in the harmony of other things with man and his feveral powers. The higheft felicity of man confifts in tranquil delight. The fountain of this delight is the rational love of man and of God. Internal love and reverence are all the homage which nature teaches us to pay to God. With refpect to God, the two capital errors are atheifm and fuperftition. Superftition is worfe than atheifm. The love of God is a fupernatural affection, which prepares the foul for future felicity. The rational love of man comprehends all focial virtues. Rational felf-love includes felf-prefervation, temperance, purity, induftry, fortitude. To wife men, virtue is its own reward. Laws are appointed for the fake of fools, to conduct them to internal tranquillity, and external peace. Of fools, there are three claffes; thofe who difturb external peace; thofe who do nothing to promote it; and thofe who do not enjoy internal peace. The firft have need of authority; the fecond of authority and counfel; the third of counfel alone. The obligation of authority and law extends only to external actions, which are juft when they are conformable to law: juftice is therefore to be diftinguifhed from virtue, which refpects the internal man, and requires a conformity to the law of nature." Brucker by Enfield, vol. ii.

THOMAS. *Chriftians of St. Thomas.* See THOMÆANS.

THOMAS'*s Hofpital.* See HOSPITAL.

THOMAS, *St.*, in *Geography*, an ifland of the Atlantic, near the coaft of Guinea, fituated on the equinoctial line, of a circular form, about ten leagues in circumference, difcovered by the Portuguefe in the year 1640. The climate is infalubrious, and at fome feafons of the year the fky is even darkened by thick fogs, which are difperfed by the winds that blow in the months of July and Auguft. In this ifland the inhabitants have two winters, like thofe of other places that are under the fame parallel, but without the cold that diftinguifhes that feafon in Europe. The rains continue from December to February; and fpring begins with our fummer, in the month of May. During the firft three months of this period, the heat is infupportable, and the firft fettiers gradually inured themfelves to the climate. The foil on this ifland is vifcous and clayey, and mixed with chalk; but it is rendered fertile by the heavy night dews. The plants and fhrubs, which it rapidly produces, are burnt to afhes, and applied as the moft beneficial manure to fugar-canes; which were firft planted here by the Portuguefe: in their endeavours to cultivate which they have been difappointed. Rice and millet fucceed, and vines of the richeft kind, as well as melons, cucumbers, figs, ginger, and all forts of roots, pulfe, and pot-herbs, are cheaply reared, and they arrive at the utmoft perfection. Yams are in this ifland a very wholefome and delicious diet. The land of this ifland is well watered, and much fertilized by its rivers and ftreams. In the centre is a high mountain, covered with wood and fruit-trees, whofe fummit is neverthelefs always covered with fnow. Its quadrupeds, birds, and fifhes, are very various, and abundant; and St. Thomas would be equal to any fpot in the globe, if its temperature correfponded to its other qualities. The inhabitants are the defcendants of the Portuguefe firft fettlers and the negroes, who are retained in the fervice of Europeans, and fuch as prefer a refidence here to Angola. They are for the moft part Roman Catholics, and extremely ignorant, fuperftitious, and bigotted. The ecclefiaftical government is under the direction of the bifhop, who is a fuffragan of the archbifhop of Lifbon. E. long. 8° 6'.—Alfo, a town of Hindooftan, on the coaft of Coromandel. Here was formerly a powerful city, called "Meliapour," or "Meilabour," the capital of the kingdom of Coromandel; but on the ruins of this city the Portuguefe erected the ftately city of St. Thomas. This is inhabited chiefly by weavers and dyers, who manufacture the beft coloured ftuffs in India. The Portuguefe, who rebuilt this place in 1545, have raifed it from a ftate of defolation to a flourifhing ftate, both with regard to its buildings and inhabitants. Whilft the Portuguefe retained it, it was a bifhopric under the archbifhop of Goa; and they had feveral churches, befides monafteries, and a college for the inftruction of the Portuguefe and Malabar children. Here is alfo the famous church of St. Thomas the Apoftle, where it is pretended that he was buried. (See THOMÆANS, and CHRISTIANS *of St. Thomas.*) The city had feven gates, and was, on account of its fituation, guarded by the fea on one fide, and a chain of mountains on the other, very ftrong: neverthelefs it was taken by the Moors after a long fiege, and retained in their poffeffion.—Alfo, a town of Germany, in the archduchy of Auftria; 6 miles N.W. of Grein.—Alfo, a town of Savoy, in the county of Maurienne; 3 miles N. of Monftier.—Alfo, the principal of the Virgin Iflands, in the Weft Indies, about fix leagues in circumference, belonging to the Danes. It abounds with potatoes, millet, manioc, and moft forts of fruits and herbage, and efpecially fugar and tobacco, but is much expofed to the attacks of mofquitos and other vermin. The Englifh had formerly a fpacious fettlement in this ifland; and here is a fafe and commodious harbour, with two natural mounds upon it, fitted for the reception of two batteries to guard its entrance. Nearly in the centre of the harbour is a fmall fort; and about 50 or 60 paces W. of it is the town, confifting chiefly of one long ftreet, at the end of which is the Danifh factory, with convenient warehoufes. On the right fide of this factory is the Brandenburgh quarter, containing two fmall ftreets, full of French refugees from Europe and the iflands. Moft of the houfes are built of brick, and one ftory high. The trade of this fmall ifland is confiderable, particularly in time of peace; as it is the ftaple for fuch articles of traffic as the French, Englifh, Dutch, and Spaniards are not allowed to deal in publicly in their own iflands; and

 in

in war, their privateers bring their prizes hither for sale. N. lat. 18° 22′. W. long. 64° 50′.—Alfo, the capital of Spanifh Guiana, called "San Tomé," which is fituated at the foot of a fmall mountain on the right bank of the Oronoko. For its defence, a fort is placed oppofite to the city and on the left bank of the river; it is furrounded by a number of houfes, dependent, like the fort, on the province of Guiana. They call this place Port Raphael; and it is here the communication between Guiana and the provinces of Venezuela and Comana is found. Between Port Raphael and the city is feen the ifland called "Del Medio," or the Middle, becaufe it is in the middle of the river. It is a rock, which, in its fouthern part, difcovers itfelf in fummer, and is under water in floods. The principal channel is between the city and this ifland: when the water is low it has 200 feet, and on the increafe of the river 50 or 60 more.—Alfo, a town of the United States of America, in South Carolina; 21 miles N. of Charleftown.—Alfo, a town of the ifland of Cuba; 130 miles W.S.W. of Havannah.

THOMAS *de Caftile*, *St.*, a town of North America, in the government of Mexico, and province of Guatimala.

THOMAS's *Bay*, a bay on the W. coaft of Antigua.

THOMAS's *Creek*, a river of South Carolina, which runs into the Great Pedee.

THOMAS's *Gulf*, *St.*, a bay of the Atlantic, on the W. coaft of Africa. S. lat. 24° 50′.

THOMAS's *Head*, *St.*, a cape of England, on the N.W. coaft of the county of Somerfet, at the mouth of the Severn. N. lat. 51° 20′. W. long. 73° 35′.

THOMAS's *Hofpital*. See HOSPITAL.

THOMASBRUCK, in *Geography*. See THAMSBRUCK.

THOMASIUS, JACOBUS, in *Biography*, a writer in hiftory and philofophy, profeffor of eloquence in the univerfity of Leipfic, and chiefly diftinguifhed as the preceptor of the illuftrious Leibnitz, was born at Leipfic in the year 1622. Having obtained diftinction by his lectures and public thefes in his native city, he was advanced to the office of co-rector, firft of the college of St. Nicholas, and afterwards of that of St. Thomas. His erudition was extenfive, nor was he lefs diftinguifhed by his modefty and by his difinclination to controverfy. Among his numerous works, the principal are "Antiquities of Philofophical and Ecclefiaftical Hiftory:" "Differtations on the Stoical Philofophy, and on other Subjects relating to the Hiftory of Philofophy;" and "A Differtation on Literary Plagiarifm, with a Lift of 100 Plagiaries," all in Latin. He died in the year 1684. Brucker. Moreri.

THOMASIUS, CHRISTIAN, fon of the preceding, an eminent jurift, was born at Leipfic in 1655. Having ftudied the law at Francfort on the Oder, he was made a doctor in that faculty in 1679; and returning to his native city, he attended the bar, and wrote fome treatifes on the law. He was the friend of Puffendorf. By oppofing the fcholaftic philofophy in a German journal, commenced in 1688, he excited oppofition, and raifed againft himfelf many enemies. Many circumftances occurred which increafed the number of his adverfaries, and at length he was denounced to the court of Drefden as a heretic and Calvinift. The dread of perfecution induced him to withdraw to Berlin, and the king of Pruffia offered him an afylum at Halle, where he intended to found an univerfity. In this inftitution he occupied the fecond chair of law, and on the death of Stryckius, in 1710, he was advanced to the firft chair. In 1713 he defended concubinage, and being denounced for this opinion by the theological faculty of Halle, orders were iffued for proceeding againft him criminally. But upon the examination of his thefes, by commiffioners, the proceedings againft him were ftopped. The difpute, however, continued; neverthelefs he rofe to the poft of privy-counfellor to the king, and director of the univerfity of Halle, and died in 1728. Mofheim has given this character of Thomafius. "His views were vaft; he aimed at the reformation of philofophy in general, and of the Peripatetic fyftem in particular; and he affiduoufly employed both the power of exhortation and the influence of example, in order to perfuade the Saxons to reject the Ariftotelian fyftem, which he had never read, and which moft certainly he did not underftand. The fcheme of philofophy which he fubftituted in its place was received with little applaufe, and foon funk into oblivion; but his attempt to overturn the fyftem of the Peripatetics, and to reftore the freedom of philofophical inquiry, was attended with remarkable fuccefs, made in a little time the moft rapid progrefs, and produced fuch admirable effects, that Thomafius is looked upon, to this day, as the chief of thofe bold fpirits who pulled down philofophical tyranny from its throne in Germany, and gave a mortal blow to what was called the Sectarian philofophy in that country." Mofheim's Eccl. Hift. Moreri.

THOMASSIN, LOUIS, an ecclefiaftical writer, was born at Aix, in Provence, in 1619, and was admitted into the congregation of the Oratory in the fourteenth year of his age. He afterwards became profeffor of theology at Saumur, and laying afide fcholaftic fubtleties, adopted the method of teaching by the fcriptures, fathers, and councils: and in 1654 he was called to the feminary of St. Magloire at Paris. His "Latin Differtations on the Councils," were publifhed by the defire of the archbifhop of Paris, of which the firft and only volume appeared in 1667, 4to. In the following year he publifhed "Memoires fur la Grace," 3 vols, 8vo., in which work he attempts to conciliate the Greek fathers with St. Auguftine. This was reprinted in 1682, with the addition of two memoirs. In 1678 he publifhed the firft volume of a work, entitled "De la Difcipline Ecclefiaftique," which was followed by a fecond volume in 1679, and a third in 1681. This work was tranflated into Latin, in 3 vols. fol. from refpect to pope Innocent XI. and for the advantage of more unlimited circulation. His other works, which we can merely enumerate, were "Dogmata Theologica," 3 vols. 1680–89; "The Difcipline of the Church and Chriftian Morality;" "On the Divine Service;" "On Feftivals;" "On Fafts;" "On Truth and Falfehood;" "On the Unity of the Church;" "On Alms, Trade, and Ufury;" "Methode d'enfeigner chretiennement la Grammaire, ou les Langues par rapport a l'Ecriture Sainte," 2 vols. 8vo.; and "Gloffaire univerfelle Hebraique," which latter appeared after his death in 1697, folio.

Thomaffin died in the year 1695, having for fome time enjoyed a penfion of 1000 livres granted to him by the French clergy, and of which he gave one half to the poor. One of his biographers characterifes him as "humble, modeft, and mild, fond of ftudy and retirement, and fhunning difputes."—Although his reading was extenfive, his erudition was not of the higheft clafs, and it is faid that his work on Difcipline contains many miftakes where Greek authors are cited. Moreri. Gen. Biog.

THOMASTOWN, in *Geography*, a poft-town of the county of Kilkenny, Ireland, fituate on the river Nore, over which it has a fine bridge. The caftle was built about 1180, by Thomas Fitzanthony, from whom the town takes its Irifh name of *Bally-mac-Andan*; *i.e.* town of Anthony. It was a borough, and fent two members to parliament, but loft that privilege by the Union. The Nore is navigable to this town for ſmall veſſels. It is 59 miles S.S.W. from Dublin, and $15\frac{1}{2}$ N. from Waterford.

Thomastown, a poſt-town of the United States, in the diſtrict of Maine, and county of Lincoln, containing 2100 inhabitants.

THOMISM, or Thomaism, the doctrine of St. Thomas Aquinas, and his followers the Thomiſts, chiefly with regard to predeſtination and grace. See his biographical article.

There is ſome doubt what the true, genuine Thomiſm is: the Dominicans pretend to hold pure Thomiſm; but there are other authors who diſtinguiſh the Thomiſm of St. Thomas from that of the Dominicans.

Others, again, make Thomiſm no other than a kind of Janſeniſm diſguiſed; but Janſeniſm, we know, has been condemned by the popes, which pure Thomiſm never was.

In effect, the writings of Alvarez and Lemos, who were appointed, by their order, to lay down and defend before the holy ſee, the dogmata of their ſchool, have ſince been reputed the rule of pure Thomiſm.

Thoſe two authors diſtinguiſh four claſſes of Thomiſts: the firſt, which they reject, deſtroys or takes away liberty; the ſecond and third do not differ from Molina. The laſt, which Alvarez embraces, admits a phyſical premotion, or predetermination, which is a complement of the active power, by which it paſſes from the firſt act to the ſecond; that is, from complete and next power to action.

This premotion, they hold, is offered in ſufficient grace: ſufficient grace is given to all men; and that they have a complete, independent, next power not to act, and even to reject the moſt efficacious grace.

THOMISTS, a ſect of ſchool divines, who maintain Thomiſm.

The avowed antagoniſts of the Thomiſts are the Scotiſts.

THOMITES. See Thomæans.

THOMMDAMM, in *Geography*, a town of the duchy of Saxe Lauenburg, on the Elbe; 25 miles S.E. of Lauenburg.

THOMPSON, *Sir* Benjamin, *Count of Rumford*, in *Biography*, diſtinguiſhed by his aſſiduity and zeal in the promotion of ſcience, and in deviſing and executing ſchemes of public utility, was born at the village of Rumford, in New England, in the year 1752; and with the aſſiſtance afforded him by a profeſſor of natural philoſophy in the American univerſity of Cambridge, acquired in early life ſuch a degree of knowledge as enabled him to give inſtruction to others. By an advantageous marriage, while he was young, his advancement was accelerated, ſo that he obtained the rank of a major in the militia of his native diſtrict. When the war broke out between the mother-country and her colonies, he took part with the former, and by means of his local knowledge, he rendered himſelf uſeful to the Britiſh generals in America. In proceſs of time he repaired to England, and recommending himſelf to lord George Germaine, the chief miniſter in the American department, he obtained a place in his office. Towards the cloſe of the war, the ſame nobleman, with a view of ſecuring for him a permanent proviſion, ſent him to New York, where he raiſed a regiment of dragoons, and by being appointed lieutenant-colonel, became entitled to half-pay. Upon his return to England, his majeſty, in 1784, conferred upon him the honour of knighthood; and for ſome time he occupied the poſt of one of the under-ſecretaries of ſtate. Soon after he made a tour to the continent, and being warmly recommended by the prince of Deux-Ponts, afterward king of Bavaria, to his relation the reigning elector-palatine, and duke of Bavaria, he was admitted into his ſervice, and occupied an eminent ſtation. He had thus an opportunity of effecting many important and uſeful reforms in the departments of the ſtate, both civil and military. His attention was at this time particularly directed to the ſuppreſſion of mendicity, which prevailed not only at Munich, the capital, but through the whole country, to an extent that rendered the reſtraint and abolition of it a very difficult and hazardous undertaking. With this view he formed a plan for employing all mendicants; and having provided a building for their reception, and materials for their labour, he ſallied forth into the ſtreets of the city on the 1ſt of January 1790 (New-year's day being ſet apart for giving alms in Bavaria), accompanied by the field-officers of the garriſon and the magiſtrates of the city; and arreſting with his own hand the firſt beggar that came in his way, his attendants followed his example, ſo that before night not a ſingle beggar was to be ſeen in the whole metropolis. Thoſe that were arreſted were conducted to the town-hall, where their names were inſcribed, and then ordered to repair to the work-houſe, where they would find employment, and a ſufficiency of wholeſome food. In conſequence of theſe prompt and vigorous meaſures, the evil was redreſſed, and the mendicants were led by habit to prefer induſtry to idleneſs, and decency to the filth, rags, and ſqualid wretchedneſs attendant on beggary. He alſo introduced into Bavaria the culture and uſe of potatoes. For all theſe ſervices ſir Benjamin was decorated by the Bavarian ſovereign with ſeveral orders, promoted to the rank of lieutenant-general, and created a count by the title of his native place, Rumford. During his abode at Munich, he commenced his experiments upon the improvement of fire-places, with reſpect to the economy of fuel, and the convenience of cooking; and alſo his plans for a cheaper and more nutritive mode of feeding the poor, which gave him peculiar celebrity. Having quitted Bavaria in 1799, he reſided for ſome time in this country, purſuing a variety of experiments on the nature and application of heat, and the conſtruction of chimneys, grates, and fire-places. He alſo promoted ſcience both by his own reſearches and experiments, and by liberally exciting emulation in others, upon a more enlarged plan. For the latter purpoſe, he transferred, on an occaſional viſit to this country in 1796, to the Royal Society of London, of which he was a member, 1000*l.* 3 *per cent.* ſtock, the intereſt of which was to be applied every ſecond year as a premium to the author of the moſt important diſcovery on the ſubjects of heat and light in any part of Europe during the two preceding years; the preference to be always given to ſuch diſcoveries as, in the opinion of the preſident and council, tend moſt to the benefit of mankind; which indeed was the leading object of all his reſearches. He alſo ſuggeſted the plan, and aſſiſted in the formation of the Royal Inſtitution, which has produced ſeveral other eſtabliſhments of a ſimilar nature.

In the year 1802 he left England for Paris, which became his fixed reſidence, and where he married the widow of the celebrated chemiſt, Lavoiſier; but this connection proving unhappy, it was ſoon terminated by a ſeparation. The count afterwards retired to a country-houſe at Auteuil, about four miles from Paris, which he rendered a delightful habitation. Beſides the improvement of his grounds, in which he took great pleaſure, he purſued a variety of philoſophical and mechanical reſearches. With his ſuperior talents he combined certain peculiarities, and a tenacіouſneſs, not to call it obſtinacy, of temper, which prevented his enjoying the pleaſures of ſocial intercourſe. Although he diſapproved both the character and politics of the French, he preferred their climate to every other; and he obtained permiſſion from the king of Bavaria to continue in France, and to enjoy his penſion of 1200*l.* a-year. He lived in a ſtate of retirement, and alſo in a courſe of abſtemiouſneſs, which

which debilitated his conftitution, and rendered it incapable of refifting an attack of low fever, by which he was carried off in Auguft 1814, in his 63d year. By his firft wife he had one daughter, now refident at Bofton.

Although count Rumford was not a learned man, he acquired by his knowledge of the French and German languages, and by his extenfive acquaintance, and frequent converfation with literary men, a large ftock of literature and fcience. His peculiar talent was that of contriving inftruments, and devifing experiments for facilitating his refearches in thofe branches of economics and fcientific philofophy to which his attention was directed. He was alfo diftinguifhed by a fteadinefs and perfeverance of purfuit, which were favourable to his attainment of the objects which he had in view. As to his perfon, his ftature was above the middle fize, his countenance was dignified and pleafing, and his manner and tone of voice mild and gentle. He was, neverthelefs, ambitious of diftinction, and too prone to dictate in tranfactions with regard to which other perfons were jointly concerned with himfelf. The papers which he communicated both to the Royal Society and French Inftitute, and which are publifhed in their Tranfactions and Memoirs, are numerous. The only feparate publication of count Rumford was a feries of "Effays, Experimental, Political, Economical, and Philofophical," commencing with the year 1796, and continued to 18 in number, and occupying 4 vols. 8vo. Gent. Mag. for October 1814.

THOMPSON, in *Geography*, a town of America, in the ftate of New York, the capital of Sullivan county; bounded N. by Wawerfing and Neverfink, E. by Mamakating, S. by Deerpark in Orange county, and W. by the Mongaup, which feparates it from Lumberland, Bethel, and Liberty. Its length N. and S. is about 34 miles, and breadth 12. The principal fettlements are Thompfon, Monticello, Bridgeville, and Concord. The whole area of Thompfon is 139,500 acres; and the population by the cenfus of 1810, confifted of 1290 perfons. The principal ftreams are the Neverfink, Mongaup, and Sheldrake.—Alfo, a townfhip of Connecticut, in the county of Windham; 20 miles N.N.E. of Windham: the place contains 2467 inhabitants.

THOMPSON'S *Creek*, a river of South Carolina, which runs into the Atlantic, N. lat. 34° 44′. W. long. 79° 46′.—Alfo, a river of Weft Florida, which runs into the Miffiffippi, N. lat. 30° 59′. W. long. 91° 30′.

THOMPSON'S *Harbour*, a harbour in Hudfon's Bay. N. lat. 60° 20′. W. long. 78°.

THOMPSON'S *Ifland*, a fmall ifland of Upper Canada, at the entrance of the river St. Claire.

THOMPSONSBOROUGH, a town of America, in the diftrict of Maine; 30 miles N.E. of Portland.

THOMSI, a town of Hungary; 11 miles S.W. of Canifcha.

THOMSON, JAMES, in *Biography*, a popular Englifh poet, was born at Ednam, near Kelfo, in Scotland, in the year 1700, being one of the nine children of the minifter of that place. Whilft he was at fchool at Jedburgh, he manifefted no powers fuperior to thofe of other boys, except in a tafte for poetry, which he betimes indulged, and which introduced him, during his vacations, to the fociety of fome neighbouring gentlemen. Of his productions, however, he thought fo humbly, that on New-year's day he committed to the flames thofe of each preceding year. From Jedburgh he was removed to the univerfity of Edinburgh, where he perfevered in the cultivation and exercife of his poetical talents; but upon the death of his father, he complied with the wifhes of his friends by entering on a courfe of divinity. His probationary exercife was the explanation of a pfalm, which was written in a ftyle fo fplendid, as to incur reproof from the theological profeffor, as being altogether unfuitable to the audience which might probably attend his future miniftry. Having no great inclination for the office, this admonition induced him to devote himfelf entirely to poetry: and after fpending fome time as private tutor in the family of lord Binning, he determined, at the fuggeftion of a lady, who was his mother's friend, to try his fortune in London. In 1725 he came to London, and meeting with his college acquaintance Mallet, he fhewed him his poem of "Winter," in an imperfect ftate; who advifed him to finifh and publifh it. Mr. Millar, a well-known London bookfeller, bought it for a fmall fum, and publifhed it in 1726. At firft it attracted little attention; but Mr. Whateley, a gentleman of acknowledged tafte, giving a favourable account of it, brought the poem and its author into notice. The author was introduced to Pope, and recommended by bifhop Rundle to lord chancellor Talbot. In 1727 he publifhed his "Summer," and in the fame year "A Poem facred to the Memory of Sir Ifaac Newton," juft deceafed, and alfo his "Britannia." His "Spring" was publifhed in 1728; and in 1730 the Seafons were completed by "Autumn," and publifhed collectively. In 1728 Thomfon, afpiring to the popularity and emolument of dramatic compofition, fucceeded in introducing upon the ftage of Drury-lane his tragedy of "Sophonifba." Its reception, however, was not very flattering. Soon after he was appointed, by the recommendation of Dr. Rundle, travelling companion to the Hon. Mr. Talbot, the eldeft fon of the chancellor, and had an opportunity of vifiting moft of the courts and countries of the European continent. During this tour, the idea of his poem on "Liberty" was fuggefted to him, and he employed two years in completing it. In confequence of this excurfion, he obtained, by the intereft of Mr. Talbot, the place of fecretary of the briefs, which, being almoft a finecure, afforded him leifure for his private literary purfuits. His poem on "Liberty" was more coolly received than the nature of the fubject led him to expect. When lord Hardwick fucceeded the lord chancellor Talbot, Thomfon loft his place; but upon being queftioned by the prince of Wales, to whom he was introduced, by Mr. (afterwards lord) Lyttelton, as to his circumftances, a penfion of 100*l.* a year was granted to him.

Upon the introduction of his fecond tragedy, "Agamemnon," to Drury-lane, in 1738, he was fo anxious concerning its fuccefs, that he is faid to have been thrown into a copious perfpiration. His "Edward and Eleonora" was prevented from appearing by the interference of the lord chamberlain. The "Mafque of Alfred," performed before the prince at Cliefden-houfe, in 1740, was the joint production of himfelf and Mallet; and in this piece was introduced the famous fong of "Rule Britannia," the production of one or other of thefe two perfons. The moft fuccefsful of Thomfon's dramatic pieces was his "Tancred and Sigifmunda," which appeared at Drury-lane in 1745; but his "crowning performance," as one of his biographers calls it, was "The Caftle of Indolence," publifhed in 1746. Our poet was now rendered independent by the intereft of Mr. Lyttelton, who obtained for him the office of furveyor-general of the Leeward iflands, which, after payment of a deputy, yielded him about 300*l.* a year. Death, however, in confequence of a fever occafioned by a cold, deprived him, in Auguft 1748, of the comparative affluence derived from this appointment. His remains were interred in Richmond church, without any memorial; but in 1762 a monument was erected in Weftminfter Abbey, the expence of which was defrayed out of the profits of an edition of his works, publifhed by

Mr

Mr. Millar. His "Coriolanus" was brought on the ſtage by his executors, in 1749, for the benefit of the ſurviving branches of his family. The prologue, compoſed by Lyttelton, was very feelingly delivered by Quin, the intimate friend of Thomſon.

Thomſon's perſon was large and awkward, and his countenance unanimated; nor did his appearance or manners indicate genius or refinement. With ſelect friends, however, he was eaſy and cheerful, and univerſally beloved for the kindneſs of his heart, and freedom from thoſe paſſions that ſometimes diſgrace men of literary character. He was indolent and ſelf-indulgent in his habits; although "no poet," as his biographer ſays, "has deſerved more praiſe for the moral tenor of his writings. Unbounded philanthropy, enlarged ideas of the dignity of man, and of his rights, love of virtue, public and private, and a devotional ſpirit, narrowed by no views of ſect or party, give ſoul to his verſe when not merely deſcriptive; but no one can riſe from the peruſal of his pages without melioration of his principles or feelings." His poetical merit is moſt conſpicuous in his "Seaſons," and though Dr. Johnſon charges it with a defect of method, yet as a hiſtory of the year through its changes, depending upon the viciſſitude of the ſeaſons, it adheres ſufficiently to its general plan for preſerving a continuity of ſubject, with due allowances for the moral and philoſophical digreſſions by which it is varied. Its diction, though ſomewhat laboured, is energetic and expreſſive. Its verſification, though it does not indicate a nice ear, is ſeldom unpleaſantly harſh. Upon the whole, continues the biographer now cited, "ſcarcely any poem has been more, and more deſervedly, popular; and it has exerted a powerful influence upon public taſte, not only in this country, but throughout Europe. Thomſon's other pieces in blank verſe diſplay a vivid imagination, a comprehenſive underſtanding, and exalted ſentiments, but are not marked with any peculiar character. The addition to his fame as a poet has principally ariſen from his "Caſtle of Indolence," an allegorical compoſition in the manner of Spenſer." Of his tragedies, the beſt that can be ſaid is that they maintain a reſpectable rank among the productions of the modern ſchool of the drama, which, when they diſappear from the ſtage, are ſeldom taken up in the cloſet. Murdoch's Life of Thomſon. Johnſon's Lives of the Poets. Gen. Biog.

THONE, in *Geography*. See TONE.

THONE, in *Agriculture*, a term ſignifying ſomewhat damp and cold, not thoroughly dry. Alſo flaxid or limber, as undried hay, corn, or ſtraw in a moiſt ſtate.

THONGTONG, in *Geography*, a town of the Birman empire; 10 miles N.W. of Raynangong.

THONNA, a town of Saxony, in the principality of Gotha; 12 miles from Gotha.

THONNAUSTAUFF, a town of Bavaria, near the Danube; 3 miles from Ratiſbon.

THONNES, or THONNEX, a town of France, in the department of the Leman; 9 miles S.E. of Annecy.

THONON, or TONON, a town of France, in the department of the Leman, late capital of the duchy of Chablais, on the lake of Geneva, ſituated on a plain a little elevated. It is not environed with walls, but was formerly defended by a ſtrong caſtle, ſurrounded with lofty towers, where Amadeus VIII. and IX. and Louis, dukes of Savoy, reſided for ſome time. The caſtle was burned and demoliſhed, in the 16th century, by the Bernois. It has one pariſh church and ſeveral convents; 18 miles N.E. of Geneva. N. lat. 46° 18′. E. long. 6° 32′.

THOPH. See MACHUL and SISTRUM.

THOPHAIL, ABU GIAFAR, in *Biography*, a celebrated Peripatetic philoſopher and phyſician, was a native of Seville in Spain, and preceptor to Maimonides and Averröes. This philoſopher employed the Ariſtotelian doctrine to the purpoſes of enthuſiaſm, in the elegant tale ſtill extant of "Hai Ebr Yockdan;" a youth who, having been expoſed when an infant on the ſea-coaſt, was nouriſhed by a hind, and grew up in the woods, without any intercourſe with human beings; and who, by the unaided exertions of his own powers, attained to the knowledge of things natural and ſupernatural, and arrived at the felicity of an intuitive intercourſe with the divine mind. This piece is written with ſuch elegance of language and vigour of imagination, that, notwithſtanding the improbability of the ſtory, it has been univerſally admired. It exhibits a favourable ſpecimen of Peripatetic philoſophy, as it was taught among the Saracens; and, at the ſame time, affords a memorable example of the unnatural alliance, which was now ſo generally eſtabliſhed between philoſophy and fanaticiſm. This work was tranſlated by Edward Pococke, jun. from the Arabic into Latin, under the title of "Philoſophus Autodidactus," and printed in 4to. at Oxford, in 1700. It was alſo tranſlated into Engliſh by S. Hoadley, profeſſor of Arabic in Cambridge, ed. Lond. 1711, 8vo., and alſo into Dutch. Thophail is ſaid to have written ſeveral other works, and died at Seville in 1175. Brucker by Enfield. Gen. Biog.

THOR, in *Mythology*, a deity worſhipped by the ancient inhabitants of the northern nations; particularly by the ancient Scandinavians and Celts. Julius Cæſar (Com. lib. vi. c. 17.) ſpeaks of a god of the Gauls, who was charged with the conduct of the atmoſphere, and preſided over the winds and tempeſts, under the name of Jupiter: but Lucan gives him a name, which bears a greater reſemblance to that of Thor, *viz. Taranis*, a word which, to this day, in the Welſh language, ſignifies *thunder*. The authority of this deity extended over the winds and ſeaſons, and particularly over thunder and lightning. In the ſyſtem of the primitive religion, the god Thor was probably one of thoſe genii, or ſubaltern deities, ſprung from the union of Odin, or the Supreme Being, and the Earth. The Edda calls him the moſt valiant of the ſons of Odin; and in the Icelandic mythology, he is conſidered as the defender and avenger of the gods. He always carried a mace, or club, which as often as he diſcharged it returned to his hand of itſelf; he graſped it with gauntlets of iron, and was poſſeſſed of a girdle which had the virtue to renew his ſtrength as often as was needful. With theſe formidable arms he overthrew the monſters and giants, when the gods ſent him to oppoſe their enemies. Thor, Friga, or Freya, and Odin, compoſed the court or ſupreme council of the gods, and were the principal objects of the worſhip and veneration of all the Scandinavians. The Danes ſeem to have paid the higheſt honour to Odin. The inhabitants of Norway and Iceland appear to have been under the immediate protection of Thor: and the Swedes choſe for their tutelar deity Freya, or Frey, an inferior divinity, who, according to the Edda, preſided over the ſeaſons of the year, and beſtowed peace, fertility, and riches.

There was a day conſecrated to Thor, which ſtill retains his name in the Daniſh, Swediſh, Engliſh, and Low Dutch languages, *viz. Thurſday.* This word has been rendered into Latin by *dies Jovis*, or *Jupiter's day;* for this deity, according to the ideas of the Romans, was the god of thunder. Mallet's North. Ant. vol. i. p. 95.

THOR, *Le*, in *Geography*, a town of France, in the department of the Mouths of the Rhone; 9 miles E. of Avignon.

THORA, a town of Hindooſtan, in the circar of Rantampour; 45 miles S. of Rantampour.

THORA,

THORA, in *Botany*. See ACONITUM.

THORACIC, in *Anatomy*, an epithet applied to various parts in and about the cheſt, as to the aorta above the diaphragm, and to ſome branches of the axillary artery (ſee ARTERY); to ſome branches of the axillary plexus of nerves (ſee NERVE); to the trunk of the abſorbing ſyſtem of veſſels. See ABSORBENTS.

THORACICI, in the *Linnæan Syſtem of Ichthyology*, the name of the third order of bony fiſhes, reſpiring by means of gills only: the character of which is, that the bronchia are oſſiculated, and the ventral fins are placed underneath the thorax. This order in Gmelin's edition of the Linnæan ſyſtem, includes nineteen genera, and a good number of ſpecies. The genera are, the *cepola*, *echeneis*, *coryphæna*, *gobius*, *cottus*, *ſcorpæna*, *zeus*, *pleuronectes*, *chætodon*, *ſparus*, *ſcarus*, *labrus*, *ſciæna*, *perca*, *gaſteroſteus*, *ſcomber*, *centrogaſter*, *mullus*, and *trigla*.

THORÆ RADIX, in the *Materia Medica*, the name of a root which keeps its place in the catalogues of officinal ſimples, but is ſeldom uſed. See ACONITUM and ANTHORA.

The plant which produces it is the *thora valdenſis* of Gerarde. It is kept in the gardens of the curious, but grows wild in the mountainous parts of Germany. The root is compoſed of a number of granules or ſmall lumps, like that of the common ranunculus; the leaves are roundiſh, and ſtand on ſmall pedicles, and the ſtalks are about ſix inches high, and the flowers yellow, and like thoſe of our common wild ranunculuſes.

The root is acrid and corroſive, and the juice of the leaves is ſaid to poiſon animals, and to have been uſed by the ancients for that purpoſe.

THORAME, in *Geography*, a town of France, in the department of the Lower Alps; 13 miles E. of Digne.

THORAX, in *Anatomy*, that diviſion of the ſkeleton which contains the bones forming the cavity of the cheſt; or it is uſed to denote the cavity of the cheſt. See LUNG, where the bones and their articulations are deſcribed, as well as the cavity they form, and its contents.

THORAX. For an account of the operation of tapping, refer to EMPYEMA, PARACENTESIS, and WOUNDS *of the Thorax*.

The ſubject of wounds of the cheſt will be found in the article WOUNDS.

THORDO, DIACONUS or LEGIFER, in *Biography*, deſcended from an ancient family, was provincial judge in North Jutland, and flouriſhed in the time of Waldemar III., or about the year 1350. He was the author of the following work; " Conſtitutio Voldemari Regis, per Thordonem Legiferum, &c." Ripis, 1504, et Havn. 1508, 4to.; tranſlated into Latin together with Waldemar's Jutland Laws, and afterwards publiſhed in Ludewig's " Reliquiæ MSS." tom. xii. and alſo in German by Eric Krabbe, in " Weſtphal's Monuments." Gen. Biog.

THORDSEN, or THEODORI STURLA, called alſo *Frode* or *Polyhiſtor*, was born in Iceland, about the beginning of the 13th century. His father was Thordur Sturleſon, brother to the celebrated Snorro. (See STURLESON.) He is repreſented to be one of the greateſt Icelandic poets of his time, as well as an eminent lawyer and hiſtorian. His talents excited enemies, ſo that he was forcibly carried away from the iſland in 1263, and conveyed to Norway, where he was favourably received by the king Magnus Lagebæter, admitted into his council, and appointed his hiſtorian and dapifer, one of the higheſt offices at the Norwegian court. Afterwards, however, he returned to Iceland, and having been chief juſtice of the country for many years, died in 1284. His works are " Landnama Saga," or " Liber Originum Iſlandiæ," publiſhed entire by biſhop Thordur Thorlakſen, Skalholt, 1688, 4to., and by J. Finnæus, Havn. 1774, 4to.:—A continuation of " Sturlunga Saga," or the hiſtory of the Sturla family, and almoſt the whole of Iceland, during his time, which was begun by the learned biſhop Brand:—" The Hiſtory of King Haager Haagenſen," publiſhed at the expence of the crown-prince Frederic:—" The Hiſtory of King Magnus Lagebæter," compiled from the public records of the kingdom, the greater part of which has been loſt. Gen. Biog.

THORESBY, RALPH, an eminent antiquary, tbe ſon of a conſiderable merchant of an ancient family at Leeds, where he was born in the year 1658. His father belonged to the body of Preſbyterians, and being addicted to antiquarian ſtudies, founded the collection entitled " Muſeum Thoreſbianum." The ſubject of this article was intended for a mercantile profeſſion, and in order to complete his education, begun at Leeds, and proſecuted in London, he was ſent, in his twentieth year, to Rotterdam, to acquire the Dutch and French languages. But his father dying in 1679, he ſucceeded him in buſineſs, married, and ſettled in his native town. To antiquarian reſearches, for which his father's example had given him an early taſte, he devoted much time and attention. In the earlier period of his life he had been an occaſional conformiſt, in common with many of thoſe who were called Diſſenters, and diſguſted by the indiſcreet zeal of his paſtor in maturer life, as well as probably influenced by his dioceſan, archbiſhop Sharp, he joined in full communion with the eſtabliſhed church. His connection and correſpondence with perſons engaged in ſimilar purſuits with his own were gradually enlarged: and upon communicating, by Dr. Martin Liſter, an account of ſome Roman antiquities diſcovered in Yorkſhire, to the Royal Society, he was admitted a member of that learned body in 1697. In 1714 he publiſhed a work in which he had been long engaged, containing a hiſtory of his native town, and entitled " Ducatus Leodenſis; or the Topography of Leedes, and Parts adjacent," together with a catalogue of the antiquities, &c. contained in the Muſeum Thoreſbianum. An hiſtorical part, to which he often refers, and comprehending a view of the ſtate of the northern diſtricts of this kingdom in remote ages, was left in MS. continued to the ſixth century; which MS. being communicated to the editors of the Biographia Britannica, was by them printed entire in the article " Thoreſby." He publiſhed alſo " Vicaria Leodenſis, or the Hiſtory of the Church of Leedes," Lond. 1724, comprehending obſervations on the origin of parochial churches, and the ancient manner of building them, together with biographical memoirs of ſeveral clergymen. In the following year he was ſeized with a paralytic affection, which terminated bis life at the age of ſixty-eight years. Poſſeſſing an extenſive acquaintance with the hiſtory of his country, genealogy and heraldry, and ancient coins and medals, he always manifeſted a diſpoſition to aſſiſt thoſe who were engaged in works of the antiquarian and biographical deſcription. The ſentiments of Mr. Thoreſby were liberal and Catholic; his manners regular, and his diſcharge of ſocial and religious duties exemplary. Biog. Brit.

THORIGNY, in *Geography*, a town of France, in the department of the Channel; 6 miles S.S.E. of St. Lo.—Alſo, a town of France, in the department of the Yonne; 18 miles S.S.E. of Provins.

THORLASKEN GUDBRAND, in *Biography*, an Icelandic writer and prelate, was born at Stadarbakke, in the diſtrict of Holum, in 1542. In 1561 he was ſent to the univerſity of Copenhagen; in 1564 he became rector of the ſchool

school of Holum; and in 1570 he was appointed bishop of that diocese. With a view of diffusing knowledge, he established a printing-press, first at Rupusel, and afterwards at Holum, which he personally superintended. He was one of the most learned of the Icelandic bishops, but too arbitrary in the exercise of his episcopal functions. He died in 1629, in the 85th year of his age. Many considerable works, partly his own, and partly those of others, issued from his press. He also constructed a map of Iceland, which was engraved by Ortelius. Gen. Biog.

THORN, in *Geography*, a city of Prussia, situated on the Vistula, formerly the chief city of Polish Prussia. It was founded by Herman Balck, first grand-master of the Teutonic order, who built the castle of Thorn in 1231. In the following year, the foundation of the town was laid; but the building was discontinued in 1235, on account of the inconvenient situation, and Thorn was built about a German mile farther up the river, on the spot where it now stands. It is supposed to have been called Thorn, because the knights of the Teutonic order, by building this city, opened themselves a *thor* or door into Prussia. When the knights of the Teutonic order enormously abused their power throughout all Prussia, Thorn was the first city which formed the noble scheme of shaking off their oppressive yoke. The inhabitants then put themselves under the protection of Casimir the Great, king of Poland, upon advantageous conditions, as a free city. Thorn has ten gates, and is divided into the Old and the New Town, each of which had formerly its respective council, magistracy, and police. But, in 1454, they were incorporated into one city. They are, however, separated from each other by a wall and moat within the town; and without, they are defended in common by a fine double wall and moats. Thorn was formerly strongly fortified; and it gradually improved its advantageous situation, so as to become a place of very considerable trade, and one of the principal of the Hanse towns. It likewise carried on an extensive commerce in the Baltic, independently of the other cities of that confederacy; for before the river widened so much, and consequently became shallower, ships of burden could come up to the very city. From various causes, in little more than half a century, Thorn greatly declined from its flourishing condition; for it surrendered by capitulation, in 1655, to Charles Gustavus, king of Sweden; and, in 1658, after a vigorous siege, it was taken by the Poles and Brandenburghers. In 1703, it was bombarded and taken by Charles XII. king of Sweden, who not only exhausted it by the heaviest contribution, but also demolished all the fortifications, contrary to the articles of capitulation. Between the years 1708 and 1710, great numbers of its inhabitants were swept away by the plague. In the following years, the revenues of the city suffered considerably by the confederations in Poland, and no less by the commotions occasioned by the competitors for the crown of that kingdom. In 1793, some Prussian troops entered this town, and from that time it has formed part of the dominions of that king; the king of Prussia taking possession of Thorn and Dantzic, together with the palatinates of Posnania, Kalish, &c. agreeably to a proclamation, published on the 25th of March. The soap, ginger-bread, &c. of Thorn, are every where in great request; and, accordingly, great quantities of them are exported. The asparagus that grows wild on some of the city lands, is not inferior to that which is cultivated with so much care in other countries; 70 miles S. of Dantzic. N. lat. 52° 55′. E. long. 18° 30′.

THORN, or *Thoren*, a town of France, in the department of the Lower Meuse. It had a noble abbey, whose superior was a princess. This abbey was assessed in the matricula at one horse or twelve florins; 7 miles S.W. of Ruremond.

THORN, in *Botany*, a name generally given to all trees, or the larger kinds of shrubs, which are armed with spines or prickles, but more particularly applied to the Linnæan genus CRATÆGUS, now sunk in MESPILUS. (See those articles.) Otherwise this name is almost as vaguely applied as its Greek and Latin synonyms, ακανθα and *spina*, neither of which is strictly appropriated to any one plant, or family of plants. Ακανθα, in Dioscorides, is the name of that well-known herb, whose leaves compose the ornamental part of a Corinthian capital, and which is the Brank-ursine, or *Acanthus* of modern botanists, as well as of the generality of writers. But he applies the same likewise to a kind of thistle. The *Acanthus* of Virgil can scarcely be any thing else than the Common Holly, *Ilex Aquifolium*, though we do not find that this idea has occurred to his critics or illustrators. This shrub, so abundant in Italy, cannot be traced, under any other name or allusion, in the poet; while the bright aspect, the saffron or scarlet colour, the pliant twigs of his *Acanthus*; but, above all, its being evergreen and bearing berries, *Georg*. 2. 119, and subjected in winter to the shears of the gardener, *ibid*. 4. 137, are circumstances strikingly appropriate to the Holly, not to the Brank-ursine; though the name may allude to the prickly foliage of either.

THORN-*Apple*. See DATURA, and DATURA *Stramonium*.

THORN, *Black*, or *Sloe-tree*, a species of the *prunus*, called *prunus sylvestris*. See PRUNUS and SLOE.

THORN, *Box*. See LYCIUM.

THORN, *Buck*. See RHAMNUS, and RHAMNUS *Catharticus*.

THORN, *Christ's*. See PALIURUS and RHAMNUS.

THORN, *Cockspur*. See CRATÆGUS, MESPILUS, and PYRUS.

THORN, *Egyptian*, a name sometimes applied to a plant which is armed with strong thorns or prickles, and which is said to have been lately found to make a good hedge-plant when kept low by being well cut in. It is also a very ornamental shrubby tree-plant for pleasure-grounds. See ACACIA.

THORN, *Evergreen*. See MESPILUS and PYRUS.

THORN, *Glastonbury*, a variety of the hawthorn. See CRATÆGUS and MESPILUS.

THORN, *Goat's*, a species of *Astragalus*; which see. See also TRAGACANTHA.

THORN, *Haw*. The fruit of this thorn has been found useful by farmers in feeding team and other horses. See CRATÆGUS and MESPILUS.

THORN, *Lily*. See CATESBÆA.

THORN, *Purging*. See RHAMNUS.

THORN, *Scorpion's*, a species of *Ulex*; which see.

THORN, *Spanish Hedge-hog*, a species of *Anthyllis*; which see.

THORN, *White*, a species of *Cratægus*; which see. See also MESPILUS.

THORN, in *Vegetable Physiology*. See SPINA and FULCRA.

THORN-*Hedges*, in *Agriculture*, a term often applied to such as are made of that plant, whether of the white or black kind. They in most cases form the best fences. See FENCE, QUICKSET, QUICKSET-*Hedge*, &c.

THORNBACK, in *Ichthyology*, the English name of a species of ray-fish, the *raia clavata* of Linnæus, prickly on the back, and with tuberculose teeth, and a transverse cartilage in the belly: the young fish have very few spines on them, and their backs are often spotted with white, and each spot encircled with black. (See RAIA.) This species frequents our fandy fhores, is very voracious, and feeds on all forts of flat fifh, and is particularly fond of herrings and fand-eels, and fometimes eats cruftaceous animals, fuch as crabs. The thornbacks begin to generate in June, and bring forth their young in July and Auguft, which (as well as thofe of the fkate) before they are old enough to breed, are called *maids*. They begin to be in feafon in November, and continue fo later than fkate; but the young of both are good at all times of the year. Pennant.

THORNBURGH, in *Geography*, a town of Virginia; 74 miles S. of Wafhington.

THORNBURY, an ancient market-town in the lower divifion of the hundred of the fame name, in the county of Gloucefter, England; is fituated 24 miles S.W. from the city of Gloucefter, and 122 miles W. by N. from London. The town confifts principally of three ftreets, in the form of the Roman Y, "having firft," fays Leland, "one longe ftrete, and two hornes goyne owt of it." The corporation is compofed of a mayor, twelve aldermen, and a town-clerk; but the power of thefe officers is become much limited by difufe. A weekly market is held on Saturdays, but is not much frequented: here are three annual fairs. The church is fpacious and handfome: the tower is lofty, and ornamented with rich open-worked battlements, and eight pinnacles. The population, as returned under the act of the year 1811, amounted to 1083; the number of houfes to 216. At the north end of the town are the remains of an unfinifhed caftle, which was commenced by Edward Stafford, duke of Buckingham, but ftopped when he was beheaded in 1522. This caftle may be confidered as particularly deferving notice, from its affording fome interefting fpecimens of the laft gradation of caftellated architecture. The former fplendour of Richmond and Nonfuch, which were contemporary with it, are known only by defcription and engravings; and Hampton Court, though it rofe under the hands of Wolfey at the fame period, is certainly lefs rich in the minute and capricious ornaments peculiar to the buildings of Henry VII. and his fucceffor. A fmall part moft refembling Thornbury, is feen at Windfor Caftle, in an addition made by the firft-mentioned fovereign. It is evident, from a furvey made in the year 1582, that the whole fouthern fide was habitable, and that it confifted of feveral chambers, of magnificent dimenfions. The tower, the walls of which are perfect, was divided into four rooms, the duke's own apartments: this ftands at the fouth-weft angle of the caftle. The duke was meditating the completion of the quadrangle which would have inclofed an area of two acres and a half, when his fatal attainder clofed his views for ever. Within the circuit walls twelve acres were inclofed: annexed to them are fmall rooms, intended as barracks for foldiers. In the reign of Elizabeth, the principal timbers were taken away; and time has forwarded the dilapidation. A fingular coincidence has been remarked between the front of Thornbury caftle and that of Chriftchurch, Oxford; and it appears as if the rivalry of the duke and cardinal Wolfey was exerted even in their architecture. — Beauties of England and Wales, vol. v. Gloucefterfhire; by J. Britton and E. W. Brayley. Lyfons's "Gloucefterfhire Antiquities," folio.

THORNE, a market-town in the lower divifion of the wapentake of Strafford and Tickhill, in the Weft Riding of the county of York, England; is fituated near the fouth bank of the river Don, at the diftance of 10 miles N.E. from Doncafter, 29 miles S. by E. from York, and 167 N. by W. from London. The town appears to be in a progreffive ftate of improvement: it carries on a confiderable commerce by the Don; and veffels trade regularly to London. Ships of a fize fufficiently large for the coafting trade, are built at the fuburb called Hangman Hill, on the banks of the river, which is alfo the landing-place for all the merchandize. A canal cut from the Don to the Trent paffes within a furlong on the weft fide of the town. A weekly market is held on Wednefdays; and two fairs annually, each of three days continuance, for horned cattle, woollen cloth, &c. According to the population returns of the year 1811, Thorne contained 637 houfes, the number of inhabitants being 2713. The country about Thorne is for the moft part fertile; but low, flat, and totally unpicturefque. On the eaft fide of the town is a field of rich fandy loam, and more elevated than the other lands in the vicinity. Beyond this are vaft moors, which however are moftly drained and inclofed.

At the diftance of about three miles weftward from Thorne, and on the Doncafter road, is Hatfield, a large village, famous in the annals of hiftory for the battle fought there A.D. 633, by Edwin, the firft Chriftian king of Northumbria, againft Cadwallo, king of Wales, and Penda, the Pagan king of Mercia. This conflict, which was extremely fanguinary, terminated fatally for the Northumbrians: their monarch, and his eldeft fon Offrid, were flain, their kingdom fubdued, and their country laid wafte. This village was the birth-place of William de Hatfield, the fecond fon of king Edward III. The extenfive level of Hatfield Chace is faid to contain within its limits 180,000 acres, of which nearly one-half was formerly a great part of the year under water. It was fold by Charles I. to Cornelius Vermuiden, a naturalized Dutchman, without the confent of the commiffioners and tenants, to drain and cultivate; which he effected at the expence of about 400,000*l.*, but the affair involved him in ruinous law-fuits. In the year 1811, an act was obtained for inclofing between eight and nine thoufand acres of rich common in this neighbourhood, which muft be ultimately productive of great public and private advantage. — Beauties of England and Wales, vol. xvi. Yorkfhire; by J. Bigland.

THORNE, a fmall ifland of Denmark, in the Little Belt, near the ifland of Funen. N. lat. 59° 15′. E. long. 9° 53′.

THORNESS BAY, a bay on the N.W. coaft of the Ifle of Wight, between Newtown and Cowes.

THORNEY, a market-town in the north part of the hundred of Witchford, and county of Cambridge, England; is fituated in the north-weft fide of the county bordering on Northamptonfhire, 10 miles W. from March, 5 miles S.E. from Crowland, and 84 miles N. from London. It is furrounded by low and fertile grounds, which are now in a very complete ftate of drainage, the expence of which is defrayed by an annual tax of about a fhilling *per* acre. Its ancient appellation was Ankeridge, which it obtained from the anchorites who dwelt in a monaftery, or rather an affemblage of hermitages, founded here about the year 662, by Saxulphus, the firft abbot of Peterborough. The Danes deftroyed thefe hermitages in 870, and the place lay wafte till 972, when Ethelwold, bifhop of Winchefter, founded on the fcite an abbey for Benedictine monks, which became an opulent eftablifhment, and ranked among the mitred abbeys. In the year 1085, the ancient church was taken down, and a new one commenced by the abbot Gunter, but it was not completed till 1128. This ftructure poffeffed confiderable magnificence, and was, according to Brown Willis, "at leaft five times as large as at prefent." When the abbey was diffolved by Henry VIII. great part of the church was deftroyed; but the remainder efcaped by being made parochial. The weft front, which is the entrance to the church,

church, is the moft perfect part of the ancient building. The revenues of the abbey were eftimated, at the diffolution, at 411*l.* 12*s.* 11*d.* clear yearly value. Great part of its poffeffions, with the fcite, was granted in 1549 to John, lord Ruffell, anceftor to the duke of Bedford, who is lord of the manor, and owner, not only of the town, but alfo of 19,000 acres of the furrounding lands. This extenfive property is divided into farms from 25*l.* to 400*l.* *per annum*, generally in a very improved ftate of cultivation. A market is held on Thurfdays, and two annual fairs were granted for Thorney to Francis, earl of Bedford, in the 13th year of Charles I. by the charter of incorporation for the government of the Bedford Level. The inhabitants of the parifh, who are chiefly the defcendants of French Proteftants, are ftated in the population return of the year 1811, to amount to 1675: the number of houfes being 251.—Lyfons's Magna Britannia, vol. ii. part 1. Cambridgefhire. Beauties of England and Wales, vol. ii. Cambridgefhire; by J. Britton and E. W. Brayley.

THORNEY *Ifland*, a fmall ifland, in a bay of the Englifh Channel, near the coaft of Suffex, about four miles in circumference, with a village of the fame name, at the mouth of the Lavant; 7 miles S.W. of Chichefter.

THORNHILL, *Sir* JAMES, in *Biography*, may be called the father of hiftoric painting in England. He was the fon of a gentleman of an ancient family in Dorfetfhire, and was born at Weymouth in 1676. His family having fallen in fortune, he was obliged to refort to fome profeffion for fupport, and guided by an early tafte for painting, fixed upon that art as a bafe on which to raife a fortune and a name. He came to London, and was affifted by the celebrated phyfician Sydenham, who placed him under the tuition of an artift of little note, whofe name is not known, and to whom, from the ftate of the art at the time, he muft have been far lefs indebted for the progrefs he made, than to his own ingenuity and induftry. After having practifed for a while with fome celebrity, he travelled to Holland and to Flanders; and thence vifited France, but did not proceed to Italy. Moft probably his object in this journey was only to acquire a knowledge of colouring; and he might have fatisfied his mind on compofition and form, by having fpent three years in copying the cartoons of Raphael, which he was permitted to do by the favour of the earl of Halifax. Thefe copies are in oil, and were bought after his death by the then duke of Bedford; and by his grace's fucceffor, the late duke, were prefented to the Royal Academy. They are wrought with care, but lack the delicacy of character and feeling obfervable in the originals. On his return to England, his reputation was increafed, and honour and employment accompanied it. Queen Anne commiffioned him to paint the interior of the cupola of St. Paul's, which he did in eight compartments. The fubject affigned him was the hiftory of St. Paul; and he treated it with confiderable grandeur of ftyle, both as to compofition and execution; but his defign wanted chaftity and fimplicity, and the heads of his figures have not fufficient refinement of expreffion. It was, however, the firft attempt by an Englifhman of the kind, and fully juftified the preference given to him over La Guerre and La Foffe, who were then painting the halls and ftaircafes of our nobility. He was afterwards employed to decorate an apartment at Hampton Court, with emblematical allufions to the hiftory of the queen, and her union with her confort, George, prince of Denmark. But his grand work is the great hall at Greenwich Hofpital, where he has painted naval trophies and allegorical figures in great profufion; and if much praife cannot be given to the purity of the defign, it ought not to be withheld from the brilliancy and vigour of the execution. Altogether, it is a work unrivalled in its kind here, and well entitled him to the honour of knighthood, which George I. foon after conferred upon him. This was fome compenfation to him for the mortification of having his demand for thefe paintings contefted, and being in the end paid only at the labourer's rate of fo much *per* fquare yard, (40*s*).

He had the honour of fo far re-eftablifhing his family influence as could be effected by being chofen to reprefent his native town in parliament; but he did not enjoy his honours long, as he died at the early age of 57, leaving a fon, named alfo James, for whom he had procured the appointment of ferjeant-painter to the king, and a daughter married to Hogarth.

THORNY TREFOIL, in *Botany*. See FAGONIA.

THORNY *Reft-Harrow*, in *Agriculture*, a frequent weed in poor barren pafture land, which is not removed without difficulty, in confequence of its perennial nature.

THOROE, in *Geography*, a fmall ifland of Denmark, in the Little Belt, near the ifland of Funen. N. lat. 55° 15′. E. long. 9° 53′.

THOROLD, a townfhip of Upper Canada.

THOROUGH, the common name of an inter-furrow between two ridges. They fhould always be clean and well-drawn.

THOROUGH-*Bafe*, or accompaniment to a continued bafe by figures.

Thorough-bafe is but an aukward tranflation of the Italian terms *baffo continuo*, by which *accompaniment by figures*, without any other guide for the right-hand on keyed inftruments, was at firft called.

The French term *accompagnement* is the fhorteft and moft comprehenfive title for the harmony expreffed by figures over the bafe; if, as Rameau has done in his "Code de Mufique," we add "for the harpfichord or organ," as there are feveral other kinds of accompaniment befides that on keyed-inftruments.

Rameau defines *accompaniment* or *thorough-bafe* in the following manner. "Accompaniment on the harpfichord or organ, confifts in the execution of a complete and regular harmony, by feeing only the notes of one part of that harmony; and this part is called the bafe, being in reality the bafis or foundation of the whole compofition. This bafe is played with the left-hand, and its harmony with the right."

We fhall endeavour to affift our mufical reader, who has every thing to learn in the art of accompaniment, more by example than precept, and fhall give him a feries of progreffive leffons in the mufical plates, which will explain the whole myftery of mufical combinations from the common chord, to the moft extraneous harmony.

We take it for granted that he is perfectly acquainted with the mufical fcale or gammut, in the bafe and treble clefs at leaft, as well as with the time-table; and that the accidents of flat, fharp, and natural, are familiar to him.

The firft thing, therefore, that we fhall recommend to his ftudy, is a table of intervals, both in notes and figures. See *Plate* II.

N° 1. prefents a fcale in half notes, in which all the flats occur, from the unifon to the 9th; another fcale expreffed by fharps.

2. Number of femitones above the bafe in each interval.

3. Common chords, major and minor, to all the twelve femitones, modulating by 5ths.

4. Modulation in common chords, major and minor alternately, the bafe falling a 3d at each change. And in

 order

order to familiarize the ftudent to thefe chords in every part of the inftrument, he is advifed to make three voyages round the harmonical world: beginning with the 8th uppermoft, then the 5th, and laftly the 3d; and if no miftake is made, the laft chord in each of thefe circumnavigations will be an octave above the firft. But all difficulty in thefe exercifes will be removed, if it be remembered that, in going from chord to chord, only one note is to be changed by the right-hand, which note is always the octave of the new bafe.

5. Exercife of common chords in accompanying the hexachords in all the keys, major and minor, to their fundamental bafes: in the practice of which, dots are placed on the notes in the treble, which are to be played with the little finger. And though only the firft hexachord, or fix notes, is written backwards, each of them is intended to be played backwards as well as forwards.

Many years ago, we tried to reduce all the rules of thorough-bafe to the compafs of a *meffage-card*, and almoft all the combinations expreffed by figures to common chords. And now, if the preceding exercifes of the hand in common chords have done their duty, the ftudent will perceive, from an engraving of the two fides of this *thorough-bafe card*, that what has been explained in words and figures on one fide, is illuftrated with notes on the other.

The fecond card goes fomewhat deeper into harmonical myfteries, by what the French call *la regle de l'octave*, or rule for accompanying with a fpecific chord every note of the key, afcending and defcending; which, if practifed well in all the 24 keys, and impreffed on the memory, will enable the ftudent to figure a bafe himfelf, or to play without figures; and by a feeming divination, without a treble part, to know the harmony that belongs to each bafe of a regular compofition, in a diatonic afcent and defcent.

After thefe chords are literally at the *fingers'-ends* of the ftudent, the following eight rules and exceptions in playing without figures muft be obferved.

1. An accidental *fharp* note in the bafe is generally accompanied with a $^{6}_{5}$, and changes the key to the half note above fuch fharp.

2. An accidental *flat* note in the bafe is generally accompanied with a $^{4}_{2}$, and changes the key to the 4th below fuch flat.

3 To the 5th of a key, if repeated at a clofe, two chords are generally played in modern mufic; the $^{6}_{4}$ and $^{5}_{3}$: in old mufic, the $^{5}_{4}$ $^{-}_{3}$, and fometimes the 7th with the common chord.

4. When the bafe moves *per faltum*, a 3d, 4th, 5th, or 6th, common chords will do.

5. When the bafe rifes a 4th, and falls a 5th alternately, and the contrary, each note may be accompanied by a 7th.

6. In fyncopated or binding notes the $\substack{6\\4\\2}$ are played to the laft part of the ligature, by *anticipation*.

7. Slow notes in the bafe, in old mufic, are generally accompanied, as on the plate, by a $^{4}_{3}$ and $^{9}_{8}$ alternately.

8. *Sufpenfions* of a whole chord, or part of a chord, are expreffed by a dafh (—) preceding the refolution.

The reverfe of the fecond card contains explanations of thefe eight rules in notation.

It muft be remembered, that whoever is ambitious of playing thorough-bafe *without figures*, muft previoufly poffefs the art of accompanying readily *with figures*. See COMPOSITION and COUNTERPOINT, to which thorough-bafe is the beft introduction: as what is good in playing, would be good, as far as *harmony* is concerned, in writing. Invention, fancy, and good tafte, are neceffary to break thefe chords into *melody*.

THOROUGH-*Wax*, in *Botany*. See BUPLEURUM.

THORP ARCH, in *Geography*, a village of England, in the county of York, where is a medicinal fpring, impregnated with fulphur and fteel; 3 miles S.E. of Wetherby.

THORP, *Bifhop's*, a village of England, in the county of York, where the archbifhop has a palace, built by archbifhop Gray in 1241; 3 miles S. of York.

THORPNESS, a cape on the eaft coaft of England, in the county of Suffolk, forming the fouthern part of Solebay.

THORSAKER, a town of Sweden, in Geftricia; 21 miles S.W. of Gefle.

THORSBERG, a mountain of Norway, in the province of Aggerhuus; 18 miles W. of Tonfberg.

THORSHAVEN, a fea-port town of the ifland of Stromoe, and capital of ali the Faroer iflands, as well as the common market, and refidence of the landvogt, and king's counfel.

THORSTORP, a town of Sweden, in Weft Gothland; 28 miles S.E. of Gotheborg.

THOS, THOUS, Θως, in *Zoology*, a name given to an animal of the wolf-kind, but larger than the common wolf, common in Surinam. It is a fpecies of the canis, with a light bent tail, and white belly. It never touches men or cattle, and rather provides its food by cunning than open force; preying chiefly on poultry and water-fowl.

THOTCHI, or THATCHI HOTUN, in *Geography*, a town of Chinefe Tartary; 368 miles W. Tourfan. N. lat. 42° 52'. E. long. 83° 24'.

THOTRA, a town of Hindooftan, in the circar of Rantampour; 40 miles S.S.W. of Rantampour.

THOU, JAMES AUGUSTUS DE, (THUANUS,) in *Biography*, an eminent magiftrate and hiftorian, was the fon of Chriftopher de Thou, prefident of the parliament of Paris, diftinguifhed for integrity and patriotifm, and born at Paris in the year 1553. In the college of Burgundy, where he was placed at the age of ten years, his education was interrupted by a fever, which feemed for fome time to have proved fatal to him; but upon his recovery he ftudied the civil law, firft at Orleans, and afterwards at Valence, under the celebrated Cujacius, in which latter place he commenced an intimate acquaintance with Jofeph Scaliger, which was continued through life. Upon his return to Paris in 1572, he witneffed the horrors of the maffacre of St. Bartholomew, and this fcene impreffed him with an eternal deteftation of bigotry and intolerance. He was originally deftined for the church, with the profpect of valuable preferments, which his uncle, the bifhop of Chartres, intended to refign to him. In the mean while he travelled to Italy, the Low Countries, and Germany; but upon the death of his brother, his views were changed, and the law became his deftined profeffion. After the death of his father, whofe memory he held in high veneration, he was made mafter of requefts in 1584; and in 1587, he married Marie Barbanfon, a lady of a noble family. Upon the revolt of Paris, on occafion of the league, in 1586, he repaired to Henry III. at Chartres, and was deputed by him to confirm the province of Normandy in its allegiance. On the affaffination of the duke of Guife, his family at Paris received public infults, which made it neceffary for his wife to make her efcape in difguife, and he went to the king at Blois, who was almoft deferted, and induced him to form a coalition with Henry, king of Navarre. Being at Venice, he was informed of the affaffination of Henry III., after which he immediately joined the legitimate fucceffor to the crown,

crown, Henry IV., at Chateaudun. The king, fully apprized of his excellent qualities, repofed confidence in him, and employed him in many interefting negociations. On the death of Amyot, the king's principal librarian, De Thou was nominated his fucceffor; and in 1594 he fucceeded his uncle as "prefident á mortier." He officiated as one of the Catholic commiffioners at the theological conference of Fontainebleau between Du Perron and Du Pleffis Mornai; and in the regency of Mary de Medicis, he was one of the directors-general of the finances. At the conference of Loudun, he acquired diftinguifhed reputation by his virtue and ability; and he was joined with cardinal Du Perron in a commiffion for the reform of the univerfity of Paris, and the conftruction of the college-royal, the edifice of which was begun under his fuperintendance. Although De Thou was occupied in a variety of public tranfactions, he referved time for the cultivation of literature, and particularly for that of Latin verfe, in which latter department he publifhed, in 1584, a didactic and defcriptive poem, "De Re Accipitraria," (on Hawking,) which was well received by the learned. He alfo gave to the public other pieces of Latin poetry, fome of which were on fcriptural fubjects. But his "Opus majus," as we may call it, which has eftablifhed his permanent fame, was "The Hiftory of his own Times," the firft part of which appeared in 1604. The condemnation of this interefting work reflects indelible difcredit on Henry IV. and his court: the ground of their enmity feems to have been the freedom with which he fpoke of the popes, clergy, and the houfe of Guife, and the difpofition he manifefted to extenuate the offences charged upon the Huguenots, and to extol the virtues and abilities of that fect. Our author's Hiftory, when completed, confifted of 138 books, comprehending the events from 1545 to 1607. No perfon could be better qualified for undertaking fuch a work; and when we confider his native candour and love of truth, no one was more likely to execute it with impartiality. Mr. Hayley, in his "Effay on Hiftory," has with equal juftice and eloquence characterized this illuftrious writer in the following lines:

"There, in the dignity of virtuous pride,
Thro' painful fcenes of public fervice try'd,
And keenly confcious of his country's woes,
The liberal fpirit of Thuanus rofe:
O'er earth's wide ftage a curious eye he caft,
And caught the living pageant as it paft:
With patriot care moft eager to advance
The rights of nature, and the weal of France!
His language noble, and his temper clear
From faction's rage, and fuperftitious fear!
In wealth laborious! amid wrongs fedate!
His virtue lovely, as his genius great!
Ting'd with fome marks that from his climate fpring,
He priz'd his country, but ador'd his king;
Yet with a zeal from flavifh awe refin'd,
Shone the clear model of a Gallic mind."

To this work De Thou has annexed "Commentaries or Memoirs of his own Life."

Having loft his firft wife in 1601, whofe virtues he celebrated in a Latin poem; and having no iffue, he married, in 1603, a fecond wife, of a noble family, by whom he had three fons and three daughters, and fhe died in 1616. This lofs, and the calamities that befel his country on the murder of Henry IV., are fuppofed to have haftened his own death, which happened in 1617, at the age of 64 years. His library, which was very valuable, and which by his will was to have been kept undivided in his family, was neverthelefs fold after the death of one of his fons. The moft complete edition of De Thou's Hiftory is that publifhed at London in 1733, by Buckley, in 7 vols fol. with memoirs of his life, and other pieces not before publifhed. Dr. Mead, always diftinguifhed as the munificent patron of letters, contributed to render this edition peculiarly valuable, by the purchafe of Carte's papers, which he had collected during his refidence in France.—Mem. of De Thou, by himfelf. Moreri. Nouv. Dict. Hift. Gen. Biog.

The eldeft fon of De Thou, *viz. Francis Auguftus de Thou*, born in 1607, inherited the virtue and talents of his father, and became a mafter of requefts, and afterwards grand-mafter of the royal library, and acquired, by the gentlenefs of his manners and profound learning, general efteem. But falling under the difpleafure of cardinal Richelieu, he was kept out of all confidential employments; and by this flight he was induced to join the party of the favourite Cinqmars, who entered into a fecret negociation with Spain. De Thou was implicated in the confpiracy, and capitally condemned. He was beheaded at Lyons, in 1642, at the age of 35, dying with great refolution, and univerfally lamented; a victim to the vindictive feeling of Richelieu, becaufe his father, in his Hiftory, had fpoken in opprobrious terms of one of his family.

THOUARCE', in *Geography*, a town of France, in the department of the Mayne and Loire; 12 miles S. of Angers.

THOUARE', a town of France, in the department of the Lower Loire; 5 miles N.E. of Nantes.

THOUARS, a town of France, and principal place of a diftrict, in the department of the Two Sevres, near the river Thoue. The place contains 2035, and the canton 13,950 inhabitants, on a territory of $317\frac{1}{2}$ kiliometres, in 24 communes; 31 miles W. of Poitiers. N. lat. 46° 58'. E. long. 0° 8'.

THOUE, a river of France, which runs into the Loire, a little below St. Florent.

THOUGHT, Sentiment, a general name for all the ideas confequent on the operations of the mind, and even for the operations themfelves.

As, in the idea of thought, there is nothing included of what we include in the idea of an extended fubftance; and that whatever belongs to body, may be denied to belong to thought; we may conclude, that thought is not a mode of extended fubftance, it being the nature of a mode not to be conceived, if the thing, of which it is the mode, be denied. Hence we infer, that thought, not being a mode of extended fubftance, muft be the attribute of fome other fubftance very different.

F. Malebranche, with the fpirit of a Cartefian, denies that a man who thinks ferioufly on the matter, can doubt but that the effence of the mind confifts altogether in thought, as that of matter does in extenfion; and that, according to the various modifications of thought, the mind fometimes wills, fometimes imagines, &c.; as, according to the various modifications of extenfion, matter is fometimes water, fometimes wood, fire, &c. By the way, by thought he does not mean the particular modifications of the foul, *i. e.* fuch or fuch a thought, but thought, or thinking in the general, confidered as capable of all kinds of modifications, or ideas; as by extenfion he does not mean fuch or fuch an extenfion, as a fquare, oval, or the like, but extenfion in the abftract, confidered as fufceptible of all kinds of modifications or figures.

He adds, that he takes it to be impoffible to conceive a mind which does not think, though it be eafy to conceive one which does not feel, or imagine, or will; in like manner as it is impoffible to conceive a matter which is not extended, though it be eafy to conceive one that is neither earth nor metal, nor fquare, nor round, nor that is even in motion.

Hence it may be concluded, that as it is poffible there may be matter which is neither earth nor metal; nor fquare, nor round, nor even in motion; it is alfo poffible, that a mind may neither perceive heat nor cold, nor joy nor grief, nor imagine any thing, nor will any thing; fo that thefe modifications are not effential to it. Thinking alone, therefore, according to this author, is the effence of the mind, as extenfion alone is the effence of matter.

But this doctrine is not now generally received. The followers of fir Ifaac Newton, and the new philofophy, deny extenfion to be the effence of matter; and the followers of Mr. Locke deny thought to be the effence of the mind.

Thoughts, or *Thaughts*, in a *Boat*, a name given by feamen to the benches on which the men fit down to row.

THOUINIA, in *Botany*, a noble genus, though confifting of only one known fpecies, fo named by the writer of this, in grateful remembrance of his diftinguifhed friend M. André Thouin, member of the Inftitute, and at prefent Profeffor of Agriculture at Paris. This gentleman is one of the original foreign members of the Linnæan Society, and ranks among the beft and moft philofophical cultivators, as well as botanifts, of this or any age. The prefent plant was felected out of the large and fine collection of new and rare fpecimens, given by himfelf to the younger Linnæus, chiefly from the herbarium of Commerfon. We were not aware of its having been named *Humbertia* by its difcoverer, or Endrachium by Lamarck (fee the latter article); where we have remarked that the name is barbarous; we fhould therefore not have adopted it, if known. *Humbertia* is not accounted for, there being no botanift on record of the name of Humbert, nor has any body explained or defended this appellation. The younger Linnæus had indeed eftablifhed a *Thouinia*, *Suppl.* 9, after Thunberg; neither of them fufpecting their plant to be a real *Chionanthus*, the *zeylanica* of *Linn. Sp. Pl.* 11. Swartz moreover, in his *Prodr.* 14, added a fecond fpecies to this fuppofed genus, which he afterwards diftinguifhed from it, by the name of Linociera, under which head our doubts refpecting even that matter are recorded. Confidering therefore our original name no more juftly fuperfeded than our genus, we cannot allow it to give place to M. Poiteau's *Thouinia*, *Ann. du Mufée fafc.* 13, though De Theis has decided otherwife.—Sm. Plant. Ic. 7. Schreb. 793. Willd. Sp. Pl. v. 1. 935. Mart. Mill. Dict. v. 4. (Endrachium; Juff. 133. Humbertia; Lamarck Dict. v. 1. 356. Illuftr. t. 103.)—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Convolvuli*, Juff.

Gen. Ch. *Cal.* Perianth inferior, permanent, of five roundifh, coriaceous, concave leaves; the three outer ones moft thick and rugged, naked; two inner membranous at the margin, filky at the back. *Cor.* of one petal, twice the length of the calyx, bell-fhaped, plaited, externally briftly; its margin in five triangular blunt fegments. *Stam.* Filaments five, awl-fhaped, fmooth, declining, twice the length of the corolla, and inferted into its bafe; anthers incumbent, heart-fhaped, of two lobes. *Pift.* Germen fuperior, ovate, very hairy; ftyle of the length, figure, and fituation of the ftamens, a little fwelling upward; ftigma obtufe, notched. *Peric.* Berry globofe, coriaceous, ftanding on the permanent calyx, of two cells. *Seeds* two in each cell, triangular, fomewhat ovate.

Eff. Ch. Calyx inferior, of five unequal leaves, permanent. Corolla of one petal, bell-fhaped; externally briftly. Style fimple. Berry coriaceous, of two cells. Seeds two in each cell.

Obf. We fee no reafon to adopt Juffieu's or Lamarck's idea of this fruit. They call it a coriaceous, or woody, *capfule*, which does not burft. Commerfon, who alone has examined it frefh, denominates it a *drupa*, which term we would reftrain to pulpy fruits with a fingle *nut*, and therefore we judge the prefent to be a *bacca*, however tough or dry its fubftance may appear when dry.

1. T. *fpectabilis*. Beautiful Thouinia. Sm. Pl. Ic. t. 7. Willd. n. 1. (Humbertia madagafcarienfis; Lamarck n. 1. "H. æviternia; Commerf. MSS. et Ic. Endrach-Endrach; Flac. Hift. Madagafc. 137. f. 100. Arbre immortel.")—Native of Madagafcar; unknown in the gardens of Europe. A tall and large *tree*, whofe wood is yellowifh, compact, heavy, as hard as iron, and almoft incorruptible even under ground. *Lamarck.* The *branches* are round, fcarred, filky towards the ends, where they bear tufts of *leaves*, intermixed with axillary *flowers*. The *leaves* are fcattered, two or three inches long, obovato-lanceolate, obtufe, entire, fmooth and fhining, with a ftrong mid-rib, on channelled filky *footftalks*, without *ftipulas*. *Flowers* on folitary, axillary, fimple *ftalks*, rather fhorter than the leaves, each with a pair of fmall *bracteas* about the middle. Of the colour of the *corolla* we have no account; its length is about an inch; and the filky hairs on the outfide, in a dry ftate, are of a fhining brown. *Fruit* the fize of a fmall plum.

THOUN, in *Geography*, a town of Perfia, in the province of Khoraffan; 75 miles W. of Herat.

THOURY, a town of France, in the department of the Eure and Loire; 3 miles E. of Janville.

THOUSAND. See Numeration.

Thousand *Years' Reign*. See Millennium.

Thousand *Iflands*, in *Geography*, a clufter of fmall iflands in the Straits of Sunda. S. lat. 5° 33′. E. long. 106° 33′.—Alfo, a number of fmall iflands in the river St. Laurence, a little below lake Ontario; the part of the river being called Thoufand Ifland Lake.

Thousand *Lakes*, a name given to a number of fmall lakes in America, near the river Miffiffippi; 60 miles above St. Anthony's Falls.

Thousand *Rocks*, rocks in the river St. Laurence; 72 miles S.W. of Montreal.

THOWLES, in a *Boat*. See Tholes.

THOYNARD, Nicholas, in *Biography*, a native of Orleans, was born in 1629, and at an early age a proficient in the learned languages, and in medallic fcience. His own original works were few, but he was liberal in the affiftance he afforded to other writers. He publifhed two fhort Latin differtations on particular medals, and notes upon "Lactantius de Mortibus Perfecutorum," and alfo a Critique on R. Simon's tranflation of the New Teftament; but his principal performance was "A Concord of the Four Evangelifts," in Greek and Latin, which was printing at the time of his death at Paris in 1706, and appeared in 1707, with learned notes, chronological and hiftorical. In this work he maintains that St. Matthew, of all the evangelifts, paid the leaft regard in his narrative to the order of time. This work was printed at confiderable expence, and is now rare. Moreri.

THOYT. See Thaut.

THRACE, in *Ancient Geography*, an extenfive country of Europe, fituated in the S.E. Its natural boundaries are, on the S. the Ægean fea, the Propontis, and the Bofphorus of Thrace; on the E. the Euxine fea. Its limits to the N. and W. are not fo determinately afcertained. A penin-

A peninfula to the S., between the Melanic gulf and the Hellefpont, made part of the continent of Thrace, but it affumed the name of the Cherfonefus of Thrace.

The continent may be confidered as divided into fix parts: *viz.* 1. The part bounded to the W. by the river Melas, which difcharged itfelf into a gulf of the fame name. To the S. it had the Cherfonefus and the Propontide, and to the E. the Bofphorus of Thrace and the Euxine fea. The chief towns of this part were, on the borders of the Propontide, Ganos, Bifanthe or Rœdeftus, Perinthus called alfo Heraclea, Selymbria, Byfantium; and on the Euxine fea, Dercon, Salmydeffus.

2. The fecond part of Thrace extended from Melas to the Hebrus. It had feveral towns on the banks of the Hebrus, of which, the principal were Philipopolis and Adrianopolis, called alfo Oreftes, and Trajanopolis. The Hebrus took its rife in mount Hæmus, and difcharged itfelf into the Melanic gulf, near the town of Enos.

3. The third part lay between the Hebrus and the lake Biftonis to the W., confifting, according to fome authors, of two fubdivifions, *viz.* from the Hebrus to Liffus, and from Liffus to the lake Biftonis. On the fea-coaft was fituated Maronea, and in the interior of the country Scaptahyla, enriched by its mines.

4. The fourth part was narrow, and lay between the lake Biftonis and the Neftus to the W. The Neftus had its fource to the N.W. of mount Rhodope, and near it were the towns of Jamphorinum and of Nicopolis ad Neftum.

5. The fifth part was fituated N. of the Tæarus, a river which had its fource in the mountains S. of Delnetum, and not far from the Euxine fea, and which ran into the Hebrus on the left fide of it.

6. The fixth part lay N. of that part of the Hebrus which ran from Beffa towards the S.E. to Oreftis. In this part were the towns of Berœa and that of Cabyla, S. of the Hæmus.

The Cherfonefus of Thrace had for its boundaries to the S.E. the Hellefpont and a fmall portion of the Propontide; to the N. the continent of Thrace; to the N.W. the Cardiac or Melanic gulf; this is the peninfula of Romania; and a wall feparated it from the continent.

Thofe who feek the origin of the Thracians in the Old Teftament, trace them to Tiras, one of the firft defcendants of Japhet. But whatever was the origin of thefe ancient people, it is certain that they were warlike and ferocious, and lived very much like favages. They were divided into different hordes, like the ancient Scythians or modern Tartars. This country, on account of the coldnefs of its climate, attributed to its mountains, was regarded by the Greeks with a kind of horror.

Thrace, in the Notitia Imperii, is divided into fix provinces, *viz.* Europe, Rhodope, Thrace, Heminont, the fecond Mœfia, and Scythia. According to the Notitia of Hierocles, thefe fix provinces contain 53 cities, of which the Thrace of Europe contained 14.

Thrace was anciently governed by kings; of thefe, the firft who gave them laws for regulating and civilizing their manners was Zamolxis, a difciple of Pythagoras. Our limits will not allow us to trace its fubfequent hiftory, as far as it is known. The whole, or various parts of this country were poffeffed by Philip of Macedon, by the Athenians, by the Lacedæmonians, and by Alexander, who made a conqueft of the whole country, nor did they recover their liberty till after his death. Lyfimachus, one of the fucceffors of Alexander, was vanquifhed by a defcendant of one of the ancient fovereigns of Thrace. But the tranquillity of the country was of fhort duration; for a party of Gauls, under Brennus, ravaged Greece, and took poffeffion of Thrace. The Thracians afterwards exterminated the Gauls, and reftored the race of their ancient kings. This prince, whofe name was Seuthes, and his defcendants, reigned without interruption till the time of Vefpafian, who reduced Thrace into a Roman province. It afterwards became fubject to the Turks, who now poffefs it. See ROMANIA.

THRACES, or THRACIANS, in *Antiquity*, were an order of gladiators, reputed to be the moft fierce and cruel of all. They were fo called, either becaufe they were natives of Thrace, or wore armour after the manner of that country. The particular weapon they ufed was the *fica*, or faulchion, and their defence confifted in a *parma*, or a little round fhield, proper to their country.

THRACIA GEMMA, a ftone mentioned by Pliny, and defcribed by him to be of three kinds: the one of a plain green, but a confiderably deep and ftrong colour; the other of a paler green, without variegation; and the third fpotted with blood-coloured fpots. This is a fhort defcription, but the ftone feems to have been a jafper, of the nature of our green Oriental jafper and heliotrope.

THRACIUS LAPIS, in the *Natural Hiftory of the Ancients*, a ftone often mentioned, and firft called *Benæ lapis*, from the place where it was firft found, which was in the neighbourhood of Bina, or Bena, a town in Thrace. It has been by fome authors allowed a place in the catalogues of the materia medica; but it is impoffible for us to fay, with any certainty, which, of feveral fubftances now known (which all anfwer in fome degree to the accounts left us of it) is the real body they meant by that name.

It was an inflammable body, found in mines, and in the beds of rivers; and, in burning, afforded a very offenfive fmell.

Some of the late authors have fuppofed it was our common pit-coal the ancients expreffed by this name; others, that it was jet; and others, the common cannel coal. Hill's Theophraftus, p. 34.

THRANITÆ, in the *Roman Trireme-gallies*, or thofe which had three rows of rowers; thofe of the upper row were called by this name, the fecond the *zygitæ*, and the loweft *thalamitæ*.

The *zygitæ*, or middle row of men, in thefe veffels, took up but very little room, having a conveniency of moving their hands and oars under the feats of thofe who fat next before them. See ENNERIS and POLYCROTA.

THRAPSTON, in *Geography*, a fmall market-town in the hundred of Navisford, and county of Northampton, England; is fituated on the fouthern banks of the river Nen, 22 miles N.E. by E. from the town of Northampton, and 75 miles N.N.W. from London. The town, in general, is well-built; and at the weft end is a handfome ftone bridge croffing the Nen. By this river a confiderable trade is carried on with Lynn, Northampton, and various other towns in its courfe. The country round Thrapfton is open, and affords extenfive profpects: from an eminence, half a mile to the fouth-eaft, may be feen at one view thirty-fix church towers and fpires. An annual court-leet and court-baron is held here; at which are appointed the governing officers, a conftable, and a thirdborough; and alfo bread-weighers, whofe office is to fee that the bread, butter, and every other marketable commodity, is good and of juft weight. A well-fupplied market is held on Thurfdays; it is the largeft mart for hogs in the country: that branch alone returns every market-day, on an average, about 500*l.* Here are alfo two annual fairs, befides a large market, equal to either of the fairs, which is held yearly at Michaelmas. The population return of the year 1811, ftates the number of houfes in this town to be 133, occupied by 708 perfons. It appears from Leland, that there was formerly a monaftic eftablifhment here. He fays, "At the very end of Thrapefton bridge ftand ruines of a very large hermitage, and principally welle buildid, but a late difcoverid and fuppreffid."—Beauties of England and Wales, vol. xi. Northamptonfhire; by J. Evans and J. Britton.

THRASEA Pætus, in *Biography*, a Roman fenator, who deferves to be recorded for his integrity and patriotifm, was a native of Padua; educated in Stoical tenets, and a great admirer of Cato of Utica, whofe life he compofed. As a fenator, he was a ftrenuous affertor of the liberty that remained under imperial defpotifm, and on this account he expofed himfelf to the obloquy of all the fycophants of power. His integrity commanded the acknowledgment of Nero, the execrable tyrant who put him to death, and many inftances occur of his undaunted fortitude in maintaining it. We can only felect the following: After Nero had committed the deteftable crime of matricide, when the fervile fenate was decreeing folemn thankfgiving and annual feftivals to commemorate the event, Thrafea, who, we are told, had been accuftomed to fuffer other adulations to pafs in filence, or with a flight affent, marked the profligacy of thefe motions by walking out of the fenate-houfe; thus openly expofing his life to a danger which he contemned; for, conformably to the Stoical principles, he was ufed to fay, 'Nero may kill me, but he cannot hurt me.' But though Thrafea often efcaped the brutal vengeance of this imperial tyrant, his fate was at length decreed. In the year 66, the 13th of Nero, this monfter having imbrued his hands in the blood of many of the moft illuftrious Romans, now refolved, fays Tacitus, to extirpate virtue itfelf, by the deftruction of Thrafea Pætus and Barcas Soranus. The amount of the charges againft Thrafea only evinced his contempt of the bafe adulation of the fenate, and his difpleafure with the vices and enormities of the reign. No defence could be of any avail, and therefore Thrafea prepared in filence to fubmit to his fate. When the determination of the fenate was announced to him, he was in his garden furrounded by a number of illuftrious perfons of both fexes, and attentively liftening to Demetrius, a Cynic philofopher, who was difcourfing on the nature of the foul, and its feparation from the body. Having received the decree of the fenate, he retired into his bed-chamber, and laid bare the veins of both arms, and then bled to death. Tacit. Annal. Suetonius. Dion Caff. Plin. Epift.

THRASHING, &c. in *Agriculture*. See Threshing.

THRASOS, a term ufed by Hippocrates, to exprefs a wildnefs and fiercenefs in the eyes of perfons who approach to a delirium.

THRASYBULUS, in *Biography*, an eminent Athenian, was the fon of Lycus, and the reftorer of liberty to his country. When the government of the 400 fucceeded the overthrow of the democracy in the year B.C. 411, he was commander of a galley; and in connection with Thrafyllus, he deftroyed the ariftocracy in the camp at Samos, and re-eftablifhed democracy there, and then propofed the recall of Alcibiades, in exile at Magnefia, and reftored him to his country. Thrafybulus and Thrafyllus, having purfued the Peloponnefian fleet, brought it to an action in the ftraits between Seftos and Abydus, in which the Athenians captured 20 fhips of the enemy, with the lofs of 15 of their own. Another engagement foon after occurred, and the refult of the arrival of Alcibiades's fquadron was a complete victory on the part of the Athenians. When Alcibiades was made general of the Athenian forces both by fea and land, he nominated Thrafybulus for one of his colleagues; but a mifunderftanding afterwards taking place between them, Thrafybulus impeached Alcibiades before an affembly of the Athenians, and procured his difgrace. On occafion of the eftablifhment of the thirty tyrants at Athens by the influence of the Lacedæmonians, Thrafybulus was one of feveral other citizens who took refuge in the Theban territory; and zealous for the emancipation of his country from fervitude, he engaged a fmall body of fugitives to join him in an expedition to Attica, and took poffeffion of the important fortrefs of Phyla, on the frontiers of Bœotia. Befieged by the Greeks, Thrafybulus by his activity repulfed them, and even followed them in diforder to Athens. Having alfo furprifed a poft which they occupied near Phyla, the thirty tyrants removed from Athens to Eleufis, and Thrafybulus feized this opportunity of attacking the Piræus, and his enterprife fucceeded. He then iffued a proclamation, animating the Athenians to refift their tyrants, and to reftore a free government. Having done this, he eftablifhed himfelf in the Piræus. The conftitution of Athens was then changed, by fubftituting inftead of the thirty tyrants, ten magiftrates, one from each tribe. The Lacedæmonians ftill retained their influence over thefe magiftrates, who fent to Sparta foliciting affiftance againft Thrafybulus. At length, however, this refolute commander prevailed fo as to open a negotiation between the Athenians and the Spartan government, which terminated in the withdrawing of the Spartan garrifon, and the re-eftablifhment of a popular conftitution at Athens. This happy clofe of the conteft was followed by the union of citizens of both parties, in a folemn thankfgiving to Minerva at her temple in the citadel, when Thrafybulus exhorted them to future concord. The remaining tyrants at Eleufis endeavoured to foment diffenfions in Athens; but the bufinefs terminated in an act of amnefty or oblivion, which was paffed by the influence of Thrafybulus in the affembly of the people, and ratified by an oath. This revolution happened in the year B.C. 401. In accomplifhing this event, Thrafybulus acted with the moft difinterefted patriotifm; for the thirty tyrants, when he feized the caftle of Phyla, had offered to make him one of their number, and to pardon any twelve of the exiles whom he might name; to which offer he replied, that exile was much more honourable than any civil authority purchafed on fuch conditions. Thrafybulus remained for fome time in unmolefted retirement, enjoying the honour accompanying the olive wreath, which, according to the fimple manners of the age, was beftowed upon him for his fervices. But in the year B.C. 390, after the death of Conon, the foreign poffeffions and influence of the Athenians were in danger of being loft; and therefore a fleet of forty fhips was placed under the command of Thrafybulus, with which he failed to the Hellefpont. On this occafion he induced two Thracian princes to become allies to Athens, and compelled the Byzantines and the inhabitants of fome other cities to abolifh their ariftocratical governments, and accept of the Athenian model and alliance. He next proceeded againft the ifle of Lefbos, in the Lacedæmonian intereft, and reduced the whole ifland to obedience. Thence he failed for Rhodes, having previoufly raifed fupplies from the maritime towns of Afia, and the capital of Pamphylia. He alfo indulged his men in private pillage; and thus fo much provoked the inhabitants, that they made an attack in the night on the tents, and put a number of the Athenians to the fword, among whom was Thrafybulus himfelf. Such was the inglorious termination of a life that had been devoted to the benefit of his native country. Corn. Nepos. Un. Hift. Gen. Biog.

THRAVE, or Threave, *of Corn*, in moft parts of England, is twenty-four fheaves, or four fhocks of fix fheaves to to the ſhock: though, in ſome counties, they only reckon twelve ſhocks to the thrave.

King Athelſtan, anno 923, gave by charter, to St. John of Beverley, four thraves of corn for every plough-land in the Eaſt Riding of Yorkſhire.

> "Ya fou *threve* be heaven king,
> Of ilka plough of eſt riding."

THRAUPIS, in *Ornithology*, a name given by many authors to the bird more commonly called citrinella.

THRAUSMA, a name given by the ancients to a kind of gum ammoniacum, which was drier than the common, and more eaſily crumbled to pieces.

THRAUSTOMICTHES, in *Natural Hiſtory*, the name of a genus of compound earths. The word is derived from the Greek θραυστος, *brittle*, and μιχθεις, *mixt*.

The bodies of this genus are loams compoſed of ſand and a leſs viſcid clay, and are therefore of a friable or crumbly texture.

The earths of this genus are generally uſed to make bricks; and there are ſeveral ſpecies of them. Hill.

THREAD, in the *Linen Manufacture*, a ſmall line or twiſt of flax, the weaving of which compoſes cloth. There is a ſtronger kind made uſe of to ſew the ſeams of linen garments, or to mend them. The ſame term is applicable to cotton or wool. See SPINNING.

Thread, ſays an eminent French writer (Pajot des Charmes), bleached by the oxygenated muriatic acid, may be uſed by the ſempſtreſs with much greater ſpeed and briſkneſs than thread of the ſame quality bleached in the field: it is leſs brittle, and may be ſtruck much more effectually home to its place in weaving, and does not move afterwards. This information, he ſays, was received by him from impartial and unprejudiced manufacturers.

The thread of the Laplanders is very fine, white, and ſtrong, but it is of a very different nature from our's; they know nothing of flax or hemp, nor of any other plant whoſe ſtalks might ſupply the place of theſe in making thread, but their's is made of the ſinews of the rein-deer.

They kill of theſe animals a very great number continually, partly for food, partly for the ſkins, which they uſe in clothing themſelves, covering their huts, and on many other occaſions; the ſinews of all they kill are very carefully preſerved, and delivered to the women, whoſe province it is to prepare this neceſſary matter. They beat the ſinews very well, after having ſteeped them a long time in water, and then they ſpin them out.

The thread they thus make is of any degree of fineneſs they pleaſe; but it is never any longer than the ſinew from which it is made. They uſe this in ſewing their clothes, ſhoes, gloves, &c. and the trappings of their rein-deer. The threads of the ſame ſinew are laid up together, and are all of a length; and as the different ſinews afford them very different lengths, they accordingly pick out ſuch as the preſent uſe requires, both in regard to length and fineneſs. This ſort of thread is made with much more labour than our's; but it is greatly ſuperior to it on many occaſions, where ſtrength is rather required than beauty.

Theſe people have, beſides this, a way of making a ſort of yarn of ſheep's wool, which they weave into garters and a ſort of ribbands, uſed by way of ornament; but they place no value on it, becauſe of its want of ſtrength. Scheffer's Hiſt. Lapland.

THREAD, in *Botany*, is underſtood of thoſe capillaments uſually found in the middle of flowers, as in the lily, tulip, roſe, &c. There are two kinds; thoſe which ſupport apices, are particularly called *ſtamina*; and thoſe which have none, *piſtilla*.

THREAD, *Gold*. See GOLD.

THREAD, *Virgin's*. See VIRGIN.

THREADS, *Air*, a term uſed by ſome to expreſs thoſe fine long white filaments, or thready ſubſtances, which we meet with in vaſt numbers floating about in the air in Auguſt and September.

The world has been much perplexed about the generation of theſe, till it was known that they were the work of ſpiders, and that they ſerved thoſe creatures to move from place to place by. They are long, downy, and very ſoft, and though they hold together when untouched, they ſtick to the fingers in handling, and eaſily break with a light touch.

The general method of theſe creatures ſpinning and weaving the webs, is by letting down the thread, then drawing it after them, and ſo diſpoſing it as they think proper; but in the midſt of their work of this ſort, if they are cloſely obſerved, they will be ſometimes found to deſiſt, and turning the tail to the contrary way of the wind, they will emit a thread with great violence, no leſs than that with which a jet of water is diſcharged from a cock. In this manner they continue darting forth the thread, which the wind takes, and carrying it forwards, it ſoon becomes many yards long. Soon after this the creature will throw herſelf off from the web, and truſting herſelf to the air with this long tail, will aſcend ſwiftly, and to a great height with it. The fragments of theſe lines, or the whole lines, and the ſpiders attached to them, though unobſerved, make theſe air-threads, and the uſe nature deſtines them for, is evidently the wafting of the creature along the air, and giving it an opportunity of preying on gnats, and many other inſects that inhabit the air, out of the reach of theſe creatures by any other means.

When the threads are newly ſpun, they are always ſingle, and are generally ſeen aſcending higher and higher in the air; but when they are ſeen coming down, they are found ſometimes compoſed of three or four others, and either without any ſpider at the ends, or with two or three, or more. It is plain that this happens from the meeting of theſe threads one with another in the air, and their tangling together; and this incommodes the creatures, and brings them down.

Theſe are what fill the air with the looſe threads we ſee in autumn; and as theſe ſoon entangle together, and bring one another down, it is no wonder that they are more frequent in the lower regions of the air, than thoſe with the ſpiders adhering to them, which uſually riſe to great heights, and ſuſtain themſelves there. And hence the origin of the threads was much perplexed among the enquirers, becauſe they were found without any mark of the animal to which they owed their exiſtence. The buſineſs of feeding is not all the uſe of theſe threads, but the creatures evidently ſport and amuſe themſelves by means of them, floating about in the air, and changing height and place at pleaſure.

When a ſpider has once raiſed itſelf from the earth in this manner, it does not deſcend always on the ſame thread it aroſe by, but draws that up at times, and winds it up into a hank with its fore-feet, and darts out another by way of ſupport; and the new thread is made more or leſs long, as it is intended for a higher or lower flight. Philoſ. Tranſ. N° 50.

THREAD *of Glaſs* may be obtained of indefinite minuteneſs by means of the blow-pipe. When no thicker than fine

fine hair, it is extremely flexible and elastic; and if still finer, it may be wound almost like common thread without breaking. The way of doing it is very simple. A piece of glass tube is heated in the lamp, and the end drawn out into a thread by means of another piece of glass cemented to it. When a fine thread is once drawn, the end is carried round a reel or wheel two or three feet in diameter, and by turning the wheel and continuing to heat the tube, an endless thread is drawn out, winding round it as long as the artist pleases or the glass lasts. The quicker the wheel revolves, and the hotter the glass is kept, the finer is the thread, which may thus be made as delicate as a single silk-worm's thread, with extreme flexibility. Different coloured threads are made in this way by using very deeply coloured glasses instead of common glass.

Threads, in *Glass*. See Glass.

THREAF, in *Agriculture*, a term signifying a handful, a bundle, or a pottle, in different districts of the country.

THREATENING Letters, in *Law*. By statute 9 Geo. I. c. 22. amended by stat. 27 Geo. II. c. 15. knowingly to send any letter without a name, or with a fictitious name, demanding money, venison, or any other valuable thing, or threatening (without any demand) to kill any of the king's subjects, or to fire their houses, out-houses, barns or ricks, is made felony without benefit of clergy. This offence was formerly high treason, by 8 Hen. V. c. 6.

The offence of sending letters, threatening to accuse any person of a crime punishable with death, transportation, pillory, or other infamous punishment, with a view to extort from him any money or other valuable chattels, is punishable by stat. 30 Geo. II. c. 24. at the discretion of the court, with fine, imprisonment, pillory, whipping or transportation for seven years. Blackst. Com. book iv.

THREATS, a species of personal injury. Threats and menaces of bodily hurt, through fear of which a man's business is interrupted, are comprehended under this description. A menace alone, without a consequent inconvenience, does not constitute the injury; but, to complete the wrong, there must be both of them together. The remedy for this is in pecuniary damages, to be recovered by action of trespass, *vi et armis;* this being an inchoate, though not an absolute violence. Blackst. Com. book iii.

THREAVE. See Thrave.

Three *Chapters*. See Chapter.

Three *Legs*, *Compasses of*. See Compasses.

Three, *Ombre by*. See Ombre.

Three, *Rule of*. See Rule.

Three-*legged Staff*, an instrument consisting of three wooden legs, made with joints, so as to shut all together, and to take off in the middle, for the better carriage; and usually having on the top a ball or socket: its use is to support and adjust instruments for astronomy, surveying, &c.

Three-*pointed Pick*, in *Agriculture* and *Rural Economy*, a tool of the pick-kind, having the broad end formed in a three-toothed manner, about six inches in length, of great strength, and having the width, from the outsides of the teeth or prongs, of about six inches. The other end is formed in the gently curving ordinary one-pointed manner. When complete, it is provided with a handle of the strong wooden kind, inserted into the eye or socket of the head-part.

Three-*pronged Fork*, a name sometimes applied to the common fork which is employed for various purposes on farms. See Prong and Spud.

Three-*share Horse-hoe*, a light three-shared tool of the horse-hoe kind, for one horse, which is often found very convenient and useful in working the intervals of ridged turnip crops, and those of similar kinds, as well as for different other purposes of tillage husbandry.

It is constructed and wrought somewhat in the form and manner of the common plough, the hoe parts being so contrived and set as to pare and clean the sides and bottom of each of the ridges in the same operation. See *Horse-Hoe*.

Three *Brethren Hill*, in *Geography*, a town of Scotland, in the county of Selkirk; 5 miles N.W. of Selkirk.

Three *Brothers*, three islands in the Indian ocean. S. lat. 3° 44′. E. long. 62° 25′.—Also, three islands in the East Indian sea. N. lat. 10° 42′. E. long. 108°.—Also, three small islands on the coast of Guiana, in the mouth of the Essequibo.—Also, three small islands in the Indian sea, near the E. coast of Madagascar. S. lat. 13° 20′. E. long. 51° 10′.—Also, three small islands in the East Indian sea. S. lat. 5° 30′. E. long. 132° 15′.—Also, three small islands in the Atlantic, near Prince's island. N. lat. 1° 32′. E. long. 7°.—Also, three small islands in the East Indian sea, near the W. coast of Amboyna. S. lat. 3° 39′. E. long. 128° 18′.—Also, small islands in the East Indian sea, near the S.W. coast of Celebes. S. lat. 5° 25′. E. long. 119° 38′.—Also, small islands in the bay of Gunong Tellu, on the coast of Celebes. S. lat. 1°. E. long. 120° 27′.—Also, small islands in the Indian sea. S. lat. 6°. E. long. 71° 36′.—Also, three hills on the N.E. coast of Terra del Fuego; 9 miles W. of Cape St. Diego.—Also, three hills on the E. coast of New Holland, so called by captain Cook. S. lat. 31° 40′.—Also, three islands on the Spanish Main, near the Mosquito shore. N. lat. 11°. W. long. 82° 52′.

Three *Creek Run*, a river of Virginia, which runs into the Nottoway, N. lat. 36° 36′. W. long. 77° 12′.

Three *Hill Island*, a small island in the Mergui Archipelago. N. lat. 10° 13′.

Three *Hills Island*, one of the New Hebrides, in the South Pacific ocean, about 12 miles in circumference. S. lat. 17° 7′. E. long. 168° 35′. See Hebrides.

Three *Island Harbour*, a bay on the coast of Patagonia, in the Straits of Magellan; 8 miles N.N.W. of Batchelor's river.

Three *Islands*, small islands in the East Indian sea, near the E. coast of Bintang. S. lat. 1° 10′. E. long. 105° 2′.—Also, small islands in the Indian sea, near the coast of Africa. S. lat. 4° 50′.

Three *Islands Bay*, or *Harbour*, a bay on the E. coast of the island of St. Lucia.

Three *Kings*, an island in the South Pacific ocean, near the N. coast of New Zealand, discovered by Tasman. S. lat. 34° 12′. E. long. 172° 12′.

Three *Rivers*. See Trois *Rivières*.

Three *Rivers Harbour*, a bay on the E. coast of the island of St. John, in the gulf of St. Laurence. N. lat. 46° 8′. W. long. 62° 10′.

Three *Sisters*, three small islands on the W. side of Chesapeak bay.—Also, small islands in the East Indian sea. S. lat. 5° 42′. E. long. 105° 41′ 36″.

Three *Stone Oar*, a rock, near the W. coast of Cornwall. N. lat. 50° 11′. W. long. 5° 32′.

Three *Sugar Loaves*, small islands in the Mergui Archipelago. N. lat. 9° 13′.

THRELKELDIA, in *Botany*, has been so named by Mr. R. Brown, in memory of Dr. Caleb Threlkeld, a Dublin physician, who published a *Synopsis Stirpium Hibernicarum*

rum in 1727. This is an alphabetical catalogue, principally founded on the papers of Dr. Thomas Molyneux, or the communications of other people; nor does it, according to our judgment, entitle its editor to any ſcientific rank.—Brown Prodr. Nov. Holl. v. 1. 409.—Claſs and order, *Triandria Digynia*. Nat. Ord. *Holeraceæ*, Linn. *Atriplices*, Juſſ. *Chenopodeæ*, De Candolle, Brown.

Eſſ. Ch. Calyx pitcher-ſhaped, with an abrupt inner margin. Petals three, membranous. Stamens oppoſite to the petals, inſerted into the receptacle. Capſule membranous, imbedded in the pulpy permanent calyx. Seed ſolitary, ovate.

1. T. *diffuſa*. Spreading Threlkeldia.—Gathered by Mr. Brown on the ſouth coaſt of New Holland, and in Van Diemen's iſland, growing on the beach. This is a ſmall, diffuſe, ſmooth *ſhrub*. *Leaves* alternate, ſemicylindrical. *Flowers* axillary, ſolitary, ſeſſile, without *bracteas*. *Seed* furniſhed with albumen, which is embraced by the circularly inverted embryo. *Brown*. We have preſumed to take for *petals*, though by no means pertinaciouſly, what Mr. Brown, led by the analogy of the natural order of the plant, conſiders as mere ſcales belonging to the *calyx*.

THRENGI, or Threnges, in our *Ancient Cuſtoms*, a denomination given to vaſſals, but not thoſe of the loweſt degree, but ſuch as held lands of the chief lord; otherwiſe called *drengi*, or *drenches*.

"Quia vero non erant adhuc tempore regis Willielmi milites in Anglia, ſed threnges; præcipit rex, ut de eis milites fierent ad defendendam ferram: fecit autem Lanfrancus threngos ſuo milites, &c." Somm. Gavelk.

The name was impoſed by the Conqueror: for when one Edward Sharnbourn, of Norfolk, and others, were ejected out of their lands, they complained to the Conqueror, inſiſting that they were always on his ſide, and never oppoſed him; which, upon inquiry, he found to be true; and therefore he commanded that every one ſhould be reſtored to their lands, and be for ever after called *drenches*, or *threnges*. Spelm. Du-Cange.

THRENODY, Threnodia, formed of θρηνος, *mournful*, and ᾠδη, *ſong*, a mournful or funeral ſong.

THRESHER, in *Ichthyology*, a name ſometimes given to the ſea-fox.

Thresher, in *Agriculture*, a perſon employed in threſhing out grain and other ſeed crops by means of the flail. See Threshing, and Threshing-*Machine*.

THRESHING, the act of beating out the corn or other produce from grain or other crops. The flail was the implement formerly uſed for threſhing of corn, and which ſeparated the grain from the ſtraw and huſks effectually and expeditiouſly; but which is now become much too tedious and expenſive, as well as liable to many other objections, and always bruiſes a great many ſeeds, beſides leaving many in the ears. It has been attempted to avoid theſe inconveniencies by proper machines provided with a number of flails, or other parts anſwering the ſame purpoſe, made to move by the power of water, wind, ſteam, or horſes. Of theſe, various ſorts have been lately invented, and brought to very great perfection. See Threshing-*Machine*.

Although there are many different methods made uſe of in ſeparating the grain from the ear of the corn, that by the flail is the moſt general and common.

Sometimes two perſons threſh together: and where more than two are employed together, which is ſometimes the caſe, there muſt be frequent interruptions, and a conſequent loſs of time. It is ſuggeſted alſo, that the tool by which this ſort of buſineſs is performed, ſhould be well adapted to the ſize and ſtrength of the perſon who uſes it, for preventing prejudicial fatigue. The beſt method of attaching the different parts of the implement together, is probably, it is thought, by means of caps and thongs of good tough leather. Iron is, however, ſometimes employed. In the execution of the work, when the corn is bound into ſheaves, it is uſual for the threſhers to begin at the ear-ends, and proceed regularly to the others; then turning the ſheaves in a quick manner by means of the flail, to proceed in the ſame way with the other ſide, thus finiſhing the work in a quick eaſy manner by their becoming looſe and open.

It is, however, obſerved by the author of the "Experienced Farmer," that threſhing with the flail is uncertain when moſt carefully performed, for the threſher may beat a long time and not meet with every head, which with the machine it is hardly poſſible to miſs; and that the grain waſted by the uſe of the flail is certainly great. In ſhort, he is of opinion that the corn loſt by threſhing with the flail, is more than would pay for threſhing it by the machine all over the kingdom.

In ſome places it is the practice to threſh by the meaſure of grain, as the buſhel, quarter, &c. while in others it is done by the threave of twenty-four ſheaves, and in ſome by the day.

In whatever way the farmer has this ſort of buſineſs performed, there is always much neceſſity for his conſtant inſpection, in order to prevent the frauds and impoſitions that are too frequently practiſed upon him by the perſons engaged in the execution of it.

The flail practice, however, from its being ſo extremely ſlow, tedious, and expenſive, and at the ſame time requiring a great number of labourers, is perhaps only capable of being had recourſe to with advantage on the ſmaller kinds of grain-farms, that are cheaply ſituated in regard to the command of workmen, and where the expence of having large machines would be much too great for the quantity of grain which they produce. But even in theſe caſes, if the ſmall horſe or hand threſhing engines that are conſtructed on cheap ſimple principles, and which occupy but little room, ſhould be brought to perform the buſineſs in an eaſy, expeditious, and effectual manner, which ſeems not improbable from the improvements that have been recently made in this ſort of machinery, it will moſt probably be to the advantage of ſuch farmers to abandon it, as the ſaving in various ways muſt ſoon repay them the expence of the machine, and at the ſame time afford them a conſiderable profit.

It is moreover ſtated, that where threſhing is performed by the flail, expenſive barn-floors, either of the fixed or moveable kind, will conſtantly be neceſſary; but that the latter ſort may ſometimes be capable of being converted to other purpoſes, which may render it uſeful in other views and intentions, and thereby leſſen the heavy charge of providing them. See Threshing-*Floor*.

It is ſtated by the author of "Practical Agriculture," that the ſuperiority of the method by machinery over that of the flail is very conſiderable in many other reſpects, beſides thoſe of its executing the work in a much more clean and perfect manner, more cheaply, and with much greater diſpatch, ſo as to admit of the farmer being preſent during the proceſs in moſt caſes.

It has been further ſaid, that the flail is a tool which is only fit for the rude or ſavage ſtate of a people; while the threſhing by the machine can be performed at any ſeaſon, as when the weather is wet, and when no other ſort of work can be done, eſpecially of the out-door kinds; and it will employ women and children, or boys, as well as other forts of labourers. By the ufe of it, the farmer is enabled to get the advantage of markets, as he has thereby the power of felling and delivering almoft any quantity within a little time; and by threfhing out and placing the corn in a fecure ftore room or granary, the great lofs often occafioned by vermin may be wholly prevented and removed. Numerous other beneficial confequences may likewife refult from the practice of threfhing by means of machinery, but particularly that of faving the heavy expence of raifing and upholding many different large buildings of the barn kind, on extenfive farms of the arable defcription.

It may be ftated, that the writer of the Account of the State of Agriculture in the County of Kent, found, on having different parcels of wheat-ftraw, of thirty-fix pounds each, threfhed out clean by the flail, by different farmers, and the fame weight of ftraw threfhed after it came from the machine, the average produce of corn left in the ftraw by the common mode of threfhing was half a pint in every thirty-fix pounds of ftraw, more than that left in by the machine method. And that, befides, fufficient fupplies of both corn and ftraw may at any time be almoft immediately provided, either for the purpofes of feed, the market, or the feeding of animals, without the other operations of the farm being in any degree interrupted. It is likewife obtained with much lefs wafte of the grain, and with lefs danger of its being injured by being bruifed. Likewife, that from the then increafing fcarcity of labourers, the great advance in the price of labour in all the well-cultivated diftricts, and the impoffibility of having this fort of work performed in a clean and exact manner by the flail, the neceffity as well as utility of the machine are eftablifhed. And it is further contended, that the principal obftacles to machines of this nature being more generally made ufe of, are thofe of expence in their conftruction and erection, and the littering flovenly practice which prevails in fome of the more fouthern diftricts of harvefting or fecuring the grain crops in a loofe uneven manner. But the firft of thefe objections may probably, it is fuppofed, be obviated by the conftruction and introduction of hand, or one-horfe, or ox-threfhing machines; and the latter by the daily difcoveries that are making in the improvement of this fort of machinery.

It is conceived, that the oppofition that has been raifed againft this practice, on the ground of its being calculated to deprive and prevent the labourers of employment during the winter feafon, is fcarcely deferving of notice, as experience has fully fhewn that no injurious confequences can refult from it, as there muft always be work enough of other kinds at fuch periods, where farms are under a judicious mode of cultivation.

It is on the whole fuppofed, however, that the faving of expence in this mode of threfhing over that of the flail, muft differ much according to the nature and manner of conftructing the machinery, the power by which it is wrought, and alfo on the ftate and condition of the grain at the time of performing the operation, as well as the full manner and regularity with which it is fupplied and managed. By fome farmers it is confidered as nearly, if not quite, one half, while others make it much lefs than that proportion. But with the beft conftructed machinery, there can be little doubt but that it will be performed on an average of different forts of grain, and different ftates of them, at lefs than one-third the expence of the flail method, without taking into the account any thing for the vaft faving in grain, in which fome reckon a profit of at leaft 5 *per cent.*; others, as equal to the feed and prices of threfhing, which is fomewhat more than half the price in the flail method; or either of the other operations that may be performed at the fame time with the fame machinery, fuch as thofe of winnowing or cleaning the corn, cutting ftraw into chaff, bruifing and grinding the grain for cattle food, breaking bones for manure, and various other purpofes and works.

In addition to the advantages that have been chiefly confidered in refpect to thefe machines, there is another which, in the then fcarcity of procuring labourers, and indeed at all feafons and times, muft be of great importance to the farmer, which is that of their enabling him to perform his work with greater certainty and convenience, and at much lefs expence of labour. It has indeed been ftated by a writer, in a late periodical work on farming, that with a machine, two labourers on a farm will be equal to four without it; as they are left at liberty, during the winter months, for performing various other forts of farm labour.

It has already been noticed, that the charge of this fort of work with thefe machines will vary confiderably, according to the manner in which they are conftructed. In the Agricultural Survey of the County of Kent, the expences and produce of threfhing *per* day, in different forts of corn, with an engine of the common conftruction, without the late improvements, are ftated in the manner following:

Eftimate of Threfhing Expences, &c. by the Machine.

For Wheat.

	£	s.	d.
Eight men, at 1*s.* 4*d.* each - - -	0	13	4
Four boys, at 1*s.* each - - - -	0	4	0
Four horfes, at 2*s.* 6*d.* each - - -	0	10	0
Cleaning and meafuring 24 qrs. at 3*d.* each -	0	6	0
	1	13	4

This is about 1*s.* 4*d.* *per* quarter, or nearly half the price of the flail method.

For Barley.

	£	s.	d.
Cleaning and meafuring 32 qrs. at 3*d.* each -	0	8	0
Other expences, as above - - -	1	7	4
	1	15	4

This is fomewhat more than half the price of the flail method, this fort of grain having of late been ufually threfhed at about 1*s.* 6*d.* the quarter.

For Oats.

	£	s.	d.
Cleaning and meafuring 40 qrs. at 1*d.* each -	0	3	4
Other expences, as before - - -	1	7	4
	1	10	8

This is a little more than half the price of that by the flail; this fort of grain being commonly threfhed at about 1*s.* 3*d.* *per* quarter.

The expences are here, however, calculated confiderably too low for the fucceeding times, as the men would fince require 2*s.* or 2*s.* 6*d.* and the horfes 5*s.* or 6*s.* each at leaft for the day.

But in the improved machinery of this kind fewer hands are required, and a number of other operations are performed

formed at the ſame time, which greatly leſſens the expences of executing the work.

In threſhing with a powerful improved machine belonging to Mr. Harbottle, on the Riminham farm in Berkſhire, according to the writer of the Agricultural Report of that diſtrict, the comparative calculations of expence and ſaving ſtand as below.

Eſtimate for Wheat.

	£	s.	d.
A man to feed the machine with ſheaves, at *per* day	0	2	6
A woman to throw up the ſheaves into the ſheaf-ſhelf, at *per* day	0	0	8
A girl or boy to hand and unbind the ſheaves to the man who feeds, at the ſame	0	0	8
A man to riddle or ſift the corn from cockles, or ſmall chaff, at	0	2	6
A woman to aſſiſt him	0	0	8
Two men to remove the ſtraw, and to make it up into bundles, at 2*s.* 6*d.*	0	5	0
A boy to drive the horſes, and attend to their paces, at	0	1	6
In all eight perſons	0	13	6
Four horſes, at 7*s.* 6*d.* *per* day, a liberal allowance	1	10	0
Expence of threſhing 20 qrs. which is done in the day of 12 hours	2	3	6
Ditto by the flail, at 3*s.* 6*d.* *per* quarter, ſuppoſing a man can threſh a quarter in the day, which is too much	3	10	0
Saving by the machine in 20 qrs.	1	6	6
Or by the quarter	0	1	4

Eſtimate for Barley.

	£	s.	d.
Two men to feed and looſe bands, at 2*s.* 6*d.*	0	5	0
Two women to pitch up and ſupply machine, at 8*d.* each	0	1	4
Two women to riddle, at 8*d.*	0	1	4
Two men to remove ſtraw, at 2*s.* 6*d.*, and one boy ditto, at 1*s.* 6*d.*	0	6	6
One boy to drive	0	1	6
In all nine perſons	0	15	8
Four horſes, at 7*s.* 6*d.* each	1	10	0
	2	5	8
Uſual price by the flail, 2*s.* 2*d.* *per* quarter, 30 qrs. the quantity done in the day of 12 hours	3	5	0
Saving on the above quantity	0	19	4
Or by the quarter	0	0	8

Eſtimate for Oats.

	£	s.	d.
Nine perſons employed, as for barley, and the ſame number of horſes	2	5	8
Uſual price by the flail 2*s.* *per* quarter, on 40 qrs., the quantity done in the day of 12 hours	4	0	0
Saving on the above quantity	1	14	4
Or by the quarter	0	0	10½

It ſhould be noticed, that theſe calculations are made fully to the higheſt, which is ſo much the more in favour of the machine.

In ſome of the northern diſtricts, the execution of this ſort of buſineſs by the machine is ſometimes undertaken by labourers, the farmer finding horſes. By this method, in Yorkſhire, the work coſts for wheat 1*s.* the quarter, and oats 6*d.* And in Northumberland they make uſe of a machine, which threſhes at the rate of 33 buſhels *per* hour, or 264 in the day of eight hours. In this machine, the expences in the attendance of the threſhing and dreſſing parts of it being merely that of three women; one to feed in, another to hand the ſheaves to the feeder, and a third to take away and riddle the corn after it is winnowed; conſequently the threſhing and dreſſing the above number of buſhels only coſts 1*s.* 6*d.*, while the threſhing the ſame quantity by the flail would be $\frac{1}{25}$th part, or 10½ buſhels, which at 2*s.* the buſhel is 21*s.*; to which muſt be added 2*s.* for the expence of a man and two women to aſſiſt in winnowing, which makes in all 23*s.*

But in the Agricultural Survey of the County of Norfolk, there is an account of the expence of threſhing with the machine in compariſon with that of the flail, which furniſhes a very different reſult. The machine was built by a perſon from Leith in Scotland, for Mr. Bevan, and coſt 100*l.*; and ſtrongly ſhews, it is thought, that bad machines are worſe than the old method of the flail.

Threſhing by Means of the Flail.

	£	s.	d.
Forty coombs of barley, at 7*d.* come to	1	3	4
To dreſſing of ditto	0	2	0
	1	5	4
Fifty coombs of oats, at 6*d.*	1	5	0
Dreſſing ditto, at 1*s.* *per* ſcore	0	2	6
	1	7	6
Forty coombs of rye, at 9*d.*	1	10	0
Dreſſing ditto, at 1*s.* *per* ſcore	0	2	0
	1	12	0
Forty coombs of wheat, at 1*s.*	2	0	0
Dreſſing ditto	0	2	0
	2	2	0

Threſhing by the Machine.

	£	s.	d.
Forty coombs of barley take eight horſes, at 2*s.* 6*d.*	1	0	0
Ten men, at 1*s.* 6*d.* each	0	15	0
To dreſſing ditto, five men one day	0	7	6
	2	2	6
Thus barley coſts more by 17*s.* 2*d.*			
Fifty coombs of oats take eight horſes, at 2*s.* 6*d.*	1	0	0
Ten men, at 1*s.* 6*d.* each	0	15	0
To dreſſing ditto	0	7	6
	2	2	6
Thus oats coſt more by 15*s.*			
Forty coombs of rye take eight horſes, at 2*s.* 6*d.*	1	0	0
Ten men, at 1*s.* 6*d.* each	0	15	0
To five ditto, at 1*s.* 6*d.* one day dreſſing	0	7	6
	2	2	6
Thus rye coſts more by 10*s.* 6*d.*			

Forty

	£	s.	d.
Forty coombs of wheat take eight horfes, at 2s. 6d. - - - - - -	1	0	0
Ten men, at 1s. 6d. each - - - - -	0	15	0
Five ditto to drefling - - - - -	0	7	6
	2	2	6

And wheat cofts more by 6d.

The calculations of the expences are here made greatly under the rate of wages and hire of horfes which has fince taken place.

The above fhould lead the farmer to be careful in putting up thefe machines; and to be certain of their being conftructed in fuch a way, as to anfwer the purpofe in a perfect manner before he begins the work.

It is well obferved by Mr. Somerville, in the Agricultural Report of Eaft Lothian, in calling the attention of the public to the unrewarded merits of Mr. Mickle, in bringing the threfhing machine to a ftate of perfection, that it is computed, by thofe who have paid every poffible attention to the fubject, that in Britain about 7,500,000 acres are annually employed in raifing grain, the produce of which, if averaged at three quarters *per* acre, amounts to 22,500,000 qrs.; and, as it is admitted that the furplus quantity gained by the ufe of threfhing machines is at leaft a twentieth part more than when the flail is ufed, it will appear that 1,112,500 qrs. would be faved annually, were the whole of the grain in the kingdom threfhed in that way; the value of which, if only calculated at 32s. *per* quarter, would be 1,781,250l.; to which adding the favings of expence, at 1s. *per* quarter, upon 22,500,000 acres, *viz.* 1,125,000l., it would make the enormous fum of 2,906,250l. fterling; a fact almoft incredible to any but thofe who have turned their attention to the fubject, and are well acquainted with the great difference between the threfhing-machine and the flail.

All forts of grain fhould be in a proper, hard, dry condition, when it is to be threfhed out, otherwife the work cannot be performed in a clean and perfect manner, whether it is to be executed by the flail or the machine.

It is a remark of the time of Lifle, founded on his own extenfive experience, that wheat threfhed in damp weather generally yields but little flour, with a great deal of bran, when it is ground; and that if it be put into facks, it will grow mufty in lefs than three weeks, let the weather be ever fo dry afterwards: but if, on the contrary, it be threfhed when the air is perfectly clear and dry, it will keep well in facks for a long time, efpecially if thefe are laid upon treffels high enough to fecure them from the dampnefs of the ground or floor.

But for keeping of the meal or flour, in general, there is no better way than firft to bolt and clean it from the bran or hufks, which is apt to make it mufty, and then to tread it down as hard as poffible, and head it up clofely in clean, dry, tight, and well-bound cafks, which muft be laid in a cool dry place.

It may be noticed, that the beards of barley come off beft, in threfhing, when the fheaves or fwarths of this corn have taken the dew before their being houfed. It will keep well in the mow unthrefhed for one year; but for making it into malt, which muft be done before the heat of the fummer comes on, it fhould not be kept above a year and a half, or at moft two years: otherwife it will be filled with weevils or infects; unlefs it has been previoufly cured in a ftove or kiln.

But oats, from their being defended with a double hufk, are the grain leaft fubject to harbour vermin. The beft way to keep them after they are threfhed, which fhould be done when dry, is to dry them well on a kiln, and then to barrel them up in clean clofe cafks.

As for beans and peas, they always threfh beft after they have fweated in the mow, which they are very apt to do; as the whole crop of either of them never ripens altogether, the green parts heat, and communicate their ferment to the whole heap. The danger to be guarded againft is, that they do not heat too much. For this reafon, farmers generally choofe to ftack them without doors, rather than to houfe them; that they may be the more thoroughly dried by the fun and air. As beans are a very large feed, and confequently full of moifture, it is found beft to let thofe that are intended for keeping, fweat and feafon in the mow until March, when they may be threfhed without danger, for beans never give again, after they have once been thoroughly dried and hardened.

And vetches, when wanted for fowing immediately after they are cut, may be threfhed very well on a hurdle, with a cloth; though they then be too foft, notwithftanding their being ripe, to be threfhed on a floor, where the flail and the threfher's feet would bruife and break them.

In general, in the bufinefs of threfhing, as the work proceeds, it will from time to time be neceffary to remove all the long ftraw from the corn beaten out of it, which laft always lies underneath, with a prong or fork, and then the pieces of ftraw, broken ears, &c. with a wooden rake. The remaining grain fhould then be fhovelled up on one fide of the floor, and the work be repeated till enough be threfhed out to make what is commonly called a clearing. The heap fhould then be wholly paffed through a wide fieve, which retains only the bits of ftraw, and fuch fragments or ends of the ears as have efcaped the flail. Thefe frequently contain fome good corn, and form an ufeful fodder for moft forts of animals, being what are commonly called *cavings*, as feen below.

Much labour may often be faved in the ufe of the fieve by faftening a loop to its rim, and refting it thereby on a hook fufpended by a rope. This will fuftain half the weight of the corn, and the neceffary circular motion may more eafily be given to it.

After much threfhed grain has thus accumulated on the threfhing-floor, and the fhort ftraw and chaffy matter have been feparated from it, as juft noticed, by paffing it through a wide riddle or fieve for the purpofe, which fhould always be done before too much grain has been collected, as in that way the bruifing of it is more effectually prevented; it muft be put by to afford more room. The fhort chaffy fubftance thus feparated from the grain is in fome diftricts denominated *cavings*, or *caving-chaff*, and is capable of being employed with advantage, as feen above, in the feeding of horfes, or neat cattle and fheep. When this has been done, the loofe grain fhould be thrown into a chamber or other place conveniently formed for receiving it, where it fhould remain till a fufficient quantity has been collected to render the clearing and cleaning of it by fome kind of machine for the purpofe, requifite. But the improved threfhing machines render this unneceffary, as they drefs or clean it at the fame time it is threfhing out. See WINNOWING *Machine*.

Furze tops in their young ftates of growth are in fome northern fituations beat or threfhed by the flail, and in that way bruifed as horfe-food, where proper machinery for this purpofe is not at hand. The work-horfes during their ufe have little other food, it is faid, though performing great labour.

From the whole of what has been faid, it is evident that the farmer fhould always confider well before he decides on the mode of threfhing which may be the moft proper and advan-

advantageous, as well as the moſt ſuitable, to the ſort of farm which he holds.

Threshing-*Floor*, the floor on which grain is threſhed out in the barn or other place. All floors of this ſort ſhould be well formed and conſtructed, of whatever ſort of materials they are made, as without it they give way and fall to pieces. When the material employed in this intention is wood, the timber ſhould always be of the beſt kind, and well ſeaſoned, being put together in a careful and firm manner; and when of the earthy kind, the different matters be well reduced, wrought together, and laid up for ſome length of time before the floor is formed, being then laid down in a ſmooth even manner, and made firm and ſolid by frequent ramming with a proper tool for the purpoſe, until the flooring ſubſtance, whatever it may be, becomes quite dry.

It has been obſerved, that as grain is threſhed out by machinery, from the circumſtance of its being ſeparated from the ſtraw immediately, and not permitted to remain upon the floor for above an hour or two, when brought to market, is always much drier, looks better, and brings a higher price than that which is threſhed by the hand, and ſuffered to remain upon the floor for weeks, where it becomes muſty, loſes its colour, and is ſo raw, that much of it is bruiſed and rendered uſeleſs in the working. Therefore, if the flail-mode of threſhing is ſtill purſued, it is ſuppoſed that the inconveniences above-mentioned may, in ſome degree, be remedied, by paying proper attention to the materials of which the floor is made, and raiſing it ſufficiently above the reach of moiſture. Where the barns are very extenſive, and the price of wood uncommonly high, as is the caſe at preſent, a very good and durable threſhing-floor may ſometimes be made by laying an uniform ſtratum of round gravel, covering it with a coat of well-tempered clay; above which, a mixture of clay, brick-duſt, forge-aſhes, and a ſmall proportion of lime, will make it a hard uniform floor, proper and ſuitable for the purpoſe of threſhing upon. It is obſerved that the brick-duſt and forge-aſhes ſhould previouſly be beaten very ſmall, and well incorporated with the clay, uſing a ſufficiency of water to bring the whole to the conſiſtence of mortar; in that ſtate the lime, having been previouſly ſlaked, ſhould be incorporated with the other ingredients; the whole ſmoothed over with the back of the ſpade, and allowed to remain in a round heap for two or three weeks, at the end of which time it ſhould be turned over in the ſame manner as plaſter lime, and after being rendered ſufficiently ſoft with water, it may be ſpread upon the floor, an operation that will require ſome pains on the part of the workman. The floor, in the firſt inſtance, ſhould have the coat of clay, that is laid above the gravel, rendered perfectly ſmooth and uniform, by rolling, beating, or otherwiſe; the finiſhing coat, compoſed of the mixture above-mentioned, may then be applied, taking care to break the ſurface of the clay with ſhallow lines, in the way practiſed by plaſterers, for the purpoſe of making one coat adhere to another in a firm and perfect manner.

Many other ſorts of materials, ſomewhat of this nature, are made uſe of for threſhing-floors in different diſtricts of the kingdom.

The following plan has been ſuggeſted as the means of excluding rats and mice from the barn and threſhing-floors. Firſt, that when the floor is entirely of wood, the ſpace between the ſleepers, upon which the boards are laid, ſhould be entirely filled with waſhed gravel, well beat down, an operation which, when properly done, will effectually prevent the entrance of either rats or mice; where this precaution is not taken, when the floor is laid, openings ſhould be made at the bottom of the wall large enough to admit cats, a contrivance that will have the two-fold effect of deſtroying the vermin, and affording a free circulation of air. Secondly, that when the floor is of clay, the vermin generally burrow under the foundation, and have the entry to their retreats at the bottom of the wall: in ſuch caſes, their acceſs into the barn will be, in ſome meaſure, if not entirely, prevented, by mixing a conſiderable quantity of broken glaſs with the materials with which the threſhing-floor is made. It does not appear neceſſary to mix the glaſs with the clay over the whole floor; perhaps two feet from the wall quite round will be ſufficient. And thirdly, that the top of the wall, as furniſhing a temporary retreat for vermin, deſerves alſo to be noticed: in every inſtance it is cuſtomary for the maſon to level the top of the wall previous to the roof being put on, which, when the building is finiſhed, is left in that ſtate, by which a conſiderable ſpace remains for the ſhelter of rats and other vermin: to prevent this, as ſoon as the roof is finiſhed, the building of the wall on the inſide ſhould be continued upwards till it joins the roof, to which it ſhould be cloſely united by hard plaſtering. It is ſuppoſed, by theſe precautions, and ſmooth plaſtering, the walls of barns as well as the threſhing-floors may be preſerved free from vermin.

Threshing-*Machine*, an engine of the mill kind, contrived for the purpoſe of threſhing grain, ſeeds, and pulſe out of the ſtraw or the ear.

This is a ſort of mill or machine that has been chiefly conſtructed on the ſame principles as thoſe of the flax-mill, and which is capable of being wrought by different powers, as thoſe of horſes, oxen, wind, water, and ſteam; but thoſe of water and animals are the moſt proper and convenient in moſt inſtances: in ſome caſes, the grain being beaten or ſwingled out of the ears by means of beaters attached to a cylinder that has much velocity, while in others it is rubbed out by ſuitable means againſt confined cylinders, as will be more fully ſeen and explained in what is ſaid below.

There is ſome reaſon to ſuppoſe, that the original hint or notion of theſe mills or machines, was derived a long time ago from Holland or the Low Countries, and thence brought into the northern parts of this country, where the different parts of the machinery of them have ſince been gradually undergoing much modification and improvement, to render them more ſuitable and efficient for the purpoſe; ſo that they have now attained a conſiderable ſtate of perfection in moſt parts of the kingdom. The firſt of theſe improved machines was, as Mr. Somerville ſays, invented by a Mr. Menzies, brother to the then ſheriff *depute* of the county: the machinery was driven by a water-wheel, which put in motion a number of flails of the ſame kind with thoſe uſed in threſhing by the hand. Trials made with theſe machines were ſo far ſatisfactory, that a great deal of work was done in a given time, but owing to the velocity required to do the work perfectly, they ſoon broke, and the invention fell into diſgrace.

Some time in the year 1758, another attempt was made by a farmer in the pariſh of Dumblane, in Perthſhire. His machine was conſtructed upon principles ſimilar to the flax-mill, having an upright ſhaft with four arms incloſed in a cylinder, three feet and a half in height and eight in diameter, within which the ſhaft and its arms were turned with conſiderable velocity by a water-wheel. The ſheaves, being preſented by the hand, were let down from the top upon the arms, by which the grain was beat out, and together with the ſtraw deſcended through an opening in the floor, where they were ſeparated by riddles and fanners, alſo turned by the water-wheel.

And it is added, that, about twenty years after this, a third attempt was made by a Mr. Elderton, near Alnwick, and a Mr. Smart, at Wark, both nearly about the fame time. Their machines were fo conftructed as to act by rubbing, in place of beating out the grain. The fheaves were carried between an indented drum, about fix feet in diameter, and a number of rollers of the fame defcription ranged round the drum, towards which they were preffed by fprings, in fuch a way as to rub out the grain when the drum was turned round. Upon trial, this method of conftruction in thefe machines was alfo found defective, as along with its doing very little work in a given time, it bruifed the grain, and fo materially hurt its appearance, as to leffen its value confiderably in the markets.

It is further ftated that the machine, in its then imperfect ftate, was feen by the late fir Francis Kinloch, bart. of Glimerton, a gentleman well acquainted with mechanics, and who had paid much attention to country affairs: it occurred to him, that the machine might be rendered more perfect, by inclofing the drum in a fluted cover, and fixing on the outfide of it four fluted pieces of wood, capable of being raifed a little from the circumference by fprings, in fuch a way as to prefs againft the fluted cover, and to rub out the grain as the fheaves paffed between them; but after repeated trials, it was likewife found to bruife the grain nearly as much as the model from which it was copied. In that ftate it remained for fome time, and was afterwards fent by fir Francis to a very worthy and ingenious character, Mr. Mickle of Know-Mill, in his neighbourhood, (a millwright by profeffion,) who had for a confiderable time employed his thoughts upon the fame fubject. After much confideration, and feveral trials, it appeared to Mr. Mickle, that the purpofe of feparating the grain from the ftraw might be accomplifhed upon a principle different from any that had hitherto been attempted, namely, by fkutches acting upon the fheaves by their velocity, and beating out the grain, in place of preffing or rubbing it out. Accordingly a model was conftructed at Know-Mill, in which the grain was beat out by the drum, to which it was prefented through two plain feeding rollers, which were afterwards altered for fluted ones. The firft machine, on a large fcale, executed upon this principle, was, it is faid, done by a fon of Mr. Mickle's, for a Mr. Stein of Kilbagie, in the year 1786, which, when finifhed, performed the work to the fatisfaction of all parties. A patent was afterwards applied for and obtained in 1788. Since that period, as well as the firft introduction of thefe machines, many other improvements have been made on them by different ingenious artificers in many different places; a fcreen has been added for the grain to pafs through into a winnowing machine, and a circular rake to remove the ftraw from it; as before this addition, the ftraw was forced out from the beater upon the upper barn-floor, and required much time and labour in fhaking and putting it into order, which by this contrivance is faved. And befides having a fufficient degree of velocity, without its being fo great as to injure the machinery, it is found that a point upon which the clean threfhing of all forts of grain materially depends in the ufe of this machine, is the management of the iron covering, under which the beating-wheel, having fix or more beaters, moves: in fome machines this is fixed, while the beating-wheel is capable of being raifed or depreffed at pleafure; but a more late improvement is to render the iron roof moveable and the wheel fixed, the iron being placed fo clofe to the beaters, that the grain is rubbed as well as fhaken out of the ear. And in fome cafes the beaters are fomewhat rounded, but the flat form is probably better.

Different machines of this fort are alfo faid to have been lately conftructed fo as to work with chains inftead of cogs, and to perform the bufinefs in a fatisfactory manner. Another great improvement is likewife believed to have been made on the feeding rollers; which is that of having the upper roller, inftead of being one folid cylinder of wood, with rods of iron fixed upon it, as was formerly the cafe, an octagon or decagon of caft iron, and divided into four parts, which are loofely joined into each other, fo that in turning round, each part can rife or fall in a feparate manner, according as the corn is fpread out in a thicker or thinner way. The advantage is, that by means of this contrivance the corn is regularly held; whereas, by the roller being all of one piece, if at one part the grain fhould happen to be more in a heap or lump than at another, the whole roller is raifed, and a great part of the grain paffes through, without having been held fufficiently to the beaters, and is confequently imperfectly threfhed out.

This fort of machine is fometimes conftructed with a vertical fhaft, on which is fixed in a horizontal manner an iron bevil wheel, fix feet in diameter, which drives another about eighteen inches diameter upon a tumbling fhaft, upon which is alfo an iron fpur-wheel, three feet fix inches in diameter, driving one about ten inches upon a fhort iron fhaft, which likewife carries a drum or pulley, three feet fix inches in diameter, from which a fix-inch ftrap drives one nine or ten inches in diameter, hung upon the iron fhaft or fpindle which runs quite through the wood-beater or barrel, two feet in diameter, and three feet in length, having fixed upon it, by means of ftrong fcrews into its iron bonds, twelve wrought-iron bars, about an inch fquare, which beater making upon its horizontal axis about three hundred revolutions in a minute, and confequently nearly three thoufand fix hundred ftrokes in that fpace of time; the corn being carried to it by means of a cloth, which is moved forwards by rollers, lying nearly upon a flat furface of fix feet long, by three feet wide, two to three feet high from the ground-floor, which is a very convenient pofition to feed upon, and paffing between a pair of fluted rollers, over a bar, comes in contact with the beater, through a cavity, which may be varied by fcrews, from an inch in width, to the thicknefs of a grain of corn, when the ftraw is immediately delivered, perfectly clean upon the floor on the outfide of the machine, no more injured for thatch, or other purpofes, than by the flail, and the corn in its paffage under the beater is filtered through a wooden frame to the floor, where it remains for removal. Upon this kind of threfhing-machine many different trials have been made in the view of afcertaining what fort of power, conftruction, and velocity or fpeed, would produce the beft and moft beneficial effects on the work, and many improvements have been fuggefted which we have not room for reciting.

Some machines of this fort have large wooden fly-wheels, of from twelve to fifteen feet diameter, fixed upon the tumbling-fhafts, which run over or above the horfe's heads, perhaps made of fir-timber, as cork unfortunately is feldom to be met with; but as their fpeed, in fuch a fituation, can rarely afford any affiftance, the lighter they are, the lefs impediment, it is fuppofed, they will produce. The bars or beaters are alfo fometimes as much as an inch and a half, or two inches thick, from the barrel or roller upon which they are fixed, and the roller itfelf three feet or more in diameter; but fo much of the bar is certainly, it is thought, unneceffary, as exceeds the length of ftraw drawn in by the rollers, during each interval between the ftrokes, and which is feldom more than half an inch; confequently, whatever is more than three quarters, produces an increafed impediment.

ment. The greater the diameter of the fame beater, from meeting with the principal refiftance, fo much farther from the centre, of courfe, the proportionately greater power is required to work it; but this laft defcription of beater is faid, in general, to be found to make the beft work, and the reafon is thought obvious: they are neceffarily driven by water, fteam, or a number of horfes, and, it is concluded, calculated to make the fame number of revolutions in a minute as one of two feet, in which cafe their velocity, on which all depends, is juft half as much more — a moft important point indeed. The means of regular fteady driving is likewife of material importance in all machines of this nature, where animal labour is neceffary.

A very powerful improved machine belonging to Mr. Harbottle, of the Riminham farm, near Henley on Thames, confifts of a horfe-wheel which contains 136 teeth, or pinion wheel with 26, a large wheel with 88, another with 21, the fame with 88, and a further one with 21, forming the drum. Underneath the drum is the contrivance for winnowing, or the wheel that feparates the chaff from the corn, by blowing it back into a bin below the feeder, and allowing the corn to fall into a box, from whence it runs. Every revolution of the horfe-wheel in this machine produces eighty-eight and a half of the drum; and as the horfe-wheel goes about three rounds of twenty-four yards each *per* minute, or two miles and a half in an hour, the drum of confequence muft revolve on its circumference, of three yards and a half, 265 times in a minute, or 927 yards. The feeding-board is five feet four inches wide. The drum-wheel is four feet four inches diameter, being covered with fheet-iron, and has four beaters, which project four inches; making the above number of revolutions to one of the horfe-wheel, and the horfes going the above diftance in the hour; in a path twenty-feven feet diameter. The cogs of the wheels are of white thorn properly feafoned, working into others of caft-iron; payed only with black lead, not any greafe being employed. The level of the ftage on which the men ftand to feed, is eight feet above tho barn-floor in which the machine is fixed.

The drums of threfhing-machines, it is remarked, in general revolve from fixty to a hundred times for one revolution of the horfe-wheels; and that in proportion as thefe move flower, the horfes muft go fafter, fo that the utmoft nicety is neceffary to properly adjuft this: as if the horfes are under the neceffity of trotting, they are greatly injured in long continued exertion, and if they move too flowly, the work is imperfectly performed. A fteady common walk is the pace at which horfes fhould be kept, and the drums of machines fhould be formed accordingly, in order fully to effect their work, and at the fame time to enable the horfes to do a good day's labour without too much fatigue and inconvenience.
